PROCEEDINGS

of the American Academy of Forensic Sciences 69th Annual Scientific Meeting

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Meeting. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, engineering, immunology, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions which are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to "peer-review" each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so that they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues.

The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

SPECIAL SESSIONS

S1 Interdisciplinary Symposium: The Evolution of Daubert and Its Effects on the Forensic Sciences

Marla E. Carroll, BS, Forensic Video & Audio Associates, Inc, 6919 W Broward Boulevard, Ste 222, Plantation, FL 33317; Linton Mohammed, PhD*, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; W. Milton Nuzum, JD*, 65 S Front Street, Columbus, OH 43215; Stephen Goudge, LLB*, Paliare Roland Barristers, 155 Wellington Street, W, FL 35, Toronto, ON M5V 3H1, CANADA; Neal H. Haskell, PhD*, 425 Kannal Avenue, Rensselaer, IN 47978; Peter V. Tytell, BA*, Forensic Research, LLC, 15 Maiden Lane, Ste 308, New York, NY 10038-4017; Joseph J. Maltese, JD, PhD*, New York Supreme Court, Appellate Division, Second Judicial Dept, 26 Central Avenue, Ste 503, Staten Island, NY 10301; Barry C. Scheck, JD*, The Innocence Project, 40 Worth Street, Ste 701, New York, NY 10013; Mara L. Merlino, PhD*, 1066 Tamworth Lane, Frankfort, KY 40601; and John J. Lentini, BA*, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036*

After attending this presentation, attendees will better understand how forensic science practitioners have addressed the evolution of *Daubert* and the reaction of the legal community as the standard has progressed. Attendees will be exposed to the challenges faced by forensic scientists and the research that is addressing criticisms. Furthermore, the Interdisciplinary Symposium will help attendees understand how the courts understand *Daubert* and how they address the admissibility of forensic practitioners and science.

This presentation will impact the forensic science community by discussing the past, present, and future ramifications of the *Daubert* Trilogy on the admissibility of forensic evidence from the viewpoint of practitioners, attorneys, educators, and judges.

Stephanie Domitrovich, JD, PhD; W. Milton Nuzum, JD - The American Bar Association (ABA) recently adopted a Resolution wherein the ABA urges the National Commission on Forensic Science to support the development of a model curriculum in the law and forensic science as well as training in that curriculum for federal, state, territorial, and tribal judges. The NAS recommended: "Better connections must be established and promoted between experts in the forensic science disciplines and law schools, legal scholars, and practitioners." Specifically, the NAS Report further indicated: "And judges need to be better educated in forensic science methodologies and practices." Consistent with these recommendations, presenters in this session will discuss the evolving developments in judicial education over the years in providing state and federal trial judges the necessary tools for their tool boxes to become better equipped to understand forensic scientific evidence issues in both *Daubert* and *Frye* jurisdictions. Judicial educators will discuss the design of such curricula to teach state and federal trial judges to become more competent gatekeepers when deciding scientific issues in all areas, for instance, civil, criminal, family, and orphans' court. Judicial educators will also discuss implementing needs assessments, curricula development, and adult education principles as their latest tools in education theories to accomplish these goals.

Stephen T. Goudge, LLB - This presentation will address the public inquiry Judge Goudge chaired into Pediatric Forensic Pathology in Ontario. The Inquiry was created by the government of Ontario because unreliable opinion evidence from this science had resulted in a number of wrongful convictions. In his report, Judge Goudge addressed the challenge of unreliable scientific opinion evidence and how the justice system could guard against it.

Neal H. Haskell, PhD - The science of Forensic Entomology (FE) has regularly entered the courtroom in the United States within the past three decades. At first, it was perceived as a "new and novel science" using insects to answer questions regarding a human death. During this time, the *Frye* test of acceptability in courts was the

standard method of reliability. Only a handful of states had actually utilized FE in courts. This led to numerous challenges of its use in courts as more states sought use of FE, the gatekeepers being the justices on the bench.

As was explained to each new state where testimony was given, whether *Frye* or *Daubert*, FE is nothing more than proven and reliable entomological scientific principles dating back to 1265 China in a murder case. Forensic application of entomology is one of the oldest sciences to be used in the courtroom. In short, FE is the use of biological aspects of entomology encompassing insect biology, insect behavior, insect growth and development, insect ecology, interacting with climatology and environmental biology, all of which have been studied for centuries and are fully accepted in the biological sciences.

Peter V. Tytell, BA - One practical change in post-*Daubert* courtrooms has been at the *voir dire* stage of an expert's appearance. Previously, opposing counsel would challenge the specifics of the education, training, and experience of the witness in an effort to disqualify that individual as an expert in a certain discipline (or at least lessen the witness's credibility in the eyes of the jury). Today, the challenge is often to the reliability of the discipline itself rather than the qualifications of the witness as a practitioner. It is increasingly likely that the *voir dire* will be conducted outside the presence of the jury, and that it will be essentially indistinguishable from a *Daubert* hearing in content and intent.

Today's expert witness must be prepared not just to present the results of an examination and to explain the specifics of each of the findings, but must also be prepared to present the basis for the reliability of the discipline with specifics relating to each of the *Daubert* factors and the requirements of Rule 702. Of equal importance, today's trial attorney must be prepared not just to present the facts of a case, but must also be prepared to ask the right questions of the expert and to present *Daubert*-appropriate references, citations, and arguments. This presentation will illustrate these changes as they relate to forensic document examiners with case examples highlighting problems that can arise in these situations.

Joseph J. Maltese, JD, PhD - The expansion of *Daubert* and *Kumho Tire* standards into the Federal Rules of Evidence, and their adoption by many state courts, have served as a catalyst for the criminal defense bar to challenge the reliability of the "specialized knowledge" utilized in most of the forensic disciplines. With greater scrutiny being applied by the courts, many forensic disciplines have attempted to validate or revalidate their methodology and procedures to withstand objections raised by attorneys and skeptical judges about the admissibility of such evidence, which was rarely subject to objection before the *Daubert* revolution. This presentation will address some of these issues.

Barry C. Scheck, JD - As the National Commission on Forensic Science recently acknowledged in a views document, protecting against cognitive bias through blind examinations and sequential unmasking is critical to conducting sound science. Forensic scientists, lawyers (prosecutors and defense), judges, and police officials must all take simple, systematic precautions to minimize the effects of cognitive bias in their investigations, scientific testing, and assessments of evidence. Fashioning judicial remedies to enforce best practices plays an important role in this process.

Mara Merlino, PhD - This presentation will discuss the issues faced by forensic practitioners as the various forensic disciplines work to articulate and standardize education, training, and other practices to ensure that valid and reliable evidence is produced in service to the justice system. The process of the social construction of scientific knowledge and the impact of legal requirements on scientific "facts" that cross the boundary of admissibility to become scientific "evidence" will be discussed in the context of *Daubert, Joiner,* and *Kumho* decisions.

John J. Lentini, BA - While *Daubert* challenges are becoming more and more common in all expert disciplines, fire investigation seems to attract a significant number of them. The first *Daubert* challenge occurred in 1997, in the case of *Michigan Millers Mutual Ins. v. Janelle R. Benfield*, when a fire investigator with 40 years of experience was precluded from testifying because he could not articulate the scientific method, even though he claimed to have used it. However, in the same case, a firefighter was allowed to render an opinion based on his "experience." Courts have ruled on hundreds of *Daubert* challenges, including the Supreme Court. Sometimes the court gets the science completely wrong, as the 10th circuit did in the case of *Truck Insurance Exchange, A Farmers Insurance Company v. Magnetek, Incorporated*. They arrived at the correct result, but in so doing, completely confused a lot of other courts.

The prevalence of *Daubert* challenges has led to a more general "Rule 702" challenge. In the past, challenges to fire investigators have focused mainly on methodology. There is a trend now toward challenging an investigator's qualifications. After being unable to answer simple fire chemistry questions, an investigator is likely to be withdrawn and the case is likely to settle. Such cases will not result in new case law.

In fire cases, the *Daubert* challenge is now as common as motions for summary judgment. This presentation will discuss several important fire-related *Daubert* cases and what they portend for the future of fire investigation.

Daubert, Evidence, Admissibility

S2 What Shapes Our Future?: Foundations and New Directions

Brianna B. Bermudez, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695; Brittany N. Beyer, MS*, Houston Forensic Science Center, 1301 Fannin, Ste 170, Houston, TX 77002; Jeremy M. Manheim, 605 Driftwood Drive, E, # 200, Lafayette, IN 47905; Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Betzaida L. Maldonado, MSFS, 3433 N Druid Hills Road, Apt #S, Decatur, GA 30033; Alyssa J. Badgley, MS, Michigan State University, 560 Baker Hall, East Lansing, MI 48824; Alicja K. Lanfear, PhD, Middle Tennessee State University, Dept of Biology, Box 60, Murfreesboro, TN 37132; Vienna C. Lam, BA, Simon Fraser University, School of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; Kelsey A. Carpenter, MS, Mercyhurst University, Dept of Applied Forensic Sciences, Erie, PA 16546; Jacob Griffin, BS, 16665 Danville Road, Danville, IA 52623; Ashley E. Foster, MAS, Texas Department of Public Safety, 5800 Guadalupe Street, Bldg U, Austin, TX 78757; Roderick T. Kennedy, JD*, PO Box 7041, Albuquerque, NM 87194-7041; Dean Michael De Crisce, MD*, Special Treatment Unit, 15 Paddock Street, Avenel, NJ 07001; Peter R. Stout, PhD*, Houston Forensic Science Center, 1301 Fannin St Ste 170, Houston, TX 77002; Joan A. Bytheway, PhD*, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; Eugenia Cunha, PhD*, Universidade de Coimbra, Dept of Life Sciences, Forensic Anthropology Lab, Universidade de Coimbra, Calçada Martim de Freitas, Coimbra, Coimbra 3000-456, PORTUGAL; Nicolene Lottering, PhD*, University of Adelaide, Medical School N, Lvl 3, Frome Road, Adelaide, South Australia 5005, AUSTRALIA; Jason H. Byrd, PhD*, University of Florida, Maples Center for Forensic Medicine, 4800 SW 35th Drive, Gainesville, FL 32608; Jeri D. Ropero-Miller, PhD*, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709; Eric Baccino, MD*, Hopital Lapeyronie, 371, Av du Doyen Gaston GIRAUD, Montpellier, Cedex 5 34295, FRANCE; Gulnaz T. Javan, PhD*, Alabama State University, Forensic Science Program, 915 S Jackson Street, Montgomery, AL 36104; John M. Butler, PhD*, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899; Kimberly S. Kobojek, MS*, ASU New College, Arizona State University-W Campus, PO Box 37100, Phoenix, AZ 85069-7100; Megan E. Grimes, MFS*, 5187 Salt Pond Place, Woodbridge, VA 22193; Lauren Traveller, DNP*, 725 S Hualapai Way, #2037, Las Vegas, NV 89145; Tabidrik A. Reed, MSFS, AFOSI 4th Field Investigations Squadron, Unit 3023, APO, AE ; Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; C. Ken Williams, MS, JD*, NJSP Office of Forensic Sciences, Central Regional Laboratory, 1200 Negron Drive, Hamilton, NJ 08691; and Cheryl D. Hunter, 403 Pioneer Creek Drive, Florissant, CO 80816*

After attending this presentation, attendees will better understand the different forensic science disciplines as well as the current issues in the field of forensic science. Additionally, attendees will have the opportunity to listen to prominent scientists share their experiences, cases, and thoughts on the future directions of the field.

This presentation will impact the forensic science community by providing a forum for young scientists to learn more about the field, share their ideas, and network with other professionals.

The purpose of the Young Forensic Scientists Forum Special Session is to educate college students and young professionals about the exciting field of forensic science. In addition to the presentations given by Academy members, the session provides attendees with information regarding AAFS membership and mentorship opportunities. The Bring Your Own Slides and Bring Your Own Posters Sessions will give young scientists the opportunity to present their research, and the Breakfast Session will connect attendees with established professionals for résumé reviews and feedback.

The 2017 YFSF Special Session entitled, *What Shapes Our Future? Foundations and New Directions,* is a day-long session scheduled for Tuesday, February 14, that features speakers from many Academy sections. Topics will include current issues in various fields of forensic sciences, as well as forthcoming changes in these fields. Attendees will learn about Academy membership and will have the opportunity to build professional relationships through networking and mentorship. This special session will also showcase two Forensic Sciences Foundation, Inc. Emerging Forensic Scientist Award winners, who will be presenting their award-winning papers.

The Bring Your Own Posters (BYOP) and Bring Your Own Slides (BYOS) Sessions are two opportunities provided by the YFSF for students and young scientists to present their research. The BYOP Session will take place the evening of Tuesday, February 14, and the BYOS will be held on the evening of Wednesday, February 15. YFSF does not require presenters of YFSF BYOS and BYOP Sessions to be members of AAFS and does not require they attend the special session, but they are encouraged to do so. The program will conclude on Thursday, February 16, with the annual YFSF Breakfast Session which includes a résumé review panel. Attendees of the breakfast session must be registered for the YFSF Special Session.

The Breakfast Session on Thursday morning will feature two speakers, followed by a Question and Answer Session. The theme for the Breakfast Session is *Professionalism and Etiquette "Eggs-pectation*s" and will cover topics in courtroom conduct and testimony. Attendees will then have the opportunity to meet with established AAFS members and receive feedback on their résumés.

YFSF, Education, Mentorship

BS1 The Mummies of Central New York — A Unique Experience for a Medical Examiner's Office

Ronald Brunelli, Onondaga County Medical Examiner, 100 Elizabeth Blackwell Street, Syracuse, NY 13210; and Robert Stoppacher, MD*, 100 Elizabeth Blackwell Street, Syracuse, NY 13210*

After attending this presentation, attendees will learn about the unique opportunity the Onondaga County Medical Examiner's Office had in examining two Egyptian mummies. Participants will be able to understand how a multidisciplinary approach led to interesting historical findings as well as a cancer diagnosis. The cancer diagnosis discussion will ask the question, "Does this diagnosis change theories that cancer is a result of modern lifestyles and environment?"

This presentation will impact the forensic science community by explaining: (1) how the medical examiner's office examined two Egyptian mummies; (2) the collaborative efforts of other forensic science disciplines; and, (3) the modern forensic techniques that lead to interesting historical information and possible information for the future.

Medical examiner personnel often see the effects of human mummification in their daily operation. This postmortem change typically occurs on human bodies that have been left in a dry, hot environment for a period of time. This type of postmortem change is often referred to as natural mummification.

From 6000 B.C. to 600 A.D., ancient Egyptians were known to have been the first civilization to perform preservation of not only dead humans, but also non-human remains such as cats and birds. This preservation process was performed by removing the brain, evisceration, immersion, dehydration, and wrapping the body in cloth. Egypt's desert environment aided this mummification process. This is an example of artificial mummification.

The Onondaga County Medical Examiner's Office had the opportunity to examine two Egyptian mummies. One mummy was a mummified head that had been found during an estate auction of a World War II United States Army veteran. He had found the head in a castle while he was stationed in Germany and brought it home at the end of his tour. Research revealed that Napoleon stowed two mummy heads there during his raid of Egypt. After this invasion, Napoleon had been known to stay in this castle on his way back to France.

The other mummy was a full body that had been on display at a local library's Egyptian exhibit. This mummy had been brought to this community in the 1800s by a well-known wealthy citizen of this village. When he died, his Last Will and Testament was read in which this mummy and other Egyptian artifacts were donated to the library.

The forensic disciplines involved in these examinations were pathology, anthropology, trace evidence, chemistry, and radiology. Carbon dating was also performed. Information from these disciplines revealed information about the age at time of death, the possible eras in which these people lived, and their possible status in society. The full body mummy was determined to have had cancer. Does this cancer revelation provide humans with any information about future cancer research?

The routine day-to-day death investigations at a medical examiner's office often involve decedents who have been naturally mummified; however, it is a unique experience for a moderate-sized office to have the opportunity to examine two Egyptian mummies within a one-year time frame. This presentation will discuss this involvement.

Mummies, Radiology, History

BS2 Analysis of Black-and-White Documents — Seeing Beyond the Monochrome

Irina Geiman, MS, United States Secret Service, Criminal Investigative Division, 950 H Street, NW, Ste 5000, Washington, DC 20223; Julia M. Barker, MSFS*, USSS CID, 950 H Street, NW, Washington, DC 20223; and Amanda Moffett, MFS*, 9611 Laurel Oak Place, Fairfax Station, VA 22039*

After attending this presentation, attendees will understand the basic scientific methodology used in the forensic examination of black-and-white documents. Attendees will have an opportunity to learn how physical, optical, and chemical analyses are utilized in the examination of inks, toners, and papers.

This presentation will impact the forensic science community by demonstrating the importance of using the best analytical practices in the scientific analysis of questioned documents. This presentation will discuss the application of Thin-Layer Chromatography (TLC), Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) spectroscopy, and X-Ray Fluorescence (XRF) spectroscopy in the analysis of inks, toners, and papers. This presentation will also showcase how the evolution of forensic document examination techniques has improved sample discrimination through the expanded use of analytical chemistry and statistical analysis.

Forensic examination of documents commonly includes microscopic analysis utilizing white light and other energy sources such as Ultraviolet (UV) and Infrared (IR). Although this level of examination may be sufficient for the analysis of color inks and papers, in many instances it does not provide enough discriminating power to differentiate components of black-and-white documents. For example, black toners often appear similar microscopically with the possible difference of fusing patterns. Black inks may, to an extent, be distinguished based on their physical and optical characteristics and white papers may contain IR luminescent fibers or UV brighteners, allowing for a certain degree of discrimination. While optical examinations provide a wealth of information, it is prudent to recognize their limitations, such as false positive results from document contamination or alteration.

The best practice is to continue with chemical analyses upon completion of the physical and optical examinations. Optimally, a suite of analytical techniques should be used to evaluate various aspects of the sample, including colorants, resins, and elemental composition. For example, TLC is a well-established technique for the analysis of soluble colorants in inks and brighteners in papers. It is also successfully used to evaluate resins and waxes found in toner particles. FTIR spectroscopy is employed to characterize toner polymers and paper coatings. XRF spectroscopy is used to examine elemental composition of analytes and may allow discrimination of papers and toners based on concentrations of iron, silicon, sulfur, titanium, or other elements.

This presentation will demonstrate that chemical examination of black-and-white documents provides a significant amount of information that may be crucial in discriminating samples. As forensic examination of documents has progressed significantly over the past century and moved from penmanship teachers conducting physical examinations using a loupe to highly trained chemists performing analyses using sophisticated instrumentation, it is important to employ the current best practices, which include a full spectrum of techniques.

Ink Analysis, Toner Analysis, Paper Analysis

BS3 Reliving the Jeffrey Dahmer Case 25 Years Later

Jeffrey M. Jentzen, MD, University of Michigan, 300 N Ingalls, NI2D19 - SPC 5452, Ann Arbor, MI 48109; and Carl J. Schmidt, MD, Wayne County MEO, 1300 Warren, Detroit, MI 48207*

After attending this presentation, participants will recognize the characteristics of organized and disorganized serial killers.

This presentation will impact the forensic science community by providing a model death investigation of a serial killer and his motives.

On July 23, 1991, personnel from the Milwaukee County Medical Examiner Office and Milwaukee Police Department responded to an apartment where partially skeletonized remains of 11 individuals had been detected. The assailant, Jeffrey Dahmer, was quickly taken into custody. In this unique situation, Dahmer freely discussed his role in the murders with law enforcement and provided a valuable resource for collaboration of scene, anthropological, and autopsy findings to pathologists and law enforcement personnel during the investigation. Scene investigation and autopsy analysis of the bodies provided prosecutors with detailed evidence of motives and the psychological state of Dahmer during the course of a death spree that lasted nine months.

The evaluation of the scene allowed investigators to: (1) establish methods of death; (2) begin the preliminary identification process; and, (3) demonstrate the deteriorating mental capacity of the assailant. Forensic pathologists assisted with the identification, established the cause of death, and documented injuries that allowed investigators to question Dahmer on various injuries he inflicted upon his victims. An anthropological examination assisted with the identification and also resulted in the establishment of victim profiles.

A forensic psychiatrist constructed Dahmer's psychological profile, which was characterized by a destructive behavior in which his collection of fetishistic memorabilia provided an expression of his deep ambivalence and mixed hostility toward his victims. Frustrated with his sexual immaturity and continual rejection, Dahmer channeled his hostility into a sadistic sexual behavior characteristic of the psychopathology of a serial killer.

The multidisciplinary investigation that followed provided a number of conclusions that permitted the successful prosecution and conviction of Jeffrey Dahmer. Dahmer strangled his victims following his use of "chemical" restraints. He experimented with a method of injecting caustic material into the brains of his victims to sedate and pacify them into being helpless "zombies." Forensic autopsies demonstrated the methods of death, postmortem dissection, and disposition. Anthropological analysis suggested Dahmer was attracted to a certain anthropometric body type. Materials recovered from the scene confirmed the methods of an "organized" serial killer with souvenir-taking to enhance sexual pleasure.

The Jeffrey Dahmer case has captured and captivated the American consciousness for the past 25 years. This presentation will discuss pitfalls in the investigative process using the lessons learned in the Dahmer case. Participants will understand the complexity of the crime and relive the experience by confronting the difficulties encountered in real time by investigators at the scene, which played an important role in the judicial proceedings that followed.

Jeffrey Dahmer, Serial Killers, High-Profile Murders

BS4 Cold Cases: An Exploratory Study of the Status of Unresolved Homicides in the United States

Sarah L. Stein, PhD, The CRUC, 409 Belchertown Road, Ware, MA 01082; Erin H. Kimmerle, PhD*, University of South Florida, Dept of Anthropology, 4202 E Fowler, SOC 107, Tampa, FL 33820; James M. Adcock, PhD*, 4586 Mayfield Woods Circle, Unit 206, Collierville, TN 38017; and Sara A. Martin, MS*, 26 Hillock Drive, Wallingford, CT 06492*

After attending this presentation, attendees will have a better understanding of the status of unresolved homicides in the United States. More specifically, attendees will: (1) realize the total number of unresolved homicides in the country is far greater than previously believed and is increasing each year; (2) understand how each jurisdiction varies in their own definition of what constitutes a "cold" case; (3) see the varying degrees of perspectives as to what does and does not solve cold cases; and, (4) be more informed as to the status and influence of the unidentified dead and missing persons in our system and how this relates to open homicides.

This presentation will impact the forensic science community by providing information new to this forum that will hopefully guide future decision making as it relates to: (1) the funding and efforts put forth toward the investigation of not only the unresolved homicides, but also the "hot" cases that are presently being investigated; and, (2) how we can improve the manner in which we are investigating the unidentified dead.

In 2010, *ScrippsNews* reported that from 1980 to 2008, based on Uniform Crime Report (UCR) clearance data, the United States had accumulated nearly 185,000 unresolved homicides.[1] Until now, that figure had not been validated or refuted. In the fall of 2015, an exploratory study was initiated that consisted of three phases: Phase I — survey law enforcement agencies regarding the status of their unresolved homicides; Phase II — survey the coroners and medical examiners concerning the status of their unidentified dead; and, Phase III — perform an analysis of the UCR clearance data for homicides from 1980 to 2014.

Phase I: Utilizing Survey Monkey®, solicitations were emailed to 10,500 law enforcement agencies. After a 90-day solicitation period, approximately 1,230 responses were received. After culling out those with inconsistent or incomplete information, the survey concluded with 992 responses that were demographically balanced as to population, department sizes, and geographic location.

Some of the overall findings suggest that approximately 73% reported the "lack of investigative leads" as the primary reason for a case going cold; 56% of the agencies said they have cold cases, yet only 19% of those have a dedicated cold case team consisting primarily of one to two detectives; and only about 24% of the teams have a prosecutor assigned to the team, while very few utilize the services of an analyst.

In rating the importance of factors contributing to solving cold cases, DNA was first, followed by interviewing skills of the detectives, detective decisions, cooperation of witnesses, availability of witnesses, latent prints, and other physical evidence. It was not surprising to see DNA identified as the leading solvability factor for cold cases, but this is contrary to what the research tells us about ongoing homicide investigations where DNA's role is minimal compared to detective decisions.[2-4] A further review and analysis of this data with significant correlations will be provided.

Unresolved Homicides, Unidentified Dead, Death Investigation

L1 Murder on Campus — Understanding the Critical Incident and Forensic Response to a Targeted Murder on a College Campus

Matthew C. Wietbrock, BS, 629 N 6th Street, Lafayette, IN 47909; and Carrie Costello, BA*, 6329 Munsee Drive, West Lafayette, IN 47906*

After attending this presentation, attendees will gain a better understanding of the events surrounding a brutal targeted murder on the campus of Purdue University, including lessons learned from the initial response to the scene of a critical incident and the coordination of processing multiple scenes in separate jurisdictions.

This presentation will impact the forensic science community by detailing the facts surrounding the response to a critical incident, the communication challenges faced by first responders, safety concerns when responding to an active scene, and the forensic tasks employed to process multiple crime scenes properly. Subsequent laboratory analysis and court preparation will also be discussed.

In recent years, professional police agencies around the nation and world have trained to confront and to neutralize active shooter events. The Purdue University Police Department is among those agencies. While this incident did not claim multiple victims, as it was a targeted murder, lessons from the initial police response, crime scene investigation, and meeting the subsequent community expectations will be of great impact to the forensic community.

Tuesday, January 21, 2014, was a frigid winter day in West Lafayette. Students had recently returned to campus after the holiday break and were settling in to a new semester. Community members were making lunch plans without an inkling that tragedy was about to strike.

At 12:03 p.m., the Purdue University Police Department started receiving numerous Emergency 911 calls reporting that shots had been fired within the Electrical Engineering Building and that a killer was on the loose. As this report was dispatched via police radios, officers from three area agencies began to respond to the area. Responding officers made entry into the academic building, prepared to confront an active shooter. In accordance with their training, they rushed past the panicked students and faculty and made their way toward the basement. When the first officers made it to the scene, they found to their surprise, that the classroom laboratory was still full of students. Some of the students were even standing over their deceased teaching assistant, too shocked to move. Police quickly took control of the environment by ensuring that the student witnesses were taken care of and sequestered. Officers then began to search the area, looking for the killer. These searches quickly bore positive results, as the suspect surrendered himself outside of the building, not 100 yards from where he had claimed a life. Secondary searches of the building commenced as officers began to look for additional threats to the public. Investigators closest to the apprehension of the suspect were given strong reason to believe that the suspect had acted alone. To the rest of the responding officers, the "fog of war" had descended and situational awareness became the greatest of currency. Rumors of additional shooters abounded in the early minutes of the response. These rumors were compounded by confusing radio communication and the activation of the fire alarm, which triggered a full evacuation of the building.

Even while the scene remained chaotic, crime scene professionals from four separate agencies began to descend upon the scene. A true team effort would take place in the processing of the murder scene. This effort would include many specializations such as blood spatter analysis, photogrammetry, medicolegal death investigation, and computer forensics.

Murder, Critical Incident, Crime Scene Investigation

EVENING SESSION

E1 The Last Lecture

Julie A. Howe, MBA, Saint Louis University, Franklin, Jefferson & St Charles M.E. Offices, College of Health Sciences, 3084, St. Louis, MO 63104-1028; Christine Funk, JD, Unlisted, Washington, DC 20024; Jan C. Garavaglia, MD, 10596 Pulver Road, Burlington, WA 98233; John J. Lentini, BA*, Scientific Fire Analysis, LLC, 88005 Overseas Highway, #10-134, Islamorada, FL 33036; Kenneth E. Melson, JD*, GWU Law School, 15610 Golf Club Drive, Montclair, VA 22025; Katherine Ramsland, PhD*, DeSales University, 2755 Station Avenue, Center Valley, PA 18034; and Douglas H. Ubelaker, PhD*, Smithsonian Institution, Dept of Anthropology, NMNH, MRC 112, Washington, DC 20560*

After attending this presentation, attendees will gain insights relating to life and work from fellow Academy members.

This presentation will impact the forensic science community by providing personal insights into the speakers' journeys throughout their personal and professional lives.

Many times, professors are asked to give "last lectures" to provide guidance and advice to their students while inspiring them to achieve their dreams and take risks in both their personal and professional lives. Members of the Academy have been asked to share what they believe matters most in living a full and rewarding life, both personally and professionally.

In 2007, Randy Pausch famously presented "The Last Lecture" as the first in a lecture series entitled "Journeys." In these lectures, members of the Carnegie Melon University community shared "their reflections and insights on their personal and professional journeys." Dying of pancreatic cancer, Randy Pausch brought down the house with his talk, "Really Achieving Your Childhood Dreams." This lecture has become infamous for the inspiration it instilled in everyone who has heard it.

In the spirit of this legacy, members of the Academy have been asked to share what they believe matters most in living a full and rewarding life, both personally and professionally, including their childhood dreams and inspirations, taking risks, overcoming obstacles, and the adventures and lessons learned along their journeys. The speakers reflect varying experiences and different walks of life. Share and learn from their joys, challenges, integrity, and recognition during this entertaining and educational session.

Jan Garvaglia, MD, is the retired chief medical examiner for the District Nine Medical Examiner Office in Orlando, FL. She is best known as the reality TV star "Dr. G" on the Discovery Network. The show, *"Dr. G: Medical Examiner,"* won an International Health and Medical Media Award for "Best Health Series" in 2008. Dr. G will share her personal story about the trials of being a forensic pathologist along with the pearls of the profession, while highlighting interesting cases and discussing how the reality-based TV series has impacted her life.

John Lentini, BA, is one of a handful of people certified to conduct both fire scene investigations and fire debris analysis. He has personally conducted more than 2,000 fire scene inspections and has appeared as an expert witness on more than 200 occasions. Mr. Lentini is an independent consultant, working with both prosecution and defense in pending cases and in cases involving the wrongfully convicted.

Ken Melson, JD, has had a long and lively career within the forensic community, serving as a federal prosecutor for more than 20 years. As Director of the Office for United States Attorneys, he was responsible for the oversight of the 94 United States Attorney's Offices. He is a past president of the AAFS and has served on numerous committees. In April 2009, Mr. Melson was named Acting Director of the Bureau of Alcohol, Tobacco, Firearms and Explosives (ATF) by President Obama, where he served until August 2011. Prior to retiring from the United States Department

of Justice in 2012, Mr. Melson was the Senior Advisor on Forensic Science in the Office of Legal Policy and served as co-chair on the Subcomittee on Forensic Science within the Executive Office of the President.

Katherine Ramsland, PhD, is the Director of the Master of Arts in Criminal Justice Program at DeSales University. She also teaches forensic psychology. Dr. Ramsland is a prolific writer, with most of her attention focused on crime, forensics, and serial killers. She recently completed *Confession of a Serial Killer: The Untold Story of Dennis Rader, the BTK Killer.* However, she also authors such inspiring works as *Snap: Seizing your Aha! Moments*, focusing on "the latest neuroscience findings on spontaneous thought processes, or "snaps."" Dr. Ramsland "describes how everyone—not just geniuses—can learn to improve the likelihood of their own "eureka" moments by adopting certain rewarding attitudes and habits."

Douglas Ubelaker, PhD, is a curator and senior scientist at the Smithsonian Institution's National Museum of Natural History in Washington, DC, where he serves as a consultant in forensic anthropology. Dr. Ubelaker has published extensively and has served on editorial boards of leading scientific journals. Dr. Ubelaker is regarded as one of the world's leading anthropologists, receiving many international and national honors and awards throughout his esteemed career in the analysis of human skeletal remains with an emphasis on forensic applications. Dr. Ubelaker served as the AAFS President from 2011-12. Dr. Ubelaker works tirelessly on behalf of human rights internationally. He currently serves as Chair of the AAFS Human & Humanitarian Rights Resource Center, which promotes forensic science principles and applications to global projects requiring special assistance.

Last Lecture, Mentoring, Forensic Science

W1 Behind the Curtain: Understanding the Basic Science and Testimony of Latent Prints

Heidi Eldridge, MS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; Brendan Max, JD*, 69 W Washington, Fl 17, Chicago, IL 60602; and Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will be well-positioned to critically evaluate latent print reports and testimony. Prosecutors will be more aware of changing trends in testimony and will better understand how to prep their expert witnesses to make sure they aren't falling into "old school" traps and are well prepared to discuss the relevant literature. Defense attorneys will be able to spot unsupported statements and effectively challenge them in court. Judges will gain a basic understanding of the modern scientific research detailing the strengths and limitations of latent print comparisons, which will allow them to be more effective gatekeepers. All legal professionals will be equipped to spot the difference between the "old school" or "dogma" expert and the "transparent" expert and will be able to react accordingly.

This presentation will impact the forensic science community by assisting the legal community to better understand the basic scientific principles behind friction ridge comparisons. This workshop will provide the legal community with the tools to critically evaluate friction ridge testimony, which will in turn allow them to better advocate for the science, challenge the science, or fulfill a gatekeeping role, as their positions within the legal system dictate. These skills will improve the application of friction ridge comparison science in the legal system by helping to ensure that it is presented responsibly and used appropriately, increasing its value to the legal system.

Judges and attorneys have an important responsibility in cases involving forensic science evidence. While most judges and attorneys do not have scientific training, they nonetheless have the task of assessing forensic evidence for reliability. Attorneys have the additional responsibility of effectively challenging forensic evidence when appropriate. In recent years, there has been a growing spotlight on the idea of "junk science" in the courtroom and a growing pressure on legal professionals to better understand the science that is being presented. The prevalence of forensic evidence in criminal cases coupled with the pace of research and reform in the forensic community will cause this pressure to increase in the future.

The basics of forensic science disciplines to a legal audience will be explained in addition to tips on how legal professionals can evaluate the reliability of forensic evidence in criminal cases will be provided. An overview of the latent print discipline will be provided with a discussion of what latent print examiners do in their work and the foundational science behind latent print comparison. Reporting and testimony will also be presented detailing the traditional ways latent print examiners have expressed their conclusions, which parts are inappropriate, and why. It will also discuss the ways in which latent print testimony is shifting in the post-NAS environment. This discussion will be supplemented with discussion of some landmark studies in the discipline and how legal professionals can use these studies during litigation. What is valid and what is not in the discipline will be highlighted, providing legal professionals with some of the necessary tools and road maps to assess forensic evidence and litigate questionable forensic evidence in criminal cases.

Come take a peek behind the curtain into the science of latent print examinations.

Latent Prints, Testimony, Gatekeeping

W2 A Computational Framework for Skeletal Age-at-Death Estimation Using Laser Scans of the Adult Pubic Symphysis: Theory, Methods, and Software

Bridget F.B. Algee-Hewitt, PhD, Stanford University, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020; Dennis E. Slice, PhD*, Florida State University, Department of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306-4120; Detelina Stoyanova, PhD*, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306; Jieun Kim, PhD*, 801 Sutters Mill Lane, Knoxville, TN 37909-9702; Cristina Figueroa-Soto, MA*, The University of Tennessee, 254 S Stadium Drive, Knoxville, TN ; and Diane L. France, PhD*, Human Identification Laboratory of CO, 1713 Willox Court, Ste A, Fort Collins, CO 80524*

After attending this presentation, attendees will understand state-of-the-art skeletal age estimation, the problems forensic anthropologists face when estimating age by conventional methods, the needs of the medicolegal community, and the potential for advancing the field using new shape-based methods. Attendees will receive instruction in three new methods that apply numerical shape algorithms to laser scans of the skeletal age indicator. Attendees will also receive hands-on training in using the equipment, software, casts, and data.

This presentation will impact the forensic science community by delivering instruction on implementing three new fully computational methods for age-at-death estimation from skeletal laser scans that produce estimates that closely approximate true age, with minimal risk of subjectivity or low-method/observer-induced error.

The estimation of age-at-death in forensic anthropology represents an essential component of the biological profile, providing information on the individual that is key to medicolegal case identification. Skeletal indicators of age are widely used to estimate age-at-death from adult remains in this casework context. Of the pelvic, thoracic, and cranial features for which age-related change is known, the pubic symphysis remains the preferred, most frequently studied indicator. Common practice requires the macroscopic comparison of the bone surface morphology to a set of population-specific criteria that represent a series of pre-defined scores or phases. The case-specific age-at-death is then estimated from an age range previously associated with the assigned score or phase. While the simplicity of this approach is attractive, the limitations of this kind of visual analysis are well-documented across the field, not only for age-at-death estimation and but also for other parameters of interest to the biological profile. In general, this methodology is known to introduce a large degree of subjectivity and intra/inter observer-related error. For age estimation especially, these problems have been shown to variably impact the reliability and repeatability of results; therefore posing, significant challenges to meeting current medico-legal standards of evidence and successful forensic case identification.

In response to these concerns, an alternative, fully computational approach to the macromorphoscopic assessment methods traditionally applied to skeletal indicators of age and, specifically, to the pubic symphysis has been proposed. It is argued that accurate, precise, and objective age estimates can be obtained by sourcing three-dimensional coordinate data from laser scans of the pubic symphysis, subjecting these data to shape-analysis algorithms, and combining the resulting shape measures in multivariate regression models. In recent publications the value of this novel approach for contemporary skeletal analysis have been demonstrated. Using Bass Collection samples, forensic cases, and the Suchey-Brooks and McKern & Stewart casts, these methods produce estimates that differ from the exact age-at-death by $\approx 11.72 \pm 0.97$ years. To standardize implementation, a protocol for data collection and extraction has been formalized. The software, forAge, was developed to facilitate accurate and efficient method application among forensic practitioners, whose levels of familiarity with laser scanning technology, statistical computing, and the morphological characteristics of the pubic symphysis may vary.

This workshop will introduce forensic practitioners to the theory that underlies the methods and provide laboratory instruction on its implementation. It will also be broadly applicable to other scan and shape-related research. To contextualize the work, a review of the current state of the art of age-estimation, the demands that working within the medico-legal context places on forensic case analysis, and the advantages that these methods offer for estimation, evidence, ease of use, and data preservation or sharing. The anatomical properties of pubic symphyseal morphology that make this indicator well-suited to shape-based inference as well as the mathematical theory that supports the calculation of our shape measures will be explained. The appropriate use of these measures

and clarification of how an estimate of age is generated will be discussed. To provide practical instruction, protocols for laser scan collection using the NextEngine scanner, scan editing and manipulation using ScanStudio or Meshlab, extraction of shape information as three-dimensional coordinates, file storage of these data, and for standardization and processing of the coordinates prior to analysis will be demonstrated.

The detailed implementation of the following will be discussed: (1) the *SAH-Score* method that captures the variance on the symphyseal face to capture the gradual flattening of the surface associated with aging;[1] (2) the thin plate splines method that determines the bending energy required for transforming a perfectly flat, infinitely thin plate to match the surface of a pubic symphysis scan;[2] and, (3) the ventral curvature method that quantifies the progressive formation of a rim around the entire symphyseal surface and its later erosion.[3] A tutorial on the use of the forAge software for these analyses and to produce age-estimates via multivariate regression will be provided. With France Casting, the age-determination casts for calibration and validation will be discussed. Finally, recommendations for data collection in the field and laboratory will be offered. Workshop attendees will have the opportunity to train on the scanning equipment and software and produce age estimates directly from specimens and coordinate data in various stages of processing.

Age-at-Death Estimation, 3D Laser Scans, Computational (Shape) Analysis

W3 Shooting Reconstruction

Peter J. Diaczuk, Penn State University, 329 Whitmore, State College, PA 16802; Jack Hietpas, PhD*, Penn State University, 329 Whitmore Lab, University Park, PA 16802; Andrew J. Winter, MS*, Middlesex County Prosecutor's Office, 25 Kirkpatrick Street, 3rd Fl, New Brunswick, NJ 08901; and Linda Tran, BS*, Jefferson Parish Sheriff's Office, 1233 Westbank Expressway, Bldg G, Harvey, LA 70058*

After attending this presentation, attendees will learn some of the phenomena that must be taken into consideration when assessing a shooting scene. Several different types of ammunition will be discussed, along with their interactions with several different substrates commonly encountered. Attendees will also become familiar with evidence recognition, documentation, and recovery for laboratory analysis.

This presentation will impact the forensic science community by exploring some of the techniques used in shooting scene reconstruction and subsequent laboratory analysis of related evidence.

The complex nature of a shooting incident may generate a variety of firearm-related evidence, such as the firearm itself, cycled or discharged ammunition components, gunshot residue, trace evidence on a bullet, or impact sites with traces of the bullet's prior presence. Whether considered firearm evidence or trace evidence, this information may have to be integrated by the scientist to be most beneficial.

When a shooting incident takes place and firearm evidence is recovered at the scene, whether in the form of cartridge cases or bullets, it is likely that an examination of these ammunition components will ensue, using the well-established and proven methods of comparison microscopy. Recently, use of comparison microscopy has become the focus of criticism, but it nevertheless provides valuable information for both opaque samples using reflected light and for transparent samples using transmitted light. There are some occasions, however, where the question of which firearm was involved, or which bullet came from what firearm is not in dispute; but instead, questions arise about the specific path of a bullet, the relative positions of the shooter and the victim, the presence of an intervening object, or the sequence of the shots that were fired.

Pulling the trigger of a firearm initiates a series of events that culminates with the discharge of a bullet with considerable energy, along with primer and propellant resides as secondary ejecta. The bullet may not only impact its intended target; it may perforate an intermediate object or objects on its way to the target or it may pass completely through the target and retain sufficient energy to continue downrange and impact an unintended object.

These types of interactions and impacts invariably impart information about the event onto the bullet and onto the impacted substrates. If information from the inadvertent or intended impact is recognized, examined, and deciphered, it can be helpful in developing a more accurate shooting scene reconstruction. This workshop will consider the transfer of material from the substrate to the bullet, per the Locard Exchange Principle, the overall change to both the bullet and substrate from the energy exchange, the potential path the bullet followed, and the possibility of ricochet.

Determining the angle at which a bullet will successfully ricochet is essential information when a shooting investigation involves indirect fire. This information provides the forensic scientist with fundamental data required for the scientific reconstruction and assessment of a shooting scene. Depending upon the substrate, the bullet's design, velocity, construction, and its angle of impact, a bullet may fail to ricochet upon impact, or the bullet will successfully ricochet. Knowledge of bullet behavior with common substrates provides valuable information for scientific investigation of shooting scenes where bullets have impacted intermediate surfaces. A timely and accurate scene reconstruction is imperative in both the investigative and the adjudicative stages of a shooting incident.

Shooting, Reconstruction, Bullet Path

W4 Sex-Related Homicide and Death Investigations: Practical and Clinical Perspectives — The Significance of Pornography, Sexual Deviance, Autoerotic Fatalities, Signature and *Modus Operandi* (M.O.) in Serial Murder Investigation and Criminal Investigative Analysis

Vernon J. Geberth, MS, MPS, Practical Homicide Investigation, PO Box 105, Marco Island, FL 34146; Thomas C. McAndrew, MA*, Pennsylvania State Police, 5933 Derick Drive, Orefield, PA 18069; Barbara C. Wolf, MD*, District 5 MEO, 809 Pine Street, Leesburg, FL 34748; and Andrea Zaferes, BA*, Dutchess County Medical Examiner Office/Team LGS, PO Box 601, Shokan, NY 12481*

After attending this presentation, attendees will be aware of common assumptions made by responders on scene, such as a death is an autoerotic asphyxia death prior to investigating if more than one person may have been involved. Attendees of this presentation will better understand the significance of sexual deviancy, fantasy, and pornography in sex-related events, as well as the investigative and behavioral analysis and medicolegal considerations involved in these types of cases. This presentation will provide attendees with practical, proven procedures for crime scene documentation, law enforcement investigation, and medicolegal investigations.

This presentation will impact the forensic science community by providing and familiarizing forensic scientists and investigators with the investigative expertise and medicolegal science involved in the professional examination of sex-related homicide and death investigations. There will be case examples that focus on determining whether or not the death is a paraphilic accident or a sex-related homicide.

Sex-related homicides and other deaths occurring during sexual activities have drastically increased over the years and claim victims from all walks of life: men or women; lovers or strangers; elders or children. These fatalities may occur from recreational misadventures or sex-related crimes, which are perpetrated by sex offenders and are among the most horrific crimes imaginable. The internet has certainly provided society with technological advances but has also resulted in the proliferation of pornography and easy access to sex-related materials to anyone with a computer or computer access. It is significant that the sex industry, which consists of commercial enterprises providing adult entertainment, earns over $13 billion annually in the United States and how that may influence the increase in sex-related events.

Sexual deviance, fantasy, and the significance of pornography perform major roles in the proliferation of sex-related homicides and unnatural deaths due to autoerotic activities, which expose the participants to danger as in cases involving some of the paraphilias. In DSM-5, the term paraphilia denotes any intense and persistent sexual interest, other than sexual interest in genital stimulation or preparatory fondling with phenotypically normal physically mature consenting adults. Some paraphilias may concern an individual's erotic activities while others primarily concern an individual's erotic targets. An example would be the voyeur, who satisfies himself sexually by observing an unsuspecting person naked, in the process of disrobing or engaging in sexual activity versus the sexual sadist who is aroused by the physical or psychological suffering of another person.

The applications of clinical criteria and abnormal psychology to the investigative process are an integral parts of criminal personality profiling and have been universally recognized and accepted as genuine and legitimate investigative techniques. Detectives and criminal investigators routinely employ these techniques in their investigation of violent crime on a case-by-case basis. From a practical standpoint, there are only so many ways to kill and only so many stories to tell as an offender attempts to explain the killings. After a while, a distinct pattern emerges, which encompasses a series of clusters of behavioral information and specific typologies of offenders. Human behavior is frequently repetitive. Certain actions engaged in at the scene by certain types of personalities will tend to repeat themselves.

Clinically speaking, there is a behavioral distinctiveness in human sexuality. This unique aspect of our sexual arousal and response system accounts for why individuals differ in their sexual behaviors and engage in a specific series of behavioral patterns. In sex-related criminal incidents, the offender is oftentimes subconsciously "acting out" a sexually significant behavioral pattern, which reflects the underlying personality, lifestyle, and developmental experiences and fantasies of the offender.

Sex-Related Deaths, Sexual Deviance, Signature and M.O.

W5 The Opioid Epidemic: Trends, Challenges, and a Path Forward

Donna M. Papsun, MS, Unlisted, Willow Grove, PA 19030; Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; Joshua Yohannan, MS*, Allegheny County of the Medical Examiner, 1520 Penn Avenue, Pittsburgh, PA 15222; Kavita Babu, MD*, University of Massachusetts Medical Center, 55 Lake Avenue, N, Worcester, MA 01655; Roumen Sedefov, MD*, EMCDDA, Cais do Sodré, 1249-289, Lisbon , PORTUGAL; Istvan Ujvary, PhD*, Budapest University of Technology & Economics, Buza Ut 32, Budapest , HUNGARY; Jeff Walterscheid, PhD*, Armed Forces Medical Examiner System, Division of Forensic Toxicology, 115 Purple Heart Drive, Dover AFB, DE 19902; Amanda L.A. Mohr, MSFS*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Melissa Friscia, MSFS*, CFSRE, 2300 Stratford Avenue, Willow Grove, PA 19090; and Graham R. Jones, PhD*, Alberta Medical Examiner, 7007-116 Street, NW, Edmonton, AB T6H 5R8, CANADA*

After attending this presentation, attendees will be able to: (1) describe the current epidemiology of prescription and non-prescription opioid drugs in North America and around the world; (2) identify and distinguish between the various chemical categories of novel emerging opioid drugs; (3) implement a drug-screening protocol for novel emerging opioid drugs, looking for the most relevant drugs; and, (4) apply data from intoxication cases involving traditional and emerging opioid agonists in the interpretation of forensic toxicology and death investigation casework.

This presentation will impact the forensic science community by providing an update to the current state of the opioid epidemic in which emerging novel opioid drugs are challenging professionals in forensic chemistry, toxicology, emergency response, and death investigation.

In recent years, opioid use has increased dramatically due to the overprescribing of painkillers such as hydrocodone and oxycodone, the increased demand for heroin and other illicit drugs sold as either contaminants or substitutions, and the emergence of novel synthetic opioids, including repurposed pharmaceutical cast-offs (e.g., U-47700, AH-7921) and non-pharmaceutical fentanyls (e.g., furanyl fentanyl, β-hydroxythiofentanyl). Opioid use and abuse has garnered national attention; news stories vary from celebrity overdose deaths, to presidential campaign promises to address the opioid crisis, to the approval of nasal naloxone spray to reverse overdoses. Despite being a familiar drug class with a long history. These changes make it necessary for the forensic science community to revisit and understand the current state of the opioid problem.

The demand for heroin and other pharmaceutical painkillers has become so intense that it has created a dynamic marketplace for illicit drug manufacturers. Across the United States and Europe, users are able to buy these substances not only through a neighborhood dealer, but also through online cryptomarkets, making more substances accessible to more people. Besides the multiple ways in which these illicit drugs can be obtained, clandestine drug makers are also distributing a variety of substances that pose substantial risks to end users who do not know what, and how much, they are consuming. Perspectives regarding both the United States experience and the European experience with the current state of the opioid market will be discussed.

This workshop has been designed to provide an end-to-end update on the current opioid crisis including a discussion and review of the current trends in opioid deaths and intoxications in the United States, and a deeper look at some of the factors contributing to the increased popularity and the links between overprescribing and escalation to more intense illicit opioid abuse. The United States illicit opioids market will also be described and examine available knowledge about approaches to illicit opioid synthesis and distribution, including use of signature analysis to track the origins of illicit opioids. An emergency medical physician dealing with opioid intoxications will discuss some of the features of current intoxications with novel opioids and its impact on effectiveness of opioid reversals, and consequences for naloxone programs.

The opioid trade is now international and the experience of professionals in other parts of the world often presages our experience in the United States. Experts from the European Monitoring Center for Drugs and Drug Addiction (EMCDDA) in Lisbon will share international intelligence on the opioid trade and what may be in store for the United States. The known and emerging knowledge about factors affecting the potency of opioids including their receptor binding and functional affect, as well as structure activity relationships will be reviewed in attempts to explain the relative potency of suspected agonists.

Among the more unusual trends is an increase in abuse of the mu-opioid agonist loperamide reviewing recent reports of toxicity and fatalities associated with abuse of this drug.

The session will conclude with a panel presentation of forensic toxicology case series involving the most recently identified compounds of concern, including acetyl fentanyl, butyryl fentanyl, furanyl fentanyl, MT-45, AH-7921, U-47700, 3-methyl fentanyl, W-15, and W-18, the latest and most mysterious of the alleged novel opioids.

Opioids, Fentanyl Analogues, Heroin

W6 Taking a Bite Out of Crime and Other Hairy Situations

Anjali A. Ranadive, JD, SciLawForensics, Ltd, 1834 Overlook Ridge Road, Brookings, SD 57006; Lynn Garcia, JD*, Texas Forensic Science Commission, 1700 N Congress Avenue, Ste 445, Austin, TX 78701; Sandra Levick, JD*, 633 Indiana Avenue, NW, Washington, DC 20004; Maxwell Christopher Fabricant, JD*, The Innocence Project, 40 Worth Street, Ste 701, New York, NY 10013; Anthony R. Cardoza, DDS*, 9530 Cuyamaca Street, #101, Santee, CA 92071; Cynthia Brzozowski, DMD*, 179 Dayton Street, Sea Cliff, NY 11579; Pamela A.W. King, JD*, 151 4th Street, SE, Rochester, MN 55904; Christopher J. Plourd, JD*, Superior Court, 939 Main Street, El Centro, CA 92243; Sherry Elizabeth Sabol, JD*, FBI, 935 Pennsylvania Avenue, NW, Rm 7350, Washington, DC 20535; and Keith Harward**

After attending this presentation, attendees will understand how wrongful convictions and exonerations come to light through the post-conviction process and will be provided examples of how to respond when mistakes are uncovered.

This presentation will impact the forensic science community by highlighting what has been learned from two forensic disciplines under fire and how addressing these weaknesses has led and can lead to a stronger forensic future.

Wrongful convictions often happen for a multitude of reasons in any given case. They are also often the bellwether for change, making the need for reflection, reform, and growth within both the legal and forensic communities a priority. This workshop will delve into two specific exonerations. Each raises different issues, has sparked different responses, and is leading to the evolution of not only these disciplines but the forensic science community as a whole.

The workshop will begin by focusing on the stories of two men convicted for crimes they did not commit and the post-conviction journey that led to their ultimate exonerations. Kirk Odom was exonerated on July 13, 2012, after spending 22 years in prison and another nine years on parole as a registered sex offender for a rape he did not commit. The victim, a 27-year-old woman, who was attacked in Washington, DC at first could not identify her attacker. She would later identify Mr. Odom in a police line-up. This misidentification along with testimony from an FBI Special Agent that the hairs found on the victim's nightgown were microscopically similar to Odom's hair, "meaning that the samples were indistinguishable," contributed to his conviction. His post-conviction proceedings were handled by Sandra Levick who will speak about her experiences working on Mr. Odom's case; ultimately, leading to the certificate of actual innocence, which was signed on Mr. Odom's 50th birthday.

The second case involves a rape and murder from Virginia. In this case, Keith Allen Harward was convicted based at least in part on bitemark testimony presented at his trial. He spent 33 years of a life sentence in a Virginia prison. Mr. Harward will speak about his experience as someone wrongfully convicted of a crime and what the post-conviction process looks and feels like from the perspective of the accused. His post-conviction experience will also be discussed by the lawyers involved. In addition, two forensic odontologists will provide their perspectives into how the discipline has or is changing and what might be done in the future to avoid these kinds of errors.

Reflection alone is not enough, and in a number of ways, the forensic science community has responded to stories like those of Mr. Odom and Mr. Harward. Those responses will also be explored.

Lynn Garcia from the Texas Forensic Science Commission (TFSC) will focus on the experiences of the Commission in providing oversight, coordination, and advocacy for accredited crime laboratories in Texas. Discussion will include: (1) specific case examples of how shared expectations regarding laboratory self-disclosure can increase transparency and improve organizational culture will be discussed; (2) the importance of resisting external political agendas and adopting a collaborative approach with all affected stakeholders; and, (3) focus on the importance of a state commission's outreach to affected prosecutors, judges, and the defense bar to ensure they understand the implications of a particular forensic non-conformance. Attendees will learn about the commission's efforts to develop a statewide notice protocol to ensure potentially affected defendants receive notice in the wake of concerns in key, high-volume disciplines like DNA/forensic biology. Lessons learned from Texas may serve as a model for other states seeking to establish similar commissions to examine various aspects of the state of forensic science locally and globally.

Sherry Sabol, General Counsel from the FBI will talk about what happened in the wake of cases like Mr. Odom's. This includes a review of the testimony by other FBI analysts and what the FBI is doing in this area of comparative science not only to look back on old cases but to improve the quality of testimony for the future.

Finally, Judge Chris Plourd and Judge Pam King will discuss the challenges faced in the justice system, address the admissibility of forensic science evidence and opinions and the court's role as the gatekeeper and explore how the criminal justice system is changing and then provide some insight into the challenges to change built into the judicial system.

Post-Conviction, Hair Analysis, Bitemark Analysis

W7 How to Manage the Multidisciplinary Response to a Mass Fatality Event

Robert A. Jensen, BS, Kenyon International Emergency Services, 612 Spring Hill Drive, Ste 180, Spring, TX 77386-6032; and Anthony B. Falsetti, PhD*, Arizona State University, New College of Interdisciplinary Arts and Sciences, 4701 W Thunderbird Road - Mail Code 2352, Glendale, AZ 85306*

After attending this presentation, attendees will: (1) understand what to expect if they are involved in a mass fatality event; (2) understand who is involved; (3) understand what the expectations are of the different parties; (4) learn how to work with different government agencies, private parties, media, and families; (5) know how to provide leadership and direction; and, (6) understand the practical lessons learned from multiple events so they can review existing plans, update them if needed, and be better prepared for the variety of events in which they are likely to be involved.

This presentation will impact the forensic science community by providing practical, experienced guidance on what to expect, how to manage, and how to avoid the very common mistakes that medical examiners, coroners, law enforcement, and others who have the responsibility of preparing for and responding to mass fatality events will face when these events occur.

Mass fatalities from terrorist attacks, natural disasters, industrial accidents, and transportation losses are complex events for the forensic community to manage. Complexities include the challenges created by fragmented, potentially contaminated human remains and the collection and preservation of evidence. Events which might include the tragic loss of 100 people could easily result in a recovery scene of several square miles and over 10,000 human remains fragments. They also include the involvement of multiple local, national, and international governments at the forensic, family assistance, and political levels, often with competing interests. These factors, combined with the massive logistical requirements and the overwhelming media and public attention, can create a chaotic situation for forensic practitioners who are more accustomed to controlled environments.

Today's forensic practitioners are expected to successfully manage these events. This includes medical examiners, coroners, law enforcement, and justice officials. The goal of this workshop is to provide the practical, overall view of mass fatality event management strategy. This eight-hour workshop will cover: (1) an overview of who's involved, from occurrence of the event to final litigation/court, as well as managing the best practice teamwork that is needed for success; (2) an overview of what's involved – the functional areas beyond the morgue that need to be addressed, such as collecting antemortem information, call centers to register missing persons, and family briefs; (3) media and communications management - how and what to say; secure websites; family, media, and political briefings; (4) common mistakes in identification and release of human remains; (5) dealing with HAZMAT (including deliberately introduced) or infectious (public health) contaminated human remains and scenes; and, (6) managing the critical incident stress impact on yourself and staff.

This workshop won't cover how to do an autopsy, or how to take and compare fingerprints, hot to make an ID, or how to write a report. Rather, it teaches how to bring all areas of death investigations together in a cohesive and professional mass fatality response. Attendees will learn how to create a system to control all aspects of the response. This includes practical matters such as: quality assurance systems to manage the release of highly fragmented remains; how to develop checklists to help people who have not worked together; how to organize a morgue triage and process flow; and, how to manage and share the enormous amount of data that is both collected and requested by others.

Drawing on extensive, real-world, multi-event practical experience, participants will learn how to deal with the consequences of the event. No event is unpredictable and there are no new lessons, only new people learning lessons for their first time. This is an opportunity to learn and take the information back to your own organization to identify and fill in gaps in your own plans.

Mass Fatality Response, Multidisciplinary Approach, Mass Disasters

W8 Applications of Hair Testing in Toxicology: Legal, Technical, and Medical Challenges

Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038; Robert Kronstrand, PhD*, National Board of Forensic Medicine, Dept of Forensic Toxicology, Artillerigatan 12, Linkoping SE 587 58, SWEDEN; Carmen Jurado, PhD*, National Institute of Toxicology & Forensic Scienc, Avda. Dr. Fedrini s/n, Sevilla 41015, SPAIN; Gail Audrey Ann Cooper, PhD*, OCMENYC, 520 First Avenue, New York, NY 10016; Lauren M. Vinsick, BS*, Omega Labs, 400 N Cleveland Avenue, Mogadore, OH 44260; Pascal Kintz, PhD*, X-Pertise Consulting, 84 route de Saverne, Oberhausbergen 67205, FRANCE; and Joseph Jones, MS*, United States Drug Testing Laboratories, 1700 S Mount Prospect Road, Des Plaines, IL 60018*

After attending this presentation, attendees will be able to evaluate the usefulness of hair testing in forensic casework by becoming more knowledgeable, which will allow attendees to: (1) describe and explain the existing consensus documents on hair analysis, recognize the importance of guidelines in hair testing, and evaluate their own laboratory routines in the light of the existing guidelines; (2) describe how Ethyl Glucuronide (EtG) is incorporated into hair and interpret the results of this type of analysis; (3) describe the differences between urine/blood testing and hair testing for doping agents and be more knowledgeable concerning sport regulations in cases of doping offenses in addition to relevant political issues in using hair for doping purposes; (4) realize the possible applications of hair analysis in forensic toxicology and the circumstances and challenges that must be considered for the correct interpretation of the results; and, (5) gain an overview of workplace drug testing and the challenges of hair testing in a production laboratory.

This presentation will impact the forensic science community by allowing attendees to gain insight into the broader scope of the analysis of hair for drugs and toxins in a range of fields applicable to forensic science. By including discussion on recent changes in legislation and standards, the usefulness of these tests in the greater context of the law and recent regulatory changes will be clearer to the forensic science community.

Hair is a unique and challenging matrix for forensic toxicological testing in that detailed information on historical use is recorded over time as compared to traditional blood and urine matrices. In order to make best use of hair testing in forensic casework, a thorough understanding of the advantages and limitations of this matrix is essential. An overview of the current status of hair testing in a variety of toxicological areas including reference to current standards and consensus agreements as set by the Society of Hair Testing (SoHT) will be provided. By providing both an overview and more detailed information in workplace testing, pediatric and maternal testing, doping and alcohol biomarkers, as well as forensic toxicological testing of hair, the workshop is not only amenable to toxicologists but also relevant to pathologists and criminalists with an interest in expanding their understanding of the importance of these test in the investigation of crime. Discussion will focus on the latest technologies used for the testing of hair within the different areas covered, from screening tests to confirmation. The effects of age, sex, health, and the environment on the interpretation of results will be explained. All presentations will be given in the context of the SoHT guidelines to ensure that attendees understand best practice and safeguard against over-interpretation of results. Case examples will be discussed for each testing type and attendees will be invited to share their own casework examples for discussion by the panel of experts.

Hair Testing, Drugs, Guidelines

W9 Staged Crime Scenes: Crime Scene Clues to Suspect Misdirection of the Investigation

Grant D. Graham, Sr., MFS, 467 Hay Street, Fayetteville, NC 28301; and Arthur S. Chancellor, MA*, 131 Wed Denning Road, Angier, NC 27501*

After attending this presentation, attendees will learn three new categories of staged scenes, with case examples of different types of crimes where staging is prevalent. Additionally, attendees will learn the "red flags" or common findings in staged scenes.

This presentation will impact the forensic science community by introducing the distinct categories of staging based on the intent of the offender's scene alteration. Ultimately, applying these categories may help in the quick recognition of scene alterations or staging.

In the course of their career, most detectives and forensic practitioners will come into contact with a staged crime scene; a scene that has been altered by the offender to either mislead a police investigation as to the true facts of the crime or for other reasons understood only by the offender. Staged scenes and "staging" are possible in nearly every type of criminal offense raging from property crimes, such as arson and burglary, to violent crimes such as homicide, child abuse, or sexual assaults.

To better understand the dynamics and the general nature of "staging," this workshop will introduce distinct categories of staged crime scenes based on the intent of the offender's scene alteration. The ultimate goal of this workshop is to understand that the offender's actions to stage a scene can actually be identified through common findings or "red flags" that are often found when scenes are altered. Further, that these same red flags may help in the quick recognition of scene alterations or staging, and based on new criteria may be divided into three separate and distinct categories. These categories are herein referred to as, primary, secondary, and tertiary.

The primary staged scene is intentionally altered or changed by the offender with criminal intent to misdirect a subsequent police investigation and can be further sub-categorized into two types: ad hoc, and premeditated. The ad hoc subtype is staged without forethought and planning, at the spur of the moment after the event has taken place, and is generally intended to deflect attention away from the offender and true facts of the crime. The scene is considered premeditated when the offender preplans the scene alterations in accordance with a preconceived scenario. Premeditated staging is often designed to focus attention onto the staging and false evidence. Ultimately, through primary staging the offender in effect creates a false reality that in his/her mind will successfully and with criminal intent, misdirect the police investigation.

Secondary staging involves the intentional alteration or manipulation of the crime scene or victim by an offender that is unrelated to misdirecting or diverting subsequent investigations. This is really a new category of staged scenes and would include such examples as posing the victim's body into sexual provocative positions as found in sexual homicides or other elements of what is more commonly known as "staging" such as covering the face or body in what is generally often described as depersonalization. The perpetrator's purpose in secondary staging is not to misdirect the investigation, rather it is often something that is psychologically "part and parcel" to the crime, such as demeaning the victim or demonstrating ultimate control over the victim.

The third category to be discussed and defined consists of noncriminal, accidental, or innocent alterations (i.e., changes to the original crime scene), generally by witnesses or family members, who find the victim and alter the scene without any criminal intent. An example would be a family member finding a loved one in an embarrassing position from an autoerotic misadventure and changing the scene to prevent embarrassment to the family. These types of alterations are better described as tertiary, and are best regarded as scene artifacts.

This workshop would have application to persons in forensic pathology, criminalistics, crime scene analysts, and criminal investigations. It introduces three new categories of staged scenes, provides case examples, and explains the "red flags" commonly encountered when confronted with a staged scene. The workshop culminates with case studies for each student to work through and identify the various "red flags" in real cases.

Primary Staging, Secondary Staging, Tertiary Staging

W10 Child Abuse: A Multidisciplinary Approach

James R. Gill, MD, OCME, 11 Shuttle Road, Farmington, CT 06032; Mary E.S. Case, MD*, St. Louis University, 6059 N Hanley Road, St. Louis, MO 63134; Carole Jenny, MD*, University of Washington School of Medicine, 4800 Sand Point Way NE, M/S M2-10, Seattle, WA 98105; Mark S. Dias, MD*, Penn State University College of Medicine, 30 Hope Drive, Ste 2750, Hershey, PA 17033; Ronald G. Barr, MD*, University of British Columbia Faculty of Medicine, 1003 Pacific Street, Apt 1203, Vancouver, BC V6E4P2, CANADA; Tracey S. Corey, MD*, Louisville, KY 40207; and Andrew M. Baker, MD*, Hennepin County ME, 530 Chicago Avenue, Minneapolis, MN 55415*

After attending this presentation, attendees will be able to: (1) identify the neuropathological findings of abusive head trauma, understand how the biomechanical mechanisms of inertial brain injury create these injuries, and recognize how the distinction between focal and diffuse brain injury determines the clinical presentation of timing of symptoms, such as level of consciousness; (2) properly perform a gross and microscopic examination of the eye and document the significant pathological features of retinal hemorrhages; (3) properly perform and document the evaluation of a child's fracture; and, (4) identify and exclude cases of abusive trauma to children using all relevant clinical and pathological data and information.

This presentation will impact the forensic science community by assisting in the evaluation of head injuries in infants and young children as well as assisting in the evaluation of traumatic injuries to the chest, abdomen, extremities, and bones of young children. Child abuse deaths are fairly common deaths seen by forensic pathologists in jurisdictions of all sizes. These cases are extremely complex and represent some of the most difficult cases handled by forensic pathologists. Forensic pathologists can be assisted in their work on these cases by input from other medical specialties and areas of interest, including child abuse pediatrics, pediatric ophthalmology, pediatric neurosurgery, neuroradiology, as well as a general knowledge of developmental pediatrics. Familiarity with these other areas of expertise will allow forensic pathologists to better decide upon cause and manner of death and to answer questions about forensic issues such as timing of injuries and onset of unconsciousness.

Head injury is the leading cause of death and disability in children. Of childhood deaths resulting from head injury, inflicted neurotrauma accounts for the greatest number. Sixty-four percent of head injuries serious enough to warrant admission to the hospital (excluding uncomplicated skull fractures) and 95% of serious intracranial injuries are the result of inflicted trauma. It is estimated that in the United States, 2,000 children die each year from abuse and neglect. Head injury is the leading cause of death from inflicted trauma and accounts for a large number of nonlethal abusive injuries. Falls are frequent occurrences in childhood and most head injuries in young children are caused by falls; yet, the great majority of these fall-related head injuries are trivial and only a few are lethal. Making the distinction between inflicted and accidental head injury is a common problem in the pediatric population and concerns pediatricians, forensic pathologists, neurosurgeons, and other medical specialties. The distinction between accident and inflicted is however an exceedingly important distinction to make. The features and issues necessary in distinguishing abusive head injury from accidental injury as well as from non-traumatic conditions such as genetic causes of subdural or retinal hemorrhages will be closely considered. Certain issues in abusive head injury have caused intense discussion among the various physicians and engineers who have examined these cases. Two areas of "controversy" include the debate over shaking as a mechanism of head injury in young children and the role that hypoxia might play in the causation of subdural bleeding. These topics will be considered in this workshop.

Traumatic brain injury can be classified into static and dynamic injuries depending upon the rate at which force is loaded onto the head. Static injuries occur over longer periods of time, usually greater than 200 milliseconds, and result in crushing head injuries. Crushing head injury refers to actual crushing of the facial skeleton and skull by a heavy weight. While relatively rare in the overall number of head injuries at all ages, it is an injury seen in some accidental childhood head injuries. At all ages, the greater number of head injuries result from dynamic forces that occur when force is rapidly loaded onto the head (in less than 200 milliseconds) and imparts an impulsive motion to

the head either as a result of impact to the head, which is free to move, or as a result of an action to the body, which causes the head to move such as the collision of two athletes or the violent shaking of an infant. Impulsive loading of significant degree may create inertial movement of the brain within the cranial cavity which causes differential movement between the brain (with its attached arachnoid) and the skull (with the attached dura). This inertial movement of the brain within the cranial cavity is the cause of bridging vein failure and results in subdural and subarachnoid hemorrhage and traumatic diffuse axonal injury. Inertial brain motion is also considered to be the cause of retinal hemorrhages of the type found in abusive head trauma. Brain injuries may also be classified as either focal or diffuse injuries. Focal injuries result from direct contact injury to the head and are visible to the naked eye. Focal injuries include scalp contusion and laceration, skull fracture, epidural hemorrhage, focal subdural hemorrhage, and brain contusions. Focal injuries become clinically symptomatic by causing increasing intracranial pressure which takes place over time and may have a fatal outcome from herniation. Focal brain injuries typically have a lucid interval. Accidental head injuries in young children with sufficient focal injury may lead to fatal outcomes and need to be recognized by all medical specialists. Diffuse injuries result from inertial forces and include interhemispheric subdural hemorrhage and traumatic diffuse axonal injury. Diffuse injuries may not be visible to the naked eye and these injuries may become clinically evident by the onset of immediate traumatic unconsciousness and tend not to have a lucid interval. Inflicted head trauma is most often of the diffuse brain injury form. Multiple medical specialists will discuss their unique approaches and perspectives in examining and evaluating head injuries in young children including how each specialty can assist the others in the interpretation and appreciation of the forensic and legal implications of these injuries. This workshop is intended to provide sufficient detail and depth to be of use to forensic pathologists in particular as well as other physicians who are concerned with child head injuries.

Fractures, Child Abuse, Subdural Hemorrhage

W11 Extreme Violence in the Military: Multiple Case Studies and the Exploration of Murder, Rape, and Cold Cases in the United States Military

Brian L. Janysek, MFS, 2521 Hunter Mill Road, Oakton, VA 22124; David J. Zeliff, MFS*, 102 Glacier Way, Stafford, VA 22554; Edgar A. Collins, VI, MFS*, US Army Criminal Investigation Command (CID), 27130 Telegraph Road, Quantico, VA 22134-2253; Elizabeth Richards, PhD*, Defense Forensic Science Center, 4930 N 31st Street, Bldg 925, Forest Park, GA 30297; Louis N. Eliopulos, BA*, NCIS, PO Box 837, Occuquan, VA 22125; Alicia Marie Swartz Pitts, MS*, AFOSI, 4065 Enger Street, Honolulu, HI 96816; Ryan P. Brokaw, MFS*, US Army CID, Benning CID Battalion, 6630 Wold Avenue, Bldg 66, Fort Benning, GA 31905; T.L. Williams, MFS*, 5 Gabriels Lane, Fredericksburg, VA 22406-8446; Jessica Ann Veltri, MS*, US Army CID, 22nd Military Police Battalion (CID), Bldg 3148, 2nd Division Drive, Joint Base Lewis-McChord, WA 98433; Kiyomi M. Griffey, MFS*, 3246 Avenida Del Alba, Carlsbad, CA 92009-9535; Scott Roeske, MFS*, 2635 Miner Road, Fort Sill, OK 73503; Phillip M. Curran, MFS*, 17010 Lejeune Road, Quantico, VA 22134; Edward Mazuchowski, II, MD, PhD*, 115 Purple Heart Drive, Dover AFB, DE 19902; Anna Y. Castillo*, Air Force Office of Special Investigation, 1300 Medina Base Road, San Antonio, TX ; Erin Michaels, MFS*, Naval Criminal Investigative Service, Washington DC Field Office, 2713 Mitscher Road, SW, Bldg 168, Ste 200, Anacostia Annex, DC 20373; Steven Geniuk, MS*, 108 S Johnson Street, Bldg 31022, Fort Huachuca, AZ 85613; Rachel A. Wynalda, MS*, NCIS, 66-350 Waialua Beach Road, Haleiwa, HI 96712; Walt Henson, BA*, NCIS, PO Box 58, Naval Air Station, Jacksonville, FL 32212; Kristan A. Troop, BS*, AFOSI, 2814 S Truckee Street, Aurora, CO 80013; and Jason J. Keller, MFS*, NCIS, NCISRA Great Lakes, 2540A Paul Jones Street, Bldg 2, 2nd Fl, E, Great Lakes, IL 60088*

After attending this presentation, attendees will understand: (1) the processing of mass murder scenes; (2) the forensic roles of military criminal investigators; (3) the responsibilities of the Armed Forces Medical Examiner; (4) investigations of United States personnel in foreign countries; (5) use of digital media in death investigations; (6) linking child pornography to cold cases; (7) gunshot range determination in suspected suicides; (8) multimodal crime scene investigation methods of rape and death scenes; (9) post-blast analysis; and, (10) methods to solve an array of violent crimes.

This presentation will impact the forensic science community through the detailed accounts of multiple violent crime scenes observed around the world, as described by the 21 special agents and a medical examiner who solved the cases. All of the crimes were investigated by the military criminal investigative organizations. The investigations will present multimodal approaches elaborating on crime scene processing, evidence collection, interrogation methodology, post-black reconstruction, medicolegal death determinations, and judicial hurdles and findings.

The forensic science consultants of the Military Criminal Investigative Organizations (MCIO), which consists of the United States Army Criminal Investigation Division, the Air Force Office of Special Investigations, and the Naval Criminal Investigative Service, conduct felony investigations around the world. After an overview of each MCIO's capabilities, investigative presentations by 21 Special Agents and the Armed Forces Medical Examiner will include:

Case 1: A 20 year-old, local Japanese girl went missing. Security cameras led local authorities to interview an Air Force civilian who provided a partial confession and led investigators to the location of victim's body. Forensics agents teamed up with the local Japanese crime scene investigators to search for additional evidence; to conduct a FARO® scan of all crime scenes; and to conduct an analysis of waterways. The subject was charged with first degree murder, rape, and improper disposal of a corpse in the Japanese courts.

Case 2: The wife of a military officer observed her husband's sudden death while chatting with him over Skype during his deployment. Agents will provide an overview of the investigative techniques, the challenges of a deployed environment, and the psychological aspects of next-of-kin briefings.

Case 3: A victim's partially decomposed, nude body was found in a ravine. Investigators recognized the importance of electronic media in determining a timeline of the murder and who may have been responsible. Analysis of surveillance videos, cellular tracking, and credit card purchases solved this homicide.

Case 4: A disgruntled soldier began firing on unit personnel and continued his shooting spree at eight different locations. More than 20 were injured and four killed. The case presentation will discuss crime scene highlights and the cooperation of CID, FBI, Texas Rangers, Texas DPS, ATF, and local PDs.

The Armed Forces Medical Examiner will then explore the background and capabilities of the Armed Forces Medical Examiner System and provide further insight into the forensic pathology of cases.

Case 5: Two brothers reported they were sexually abused 30 years prior by a family friend. In January 2014, agents received a break when the subject attempted suicide and was hospitalized. He provided consent for a neighbor to access an iPad, which revealed nude images of adolescent children. A search warrant was obtained of the residence, which provided evidence of the subject molesting a young adolescent male as well as over five million images and videos of child pornography.

Case 6: A Navy victim was found dead in a closet in her barracks room. The victim had a pillow case over her head and no injuries to her body. The victim's cell phone and laptop were missing from her barrack's room. It was not until a local police officer made an observation that began to unravel a bizarre series of crimes that led to the fate of the deceased.

Case 7: In April 2014, a United States Army soldier suspected his wife of cheating on him. He kidnapped his wife and 3-year-old son and began driving around to look for the wife's suspected lover. The wife escaped and the soldier fled. Arriving back home, the soldier turned on the 3-year-old, stabbing him several times in the torso while the child laid in his crib. The soldier then attempted multiple methods of suicide – all failed.

Case 8: A victim suffered a suspected, self-inflicted gunshot wound to her face. A pistol was on the floor by her feet. The victim's husband told police he had left his wife in the living room while he went to the kitchen and heard a gunshot. The pathologist's findings would lead to a bizarre ending.

Case 9: An Air Force Cadet was found unresponsive in his dorm room with 28 sharp force injuries covering his body after having his wisdom teeth removed earlier. Bloodstain pattern analysis suggested the Cadet was alone at the time of the incident.

Case 10: A task force investigation involving the beating death of a child in Korea. The same child was a prior victim of a non-fatal aggravated assault perpetrated by the father. Prosecutors were hesitant to move forward with the case, but a month after correcting the disjointed investigative and reporting effort, charges were preferred for murder.

Case 11: A post-blast scene examination following the unexpected detonation of approximately 345 explosive rounds which killed four Explosive Ordnance Disposal (EOD) Marines during a clearing operation in California.

Homicide Investigation, Forensics, Pathology

W12 Forensic Digital Multimedia: Enhancement and Authentication

Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217; and Catalin Grigoras, PhD*, 1020 15th Street, Ste 8I, Denver, CO 80202*

After attending this presentation, attendees will understand the important components to digital audio and image/video enhancement and to digital audio and image/video authentication.

This presentation will impact the forensic science community by providing a short training opportunity on the concepts of multimedia enhancement and authentication in: (1) digital audio enhancement; (2) digital image and video enhancement; (3) digital audio authentication; and, (4) digital image and video authentication.

Media authentication has become more important than ever before. Often a crucial element discovered during investigations, digital media has become a commonly contested form of evidence. Even the trustworthiness of press photography has become questionable due to manipulation. With the proliferation of digital media manipulation tools, media manipulation is a dangerous reality in the modern digital society.

Digital media authentication is a growing field of research that seeks to determine the validity of digital multimedia by investigating known signatures within a file's data combined with signal analysis of coding and compression effects on audio or image data. This workshop will discuss the media authentication process providing the user with methods of authenticating both image and audio. It will also demonstrate the incorporation of multiple tools and techniques into unified frameworks appropriate in forensic examinations where reducing examiner bias and error is crucial.

The goal of this workshop is to provide an overall view of conducting comprehensive digital multimedia examinations which rely on the results of multiple analyses to enhance recordings or to formulate an ultimate finding or opinion. During the discussion of digital multimedia enhancement, common image and audio filters which can be useful in processing recordings to increase intelligibility or visual details will be discussed and presented within their respective order of operations. This order is based on the effects of sequential processing that have been researched and optimized into an order which provides optimal results.

Multimedia authentication analysis frameworks, focusing on different aspects of image/audio creation to determine both source and authenticity will be presented. Global analysis investigates the validity of multimedia as whole while local analysis determines temporal or pixel level manipulation. Demonstration of how both container and content analysis can be used to determine authenticity of recordings as well as the purported source. Container analysis exploits characteristics of the multimedia file format which can be used to establish media provenance. Content analysis will cover both global and local analysis.

Multimedia Authentication, Multimedia Enhancement, Digital Evidence

W13 Forensics and Social Media: The Intersection of Education, Personal Promotion, and Professionalism

Marianne Hamel, MD, PhD, PO Box 4601, Bethlehem, PA 18018; Kimberlee Sue Moran, MSc*, Arcadia University, 450 S. Easton Road, Glenside, PA 19038; and Anna N. Dhody, MFS*, Mütter Museum, The College of Physicians of Philadelphia, 19 S 22nd Street, Philadelphia, PA 19103*

After attending this presentation, attendees will be able to harness the power of social media for professional promotion while learning to avoid potential pitfalls and classic mistakes. Social media platforms to be addressed include: Instagram™, Twitter™, LinkedIn®, ResearchGate, Snapchat™, Academia.edu, Facebook®, Hootsuite™, and YouTube®.

This presentation will impact the forensic science community by instructing attendees in the appropriate use, advantages, and pitfalls of social media engagement for the purposes of professionalism, education, and outreach. It is hoped that by defining and demystifying some common platforms, attendees will be encouraged to explore this brave new world of social connectivity.

According to the Pew Research Center, nearly three-quarters of Americans use social media in some form and engage with it on a daily basis. Despite the substantial social media user-base and the currently strong interest in the forensic sciences among the general public, the forensic science community has done little to nothing to address the phenomenon or integrate itself into the social media landscape. While many forensic scientists avoid social media for fear of appearing unprofessional or violating confidentiality, social media is a powerful tool for professional promotion, education of the general public, and recruitment of potential new scientists. This goal of this workshop is to introduce a range of social media platforms, their utility, and their potential use within the forensic science community.

The professional use of limited-content platforms will be addressed. Instagram™ is an image posting application in which users are encouraged to "tell a story" through captioned pictures. Twitter™ allows for images and video to be posted, but text is limited to 140 characters forcing the user to be exceptionally precise. Figure 1© is limited to healthcare professionals allowing them to communicate and receive feedback from colleagues using HIPAA-compliant messaging. For each of these services, their benefits and limitations as well as the means by which they can be harnessed to advance the forensic science community will be defined. Additionally, the pitfalls and responsibilities inherent in establishing oneself as an influential expert with a dedicated social media following will be discussed.

Platforms designed for professional promotion and career development will also be covered. LinkedIn® provides the ability to create an online CV that can be examined by other users. Other platforms that will be covered enable the professional to share publications, projects, presentations, and educational handouts. The user community and limitations of platforms such as Academia.edu, ResearchGate, and the Academic Room will be introduced to help participants determine which service best suits their needs.

The final platforms to be discussed are those suitable for promoting one's institution or agency such as YouTube, Twitter, and Periscope. The creation of mutually beneficial relationships between institutions through social media will be covered, as will goal-directed content and analysis metrics on multiple platforms. The workshop will finish with a review of how to generate and distribute content, original quality content vs. reposting, migrating to new platforms, cross-platform posting, boundaries and sensitivities, social media plagiarism, and legal issues surrounding content ownership.

Social Media, Public Outreach, Career Development

W14 Retinal Hemorrhages (RHs) Associated With Pediatric Abusive and Non-Abusive Head Injury — Systematic Reviews and Their Evidence Base: A Review

Patrick E. Lantz, MD, WFU School of Medicine, Dept of Pathology, Medical Center Boulevard, Winston-Salem, NC 27157-1072; Candace H. Schoppe, MD*, Southwestern Institute of Forensic Sciences, 2355 N Stemmons Freeway, Dallas, TX 75207; Anna G. McDonald, MD*, Wake Forest Baptist Medical Center, 1 Medical Center Boulevard, Winston Salem, NC 27157; Maria Cuellar, MS*, Carnegie Mellon University, 5000 Forbes Avenue, Pittsburgh, PA 15213; and Robert G. Stanulis, PhD*, 10940 SW Barnes Road, Portland, OR 97225*

After attending this presentation, attendees will be able to: (1) list the limitations of systematic reviews of retinal hemorrhages in childhood head injuries; (2) recognize observational studies employing imprecise case definition, circularity, selection or information bias, and misrepresentation of data; (3) discuss the use of confessions in case definition for abusive head trauma; and, (4) review issues with proposed statistical tools for the diagnosis of abusive head trauma.

This presentation will impact the forensic science community by exploring the value and pitfalls of systematic reviews and the selected observational studies focused on the diagnostic specificity of RHs in Abusive Head Trauma/Shaken Baby Syndrome (AHT/SBS) and of a proposed analytical tool intended to make the diagnosis of AHT/SBS more objective. This presentation will help physicians understand how to identify common problems in the underlying studies and the analyses, including logical fallacies, circularity, selection and information bias, imprecise case definition including confessions, and even misrepresentation of data.

The presumed mechanism of injury in AHT/SBS is thought to be severe rotational acceleration secondary to violent shaking, direct impact, or a combination of the two. Ocular findings are pivotal in cases of AHT/SBS because retinal hemorrhages (RHs) are often considered diagnostically specific for inflicted head injury. However, researchers are now questioning both the criteria used to identify AHT/SBS and the specificity of retinal findings.

Because the evidence base for the SBS theory relies on anecdote and opinion, proponents often point to confessions as proof that shaking an infant causes the brain and ocular findings that are commonly used to diagnose AHT/SBS. This effort fails to recognize that false confessions occur and pretends that confessions are obtained independent of medical information and psychological coercion.

Case-control studies, in contrast to cohort or cross-sectional studies, begin with subjects who have the outcome (cases) and compare them to individuals who do not have the outcome (controls). A crucial issue in evaluating a case-control study is control selection and the resulting comparability of cases and controls. The selection of controls is complex and often the most controversial facet of conducting a case-control study. Observational studies are assessed in terms of internal and external validity. Internal validity refers to the strength of the interpretation from the study. External validity is the ability to infer study results to a more general, broader population. Accordingly, internal validity is essential for external validity. A systematic review is an essential tool for summarizing evidence accurately and reliably. Unfortunately, critical information is often poorly reported in either the review or the primary studies; thus, diminishing the potential usefulness of a systematic review.

The four systematic reviews are by Togioka et al. in the Journal of Emergency Medicine (2009), Bhardwaj et al. in Ophthalmology (2010), Piteau et al. in Pediatrics (2012), and Maguire et al. in Eye (2013).[1-4] The four systematic reviews identified 19 comparative studies published between 1985 and 2010 that the reviewers considered high quality. Of the 19 comparative studies, 11 studies were only selected by only one of the four systematic reviews; 5 studies were selected by two of the four systematic reviews; 1 study was selected by three of the systematic reviews; and, only 2 comparative studies were selected by all four systematic reviews. A comparative study by Vinchon et al. published in Childs Nervous System (2010) was online in November 2009, so the systematic reviews by Togioka et al. and Bhardwaj et al. could not have included it in their systematic reviews.[5]

Attendees will participate with the workshop faculty in evaluating the four systematic reviews by examining the 19 primary comparative studies for case definition criteria and for fallacies of logic including circularity, selection and information bias, and data misrepresentation. The faculty will also discuss the validity of confessions for case definition and statistical problems caused by common flaws in study design affecting the scientific tool.

Observational studies that are well designed and carefully executed can provide useful and reliable results. However, observational studies can be misleading when they involve circular reasoning, systemic bias, and skewed age distribution between case and control groups; or, if data gatherers are not blinded for the cases and controls or the study's hypothesis. Researchers in any given field may be prejudiced because of their belief in a scientific theory and claimed research findings from observational studies with methodological flaws may be measuring only prevailing bias.

W15 Considerations for Crime Scene Analysis When Utilizing Forensic Science Experts for Post-Scene Analysis

Sharon L. Plotkin, MS, Miami Dade College, 11380 NW 27nd Avenue, Miami, FL 33167; Jason H. Byrd, PhD*, University of Florida, Maples Center for Forensic Medicine, 4800 SW 35th Drive, Gainesville, FL 32608; and Teresa A. White, MA*, 4100 Mullan Road, #216, Missoula, MT 59808*

After attending this presentation, attendees will understand how forensic science experts collaborate with crime scene personnel in evaluating physical evidence present and will be able to render expert opinions and testimony for the successful outcome of the investigation. Attendees will be better able to assess which items of physical evidence could generate more probative value from expert analysis. Methods to minimize evidence contamination prior to expert analysis will also be addressed.

This presentation will impact the forensic science community by challenging law enforcement personnel, crime scene investigators (death investigators), and forensic science specialists (entomologists and anthropologists) to recognize and increase their knowledge base on how a collaborative effort with experts can and will increase the successful outcome of a criminal investigation.

Our past tells us that we need to utilize an interdisciplinary approach to solving crimes to launch ourselves into the future of forensic science in post scene analysis. This workshop will present issues that have been present on crime scenes, difficulties in rendering expert testimony due to crime scene related issues, and discuss how to overcome such obstacles in hopes of assisting in such cases in the future.

Crime scene investigators know that in many situations, only one opportunity exists to completely document and collect all pertinent physical evidence relating to the crime being investigated. This workshop will focus on the importance of documenting crime scenes and collecting physical evidence in anticipation of utilizing forensic experts such as, entomologists and anthropologists in the successful prosecution of a crime. Most agencies cannot afford to have anthropologists, entomologists, and other such forensic experts on staff. With this in mind, many times these experts may be called in at a later date to assist in the investigation. Many times after a scene is processed, events that may or may not have occurred in the crime scene may prevent future analysis from forensic science experts to be able to provide valuable information. This could be a result of improper documentation, improper handling of the evidence, lack of experience and training, and/or an unwillingness to share information. We must keep in mind that our own knowledge base may be limited and the use of experts can provide a broader, better-educated outcome of an investigation, remembering that collectively this is a joint effort of multiple individuals from multi-disciplines to accomplish the ultimate goal.

Crime Scene, Forensic Entomology, Forensic Anthropology

W16 The AAFS Humanitarian and Human Rights Resource Center: Year Two

Douglas H. Ubelaker, PhD, Smithsonian Institution, Dept of Anthropology, NMNH, MRC 112, Washington, DC 20560; Morris V. Tidball-Binz, MD*, International Committee of the Red Cross, 19, Avenue de la Paix, Geneva 1202, SWITZERLAND; Duarte Nuno Vieira, MSc, PhD, MD*, Rua Antonio Jose de Almeida, No 117, Coimbra 3000-044, PORTUGAL; Luis Fondebrider, PhD*, Rivadavia 2443, 2do Piso, Dpto.3 Y 4, 1034 Capital Federal, Buenos Aires , ARGENTINA; Katie M. Rubin, MS*, C.A. Pound Human Identification Laboratory, PO Box 103615, Gainesville, FL 32610; Roxana Enriquez, MA*, Equipo Mexicana de Antropologia Forense, A.C., Plaza Mayor 19, Queretara , MEXICO; Dolores Soto, PhD*, Fray Juan de Larios Human Rights Center, Medellin 33 Col Roma, Mexico City , MEXICO; Eric J. Bartelink, PhD*, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400; and Julie M. Fleischman, MS*, 655 Auditorium Road, Rm 355, Michigan State University, East Lansing, MI 48824*

After attending this presentation, attendees will understand the structure of the AAFS Humanitarian and Human Rights Resource Center (HHRRC or Center) and its impact on multiple global projects as well as understand the current applications of contemporary forensic science and forensic medicine principles and methodology to global issues relating to humanitarian and human rights and the impact of these efforts. Participants also will receive new information on the progress and products of the AAFS Humanitarian and Human Rights Resource Center created in 2015.

This presentation will impact the forensic science community by raising awareness of the structure and accomplishments of the AAFS HHRC and the important developments in the global application of humanitarian and human rights forensic science.

The value of the application of forensic science to humanitarian and human rights cases is growing as research expands and new global areas of need arise. This workshop will provide current information on the development, structure, and progress of the new AAFS Center and its subcommittees which promote the application of contemporary forensic science to humanitarian and human rights cases around the world. Participants will learn the difference between humanitarian applications and those relating to human rights in today's world. Specific methodology and case examples are provided on the forensic investigation and documentation of torture and ill-treatment. Capacity building represents a major application involving training and education. Detail is provided on techniques of capacity building and lessons learned from diverse global experiences. Recent years have witnessed global sharing of resources and assistance in casework, training, and expertise. Details are provided on the dynamics and successes of such global cooperation.

Casework in the humanitarian and human rights arena has defined specific problems in need of new research. With support from the AAFS HHRRC, new research is focusing on the uptake and detection of nerve agents in human bone and using stable isotope forensics as an investigative tool for geolocating unidentified border crossers from the Texas-Mexico border. Center support also has enabled training sessions to strengthen human exhumation and identification efforts in Mexico and to conserve and analyze human remains resulting from Khmer Rouge era mass violence in Krang Ta Chan, Cambodia. Principal investigators in these projects will provide information on how to formulate proposals for support and the complexities of defining, articulating, and reaching goals. Participants will gain an understanding of the challenges faced and the benefits to be attained from involvement in research and case applications in this area. Presenters from diverse research backgrounds will showcase how the new Center and its developments can facilitate progress in the application of forensic science to humanitarian and human rights issues in different contexts around the world.

Humanitarian, Human Rights, Resource Center

W17 Communication Strategies to Mitigate Bias and Strengthen Scientific Foundations in Forensic Science

Cristina Aggazzotti, MS, Harvard University, Department of Linguistics, Cambridge, MA 02138; Katherine Ramsland, PhD*, DeSales University, 2755 Station Avenue, Center Valley, PA 18034; Carole E. Chaski, PhD*, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947; E. Allyn Smith, PhD*, University of Quebec at Montreal, Dépt de Linguistique, CP 8888, Succursale Centre-Ville, Montreal, PQ H3C 3P8, CANADA; and Roderick T. Kennedy, JD*, New Mexico Court of Appeals, PO Box 25306, Albuquerque, NM 87125-0306*

After attending this presentation, attendees will recognize the myriad ways in which cognitive and linguistic biases can inadvertently affect judgment and, with heightened awareness, attendees will be able to select from a variety of potential solutions for reducing bias.

This presentation will impact the forensic science community by providing immediate methods for reducing cognitive and confirmation biases in the forensic science workflow from initiation of forensic analysis to trial.

The workshop will present state-of-the-art strategies for mitigating bias and strengthening methodologies in the lab, workplace, and courtroom. Hands-on exercises will follow each talk to encourage interaction with the audience, enable attendees to practice each skill as soon as the discussion is concluded, as well as tailor the exercise to their own job-specific environments. These exercises will also create fodder for the discussion periods, when attendees will be able to ask questions and propose topics for further discussion across the represented fields.

The workshop will begin by describing how all humans create "mental maps," learning things from our families, culture, and subcultures that subtly skew our personal interpretations in productive and counterproductive ways, especially where our reasoning processes are concerned. After discussing the importance of credibility, clarity and closure, and their implications for the legal/investigative process, proven strategies for countering such biases will be addressed.

In linguistics, a well-documented phenomenon is "semantic priming" or the ability of certain words to prime the meaning of words that occur later. Semantic priming is the root cause of much bias in forensic science pattern-recognition techniques. Forensic linguistics provides an object lesson, for many forensic disciplines, in how to overcome cognitive bias in a forensic technique that classifies patterns. Currently, there are two different approaches to forensic linguistics: qualitative and quantitative. As in other forensic disciplines, qualitative work is prone to subjective biases, an overstatement of conclusions, and confirmation bias; while quantitative work has built-in safeguards that can be even further enhanced by employing a metalinguistic filter that controls semantic priming. This filter controls semantic priming by making the implicit assumptions or mental maps explicit so that speakers and hearers communicate with awareness of linguistic triggers of bias. Thus, having both a strong methodology and a strong filter helps to counteract the cognitive bias triggered by semantic priming and its harmful effects on judgment and decision-making at each step in the forensic science process.

Though cognitive biases are hardly news across forensic science disciplines, less attention is paid to the fact that all of these biases are conveyed via the language we use when communicating. Reflecting on and altering the way we communicate is one way of addressing bias. For instance, "Were there any matches for sample A?" and "Did sample A match the boyfriend?" on the face of things are two seemingly similar questions; but the presuppositions of these questions are not the same and have the potential to create confirmation bias. We review presupposition differences and present guidelines for improving communication.

The final presentation focuses on bias in the courtroom. Many methodological, organizational, professional, and even physical solutions have been suggested to combat the introduction of bias-inducing influences and information in the analytical, reporting, and testimonial parts of the forensic process. The tension between an adversarial legal system and the ideal for the forensic scientist to produce scientifically valid results for use in court, without regard to their legal context, must be resolved by the scientist against partisan influence or affiliation. Ways of using insulation for the analysts—protecting their independence from sources of bias and preserving their integrity in their reporting of results—need to be discussed and shared.

Bias is a natural human phenomenon that pervades all disciplines and can affect the expert and layperson alike. It is thus, imperative, that we become aware of its many forms and take action against its potentially harmful effects to protect the integrity of forensic sciences. By focusing on communication strategies to heighten metalinguistic awareness, the forensic science community—law enforcement, investigators, the forensic scientist, attorneys. and judges—can mitigate the harmful effects of cognitive bias.

Cognitive Bias, Linguistic Bias and Priming, Scientific Method

W18 The Opiate Crisis, Dirty Bombs, Big Data/Big Problems, and Driverless Cars: On the Leading Edge of Forensic Science — 2017 Theoretical Forensic Sciences "Think Tank"

Laura L. Liptai, PhD, BioMedical Forensics HQ CA/FL, 1660 School Street, #103, Moraga, CA 94556; Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS; Eoghan Casey, PhD*, University of Lausanne, Batochime, CH-1015 Lausanne-Dorigny, Lausanne, Vaud , SWITZERLAND; Barry K. Logan, PhD*, NMS Labs/CFSRE, 3701 Welsh Road, Willow Grove, PA 19090; Michael F. Rieders, PhD*, NMS LABS, 3701 Welsh Road, Willow Grove, PA 19090; Eduard Van Zalen, MSc*, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague, South Holland 2494GB, NETHERLANDS; Lucy A. Davis, BHS*, LDH Consultants, 2944 N Mayo Trail, Pikeville, KY 41501; and Ivo Alberink, PhD*, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague, Zuid-Holland 2497 GB, NETHERLANDS; and Pierre G. Cassigneul, MA*, NMS Labs, 3701 Welsh Road, Willow Grove, PA 19090*

The goal of this presentation is to describe how new developments might impact forensic scientists in their work. Practical examples will be presented on lab automation, driverless cars, designer drugs, nuclear forensics, cybercrime, and big data.

A wide variety of developments that will soon impact forensic science have been identified within the Think Tank Committee of the Forensic Sciences Foundation, Inc. This presentation will impact the forensic science community by providing an overview of some of the new developments in forensic science and by opening a forum for the discussion of issues that arise regarding such developments.

The amount of data that is available from digital investigation and from sensors is rising each year and the question is if a statistical analysis of this data can be presented in court. Biometric algorithms are improving and analyzing large amounts of video and images in combination with location data and other data available provide the possibility to make summaries of the data which can be presented in court. When applying these methods, the users should also be aware of the limitations and the error rates of the algorithms used. In addition, the use of Bayesian conclusion scales are under discussion.

In this day with genetics, you can learn your ethic background, find your relatives, even learn about your predisposition to diseases right from your own home. Over two million people have paid to include their DNA information in a website's database. While many have concerns about law enforcement databases and the rights to privacy of their genetic information, others are willingly mailing their DNA to these private companies. What is the difference in these databases and how are they secured and monitored? There are numerous concerns and questions that should be addressed and discussed to inform the public about putting their genetic information "online."

We see the developments of UAVs and drones and the forensic issues with finding digital traces as one of the topics. The driverless car is also a reality and it is unknown how these cars and their drivers will perform in the real world.

The investigation within a Chemical, Biological, Radiological, and Nuclear (CBRN) crime scene and the interrogation of CBR agents present a variety of problems and are another important issue or development. Primary amongst those at the scene is an intense degree of political scrutiny and a high thermal burden. How do you accurately take high-value samples when you are in a Level A "spacesuit"? How do you know where they are and what should you prioritize in the 20 minutes of air that you will have on the scene? The European Commission Generic Integrated Forensic Toolbox (GIFT) is answering these questions and can share some of the data with you.

Another issue is designer drugs. Designer drugs are novel compounds selected for manufacture and distribution based on their pharmacological effect and questionable legal status. Starting in 2008, enterprising chemists began synthesizing and selling novel drugs whose structures were taken from or based on the pharmaceutical scientific literature and patents. For the most part, the drugs had never been evaluated or tested on humans or were never brought to market because of potentially dangerous or unknown side effects resulting in many intoxications and deaths. Testing for these drugs is often a challenge as analytical standards are not available and the substances are not in shared or commercial databases or libraries. Metabolic studies have not been performed, so frequently toxicologists do not know what metabolites to test for and fail to recognize them even when they are present. Additionally, the designer drug market turns over very quickly with many novel toxic substances appearing and

disappearing from online sales within six to nine months. To keep up, laboratories need be innovative in their approach to monitoring the market through drug user intelligence, peer-reviewed literature, building in house libraries and databases, and many other channels of drug intelligence in anticipation of possible new threats.

Forensic Science, New Developments, Cybercrime

W19 Women in the Sciences: Examining Systemic Barriers and Becoming Agents of Change

Ann H. Ross, PhD, North Carolina State University, Dept of Biological Sciences, Campus Box 7614, Raleigh, NC 27695-7614; Shanna E. Williams, PhD*, USC School of Medicine Greenville, Biomedical Sciences Dept, 607 Grove Road, Greenville, SC 29605-5601; Chelsey A. Juarez, PhD*, Department of Soc & Anthro NCSU, 1911 Bldg, 10 Current Drive, Campus Box 8107, Raleigh, NC 27695-8107; and Phoebe R. Stubblefield, PhD*, University of North Dakota, Dept of Anthropology, 236 Centennial Drive, Stop 8374, Grand Forks, ND 58202*

After attending this presentation, attendees will become better acquainted with the state of female representation in the sciences. Attendees will also learn how this representation has shifted over the past several decades, the systemic inequalities in equity and parity between the sexes, and gender-specific micro- and macro-aggressions. Finally, attendees will discuss how these issues manifest within the forensic sciences and how to work collaboratively to conceive strategies for change.

This presentation will impact the forensic science community by demonstrating how gender-specific societal bias in the sciences creates barriers for the advancement of women, contributes to gender inequity in leadership positions, and undermines forensic science's ability to live up to its full potential.

Over the last two years, gender equality has made headlines in the sciences, beginning with the ill-judged "trouble with girls" comment by a British biochemist to more serious cases of endemic sexual misconduct in astronomy and biological anthropology. As more women populate the sciences, specifically forensic science, blatant discrimination is less common, but women face numerous invisible and unacknowledged obstacles. Evaluation criterion for hiring, promotion, invited talks, and awards has been shown to still be biased toward men. In our own Academy, from 2000-2016 eighty-eight percent of AAFS presidents have been men (15/17). The International Academy of Legal Medicine (IALM) has never had a female president (1936-present).

In 2005, the National Academies created the Committee on Maximizing the Potential of Women in Academic Science and Engineering. This committee was designed to provide recommendations on how to maximize female talent in science and engineering. In 2007, the committee reported its findings. Specifically, they found that despite women having the cognitive ability to succeed in science and engineering, women interested in such fields are lost at every educational transition. Moreover, once in these professions, women are more likely to experience discrimination from implicit biases as well as face disadvantageous subjective evaluation criteria and organization structure. In response to this report, the National Institutes of Health formed the Working Group of Women in Biomedical Careers to consider barriers to women in the sciences, to develop recruitment and advancement initiatives, and created $16.5 million in funding opportunities to support research on these topics. Nearly a decade after the initial report, the results of this funding still find significant gender inequalities in compensation, research funding, work-life integration, gender consciousness, and access to mentorship. These topics will be explored in this workshop through podium presentations, panel discussions, and break-out sessions.

An overview of the current trajectory of women in the sciences and conclude by discussing current approaches and best practice to capturing and capitalizing on female talent will be provided. Finally, the audience will be challenged to create action plans to limit systemic barriers and societal biases that deprive the American Academy of Forensic Sciences and their own institutions/organizations of talented and accomplished women across all levels of leadership.

Women, Science, Inequality

W20 Instrumental Chromatographic Separation Techniques for Forensic Analyses: Application to the Analysis of Emerging Drugs

Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; Bruce R. McCord, PhD*, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199; and H. Chip Walls, BS*, Forensic, Analytical & Clinical, Toxicology Lab, Miami, FL 33143*

After attending this presentation, attendees will be better able to evaluate and select the proper chromatographic technique(s) for separating complex mixtures that are necessary for the analysis of emerging drugs present in seized drug-evidence submissions and toxicological samples.

This presentation will impact the forensic science community by providing attendees with a respectable and fundamental understanding of the different modern separation techniques and how they have been applied to the analysis of emerging drugs in forensic exhibits. This workshop has a strong interdisciplinary focus.

The expanded availability of designer drugs on the street has resulted in a confusing array of complex and difficult problems in the determination of drug identity. Many of these drugs are positional and stereoisomers, with concomitant legal issues, and in some cases significant pharmacological and toxicological differences. Isolation and identification of these materials results in numerous technical challenges, many of which cannot be resolved even by the most advanced mass spectrometric technology. Fortunately current advances manifested in separation techniques such as gas chromatography (GC), ultrahigh performance liquid chromatography (UHPLC) and ultrahigh performance supercritical fluid chromatography (UHPSFC) provides a solution to the problem. These techniques have exceptional selectivity and separation power, and in the future they will be increasingly needed in order to distinguish these compounds by retention time as other techniques fail.

The isolation problem becomes even more complex when you consider toxicological assays. Complexity increases with the need to consider drug metabolites and isolation of these materials from complex matrices. Thus we feel that the forensic community could benefit from a series of lectures on the basics of chromatographic separations and their application to problems in the separation of emerging, designer drugs.

The basic principles of chromatography will be presented. In addition, sample preparation techniques, which are integral to successful chromatographic separation will be discussed. These include liquid-liquid extraction, solid phase extraction, and vapor phase extraction techniques. The modern forensic practice of GC, LC, and SFC will be discussed including hardware, choice of columns and methods development. A comparison of GC, UHPLC, and UHPSFC for emerging drugs such as synthetic cathinones and synthetic cannabinoids will also be presented. In the field of forensic toxicology, sample preparation, and separation technology employed for the analysis of emerging drugs and or their metabolites in urine, blood, and hair will be reviewed as well as emerging drug stability *in vitro* and *in vivo*. A discussion on future directions in separation science and emerging drugs will be discussed to include questions from the attendees regarding material related to these chromatographic separations.

Separation Techniques, Chromatography, Emerging Drugs

W21 Forensic Photography and the Exposure Triangle: What Every Forensic Professional Should Know About ISO, Depth of Field (DOF), and Shutter Speed (SS)

David G. Pauly, MFS, Methodist University Forensic Science Program, TruForensics, LLC, 3512 Gables Drive, Fayetteville, NC 28311; Steven L. Downs, MFS*, Methodist University, 5400 Ramsey Street, Fayetteville, NC 28311; Dyer Bennett, BS*, Sirchie, 100 Hunter Place, Youngsville, NC 27596; Kelly Taylor, BS*, Womack Army Medical Center, 2817 Reilly Road, Fort Bragg, NC 28310; and Serena Hare, BS*, 913 Anthem Lane, Apt 2201, Fayetteville, NC 28311*

After attending this presentation, attendees will better understand the proper use of a Digital Single-Lens Reflex (DSLR) camera for crime scene, sexual assault, autopsy, and laboratory work. Specific focus will be placed on understanding the "exposure triangle," which includes settings for ISO, DOF, and SS, and the importance of knowing how to adjust each component in order to properly capture forensic evidence for presentation at a later date in a criminal or civil trial. In addition, best practices and legal standards will be presented. Compression levels and when to utilize which level of compression will be taught, so attendees can properly image crime scenes and other forensic evidence in the proper format. Attendees will learn how to utilize a DSLR camera in the *Manual* mode, instead of failing to properly capture forensic images in the *Automatic* mode. Attendees will be exposed to common crime scene photography practices, such as, "fill-flash", "back-lighting," "fill-the-frame," "film plane parallel," omitting blur, maximizing depth of field, and concepts of Painting With Light (PWL) for low-light situations. Attendees will understand how each of these principles should be applied to imaging crime scenes, physical evidence, deceased individuals, and living sexual assault victims and suspects. Forensic science professionals in all disciplines that are charged with taking forensic photographs, or those who are tasked with properly understanding the proper legal formatting of forensic images will benefit from this workshop.

This presentation will impact the forensic science community by providing professionals with a greater understanding of how photography is one of the three primary means of documenting crime scenes, autopsy findings, physical injury, and forensic evidence; yet, it remains the least-understood and least-trained discipline. This training will enhance the attendees' knowledge and competency when using a DSLR camera in the performance of their duties to properly document crime scenes and forensic evidence.

Despite law enforcement and forensic science professionals exposing a plethora of images each year in the performance of their duties; only a small number of these images are introduced into the courtroom. This is despite jurors wanting and even expecting, to see high-quality images of crime scenes, injuries, and other physical evidence. All too often, images exposed in an attempt to capture the various forensic evidence found at crime scenes and other forensic settings are lacking in quality or do not meet the basic legal standards required. In response to these recognized deficiencies, attendees will learn the basic legal requirements for introducing properly formatted images into the courtroom; including, when to utilize RAW uncompressed – lossless – settings. Informal surveys of forensic science and law enforcement professionals have shown repeatedly that most law enforcement and crime scene photographers do not understand the nuances in compression levels (such as when to utilize JPEG vs. RAW) in general crime scene work when capturing critical comparison or evidence quality images.

Forensic Photography, Crime Scene Photography, Sexual Assault Nurse Examiner

W22 Viewing Research Through Different Lenses: How to Achieve Success in Court

Jeffery K. Tomberlin, PhD, TAMU 2475, Dept of Entomology, College Station, TX 77843-2475; Heather R. Jordan, PhD*, Mississippi State University, PO Box GY, Mississippi State, MS 39762; Sarah Bankston, MS*, Medical Sciences Library, Texas A&M University, College Station, TX 77843; M. Eric Benbow, PhD*, Michigan State University, Depts of Entomology & Osteopathic Med Specialties, 288 Farm Lane, East Lansing, MI 48824; Diana Botluk, JD*, Reference Librarian & Associate Professor, Law Library, Barry University School of Law, Orlando, FL 32807; Jonathan A. Cammack, PhD*, Texas A&M University, Dept of Entomology, Campus Box 2475, College Station, TX 77843; Stephanie Domitrovich, JD, PhD*, Sixth Judicial District of PA, Erie County Court House, 140 W 6th Street, Rm 223, Erie, PA 16501; Roderick T. Kennedy, JD, PO Box 7041, Albuquerque, NM 87194-7041; Pamela A.W. King, JD*, 151 4th Street, SE, Rochester, MN 55904; Joseph J. Maltese, JD, PhD, New York Supreme Court, Appellate Division, Second Judicial Dept, 26 Central Avenue, Ste 503, Staten Island, NY 10301; Jennifer L. Pechal, PhD*, Michigan State University, 243 Natural Science Bldg, Dept of Entomology, East Lansing, MI 48824; Haskell M. Pitluck, JD, 573 Lake Avenue, Crystal Lake, IL 60014; Laura Sare, MS*, Government Information Librarian, 5000 TAMU, Texas A&M University, College Station, TX 77843; and Donald E. Shelton, JD, PhD, University of Michigan-Dearborn, Criminal Justice Program, 4901 Evergreen Road, Dearborn, MI 48128-2406*

After attending this presentation, attendees will better understand the value of scientific research in their courtroom practice. Participants will understand the value of scientific research and how to identify credible reference material, interpret information, and access such materials through the internet. Practitioners, such as forensic investigators, researchers, and lawyers, view scientific information through different lenses. Determining what is valuable and where to locate these resources is often challenging.

This presentation will impact the forensic science community by raising awareness of practitioners, scientists, and lawyers to high-quality, no-cost, as well as paid, resources available through the internet and online materials. Those in attendance will take such awareness back to their respective employers and potentially increase the use of such materials by associated individuals and their organizations. Improving participants' skills in evaluating and locating information sources could decrease their reliance on materials of questionable value.

Researchers, practitioners, and attorneys rely on published scientific information to interpret forensic evidence. Historically, individuals relied on their training within their given profession to locate such resources; however, given such training can vary depending on their profession (e.g., researcher versus attorney), the end result of these searches can be quite different which can lead to: (1) confusion; (2) reliance on low quality data; (3) conflicting terminology being applied; and, (4) frustration due to lack of training in locating resources of value. This workshop will utilize library and information science to provide participants with valuable tools for assessing published research to determine the most appropriate materials for use in court. Along with library scientists, experts in forensic entomology and microbiology will guide participants and lead discussions of discerning accurate and discriminative scientific and experimental details. Upon completion of this workshop, participants should be able to: (1) identify resources for locating scientific information on the internet; (2) identify scholarly information; and, (3) determine associated scientific merit, application, and limitations.

This "hands-on" workshop will focus on locating and evaluating information resources across the science and law spectrum through the internet. Awareness of practitioners, scientists, and lawyers to high quality, no-cost, as well as paid, resources available through the internet and online materials will be raised. Those in attendance will take such awareness back to their respective employers and potentially increase the use of such materials by associated individuals and their organizations. Improving participants' skills in evaluating and locating information sources could decrease their reliance on materials of questionable value. Entomology and microbiology will be discussed. What is thought to be known about these sciences within forensics (give a presentation making the sciences look like they are phenomenal tools for forensics) will be discussed, which will be followed by presentations demonstrating what really is known and where the challenges are located. Such contrasts are important to be emphasized to researchers, practitioners and attorneys. A review of forensic science-applicable science and legal information resources that are available for participants to use (i.e., American Academy of Forensic Sciences Reference Library, PubMed, Google Scholar) and how to potentially determine high- versus low-quality scientific research publications will be presented.

W23 Fundamentals of Printing and Graphic Arts Examinations

Lindsey N. Dyn, MFS, 2501 Investigation Parkway, Quantico, VA 22135; Peter J. Belcastro, Jr., MA*, Federal Bureau of Investigation, 2501 Investigation Parkway, Quantico, VA 22135; and Linton Mohammed, PhD, Forensic Science Consultants, Inc, 433 Airport Boulevard, Ste 406, Burlingame, CA 94010-2014*

After attending this presentation, attendees will: (1) learn about the various types of office and commercial printing processes as well as the basic microscopic characteristics used to differentiate printing technologies through discussion of the fundamental concepts associated with examination and comparison of various printing technologies; and, (2) gain experience regarding printing/graphic arts examinations by case studies and hands-on assessment of actual specimens.

This presentation will impact the forensic science community by providing forensic document examiners with the knowledge and introductory experience to conduct printing process examinations. Through participation in this workshop, attendees will: (1) gain a more thorough knowledge about the fundamentals of various printing processes; (2) acquire or improve upon their ability to properly classify and identify the printing technology used to directly produce a questioned document through observation of the physical and microscopic characteristics; (3) be able to provide investigators thorough instructions regarding the collection of proper printing standards; (4) gain competence in conducting printing source determination, while recognizing limitations and crafting proper conclusions; (5) gain useful contacts within the printing and forensic document community; and, (6) be introduced to reference materials that may assist participants with printing/graphic arts examinations.

A common request by investigators in forensic document examination cases is to determine whether a certain machine was used to print or produce a questioned document submitted for analysis. To answer this question, a multifaceted approach is required. One of the first steps in this process is the classification and recognition of various printing processes by their physical and microscopic characteristics. An overview of office technologies (e.g., ink jet and toner processes) and commercial technologies (e.g., lithographic and relief processes) will be discussed. The fundamental concepts associated with the examination and comparison of various print technologies will be the major focus of this workshop. Participants will gain an introduction to the requisite knowledge needed to classify various printing processes. Participants will work on the practical application of the information provided by conducting hands-on examinations in order to identify the printing technology used to produce various provided samples.

Recognition and classification of printing processes is just the first step in determining common source. For useful comparisons, adequate standards must be selected and submitted for examination. Procedures for the production and collection of proper standards will be discussed for various printing processes. Specifics of the process involved in printing source determination examinations will be discussed and reinforced through practical comparison exercises. Limitations regarding appropriate results and conclusions that can be rendered will be reviewed, to include suggested verbiage. While the number of cases involving definitive conclusions regarding source determination are often limited in number, these types of cases can have a significant impact on investigations. One such case study, where the association of trash marks proved pivotal in securing a plea deal in a high-profile case, will be highlighted during the workshop.

Print Process Identification, Printing Characteristics, Graphic Arts

W24 Navigating the Sea of Resources for Sexual Assault Programs

Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709; Charles M. Heurich, MFS*, National Institute of Justice, Dept of Justice, OJP, 810 7th Street, NW, Rm 7204, Washington, DC 20531; Heather E. Waltke, MS*, 810 7th St, NW, Washington, DC 20531; Heather LaSalle, MS*, FBI Laboratory, DNA, 2501 Investigation Parkway, Quantico, VA 22135; Kimberly B. Murga, MFS*, Las Vegas Metro Police Department, Forensic Laboratory, 5605 W Badura Avenue, #120B, Las Vegas, NV 89118; Jill L. Spriggs, MBA*, Private Consultant, 3155 16th Street, Sacramento, CA 95818; and Patricia A. Foley-Melton, PhD*, RTI International Center for Forensic Science, 3040 E Cornwallis Road, Bldg 3, Rm 201, Research Triangle Park, NC 27709*

After attending this presentation, attendees will understand best practices for seeking resources, including federal funding to improve policy, efficiency, and operational sustainability in the processing of Sexual Assault Kits (SAKs) and forensic evidence in their agencies and forensic laboratories. Furthermore, this workshop will bring an understanding of the benefits, comparative differences, and requirements to enable funding consideration and use.

This workshop will impact the forensic science community by highlighting how federal resources in the United States can advance victim-centered support programs, investigations, and forensic services that aid sexual assault programs, especially the processing of untested SAKs and forensic evidence, which bolster the criminal justice process.

In the United States, many jurisdictions are addressing the need to resolve the existence of unanalyzed sexual assault evidence, including sexual assault kits (SAKs). Annually, tens of millions of dollars are provided to criminal justice agencies, forensic laboratories, and researchers to support various sexual assault programs. In addition to economic support, there are many federal resources and programs that provide evidence-based research and technological developments to advance policy and practices; support survivors of sexual assault; establish effective and sustainable practices for collecting and processing forensic evidence; investigate and prosecute sexual assault cases; and, uphold justice by convicting the guilty or exonerating the innocent.

An overview of sexual assault investigations and United States support programs, specifically programs to reduce and process untested sexual assault kits and other forensic evidence more expeditiously and effectively, will be presented. Various federal funding programs will be discussed including research and evaluation (National Institute of Justice, NIJ), DNA capacity enhancement and backlog reduction (CEBR), cold case investigations (NIJ), national sexual assault kit initiative (Bureau of Justice Assistance, BJA), and sexual assault kit partnerships such as the joint venture established by the NIJ and the Federal Bureau of Investigation (FBI). A comparison of program components and requirements, their differences, and potential practitioner use of multiple resources will be included. Examples of a particular program or need within the community will be shared and an explanation of how it corresponds within a funding resource will provide further guidance. Additional resources such as NIJ's Sexual Assault Forensic Evidence Reporting (SAFER) Working Group and the Forensic Technology Center of Excellence will also be highlighted. Laboratory practitioners who have successfully utilized multiple federal programs to help reduce their SAKs, to introduce laboratory efficiencies, to inventory their forensic evidence, and to work with their jurisdictional sexual assault response teams will share their experiences.

Federal agency representatives, laboratory practitioners, researchers, and technology advocates will provide varying perspectives for resources of sexual assault programs, sharing how the programs they represent, or have used, continue to transform the landscape of sexual assault investigations and forensic services using evidenced-based practices to advance the latest technology, to improve program policy, and to reduce the number of untested sexual assault kits and other forensic evidence nationwide.

Sexual Assault, Forensic Evidence, Research and Technology

A1 Quantifying and Visualizing Skeletal Thoracic Trauma

Cortney N. Hulse, BS, 4719 Revolution Road, Chubbuck, ID 83202; Kyra E. Stull, PhD, University of Nevada, Reno, Dept of Anthropology, 1664 N Virginia Street, Stop 0096, Reno, NV 89557; and Ashley Weaver, PhD, Wake Forest University School of Medicine, Dept of Biomedical Engineering, 575 N Patterson Avenue, Winston-Salem, NC 27101*

The goal of this presentation is to introduce attendees to ongoing research in thoracic trauma and fracture pattern trends in vehicular accidents and to describe how advanced imaging techniques can act as tools in trauma research.

This presentation will impact the forensic science community by contributing statistically substantiated results, which will directly affect the interpretation of fracture patterns and ultimately further baseline knowledge of the complex interaction of variables in the thoracic region.

Trauma analysis is largely heuristic; while there have been advancements in recent years, overall statistical substantiation of findings is lacking in comparison to other research areas within forensic anthropology. Thoracic blunt trauma, in particular, is difficult because of the complexity and variation in bone morphology and muscle attachment sites. Additionally, the number and magnitude of extrinsic variables is problematic when making interpretations. The goal of this presentation is to shed light on extrinsic and intrinsic variables that should be taken into consideration when interpreting fracture patterns in the thoracic area. Specifically, this presentation will explore the relationship between rib fractures and known variables in a vehicular crash setting.

Individuals over 18 years of age that were in a motor vehicle accident, hit from the front or side, with or without the use of a seat belt were included in the study. Computed Tomography (CT) images with associated medical records of injuries to the thoracic region of 180 individuals were evaluated. The two continuous variables, age and speed, were also categorized to better observe relationships among variables. Additional variables, such as presence/absence of fractures, side (left/right) of fractures, rib number, specific location on the rib (anterior, posterior, lateral), and number of fractures were scored for each individual. Chi-squared tests and logistic regression were conducted to explore the relationship between presence/absence of fractures to the above-mentioned variables. Density plots were used in order to visualize patterns of fracture location and provide insight to overall trends.

Only one variable, age, showed a statistically significant relationship with the presence of fractures using a chi-squared test. When age category was tested against the presence of fractures, the two variables appeared to be dependent ($\chi 2(2) = 15.902$, $p < 0.05$). The null hypothesis was accepted for all other variables, suggesting no relationship ($p > 0.05$). The age category was also the only variable to demonstrate a significant relationship in the logistic regression. A middle-aged individual is 2.61 times more likely to have fractures reported than an individual in the young-age category. An older-aged individual is 5.55 times more likely to have fractures present than an individual in the middle-age category. There was a slight trend that males, on average, incurred more fractures than women; however, women in the middle-aged category were 2.6 times more likely to fracture than males in the same age category. Counterintuitively, speed was not found to be a significant variable with the presence of fractures. A slight trend appeared in the data associating a slightly higher number of fractures when hit anteriorly. The density plots displayed a lack of differentiation of number of fractures between sides but the greatest density of fractures was located laterally.

Practicing forensic anthropologists should be aware that when observing fracture patterns in the thoracic region, age will play an important role in number of fractures, while all other recorded variables exhibited little impact on the presence and location of fractures. The current project exemplifies the evolution of forensic science because of the inter-disciplinary collaboration, the utilization of advanced imaging techniques, and the incorporation of

statistical analyses, which moves us away from experience-based trauma interpretation and toward scientifically sound interpretations.

Ribs, Vehicular, Blunt Trauma

A2 Improving Non-Metric Sex Classification for Hispanic Individuals

Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621; and Stephanie J. Cole, BA, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand how two commonly used non-metric sex estimation methods for the skull and pelvis perform when applied to Hispanic individuals.

This presentation will impact the forensic science community by providing new recalibrated equations that are population-specific and more appropriate than the original methods used with Hispanic individuals who are encountered in forensic contexts.

Forensic anthropologists are tasked with helping to identify Hispanic Undocumented Border Crossers (UBCs) that die during the journey into the United States; however, current techniques used by forensic anthropologists in the identification of unknown human skeletal remains have largely been created using United States Black and White samples. When applied to Hispanic individuals, these techniques often perform poorly.[1] The increase in migrant deaths at the United States-Mexico border in recent years has created the imperative need to validate methods using Hispanic samples or to create population-specific standards for Hispanic individuals. This research examines the classification accuracies obtained by the original Walker and Klales et al. methods using logistic regression equations for non-metric sex estimation and provides recalibrated population-specific equations.[2,3]

An experienced observer collected ordinal score data of the skull using the five Walker method traits and of the innominate using the three Klales et al. method traits. The sample consisted of 55 (28 females, 27 males) Hispanic individuals housed at the Forensic Anthropology Center at Texas State University. The majority of individuals are UBCs from the Center's on-going Operation Identification (OPID) project. The remaining individuals are from the Texas State University Donated Skeletal Collection. Individuals within the donated collection are positively identified and, therefore, have known demographic information. The demographic information from the OPID UBCs had to be inferred based on a number of variables, including DNA, FORDISC®, and associated artifacts.

Frequency distributions were calculated for each trait score by sex and a chi-square test was used to test for significant differences in score frequencies between the two sexes. The scores for each individual were then entered into the original logistic regression equations provided by the Walker and Klales et al. methods to test the validity of the original equations for this sample of modern Hispanic individuals. Next, the equations were recalibrated to generate population-specific regression formulas for Hispanics, as both original publications give equations developed using only White and Black individuals. Classification accuracies between the validation and recalibration tests were compared to determine if population-specific formulas are more appropriate for Hispanic individuals.

Males and females differed significantly in score frequencies for all traits at the $p > 0.05$ level. Using the fourth Walker method, combined classification accuracy was 81.8% (females 71.4%, males 92.6%). The disparity in classification between males and females regarding the skull indicates a high sex bias (21.2%) in favor of males. Overall accuracy for combined sexes using the Klales et al. method was 87.5% (females 91.7%, males 83.3%). The disparity in classification between males and females indicates a low sex bias in favor of females (-8.4%). Recalibration of the Klales et al. equation improved accuracy (87.5% vs. 91.7%), while recalibration of the Walker method equation decreased accuracy (81.8% vs. 74.5%), but greatly reduced sex bias (21.2% vs. -8.2%).

In conclusion, classification accuracy and sex bias improved for the innominate when using the recalibrated regression equations specifically for Hispanic individuals. These results are not surprising given that similar results were obtained in another study using modern South African, Thai, and United States samples. Interestingly, the skull recalibration decreased overall accuracy in the current study; however, sex bias was reduced by 13%, thereby making the recalibrated equation more appropriate for use with modern Hispanics. Although the recalibrated equation performed worse, the original equation achieved a classification accuracy of only 81.8%, which is much lower than accuracy achieved by Walker in his original study. This study recommends placing greater emphasis on the results of the innominate rather than the skull due to the higher level of sexual dimorphism in this skeletal region for Hispanics.

Hispanic, Sex Estimation, Non-Metric

A3 Sex-Specific Patterns of Ossification in Macerated Thyroid Cartilages

Katelyn L. Bolhofner, MA, Arizona State University, 900 S Cady Mall, Tempe, AZ 85287; and Laura C. Fulginiti, PhD*, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending this presentation, attendees will be aware that the sequence of ossification of the thyroid cartilage differs between the sexes.

This presentation will impact the forensic science community by introducing sequences of sex-specific patterns of ossification in the thyroid cartilage, providing a novel component for use in sex estimation in individuals.

Previous studies of the ossification process of the thyroid cartilage using radiographs, CT scans, and macerated samples focused on potential correlations between age-at-death and patterns of ossification.[1-8] Recent research reveals there is no correlation between age and ossification of the thyroid cartilage, but there does appear to be a difference in the pattern of ossification between the sexes.[8] This finding suggests implications for the use of this structure in sex estimation. Through examination of a large sample of thyroid cartilages, significant differences in pattern of ossification between the sexes were demonstrated. Presented here are sex-specific sequences of ossification and accuracy rates for this new method of sex estimation.

This study was conducted in two parts using macerated thyroid cartilages. To observe and establish expected sequences of ossification for males and females, 390 ossified thyroid cartilages from individuals of known sex and age were examined. A subsample of 48 ossified thyroid cartilages was then employed in independent, blind tests of sex estimation.

A significant difference in the pattern of ossification was observed between males and females, specifically in the relationship between the ossification of the superior horns (cornua) and the anterior superior margin (laryngeal prominence). Ossification begins along the lateral inferior margins of the thyroid cartilage in both sexes. Ossification then extends to the superior horns and along the anterior inferior margin in females. In males, ossification extends along the anterior inferior and anterior superior margins and the laminae prior to any development of the superior horns. Thus, the superior horns appear to be the last portion of the cartilage to ossify in males, occurring after the complete ossification of the laryngeal prominence at the anterior superior margin, and at times appear not to ossify at all. In contrast, the superior horns appear early in the ossification process in females, prior to the ossification of the laryngeal prominence, which is rarely observed as ossified in females. In the subsample of 48 ossified thyroid cartilages, 17 of 28 males (60%) exhibited some degree of ossification of the superior horns (cornua) and of these, 17 of 17 (100%) also exhibited ossification of the anterior superior margin (laryngeal prominence). Twenty of 20 females (100%) exhibited ossification of the superior horns and of these, 0 of 20 (0%) exhibit ossification of the anterior superior margin.

Using these criteria, a series of independent blind tests were performed to evaluate the degree of inter-analyst correspondence and the accuracy of sex determination. Under macroscopic observation, sex was accurately estimated with a 96% two-way correspondence and 97% accuracy. These results demonstrate that the sex-specific patterns of ossification observed in this research may be employed as supplementary support in estimates of sex in individuals.

Recent immunohistochemical research demonstrates sex-specific differences in cartilage mineralization of the laryngeal structures.[9-11] These studies suggest that apoptosis and HADH-TR positive chondrocytes play a role in the ossification of cartilage in males and females, and that the chondrocytes “stay alive” longer in females than males.[11] This research also proposes that hormonal changes in men and women contribute to the ossification processes.[9] Still, these studies remain tied to the concept of age as the driving factor behind ossification, hindering interpretations of the process and the establishment of any clear sex-specific ossification sequences.

The patterns of ossification observed here appear to affirm the hypothesis that multiple cartilage types are responsible for ossification of the components of the thyroid cartilage, and those elements respond in a sex-specific manner during ossification. Further, this research demonstrates a very high accuracy rate for sex estimation using the ossified thyroid cartilage. Finally, the results of this study have implications for the forensic pathology community as well, as understanding the female pattern of superior horn ossification may alter standard autopsy procedures to better capture potential injury in strangulation cases.

Thyroid Cartilage, Ossification Patterns, Sex Estimation

A4 A Craniometric Recapitulation of Genetic Estimates of Ancestry for Individuals of Hispanic Identity: Temporal, Geographic, and Identification Trends

Bridget F.B. Algee-Hewitt, PhD, Stanford University, Rosenberg Lab, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020; Cris E. Hughes, PhD, Department of Anthropology, 109 Davenport Hall, 607 S Matthews Avenue, Urbana, IL 61801; and Bruce E. Anderson, PhD, PCOME, Forensic Science Center, 2825 E District Street, Tucson, AZ 85714*

After attending this presentation, attendees will better understand the importance that population dynamics plays in forensic anthropological casework, especially when considering individuals of Hispanic identity and Latin American geographic origin.

This presentation will impact the forensic science community by illustrating how craniometrically derived estimates of admixture recapitulate the results previously reported using forensic genetic markers, offering new evidence in support of a case identification bias.

Using genotypic data for United States-Mexico border-crossing fatalities, Hughes et al. reported greater indigenous ancestry in individuals who are currently unidentified and have been recovered in more recent years — what they called an "identification bias" in the forensic case analysis of individuals of Hispanic identity and Mexican origin.[1,2] These findings are consistent with recent demographic trends among living migrants and forensic casework statistics on undocumented border-crosser deaths. As such, they have significant implications for both casework logistics on the United States-Mexico border and the larger study of Hispanic population dynamics. It is necessary, therefore, to validate these genotypic trends using other sources of biological information relevant to the forensic context. Given the importance of craniofacial morphology to the estimation of ancestry and the historical use of quantitative cranial traits as reasonable proxies for neutral genetic markers, craniometrics were used to recapitulate these prior results.

The hypothesis that the dynamic temporal, geographic, and identification trends in United States-Mexico border casework revealed with genetic ancestry information can be equally accessed using craniometrically derived admixture estimates was tested. Hispanic cases were selected from the Forensic Anthropology Data Bank (FDB) such that craniometrics, birth year, geographic, and Identification (ID) status information were available. Proportions of admixture were sourced from the population structure analyses of Algee-Hewitt.[3]

To test for temporal trends, correlation coefficients, ρ, are calculated between birth year and the estimated admixture proportions. A significant correlation ($p < 0.05$) is found between birth year and the Native American (ρ=0.32) and European estimates (ρ=-0.31, p=0.0053). These analyses were repeated, after partitioning the sample into two groups: cases with documented place of birth and cases with recovery location only, serving as proxies for identified and unidentified cases, respectively. Significant correlations are obtained between birth year and the Native American estimates for the location born subset (ρ=0.31). For the recovery location subset, significant, and stronger, correlations are produced between birth year and both the Native American (ρ=0.50) and European (ρ=-0.49) estimates. When case year replaced birth year, the associations remain consistent and these two measures are positively related (ρ=0.60).

To assess identification bias, the location born and location recovered cases are compared for their level of indigeneity and identification status. Native American ancestry appears higher for the recovery location sample (mean 50%, median 58%) than for the sample with known birthplace (46%, 39%). When grouped by ID status codes, the location born cohort contains many more cases with confirmed identifications (89%) than the recovery location cohort (63%). A cross-classification using identification status and location categories is significant (R^2=0.12, df=2, X^2=19.04, $Prob > X^2$= <0.0001). Inverse correlations between identification status and both case year (ρ=-0.33) and Native American proportions (ρ=-0.12) are produced for the location found subset. Identification status and case year (ρ=0.12) are positively related and Native American proportions (ρ=-0.12) are negatively related for the location born subset. Over time, confidence in identification decreases for the location found and increases for the location born data. Most importantly, for both analyses, case identification success decreases as indigenous ancestry increases. These findings are supported by regression analysis of the Native American proportions for the location found subset. The full model (R^2=0.28, df=3, F = 3.56, $Prob > F$ = <0.0274) and effects tests for birth year

($F = 8.13$, $Prob > F = <0.0082$) and ID status-by-birth year ($F = 5.95$, $Prob > F = <0.0216$) are all significant, and lack of fit is not significant ($F = 0.52$, $Prob > F = <0.8622$) at $\alpha=0.05$.

These results attest to an inverse relationship between the amount of European and Indigenous ancestry and suggest an increased case representation of peoples with more Indigenous ancestry in more recent years. These findings support an identification bias among the Hispanic-labeled cases in the FDB. Individuals with higher proportions of Native American membership have less frequent birth location information on record and are more often assigned low identity status scores. They most often represent individuals not yet positively identified by other means, such as DNA profile, fingerprint, or antemortem record matching.

Hispanic Ancestry, Identification Bias, Geo-Temporal Trends

A5 Population Identifiability From Forensic Genetic Markers: Ancestry Variation in Latin America

Cris E. Hughes, PhD, Department of Anthropology, 109 Davenport Hall, 607 S Matthews Avenue, Urbana, IL 61801;and Bridget F.B. Algee-Hewitt, PhD*, Stanford University, Rosenberg Lab, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020*

After attending this presentation, attendees will better understand how the ancestry content of forensic genetic markers can contribute to the study of Latin American variation and how it can assist forensic anthropologists in choosing population-specific methods when inferring other biological profile parameters.

This presentation will impact the forensic science community by demonstrating that forensic Short Tandem Repeats (STRs), such as the Combined DNA Index System (CODIS) markers, are valuable resources for population structure analyses at micro-regional levels, specifically in Latin America. This presentation also quantifies and confirms the agreement between ancestry/admixture patterns produced from a small panel of forensic genetic markers and a large gold-standard dataset.

Ancestry information content in panels of forensic STRs, including the CODIS loci, has been most recently addressed by Algee-Hewitt et al., who demonstrated that forensic STR markers with high individual identifiability carry a non-trivial amount of information on ancestry.[1] These findings support the legacy of population research in anthropological genetics that uses forensic genetic markers in the study of population history and the analysis of contemporary variation. The observed link between individual and population identifiability also has implications for forensic anthropology. These markers have both research and practical importance: the individual identification profiles often represent the only source of genetic information for understudied populations and they provide another source of biological information on admixture and ancestry that is of concern for, broadly, casework logistics and, specifically, individual skeletal case analysis. While small sets of forensic STR loci have been used to reveal latent structure, estimate ancestry, or generate proportions of admixture, the appropriateness of these applications using these markers has not been thoroughly studied. The goal, here, is to determine the compatibility of ancestry/admixture estimates generated from forensic and non-forensic STR markers and to articulate the value of forensic loci for different levels of population identifiability in forensic anthropology.

Genetic data representing Latin America variation are used to evaluate the utility of forensic microsatellite markers for fine-grained population research. This region is of special forensic relevance because of the humanitarian crisis at the United States-Mexico border and the challenges that the identification of undocumented migrant fatalities pose for forensic anthropologists. Moreover, Latin America is composed of highly admixed populations with varied patterns of ancestry. Genotypes were sourced from the Wang et al. dataset, which includes 240 admixed individuals from 13 Latin American populations genotyped for 678 microsatellite markers.[2] Within this "Full" dataset, 9 of the traditional 15 forensic loci were identified, and tetranucleotide STR markers that recapitulate key properties of the CODIS loci. Drawing on this sample of nine CODIS and the identified CODIS-like markers, ten unique "Test" datasets, which contain 15 STRs each, were generated to reflect the traditional size of a forensic panel. Parallel STRUCTURE analyses are run for all datasets. K=2 solution, including Native American and European parental populations, is the preferred model.

As the purpose of this analysis is to determine if forensic STR panels display structure patterns and confer ancestry information in amounts statistically similar to traditionally large, microsatellite datasets not used in forensic identity testing, the Full dataset was designated as the non-forensic, gold standard. A consensus solution is obtained from the STRUCTURE results for each of the ten Test datasets (15 loci). It is compared against the results generated using the Full dataset (678 loci). The similarity statistic computed between these two sets of admixture-cluster results is high (0.86). Cross-classification using the hard (indigenous) cluster assignments from STRUCTURE is X^2 significant (R^2=0.55) and classification error is remarkably low (4.24%). Significant and strong positive correlations exist between the indigenous component estimates from the Test and Full datasets when partitioned by subpopulation ($0.66 \leq p \leq 0.96$, $p < 0.001$).

Results of two-sided paired *t*-tests for mean indigenous cluster assignments between the Test and Full datasets are significant for 3 of the 13 Latin American samples. The average of the mean differences in indigenous cluster

assignments is 6%. Kolmogorov-Smirnov testing identifies a significant distributional difference for only one sample. The cumulative analyses indicate that the CODIS/CODIS-like markers tend to overestimate the amount of indigenous ancestry, when K=2; however, this overestimation is small, systematic, and corrected when the STRUCTURE analysis includes African parental, K=3. Analysis of Variance (ANOVA) reveals significant subpopulation mean differences for the Test (R^2=0.81) and Full (R^2=0.92) datasets. Post-hoc comparisons find fewer among-population, microregional differences for the Test dataset, indicating that forensic markers provide a lower-resolution, more conservative picture of Latin American variation.

A6 Vulture Scavenging of Pig Remains at Varying Grave Depths

Aryn Klein, MA, Texas State University - San Marcos, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will better understand how vultures (*Coragyps atratus* and *Cathartes aura*) respond to and modify graves of different depths containing buried carrion. Attendees will also gain insight into the behavior of these vultures regarding digging and human disturbance at a decompositional facility.

This presentation will impact the forensic science community by providing results from a controlled experiment in an area with very little previous research. This presentation will augment research in forensic taphonomy by adding to the body of knowledge in terms of how vultures respond to carrion that is buried in a shallow grave and how they respond to human disturbance. This presentation will suggest that researchers' daily presence has so modified vulture behavior that it is now altering vulture studies at the Forensic Anthropology Research Facility (FARF) at Texas State University-San Marcos, indicating there may be a "shelf life" for outdoor decompositional facilities when used for vulture scavenging research.

Forensic anthropologists occasionally encounter human remains in burial scenarios such as shallow graves (i.e., depth of ≤1 meter) that show signs of vultures having disturbed the scene.[1-4] The purpose of this study was to examine how vultures detect graves, disturb the area, remove, disarticulate and skeletonize remains, and finally abandon the different graves in comparison to a surface deposition. Accumulated Degree Days (ADD), humidity, and wind speed were used to assess different environmental and climatic factors that may have affected the timing of vulture activity.

From November 2012 to January 2013, four pig carcasses (*Sus scrofa*) were buried at varying shallow grave depths at FARF. A fifth pig served as a control on the surface. Modification of the graves and surface deposit was recorded through the use of five motion-sensing cameras and daily on-site observation. The research intended to examine how vultures (*Coragyps atratus* and *Cathartes aura*) respond to and modify shallow graves of varying depths.

Vultures in this study did not locate or unearth the carcasses in the burials and this may be explained by vulture seasonality and migration, feeding behavior regarding digging and the specific vulture species, and most importantly, the presence of human disturbance. Season may have an effect on the migration patterns of turkey vultures, especially because the study was conducted in the early winter in a location at the edge of the summer turkey vulture range. The lack of turkey vulture involvement may have created an intervening variable in which black vultures would not and/or could not access the carcasses. Although vultures usually return to scavenging opportunities shortly after being displaced by humans (~20 minutes), consistent human presence at FARF may have influenced vulture behavior and is likely another limitation to the study. Vultures may have moved on to more consistent and secluded sources of food (known and reliable locations of carrion with minimal disturbance, human or otherwise).

This presentation highlights the first attempt at understanding vulture response to buried remains in an outdoor decompositional facility. It is suggested that future research should be conducted in a location that is not frequented by humans and/or during a season when turkey vultures are more prevalent. More information is needed regarding vulture seasonality, feeding habits, and the digging abilities of turkey vultures. Finally, it is suggested that future vulture research at FARF should be conducted in a location that is secluded and as close as possible to conditions found in nature.

A7 3D Image Technology in Forensic Anthropology: Assessing the Validity of Biological Profiles Derived From Computed Tomography (CT) 3D Images of the Skeleton

M. Julia Garcia de Leon Valenzuela, MSc, The International Institute of Forensic Sciences, 1670 E River Road, Ste 124, Tucson, AZ 85718*

After attending this presentation, attendees will understand the benefits and limitations the use of 3D technology poses on the creation of biological profiles in forensic anthropology. Attendees will also be informed as to how these issues can be addressed in current and future research.

This presentation will impact the forensic science community by exploring research results that contribute to the growing literature of virtual anthropology, the use of which could theoretically enable forensic anthropologists to derive skeletal collections from living populations and by creating population-specific standards as well as digitizing entire osteological collections, which would enable research to be conducted without the limitations that travel and accommodation costs impose on researchers.

This project explores the reliability of building a biological profile for an unknown individual based on 3D images of the individual's skeleton. 3D imaging technology has been widely researched for medical and engineering applications, and it is increasingly being used as a tool for anthropological inquiry. While the question of whether a biological profile can be derived from 3D images of a skeleton with the same accuracy as achieved when using dry bones has been explored, bigger sample sizes, a standardized scanning protocol, and more inter-observer error data are needed before 3D methods can become widely and confidently used in forensic anthropology.

3D images of CT scans were obtained from 130 innominate bones from Boston University School of Medicine's skeletal collection. For each bone, both 3D images and original bones were assessed using the Phenice and Suchey-Brooks methods. Statistical analysis was used to determine the agreement between 3D image assessment versus traditional assessment. A pool of six individuals with varying experience in the field of forensic anthropology (at the beginner, intermediate, and expert levels) scored a subsample (n=20) and the data obtained were used to explore inter-observer error. The results of the inter-observer portion of this study exhibited mixed results. While a high agreement was found for age and sex estimation for specimens scored by an expert, the inter-observer study shows that observers found it difficult to apply standard methods to 3D images. Higher levels of experience did not result in higher agreement between observers, contrary to what was expected. These results were also contrary to those obtained for the main portion of the study, in which a good correlation was found between scores obtained for dry bones versus those obtained for their 3D counterparts (n=130). Thus, a need for observer training in 3D visualization before applying anthropological methods to 3D bones is suggested. Future research should explore inter-observer error using a larger sample size in order to test the hypothesis that training in 3D visualization will result in a higher agreement between scores. The need for the development of a standard scanning protocol focusing on the optimization of 3D image resolution is highlighted.

Applications for this research include the possibility of digitizing skeletal collections in order to expand their use and for deriving skeletal collections from living populations and creating population-specific standards. Further research for the development of a standard scanning and processing protocol is needed before 3D methods in forensic anthropology are considered as reliable tools for generating biological profiles.

Virtual Anthropology, 3D Technology, Biological Profile

A8 The Accuracy and Reliability of the Klales et al. Non-Metric Pelvic Sexing Method

Kate M. Lesciotto, JD, MS, Pennsylvania State University, Dept of Anthropology, 409 Carpenter Bldg, State College, PA 16802; and Lily J. Doershuk, BS, Pennsylvania State University, Dept of Anthropology, 409 Carpenter Bldg, State College, PA 16802*

After attending this presentation, attendees will better understand the accuracy and inter-observer and intra-observer error rates for the Klales et al. method of sex estimation utilizing three non-metric traits of the pelvis.[1]

This presentation will impact the forensic science community by contributing an external validation study on the accuracy and reliability of using pelvic non-metric traits to estimate sex for unknown individuals.

When attempting to estimate sex from a set of unknown skeletal remains, the pelvis is considered to be the most reliable element. In 1969, Phenice created a now widely used method that evaluates three nonmetric traits of the pelvis: the ventral arc, subpubic concavity, and medial aspect of the ischiopubic ramus.[1] In 2012, Klales et al. created an ordinal scoring method for the Phenice traits in an attempt to provide robust statistical analysis, posterior probabilities, and error rates, as required by *Daubert*.[2] As non-metric pelvic traits are commonly used in estimating sex in forensic cases, it is imperative that this method be externally validated for both accuracy and reliability.

The Klales et al. method was used to score three nonmetric pelvic traits in United States White and United States Black individuals from the Hamann-Todd Collection (N=279).[2] Two different observers scored each of the innominates to evaluate overall accuracy rates using the ordinal scores and logistic regression equation provided in the 2012 publication. The entire sample was also utilized to examine inter-observer error rates, while intra-observer error was evaluated on a subsample of 50 innominates that were rescored by each observer. Additionally, after rescoring the traits on this subsample, each observer also blindly provided an overall "gestalt" evaluation of sex based on the traits, other morphological characteristics, size, and personal experience.

Observers A and B attained similar accuracy rates of 73.1% and 72.4% with the Klales et al. regression formula, with each observer's results exhibiting a large sex bias. Females were correctly identified most of the time by both observers (95.7% and 97.1%, respectively), while males were correctly identified with accuracy approximately equal to chance (50.7% and 47.9%, respectively). Fifty-three individuals were incorrectly sexed by the Klales regression formula by both observers, including 51 males and only 2 females. In contrast to the regression equation, both observers achieved high accuracy based on their gestalt estimation of the intra-observer error subsample (98.0% and 90.2%, respectively).

Pairwise comparisons completed using Cohen's weighted kappa were used to evaluate observer error. Both the inter-observer and Observer A's intra-observer comparison exhibited moderate agreement for the ventral arc and subpubic concavity ($kappa$=0.539 and 0.549, respectively) and substantial agreement for the medial ischiopubic ramus ($kappa$=0.651 and 0.669, respectively). Observer B's intra-observer comparison revealed moderate agreement for the ventral arc (0.572) and substantial agreement for the subpubic concavity and the medial ischiopubic ramus (0.634 and 0.645, respectively) (all $p < 0.001$). The intra-class coefficient correlation tests found similar patterns, with agreements ranging from 0.693-0. 832 (all $p < 0.001$).

Results demonstrate that each of the three non-metric pelvic traits can be scored consistently both between and within observers, with a low incidence of systematic observer bias; however, the high accuracy rates originally reported by Klales et al. were not reached. These results, combined with the high sex bias in accuracy, reveal problems with the method that will likely impact the method's use in forensic contexts when sex estimation of an unknown individual is considered to be the most important aspect of the biological profile. Additional research should be directed toward utilizing less subjective techniques to better quantify the traits and creating a more representative set of descriptions and visual guides for scoring.

A9 Organic Staining on Bone

Corey Pollock, 3 Oswald Street, Apt 3, Boston, MA 02120; James Pokines, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118; and Jonathan D. Bethard, PhD, University of South Florida, Dept of Anthropology, 4202 E Fowler Avenue, SOC 107, Tampa, FL 33620-8100*

After attending this presentation, attendees will understand the taphonomic process of organic staining on bone deposited in aqueous environments, with different organic materials introduced for extended intervals.

This presentation will impact the forensic science community by displaying taphonomic data of color staining, which will aid in investigations when questions arise concerning the environment in which remains were deposited and what type/species of plant material have made contact with the bones.

Organic staining results largely from tannins leaching from plant materials, including wood and leaves, and therefore can be seen on bone deposited in wooden coffin environments or on terrestrial surfaces. This study hypothesized that the degree of staining observed on skeletal elements would increase as the length of exposure to the organic matter increased and that different plant materials would leave different degrees or colorations of staining.

The skeletal elements consisted of 150 commercially available pig (*Sus scrofa*) femora that had the epiphyses removed and were completely defleshed. The total sample was divided into three groups with differing conditions and/or types of organic material introduced. Some were buried in a marshy environment within wooden boxes constructed of ten wood types commonly utilized in coffin construction throughout American history: chestnut (*Castanea*), walnut (*Juglans*), cherry (*Prunus*), soft maple (*Acer*), mahogany (*Swietenia*), yellow pine (*Pinus*), poplar (*Populus*), cedar (*Cedrus*), oak (*Quercus*), and spruce (*Picea*). Additional femora were deposited in plastic containers lined with the same wood types as above and filled with tap water. An additional five control bones were deposited in a container with tap water. Five additional bones were placed in a container with commercial tannic acid. The final group of femora was deposited on the ground surface surrounded by four types of dead vegetation: evergreen pine needles, northern red oak leaves (*Quercus rubra*), sugar maple leaves (*Acer saccharum*), and acorns.

The bones were removed once a month from their experimental environments and left overnight to dry to allow for the color to be recorded. The level of staining that manifested on the osseous material was recorded qualitatively using a Munsell Color Chart and a 40-watt daylight light bulb. The color staining was recorded after two months upon initiation of the study and every following month until the study's completion. After the color staining was recorded, the bones were returned to their experimental environments, and this process was repeated throughout the study.

In all of the experimental environments, staining was present after two months of contact with the organic materials and the color darkened or expanded across the bone surface with each data collection. Both groups exposed to the wood types displayed staining across the entire bone surface with a mixture of colors expressed. Over time, a few colors became dominant while minor colors were only expressed along the margins of the bone or as small patches along the shaft. As the buried boxes began to break down, which is commonly observed in coffin burials, soil was able to infiltrate the boxes and contact the bones. This resulted in multiple shades of brown (10YR 4/3; 10YR 3/3) to be present in the staining across bones in multiple wood types. The bones in the plastic containers with wood exhibited a larger variation in color staining, likely due to a higher concentration of tannins restricted to a smaller area around the bones. The staining ranged from red (10R 5/4) for bones with the mahogany to brown (7.5YR 5/3) for bones with the cedar to even dark gray (10YR 4/1) or black (10YR 2/1) on bones with the walnut. The bones in plant matter differed from the other two groups in that the organic staining was sporadic, often with large areas of very pale brown (10YR 7/3) or yellowish brown (10YR 6/4) coloration and with smaller patches of darker brown shades (10YR 4/3; 10YR 5/2).

The results from this study indicate that staining can manifest on bone within a relatively short time frame once skeletonization occurs and a variety of colorations or degrees of staining can manifest based on the plant material. This research will aid in the determination of which types of organic material have contacted osseous remains and the potential environments in which they were deposited.

A10 Postmortem Environment and DNA Quality: Investigating the Effect of Seasonal Taphonomy on Skeletal DNA Quality

Lauren J. Swift, MSc, University of Western Australia, 8/18 The Avenue, Crawley, Perth, Western Australia 6009, AUSTRALIA; Ambika Flavel, MSc, University of Western Australia, M420, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; and Daniel Franklin, PhD, University of Western Australia, Centre for Forensic Anatomy and Biological Science, MBDP M311, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA*

After attending this presentation, attendees will appreciate the impact taphonomy has on both skeletal morphology and DNA, which will assist attendees in making informed decisions regarding victim identification during routine molecular analyses.

This presentation will impact the forensic science community, specifically within the field of victim identification, by providing an insight into the survivability of skeletal DNA within harsh taphonomic environments, thus increasing the likelihood of obtaining positive identifications of descendants.

The identification of unknown decedents occurs through the collaboration of multiple forensic disciplines. When skeletal remains are discovered, identification is often the responsibility of forensic anthropologists. The analyses they perform are primarily used to ascertain estimations of age, sex, stature, ethnicity, and trauma, which collectively are known as a biological profile. The biological profile is used to narrow the pool of potential matches. Issues arise when there is a lack of antemortem information available to cross-reference with the biological profile and when taphonomy alters the physical morphology of bone such that routine anthropological assessment is no longer accurate. In these situations, the use of molecular biological practices, such as skeletal DNA extraction and amplification, is sought to aid in the identification process.

Investigating the effect that seasonal weather fluctuations, particularly wet/dry cycles as well as freeze/thaw cycles, have on the structural integrity of bone and therefore the effect this may have on the sequencability of skeletal DNA forms the basis of the current investigation. The goals of the present study were threefold: (1) to ascertain the effect that wet/dry and freeze/thaw cycles have on the sequencability of skeletal DNA; (2) to determine the effect skeletal fragmentation has on the ability to extract sequenceable DNA; and, (3) to determine whether nucleic or mitochondrial DNA is a more appropriate target for skeletal DNA amplification.

A total of 16 porcine long bones (femurs) were used as substitutes for human skeletal remains. Half of the bones were left intact and half were medially fragmented. Two taphonomic environments were simulated during the investigation: (1) wet/dry cycling, to mimic seasonal rainfall, was achieved by submerging long bones in one liter of water for two weeks, then allowing them to dry within a fume hood for a further two weeks; and (2) freeze/thaw cycling, to mimic seasonal temperature variations, was achieved by housing the bones at -20°C for two weeks followed by a two-week thaw period (20°C) under a fume hood. Two-week cycles were continued for a total of five months with skeletal DNA extraction occurring monthly. Amplification was achieved via Polymerase Chain Reaction (PCR) and Sanger sequencing using two mitochondrial DNA primers and one nucleic primer that targeted pig growth hormone. DNA sequencability was judged based on quantity (nanodrop values) and quality as measure by trace (Phred) scores following sequencing.

The results of the investigation saw dramatic morphological changes occur within both environments; bones subjected to wet/dry cycling lost structural integrity with periosteal flaking and cracking as well as disarticulation of the epiphysis. Despite the physical alterations, the results indicate that sequenceable DNA could be extracted from both groups with varying levels of success. The lowest quantity and quality of DNA as measured by low nanodrop values and trace scores occurred for bones within the wet/dry group after three months of cycling; however, readable sequences were still available for these bones indicating that over a short duration, despite relatively harsh taphonomy, skeletal DNA survivability is possible.

The most significant factor for the study was shown to be the choice of primer, with significant preferential preservation of mitochondrial DNA over nucleic DNA shown for all treatment groups.

The results of this investigation indicate that sequenceable mitochondrial DNA can be extracted from skeletal remains exposed to harsh environmental conditions after relatively short periods of time. The outcome of the present study impacts the field of victim identification for scenarios in which skeletal DNA extraction would otherwise have

been considered redundant.

Skeletal DNA, Seasonal Taphonomy, Forensic Anthropology

A11 A Transition Analysis of Pediatric Fracture Repair Stages

Nicholas V. Passalacqua, PhD, Western Carolina University, 101 McKee, Cullowhee, NC 28723; Michael W. Kenyhercz, PhD, Department of Defense POW/MIA Accounting Agency, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96816; and Diana L. Messer, MS, 2873 Neil Avenue, Apt 452B, Columbus, OH 43202*

The goal of this presentation is to discuss the utility of transition analysis in the estimation of the age of pediatric healing fractures using radiographic images.

This presentation will impact the forensic science community by providing the ages of transition between stages of fracture repair from a large known pediatric sample, as measured by the date of injury to the date of radiographic imaging. This may have significant ramifications for investigations of child abuse and the interpretation of cases involving healing skeletal fractures.

Multiple fractures in various stages of healing are considered highly indicative evidence of physical child abuse.[1] The estimation of time since fracture, while complicated by factors such as age and anatomical location, has the potential to assist in the identification of physical abuse. In both forensic and clinical settings, a radiographic skeletal survey is generally performed to assess for occult and healing fractures, and this imaging is often the basis upon which an assessment of fracture healing is performed. Yet, despite a handful of studies examining pediatric fracture healing using radiographic images, the timing of fracture healing has yet to be fully understood.[2]

The goal of this project is to present the ages of transition between fracture repair stages for the interpretation and analysis of pediatric healing fractures. This study used data collected from a series of radiographs of lower limb and forearm bone fractures from 116 individuals within the age group most at risk for child physical abuse, individuals aged 0 to 5 years. Some individuals exhibited multiple fractures for a total of 185 forearm fractures and 107 lower leg fractures examined. These data were collected and previously examined by Malone.[3] This project reinvestigates this data with a different statistical approach: using transition analysis to determine mean ages and ranges of transition between fracture repair stages.

The original analyst (Malone) scored all radiographs within the following six-phase system: Stage 1 – No healing; Stage 2 – Granulation; Stage 3 – Callus; Stage 4 – Bridging; Stage 5 – Clinical Union; and, Stage 6 – Completion.[3] Using Analysis of Variance (ANVOA) tests, Malone found statistically significant differences in rates of healing between lower leg and forearm bones, with forearm bones healing faster, as well as differences in age, with individuals aged one year or less spending less time in Stage 1 than individuals aged two years or older.[3]

The present reanalysis uses these same data; however, the goal was to generate ages of transition between different fracture healing stages. To extend transition analysis for ordinal traits, a restricted cumulative probit regression was used. All analyses used the VGAM package in R.

Results found that for all transitions except one (Stage 4 to Stage 5), the mean age of forearm fractures was ahead of the mean age of the corresponding lower leg fractures. Further, when examining individuals aged one year or less versus individuals aged two years or more, there was no trend in mean-age transition timing, with neither group consistently ahead of or behind the other.

There was a great deal of overlap in transitions, especially between the first three stages. This overlap indicates that the present six-stage system does not provide a great deal of discriminating power between the current morphological stage descriptions. Revising stage descriptions or generating new evaluative criteria for pediatric fracture healing has the potential to increase accuracy of fracture age estimates. For example, distinguishing between early features of fracture healing, such as subperiosteal new bone formation versus callus formation, has been suggested to improve interpretation of time since injury.[1] In addition, the effect of variables that influence rate of healing, such as age and anatomical location, should be further explored and considered in future work. Overall, transition analysis provides a more in-depth examination of pediatric fracture healing, allowing for broader interpretation when analyzing pediatric fractures.

Fracture, Healing, Child Abuse

A12 Musculoskeletal Stress Markers as Evidence of Manual Labor: The Allumiere Cemetery Case

Marica Baldoni, MA, University of Rome Tor Vergata, Via Della Ricerca Scientifica, #1, Rome 00173, ITALY; Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Cristina Martinez Labarga, PhD, via della Ricerca Scientifica 1, Dept of Biology, University of Rome Tor Vergata, Rome 00173, ITALY*

After attending this presentation, attendees will better understand the importance of musculoskeletal stress markers on human bones.

This presentation will impact the forensic science community by providing an additional tool to enhance the biological profile and osteobiography of unknown human skeletal remains.

Entheses are muscle and tendon attachment sites on bones that can vary morphologically in relation to muscle activity. The analysis of these marks on skeletal remains can help to identify physical activity carried out by a subject during life. An enthesis is an interface between hard and soft tissues where high biomechanical stress is concentrated. The result of this stress could be represented by acute or overuse injuries that may develop into an enthesopathy.[1] Marks on skeletal tissue could be also influenced by different factors, such as intense muscle activity, postural habits, and medical or nutritional conditions.[2]

For this study, an Italian historical skeletal collection housed at the Department of Biology of the University of Rome Tor Vergata was examined. The skeletal remains belong to a cemetery in Allumiere (Rome, Italy), an area historically related to alum exploitation. A preliminary anthropological analysis was performed in order to assess sex, age at death, stature, and general osteobiographic traits. The sex ratio value (45M:7F) supports the theory that the cemetery area was mainly used by miners.

The analysis of entheses was performed according to the protocol proposed by Mariotti and colleagues; the 23 entheses proposed in that protocol have been integrated with those proposed by Borgognini Tarli and Reale.[3-5]

The analysis focuses on three parameters: robusticity, osteophytic formations and osteolytic enthesopathies. Robusticity represents the normal bone marks at a muscle, tendon or ligament attachment site, and it is nearly always recognizable, with the exception of extensive osteolytic processes affecting the entire osseous area.[3] The analysis of the degree of development is conducted following a scaling system: degree 1 (weak-moderate enthesal expression), degree 2 (strong development), and degree 3 (very strong development). Nevertheless, subcategories (1a, 1b, 1c) were provided for degree 1, corresponding to "very slight," "low," and "medium" development. Even for the other two parameters, a scaling system was used from 0 (absence) to 3 (marked) osteophytic or osteolytic process.

High-level biomechanical stress was detected analyzing single bone entheses. The results were then clustered into functional groups (shoulder, elbow, forearm, hand, hip, knee, foot) and all entheses of the entire upper and lower limb were considered in order to reconstruct the biomechanics and body movements.

The mechanical stress experienced by a surface is proportional to the force experienced in each unit area of that surface.[6] It is undeniable that the relationship between muscle activity and enthesal morphology is neither as simple nor as obvious, but morphological variation in the attachment site does exist and likely reflects some aspects of *in vivo* stimuli. Skeletal entheses are thoroughly connected with the attaching muscles so, through them, it is possible to investigate the *in vivo* activity of those muscles.[7]

The availability of data regarding the different phases of alum production and the related labor categories opened the possibility of associating every individual to a specific work task correlated to alum extraction and exploitation making the presented case a "collector's item."[8] It was possible to assign different task groups. For instance, a young adult male showed a marked development of pectoralis major in addition to osteolytic lesions corresponding to costoclavicular ligament insertion on clavicle; this biomechanical stress that involved both the upper limb and the shoulder girdle could be related to the extraction in the cave through iron picks.

The goal of this pilot study is to demonstrate the relationship between musculoskeletal stress markers on human bones and activity patterns through a multidisciplinary approach that involves different points of view, such as

anthropological, biomechanical and historical.

In addition, this research demonstrates the potential application in forensic contexts in which anthropologists have to investigate compromised unknown human remains (decomposed, mummified, mutilated, burned, and dismembered). The possibility of identifying musculoskeletal and occupation stress markers and moreover to reconstruct *in vivo* biomechanical stimuli related to daily tasks could become an important improvement to biological profiling opening the possibility of reconstructing muscle body movements and hypothesizing activity patterns, in order to increase the chance of sorting candidates for identification.

Presented here is a pilot study that, even if limited by the small sample size, demonstrates the potential of an empirical experiment and provides an important additional tool to forensic investigations.

A13 A Statistical Method for Reassociating Human Tali and Calcanei From a Commingled Context

Ioanna Anastopoulou, BSc, University of Athens, School of Medicine, 75 M Asias Street, Athens 11527, GREECE; Fotios A. Karakostis, MSc, Eberhard Karls University at Tübingen, Rumelinstrasse 23, Tübingen, Baden-Württemberg 72070, GERMANY; Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Konstantinos Moraitis, PhD, University of Athens, School of Medicine, 75 M Asias Street, Athens 11527, GREECE*

After attending this presentation, attendees will understand the utility of using metric methods for sorting commingled human remains.

This presentation will impact the forensic science community by presenting a statistically valid means of sorting commingled remains when traditional non-metric methods need to be supplemented.

Compact human bones are highly resistant to taphonomic change and are usually found intact in the field.[1] The two largest tarsal bones, talus and calcaneus, are frequently recovered intact and in high abundance. In a commingled context, assessing that a talus and a calcaneus correspond to the same individual could become the primary step for accurately sorting human remains. In this framework, the present study seeks to develop a more accurate method for sorting an individual's talus and calcaneus by using measurements of these bones' joint surfaces.

For this purpose, the lengths and widths of the trochlea, posterior calcaneal articular surface, and posterior talar articular surface were measured in 197 individuals (105 males, 92 females) of the Athens Collection.[2,3] This skeletal collection consists of individuals of known sex, age, occupation, and cause of death. All specimens examined lived in the second half of the 20th century in Athens, Greece. Their biological age ranged between 22 and 99 years. The degree of significant correlation among measurements was calculated using the Pearson's correlation coefficient. Simple and multiple regression analyses were performed for the development of functions for reassociating an individual's talus with its corresponding calcaneus.

Simple and multiple linear regression analyses produced a total of 12 equations (six for each side) as the best statistical models for predicting measurements of the calcaneus using measurements of the talus. The standard error of the estimate ranged between 1.03mm and 2.02mm. Pearson's correlation analyses demonstrated statistically significant strong positive correlations among measurements (0.69-0.93, $p<0.05$). The coefficient of determination (r^2) scored overall higher in multiple regression analyses (0.72-0.87) compared to simple regression analyses (0.48-0.86).

In conclusion, the regression equations developed in this study are found to be suitable for sorting commingled human tali and calcanei. Future development of similar methods for other joints of the human skeleton would be beneficial for the anthropological analysis of commingled remains.

Commingled Remains, Talus, Calcaneus

A14 Long-Term Observer Error, Observer Experience, and the Value of Trait Standardization in Macromorphoscopic Trait Analysis

Kelly R. Kamnikar, MA, Michigan State University, 355 Baker Hall, 655 Auditorium Road, East Lansing, MI 48824; and Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the implications of observer experience and trait standardization on intra-observer error in the analysis of macromorphoscopic trait scores commonly used in the forensic estimation of ancestry. Attendees will also gain insight into the impact of this type of error in the estimation of ancestry.

This presentation will impact the forensic science community by addressing the role of experience, standardization, and validation in long-term observer error studies and the impact of these factors on the estimation of ancestry using macromorphoscopic trait scores.

As one part of a much larger investigation into the macromorphoscopic traits used in the estimation of ancestry from skeletal remains, a 14-year (2002 to 2016) intra-observer error study was conducted. Motivated by the development of a large macromorphoscopic database, which could potentially utilize data collected in 2002, quantification of the impact on observations caused by observer error, technological improvements in macromorphoscopic trait collection, and observer experience was necessary. To maximize comparisons between the two samples, only ten macromorphoscopic traits were assessed: (1) anterior nasal spine; (2) inferior nasal aperture; (3) interorbital breadth; (4) malar tubercle; (5) nasal aperture width; (6) nasal bone contour; (7) nasal overgrowth; (8) postbregmatic depression; (9) posterior zygomatic tubercle; and, (10) zygomaticomaxillary suture.

Paired data were collected from 185 American Black (n=127) and White (n=58) individuals from the Robert J. Terry Collection. The 2002 sample was collected on paper forms using then-standard texts, references, and line drawings. The 2016 sample was collected using Macromorphoscopic Traits v.1.61 (MMS), a data collection program designed specifically for macromorphoscopic trait analysis. Following data collection, the 2002 and 2016 samples were combined into a single data table for analysis. A traditional (unweighted) Cohen's Kappa is used to quantify disagreement between two assessments, but does not control for the degree of disagreement. Therefore, when the ratings are ordered ($1 < 2 < 3$), as in macromorphoscopic trait expressions, a quadratic weighted Cohen's Kappa is better suited to assess intra-observer error.

There was good agreement between the two observation periods for seven of the ten traits. The frequency of agreement ranged from 74.05% (postbregmatic depression) to 28.11% (zygomaticomaxillary suture). The three underperforming traits are: (1) malar tubercle (confidence interval $\kappa_w = 0.029 – 0.046$; levels = 4); (2) zygomaticomaxillary suture (CI $\kappa_w = 0.031 – 0.093$; levels = 3); and, (3) posterior zygomatic tubercle (CI $\kappa_w = 0.029 – 0.046$; levels = 4). Discrepancy between observations can be attributed to the following explanations. First, these three traits are not commonly used in forensic ancestry estimations and are therefore less familiar. Second, difficulty distinguishing between the various character state manifestations due to poorly worded definitions or inadequate capture of trait variants may occur. Finally, the experience level of the observer is potentially the most interesting factor influencing low observer agreement. Intermediate values for all ten traits demonstrated a lower proportion of agreement between observation periods; the 2016 sample demonstrated a higher proportion of intermediate scores, possibly indicating extreme trait values are less likely as the experience of the observer increases. As a final point, classification accuracies from a canonical analysis of the principal coordinates using all ten traits and a reduced model using the seven traits with good observer agreement were calculated and assessed for statistically significant differences between the 2002 and 2016 samples. Despite the noted error, all classification accuracies were promising and similarly distributed. The 2002 sample correctly classified 92.2% (seven variables) and 93.5% (ten variables) of the total sample. Similarly, the 2016 sample correctly classified 91.1% (seven variables) and 88.2% (ten variables)/

The results of this research suggest a moderate level of observer error should be expected as an analyst becomes more familiar with a methodology. As new technologies supplant older approaches, there is potential to reduce observer differences. Although observer error was significant for three of the ten traits documented in this study,

their influence on classification accuracies was not demonstrably significant.

A16 Collagen Structural Changes and Decomposition in Burnt Bone and Their Significance for Forensic Anthropology — New Insights Via Amino Acid Racemization

Sarah Ellingham, PhD, International Committee of the Red Cross, Forensic Services, 19 Avenue de la Paix, Geneva 1202, SWITZERLAND*

After attending this presentation, attendees will better understand the changes bone collagen undergoes when subjected to heating and the implications these changes have on subsequent forensic analyses.

This presentation will impact the forensic science community by shedding new light on the thermal stability of bone collagen, allowing for an improved prediction of the success rate of collagen extraction for subsequent analyses, such as dating or isotope analyses.

All amino acids found in proteins exist as one of two possible stereoisomers, known as L-amino acids and D-amino acids. With the exception of glycine, all amino acids are L-amino acids, which have the ability to change into the D-form over time. The process of reaching an equilibrium between the L and the D form is called racemization. Amino Acid Racemization (AAR) is a time- and temperature-dependent process that has found application in the dating of materials, paleothermometry, and age-at-death estimation. Currently, there is no clear consensus in the literature regarding the thermal stability of collagen, an issue on which this research sheds more light.

Sheep (*Ovis aries*) ribs were cut into 4cm-long pieces and burnt at temperatures between 100°C and 1,000°C in 50°C increments for 45 minutes. All samples were weighed pre- and post-burning. Four demineralization samples were suspended in 0.5 M HCl, which was exchanged every two days. After ten days, the HCl was removed and replaced by distilled water until a solution of pH 3 was obtained. Samples were heated at 70°C for 48 hours and subsequently filtered. The extracted collagen was frozen at -20°C and 250µL of solution from each sample were placed in a sterile glass vial, adding 100µL 7 M HCl per sample. The vials were flushed with nitrogen, heated at 110°C for 18 hours, and subsequently dried under vacuum in a centrifugal evaporator. Samples were rehydrated for analysis. The sample's amino acid composition was analyzed by reverse-phase High-Performance Liquid Chromatography (HPLC) using fluorescent detection. Then 2µL of sample was injected and mixed with 2.2µL derivitizing reagent. The amino acids were separated on a C18 HyperSil™ BDS column (5mm * 250mm) at 25°C using a gradient elution of three solvents: sodium acetate buffer, methanol, and acetonitrile. The fluorescence detector uses a xenon-arc flash lamp at a frequency of 55Hz with a 280nm cut-off filter, an excitation wavelength of 230nm, and emission wavelength of 445nm.

The D and L isomers of 13 amino acids could be analyzed, namely serine, L-threonine, L-histidine, glycine, L-arginine, alanine, tyrosine, valine, phenylalanine, leucine, and isoleucine, as well as aspartic acid and glutamic acid. The amino acid concentration rapidly decreases from 250°C onward, being below reliable detection levels from 400°C. Up to temperatures of 250°C, only aspartic acid racemizes, reaching a D/L ratio of 0.3 at 250°C. From 300°C onward, the other amino acids commence racemization. From 400°C onward, the total amino acid concentration is too low to accurately depict D/L ratios. The composition of amino acids was dominated by collagen up to 400°C.

The findings illustrate the thermal degradation of bone collagen. Up to 250°C, virtually no amino acid racemization takes place, with the exception of aspartic acid, which is one of the only amino acids which can racemize while still internally bound. Collagen, when heated, begins to locally unravel its triple helix, releasing the collagen-stabilizing H-bonded water, which leads to a gradual collapse of the triple helical structure at approximately 150°C. At temperatures between 250°C -300°C, a sudden drop in total amino acid concentration as well as the commencing of racemization of all other amino acids can be observed, indicating a catastrophic breakdown of collagen. The now-free amino acids continue racemization until their complete combustion from approximately 400°C onward.

Successful collagen extraction is the basis for a multitude of forensically relevant analyses, such as stable isotope analysis, radio carbon dating, or genetic profiling. Being able to accurately determine the point at which collagen denaturizes and amino acids are lost is therefore of paramount importance for forensic analyses.

Burnt Bone, Collagen, Amino Acid Racemization

A17 Trace Element Analysis of Dental Enamel for the Geographic Attribution of Unidentified Remains

Robert H. Stein, BS, Virginia Commonwealth, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284; Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; and Jennifer L. Hankle, DMD, ViCU School of Dentistry, MCV Campus, Lyons Bldg, Rm 430C, Richmond, VA 23298-0566*

After attending this presentation, attendees will understand the potential of utilizing trace elements in both surface and subsurface enamel to add pertinent information to biological profiles of unidentified individuals.

This presentation will impact the forensic science community by adding to existing geographic attribution methodologies to assist in the identification of unidentified remains. Ultimately, aspects of this methodology could be implemented in a forensic setting to benefit the Undocumented Border Crosser (UBC) crisis at the United States-Mexico border.

The remains of hundreds of UBCs must be examined every year and identification efforts are frequently hindered by the rapid early decomposition due to the extreme desert environment. Therefore, calcified tissues that preserve well (i.e., dental enamel) may hold the key to improving identification methods. The static, sub-surface enamel of permanent dentition remains unchanged during life after its formation *in utero* and for a brief post-natal period and thus can reflect an individual's birthplace, whereas the dynamic nature of the exchange of ions at the enamel surface can reflect the recent geographic residence of the individual.[1-3] Previous studies have shown that trace elements in dental enamel and bone, namely strontium isotopes, can be influenced by diet and geographic locality in humans.[4,5] Two drawbacks of these studies are addressed by this project: (1) lack of evaluation of other trace elements which are inevitably present; and, (2) utilization of bulk dental enamel alone.[1] By looking at both surface and subsurface (bulk) enamel separately, rather than solely bulk enamel, greater discrimination may be obtained (i.e., birthplace and recent residence geographic locality), which will aid in identification efforts.

This study examined ca. 60 teeth from 33 individuals obtained from the Virginia Commonwealth University (VCU) Dental Clinic with Institutional Review Board (IRB) consent. These individuals currently reside in Virginia, but originated from a variety of countries, including El Salvador, Mexico, Guatemala, China, and Somalia. Surface enamel was etched directly using a solution of trace metal-free nitric acid and glycerin, and bulk enamel was dissolved in trace metal-free nitric acid. Samples were analyzed for the following trace elements via Inductively Coupled Plasma/Mass Spectrometry (ICP/MS): ^{7}Li; ^{24,25,26}Mg; ^{27}Al; ^{49}Ti; ^{58,60}Ni; ^{63,65}Cu; ^{64,66,68}Zn; ^{69,71}Ga; ^{75}As; ^{86,87,88}Sr; ^{137,138}Ba; and ^{204,206,207,208}Pb. Principal Component Analysis (PCA) and Discriminant Function Analysis (DFA) were performed to assess multivariate relationships among samples and determine which trace elements drive compositional differences among the samples and the locality groups.

Based on results from the surface enamel, a correlation-matrix PCA plot was generated using ^{55}Mn, ^{63,65}Cu, ^{137,138}Ba, and ^{206,207,208}Pb isotopes as these isotopes yielded the best clustering of individuals originating from the same locality. Standardized function coefficients demonstrated that all isotopes used in the statistical analysis (i.e., ^{55}Mn, ^{63,65}Cu, ^{137,138}Ba, and ^{206,207,208}Pb) had a relatively equal influence on the separation of the individuals' teeth chemical compositions (the range of function coefficients was from 0.339 to 0.363). Variables, such as enamel erosion and age, are likely to influence the persistence of certain trace metals and require further investigation to determine their effects.

In conclusion, Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) analysis of surface and deeper enamel is a promising method for determining the birthplace and recent residence of individuals, providing essential information for identification purposes.

Dental Enamel, Trace Elements, Geographic Attribution

A18 Traditional Morphometrics of the Juvenile Skull: An Analysis of Ontogenetic Growth Patterns

Jacqueline Noble, MFS, 8/18 The Avenue, Crawley, Western Australia, AUSTRALIA; Ambika Flavel, MSc, University of Western Australia, M420, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA; and Daniel Franklin, PhD, University of Western Australia, Centre for Forensic Anatomy and Biological Science, MBDP M311, 35 Stirling Highway, Crawley, Western Australia 6009, AUSTRALIA*

After attending this presentation, attendees will understand a novel method of juvenile age estimation involving linear measurements of the cranium.

This presentation will impact the forensic science community by providing a novel method of juvenile age estimation.

This study assesses patterns of ontogenetic growth and, by association, morphological variation in juvenile crania from a Western Australian population. Current methods of juvenile age estimation largely relate to quantifying dental development and skeletal growth; the latter occurs in a predictable and known pattern and is not as readily affected as other skeletal elements by nutritional and other environmental disruptions during growth and development. The current study develops age prediction models using linear measurements of the juvenile cranium and explores novel methods of age estimation based on ontogenetic growth. The specific goals are: (1) determine the most accurate single predictor polynomial model for age; (2) determine a model of age estimation that is derived from all linear terms of predictors; (3) determine a model that includes linear, quadratic, and cubic terms of all predictors; and, (4) create age prediction models based on linear measurements.

The study sample comprised 174 cranial Multi-Slice Computed Tomography (MSCT) scans of individuals ranging in age from birth to 18.76 years (98 males and 76 females). The MSCT scans were acquired from the Western Australia Department of Health Picture Archiving and Communication Systems (PACS) database. The MSCT scans are visualized using OsiriX® and 52 homologous landmarks are acquired in each cranial scan. MorphDB and morphologika are then used to calculate 27 linear measurements between landmarks.

Prior to all data collection and analyses, the level of accuracy and precision was quantified to ensure data are repeatable and reliable. Measurement error was quantified using Technical Error of Measurement (TEM), relative Technical Error of Measurement (rTEM), and coefficient of Reliability (R). The linear measurements are analyzed with Statistical Package for Social Science (SPSS) and Excel®. Asymmetry was evaluated through correlations between bilateral measurements; a paired sample *t*-test was performed to explore the statistical significance of any bilateral variation. The root mean squared error of prediction (the calculated difference between the actual and predicted age) was used to determine the most accurate age prediction model for each measurement. Multivariate models were also considered to determine whether using more predictor variables had beneficial effects on being able to predict the response.

Age prediction models were developed based on interlandmark distances. Individual and pooled sex models were produced, with prediction accuracy ranging from ±1.3 to ±2.7 years. The single most accurate predictor of age in the pooled sex sample was palatine height (±2.3 years). Age prediction models were formulated using single and multiple linear and polynomial regression analyses; accuracy rates were deemed acceptable relative to extant methods of juvenile age estimation. This study has developed novel methods of age estimation in juvenile crania and also provides a strong foundation for further research.

Juvenile Age Estimation, Craniometric Analysis, Virtual Anthropology

A19 A Preliminary Investigation Into the Effects of Previous Freezing on Human Decomposition

Lindsey G. Roberts, MA, 912 E Cindy Street, Carbondale, IL 62901; Gretchen R. Dabbs, PhD, Southern Illinois University, Dept of Anthropology, 1000 Faner Drive, MC 4502, Carbondale, IL 62901; Jessica R. Spencer, MA, 424 S Front Street, Cobden, IL 62920-2415; and Kaleigh C. Best, MS, 2800 W Murphysboro Road, Carbondale, IL 62901*

After attending this presentation, attendees will understand the effects of prior freezing on human decomposition and whether frozen human corpses display the suite of decompositional traits previously identified in frozen pig proxies.[1]

This presentation will impact the forensic science community by providing preliminary answers to the questions of how previous freezing impacts the rate and pattern of human decomposition and whether there are visible external features that may identify previously frozen human corpses during decomposition, as were identified in pig proxies.

Freezing is an important forensic taphonomic variable as subjects may be stored in the frozen condition prior to use in taphonomic studies. Additionally, perpetrators may freeze victims in attempts to delude investigators by complicating Postmortem Interval (PMI) estimation. Freezing may impact decomposition by decreasing the viability of enteric bacteria responsible for driving putrefaction and research has shown that previous freezing significantly decreases the rate of decomposition in pigs.[1-3] In line with recent calls to validate results of forensic taphonomic studies using animal models with follow-up research utilizing human subjects, this study investigated human frozen decomposition.[4,5] It was hypothesized that the decrease in viable bacteria after freezing would result in a slower rate of decomposition in frozen human subjects, and human and pig subjects would show similar externally visible effects of previous freezing.

All subjects in this study were deposited at the Complex for Forensic Anthropology Research (CFAR) at Southern Illinois University. To understand how previous freezing alters the progression of "normal" human decomposition, two comparisons were made. A previously frozen human subject deposited on September 18, 2015, the fall season in southern Illinois, was compared to a never-frozen human control deposited on the same date and to never-frozen human subjects deposited in the fall of 2012-2015 (n=5). Additionally, the pattern of human frozen decomposition was compared to previously reported results from a similar study using pig proxies to identify whether the markers of decomposition observed in frozen pigs are identifiable in frozen humans as well.

One adult human subject was frozen at -18°C for 172 days. Fresh subjects were deposited immediately upon arrival at CFAR. Human donors arrived at CFAR within eight days of death and were kept in morgue refrigeration prior to deposition. All subjects were placed nude, directly on ground surface, within chain-link enclosures to minimize scavenging. Total Body Score (TBS), abdominal circumference, digital images, and written observations concerning insect activity, scavenging, and weather were collected daily.[6] To quantify decomposition rate, Kelvin Accumulated Degree Days (KADD) were used to measure the thermal energy required for each subject to reach several TBS thresholds: early decomposition (TBS≥6.0); halfway through early decomposition (TBS≥12.5); advanced decomposition (TBS≥19.0); halfway through advanced decomposition (TBS≥23.0); and skeletonization (TBS≥27.0). Bloat was quantified by analyzing the percent difference in abdominal circumference for each subject.

The previously frozen human subject decomposed faster than its paired never-frozen human control during both early and advanced decomposition. Percent difference in abdominal circumference was 105% for the frozen subject compared to 123% for the control. Bloat in the control subject was more rapid, substantial, and sustained. In addition to minimal bloat, the previously frozen subject displayed several differences in decomposition pattern, including grayer, pasty overall color, an absence of green discoloration, earlier onset of bone exposure, and a faster deflation of tissues compared to the control subject. With the exception of earlier onset of bone exposure, differences in decomposition pattern were consistent with previous frozen pig decomposition research. Compared to never-frozen human subjects deposited in the fall at CFAR, the previously frozen subject fell within the range of thermal energy necessary to achieve early and advanced decomposition, but at TBS≥23.0 and TBS≥27.0, the frozen subject decomposed more rapidly.

In this preliminary investigation, prior freezing was found to increase the rate and alter the pattern of human

decomposition. Additionally, the rate of frozen human decomposition did not progress as expected based on previous research on frozen pig decomposition, but expected effects on visible external features were observed. Further research is ongoing.

Forensic Taphonomy, Decomposition, Freezing

A20 The Influence of Stature on Sex Estimation

Haley E. Horbaly, BS, University of Tennessee, Knoxville, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will better understand whether body size influences the expression of traits used in forensic sex estimation.

This presentation will impact the forensic science community by illustrating the importance of understanding human variation when looking at skeletal traits in forensic anthropology.

Sex estimation of the adult skeleton is a key part of the biological profile in forensic anthropology due to its utility in feasibly eliminating half of the missing persons pool and enhancing the accuracy of other aspects of the biological profile, such as stature and ancestry; however, sexual dimorphism in the human skeleton is relatively small, and sex estimation can be further complicated by aspects of the individual's life or genetic background. The degree of sexual dimorphism is known to vary between populations, and while global patterns have been well-studied, the underlying causes of this variation are still unclear. Previous studies have established a secular pattern of increasing sexual dimorphism with increasing stature, a reduced accuracy of sex estimation methods on short-bodied populations, and have shown that body size affects morphological trait expression used for age estimation.[1-3] These findings give support to the present study, which seeks to establish whether body size also influences expression of traits useful in forensic sex estimation. The hypotheses for this study are: (1) variation in expression of sexually dimorphic traits covary with stature; and, (2) taller individuals are more accurately sexed due to a greater expression of dimorphic traits.

Sex estimation has been known to achieve 95% accuracy when a complete set of skeletal remains is present, though forensic contexts often produce incomplete remains.[4] In an effort to account for this potential limitation, this study employs three widely-used non-metric sex estimation methods, as metric methods depend on significant skeletal preservation. The three methods selected for this study (Walker, Klales et al., and Rogers) rely on the cranium, pelvis, and humerus, respectively.[5-7] Should differences in sexual trait expression in individuals of varying stature be observed, the use of three different sex estimation methods will illustrate whether this pattern is observable in multiple regions of the skeleton. This research was conducted at the William M. Bass Donated Skeletal Collection curated at the University of Tennessee, Knoxville, one of the most comprehensive modern skeletal collections of known demography. The derived sample of 127 individuals (63 males and 64 females) was controlled for ancestry and age by consisting strictly of White adult males and females. Stature is used as a proxy for body size and is treated as a continuous variable. Body mass is not considered since skeletal growth (height) is more tightly canalized than storage of fat.[8]

Preliminary statistical analyses were conducted. Overall, the methods show a higher misclassification rate than has been previously reported for reference collections (Walker: 24% misclassified; Klales: 17% misclassified; Rogers: 22% misclassified). Logistic regressions were used to test whether stature can explain the probability of individuals being assigned male or female for each method. Regression results reveal that stature is significantly correlated (p <0.001 for all cases) with all the sex estimation methods used in this study; however, this is expected due to the fact that there is sexual dimorphism in human stature and that forensic sex estimation methods are explicitly designed to detect other sex-related differences. Therefore, to remove the impact of sex on stature variation, new binary regressions were conducted for each method within sex groups to determine if the misclassified individuals can be explained by body size. The results indicate that within each sex, incorrect sex estimations were not related to individual stature (Walker: p = .080 for males/p = .250 for females; Klales: p = .058 for males/no females were misclassified using this method; Rogers: p = .447 for males/p = .808 for females). In conclusion, the misclassifications are not the result of stature, and future studies will pursue other sources of biological variation, such as donor weight or Body Mass Index (BMI), to test the hypothesis that body-size dimorphism is associated with sexual dimorphism in the skeleton.

Sexual Dimorphism, Stature, Non-Metric Method

A21 The Potential Use of Five Cranial Traits for Sex Assessment in Forensic Cases

Joe Adserias, DDS, PhD, c/ Balmes 62 30 la, Barcelona, SPAIN; Heli Maijanen, PhD, University of Oulu, Lab of Archaeology, PO Box 1000, Oulun yliopisto 90014, FINLAND; Sara C. Zapico, PhD, International Committee of the Red Cross, 19 Avenue de la Paix, Geneva 1202, SWITZERLAND; and Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will better understand five sexual dimorphic non-metric cranial traits and their potential in forensic cases.

This presentation will impact the forensic science community by illustrating the usefulness of the foramen magnum shape, the Zygomatic Arch Ending (ZAE) with respect to the external auditory canal, the sigmoid notch, the mandibular ramus flexure, and the Gonial Angle (GO) area muscle attachment for sex determination.

Sex assessment is an essential step in human identification, in both legal cases and archeological context. The highest accuracy for sex determination is achieved when the complete skeleton is available, although there are situations such as cremated, dismembered, and otherwise taphonomically altered skeletal remains in which the use of a complete skeleton is not possible. The goal of this study is to evaluate the usefulness of five non-metric cranial traits that are considered resilient in sex assessment and their potential application in forensic cases.

Previous described non-metric cranial traits (foramen magnum shape, ZAE in respect to external auditory canal, sigmoid notch, mandibular ramus flexure and GO area muscle attachment) were analyzed in 100 skulls, 45 females and 55 males, from 34 to 92 years of age. All individuals were White adults from the W.M. Bass Donated Skeletal Collection at the University of Tennessee. Statistical analysis was performed using the Statistical Package for Social Science (SPSS) version 15. Comparisons between groups were conducted using X2. Discriminant function analysis model was performed to develop specific formulas for sex determination.

Foramen magnum, sigmoid notch, and mandibular ramus exhibited no significant differences between males and females. In contrast, ZAE and GO morphology revealed strong significant differences between these two groups. Based on these two parameters, the function obtained by discriminant analysis, Sex = -1.992 + (ZAE*2.123) + (GO*0.631) with a zero result pointing to males and one result pointing to females, correctly classified 79.8% of the original cases. In fact, taking into account all five cranial traits on the discriminant function analysis, this demonstrated the usefulness of ZAE and GO for sex determination, arriving at the same formula and correctly classifying 79.8% individuals according to their sex.

This study evaluated the usefulness of five different cranial traits and their potential value in forensic cases and indicated that ZAE and GO were the best indicators for sex assessment. These two anatomical regions correspond to two highly resistant skeletal structures, allowing forensic anthropologists to use them for this purpose alone or in combination with other methodologies, when the preservation and taphonomic factors affected skeletal material, although traits that are sexually dimorphic in one population may be much less so in another. Therefore, further studies in other populations are necessary to extend the diagnostic value of these sexually dimorphic traits.

Cranial Traits, Sex Assesment, Non-Metric Traits

A22 Forensic Proteomics: A New Perspective for Age of Death and Postmortem Interval (PMI) Estimation in Porcine Bone Within the Burial Context

Noemi Procopio, MSc, The University of Manchester, Manchester Institute of Biotechnology, 131 Princess Street, Manchester M1 7DN, UNITED KINGDOM; Anna Williams, PhD, University of Huddersfield, Applied Sciences, Queensgate, Huddersfield, West Yorkshire HD1 3DH, UNITED KINGDOM; and Michael Buckley, PhD, The University of Manchester, Manchester Institute of Biotechnology, 131 Princess Street, Manchester M1 7DN, UNITED KINGDOM*

After attending this presentation, attendees will better understand the new potential applicability of proteomics to the world of forensic sciences. This presentation will introduce attendees to the basics of proteomic analyses and to the study of post-translational protein modifications related to the decay process. New biomolecular markers occurring both *in vivo* and postmortem may shine a light on the progress of tissue aging and on the estimation of the PMI from skeletonized remains.

This presentation will impact the forensic science community by illustrating the potential of a new proteomic method to address important forensic questions such as the age of death and the PMI estimation from a new, unexplored perspective. Some protein post-translational modifications, and in particular protein oxidation, deamidation, and racemization, have already been suggested as "molecular clocks" for protein turnover, development, and aging, both *in vivo* and postmortem; however, none of these modifications have been used until now on bones for forensic purposes.[1-3] This presentation will describe their new potential applications in this field to improve understanding of the biological and taphonomic decay of bone.

One of the most debated themes in forensic anthropology is the estimation of PMI as well as the approximation of the age of death from skeletal remains.[4-6] Many analytical and morphological methods have been published so far to address these goals, but the inherent limits regarding the accuracy of the current methods warrant the application of possible alternatives, including relatively new techniques, such as proteomics, to forensics. This study sought to apply proteomic methods to pig skeletal remains to look for new biomarkers that can help in estimating the animal's age of death as well as its PMI.

The first element of the study compares porcine skeletal remains from different aged animals to verify any proteomic difference between the various specimens, as well as to compare different skeletal elements within the same animal to evaluate any intra-skeletal difference. Bones from five different juvenile pigs were sampled, and their proteome was analyzed using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) techniques. The proteomes of these buried bones with one fresh bone purchased from a local butcher were also compared to evaluate the impact that the burial environment can have on proteome recovery. For the second portion of the study, an experimental burial environment in the field was created, in which four piglets of similar biological age were buried and the bones were recovered after different time intervals. The goal of this second stage was to focus on proteome decay postmortem, in order to look for biomarkers to correlate PMI with particular peptide modifications.

The results reveal intriguing differences within the proteome of bones from different aged piglets, paving the way for the estimation of the age using proteomics. Surprising differences within the same piece of bone tested in different areas across the length of the bone were also noted. While the midshaft gave the least variance, biological replicates collected at the ends of long bones (especially the proximal end) exhibited significant differences in terms of their proteome composition. Differences were also present within different bones from the same individual, underlining the intra-skeletal variability of the proteome. Furthermore, important differences between the buried bone and the fresh bone were also observed, confirming that the burial environment can affect the proteome, as these lost a notable amount of proteins due to leaching. Hence, results are proving the applicability of these types of studies to forensic remains, and that they are promising approaches for future studies on age estimation. This presentation will conclude with the comparison of these results to those obtained from the burial experiments to evaluate applicability to PMI estimation.

A23 Making Up for Missing Pieces: Scanning Electron Microscopy With Energy-Dispersive X-Ray Spectroscopy (SEM/EDX) Gunshot Residue (GSR) Analysis of the Human Cranial Bone

James J. West, MS, Lincoln Memorial University-DeBusk College of Oste, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Natalie R. Langley, PhD, Mayo Clinic College of Medicine, 13400 E Shea Boulevard, Scottsdale, AZ 85259; Stan Kunigelis, PhD, Lincoln Memorial University-DeBusk College of Oste, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and Cassie Boggs, MD, 150 N Marietta Parkway, Marietta, GA 30060*

After attending this presentation, attendees will understand the utility of nanotechnology for detecting GSR in bone. A forensic case will be presented to illustrate how the combined use of SEM and X-ray elemental microanalysis (in the form of EDX) demonstrates the presence of signature inorganic compounds found in GSR.

This presentation will impact the forensic science community by demonstrating the application of a rarely used technique that practitioners can employ to distinguish gunshot trauma from other forms of skeletal trauma when diagnostic fracture patterns or wound signatures are absent.

Cranial gunshot wounds are easily detected even in the absence of soft tissue by examining bony traumatic defects for characteristic attributes (e.g., internal or external beveling); however, these features may be absent in partial or fragmentary remains. In these instances, the forensic anthropologist cannot reliably distinguish between fractures caused by gunshot versus blunt force trauma.

Research by Berryman et al. found that SEM/EDX analysis was able to detect trace amounts of lead, barium, and antimony — components of bullet primer — in experimentally shot fleshed pig bones.[1] GSR is a combination of primer and gunpowder particles (burnt and unburnt) derived from the bullet cartridge. Ignited primer and gunpowder exit as a gaseous plume from open surfaces of the gun. Primer mixtures often comprise three inorganic compounds: (1) lead styphnate (initiator); (2) antimony sulfide (fuel); and, (3) barium nitrate (oxidizer). Sulfur, charcoal, and potassium nitrate are common organic compounds in GSR derived from the gaseous plume. SEM reveals GSR morphology, while EDX yields quantitative elemental analysis of the inorganic compounds (primer).

Partially skeletal remains were found in a shallow hole and scattered in the surrounding wooded area by animal activity. Fragments of women's clothing were also recovered. At pathological examination, the remains had areas of residual intact skin, which were devoid of injury. Residual internal organs were severely decomposed. The skull was fragmented and incomplete due to trauma.

The anthropological analysis revealed a nearly complete skeleton and partial skull. The occipital bone was absent, and the right parietal, left and right temporal, and vomer were partially absent. Four linear fractures consistent with peri-mortem trauma were present on the right parietal, and a small linear fracture was visible on the right hard palate. The etiology of these fractures could not be ascertained with scientific certainty, but the pathologist and anthropologist strongly suspected gunshot trauma.

In order to determine if the cranial fractures were caused by gunshot trauma, four cranial fragments and a control specimen of a thoracic vertebral spinous process were analyzed with SEM/EDX for elemental components of GSR. The cranial fragments were cut from the lateral and posterior aspects of the right parietal, the posterior portion of the left parietal, and the left temporal. Fragments were sputter coated prior to analyses of the inorganic residue components. Trace amounts of barium, antimony, and lead were detected on the cranial fragments, but not on the control specimen, indicating the likelihood of GSR in the skull.

A missing person fitting the biological profile provided by the anthropologist was found, and identity was confirmed via dental comparison. The cause of death was certified as disruptive head trauma and, given the circumstances of the case, the manner of death was certified as homicide. The investigation of the case is ongoing.

Forensic pathologists and anthropologists frequently work together to ensure a thorough analysis of skeletal trauma, but some cases present circumstances that require additional experts. Nanotechnology such as SEM/EDX provides a useful tool for detecting GSR in cases in which fracture patterns are atypical or remains are too fragmentary to conduct macro-morphological analyses with scientific certainty. This technique can also provide an additional line of evidentiary support, even in cases in which gunshot trauma is easily recognizable.

Gunshot Residue, Skeletal Trauma, EDX

A24 Testing the Performance of a New Age-Estimation Method on an Asian Sample

Beatrix Dudzik, PhD, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37996; Natalie R. Langley, PhD, Mayo Medical School, Mayo Clinic, Scottsdale, AZ; Jieun Kim, PhD, 801 Sutters Mill Lane, Knoxville, TN 37909-9702; Wu Jian, MD, Kunming Medical University, Forensic Center, Kunming City, CHINA; and Benison Mangel, BS, Lincoln Memorial University, DeBusk College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752*

After attending this presentation, attendees will be well versed in pubic symphyseal morphologies commonly used in age-estimation techniques.

This presentation will impact the forensic science community by providing the results of a validation study of a new component-based method that uses developmental and degenerative traits of the pubic symphysis to estimate age in individuals less than 40 years of age.

Age estimation is a crucial yet challenging task that forensic anthropologists face during the development of a biological profile. Previous methods used to analyze the pubic symphysis for indicators of age involved a higher probability of misclassification due to the overlapping physical features and broad age ranges. Additionally, previous methods have primarily used samples from American White individuals, often from samples that date to the 20th or even 19th centuries.[1-3] Validation studies of statistical models built using American White populations have shown reduced accuracy when tested on populations outside of the reference sample.[4] Practitioners at the national and international level work with skeletal samples from a large number of ancestral categories and often find that established methods for estimating the biological profile perform differently on different geographic and temporal populations. Therefore, it is necessary to assess the performance of methods on populations outside the reference sample used in initial model building. Forensic anthropologists ultimately require a methodology that is applicable to a range of ethnicities for assessing age and the first step in reaching this lofty goal is to ascertain how a method performs on samples that were not used to construct the method.

To examine the accuracy and precision of the Dudzik and Langley method, this study tested the performance on modern Asian samples collected for this study.[5] The original method was produced using forensically relevant modern American samples of known age, sex, and ancestry from the Maricopa County Forensic Science Center in Phoenix, AZ, as well as donated individuals from the William M. Bass Forensic and Donated Collections at the University of Tennessee, Knoxville. Specifically, this method assessed the accuracy of distinct morphological features of the pubic symphysis in young adults that are typically observed in ages less than forty. Five indicators were used in the decision tree to estimate the age category of each individual. The five features included the pubic tubercle epiphysis, symphyseal billowing, presence of the ossific nodule at the superior apex, presence of the dorsal plateau, and presence of the ventral rampart.

The Asian samples included Chinese individuals from Kunming Medical University (n=85), Japanese from Jikei University and Chiba University (n=50), and Thai individuals from Khon Kaen University and Chiang Mai University (n=50). Testing the method on the Chinese sample produced 72% accuracy, which is lower than the reported results using American White and Black individuals, which delivered correct percentages not lower than 83%. Accuracy rates for the pooled Asian samples were not as high as the percentages identified in the American samples reported previously and were generally less than 80%.

This study reveals the results of an age estimation method that uses a decision tree approach for component-based traits of the pubic symphysis. This analysis confirms the need for population-specific methodologies for not only age estimation but all aspects of the biological profile. Further research involving samples that span larger coverage of world populations is necessary for forensic anthropologists that practice in the ever-globalizing population of the United States. Method validation using larger sample sizes will help to reveal what aspects of the decision tree method produces the highest percentages of accuracy and identify which age categories experience the most variation across different ancestral groups. Future work in this arena will allow for modifications of existing age estimation techniques to better serve forensic anthropologists who work closely with a varied number of ancestral groups.

A25 Evaluating Differential Nuclear DNA Yield Rates Among Human Bone Tissue Types: A Synchrotron Radiation Micro-Computed Tomography (SR micro-CT) Approach

Janna M. Andronowski, PhD, University of Saskatchewan, Department of Anatomy and Cell Biology, 107 Wiggins Road, Saskatoon, SK S7M 3L7, CANADA; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; and David M.L. Cooper, PhD, University of Saskatchewan, Dept of Anatomy and Cell Biology, 107 Wiggins Road, Saskatoon, SK S7N 5E5, CANADA*

After attending this presentation, attendees will understand whether differences in bone microstructure may be used to explain differential nuclear DNA yield among bone tissue types.

This presentation will impact the forensic science community by improving current understanding of the relationship between nuclear DNA yield and osteocyte lacunar abundance, thus informing bone-sample selection for nuclear DNA analysis in a forensic context.

Molecular human identification has conventionally focused on DNA sampling from dense, weight-bearing cortical bone tissue from femora or tibiae. A comparison of skeletal elements from three contemporary individuals demonstrated that elements with high quantities of cancellous bone yielded nuclear DNA at the highest rates, suggesting that preferentially sampling cortical bone is suboptimal.[1] Despite these findings, the reason for the differential DNA yields between cortical and cancellous bone tissues remains unknown. Evidence from bone microarchitecture may help explain this variation and enrich the understanding of bone microstructural features.

The primary goal of this research is to determine whether the 3D examination of osteocytes and the quantification of their associated cellular spaces (lacunae) can be used to explain differential nuclear DNA yield among cortical and cancellous bone tissue types. Osteocytes and other bone cells are recognized as housing DNA in bone tissue, thus examining the density of their lacunae may explain why nuclear DNA yield rates differ among bone tissue types.

Methods included visualizing and quantifying osteocyte lacunae using SR micro-CT at the Canadian Light Source synchrotron facility in Saskatchewan, Canada. Forty-three bones were selected for SR micro-CT imaging from the 55 elements per skeleton sampled for DNA by Mundorff and Davoren. Representatives from each skeletal element type were chosen and bones from the left side only were sampled. Regions Of Interest (ROIs) from cortical and cancellous bone tissues (n=129) were comparatively analyzed.

Osteocyte lacunae were separated from the high-density bone using global thresholding and segmentation. Despeckling was conducted to remove noise (structures <10μm^3). Features >2,000μm^3 were assumed to be canals and remaining structures were designated as lacunae. Standard nomenclatures for lacunar indices were applied for the analysis of 3D lacunar parameters within the ROIs. The variables measured included: Total ROI Volume (TV), total Canal Volume within ROI (Ca.V), average Canal Diameter (Ca.Dm), total Number of Lacunae (N.Lc), and average Lacunar Volume (Lc.V). To determine lacunar density per mm^3 (N.Lc/BV), Bone Volume (BV) was calculated as TV minus Ca.V (TV-Ca.V). BV for cancellous bone ROIs was calculated as TV minus the volume of the marrow spaces.

Statistical analyses tested the primary hypothesis that the abundance and density of bone's cellular spaces vary between cortical and cancellous bone tissue types. Bones identified by Mundorff and Davoren to yield more DNA per mass of sample were directly correlated against the number of lacunae and osteocyte lacunar density data.

Results demonstrated that osteocyte lacunar abundance and density varied between cortical and cancellous bone tissue types, with cortical bone ROIs containing a higher lacunar abundance and density than cancellous bone. The osteocyte lacunar density values are independent of nuclear DNA yield, suggesting an alternative explanation for the higher nuclear DNA yields from predominantly cancellous bones.

At the time of this writing, this work represents the first examination of inter-element variation in osteocyte lacunar properties from cortical and cancellous bone tissues in various human skeletal elements. The use of SR micro-CT allowed for a scale of analysis that revealed a high range of variation in lacunar abundance in both tissue types and soft tissue remnants within marrow spaces. As such, it is hypothesized that soft tissue remnants, only observed via SR micro-CT, within the medullary cavities of primarily cancellous skeletal elements are driving the

high nuclear DNA yields.

The results have implications that improve current understandings of the relationship between nuclear DNA yield and osteocyte lacunar abundance, and normal variation of osteocyte lacunar parameters. Results of this work also have broader applications as they offer promise for the development of a refined method for identifying the bone tissue type most likely to yield nuclear DNA. The procurement of small, primarily cancellous bones with associated soft tissues within marrow spaces should be preferentially sampled and no longer dismissed as potential DNA sources in favor of cortical bone tissue.

3D Imaging, Nuclear DNA, Osteocyte Lacunae

A26 The Effect of Embalming on Discoloration of Burnt Bone

Michal Peer, 3973 S Sable Way, Aurora, CO*

After attending this presentation, attendees will understand how embalmed bone changes color during burning in comparison to fresh bone.

This presentation will impact the forensic science community by enhancing knowledge of how bone reacts to burning.

Although there has been previous research regarding burnt bone, it has focused on repeating and confirming color changes from previous studies, while the effect of embalming on bone is largely unknown. This study is the first to examine the interaction between embalming and exposure to heat.

This project observes the color changes associated with burned bone after embalming. It was hypothesized that embalmed bone will show no differences from fresh bone after burning as the embalming process focuses on soft tissue and only affects hard tissue after being embalmed for several months. It was also hypothesized that bones soaked individually in formalin react differently to heat exposure due to formalin solutions reportedly leaching out inorganic material from bone.

Forty femora from domestic pigs (*Sus scrofa domestica*) were obtained from a local butcher. Half were burned without alteration and half were immersed in a 10% formalin solution for a week prior to burning. Ten whole pigs were embalmed using the same process used to embalmed deceased humans in the United Kingdom, after which femora were removed for burning.

Four different temperatures were chosen based on their use as milestones in the color change of bone during heating: beginnings of color change at 200°C; carbonization at 350°C; beginnings of calcination at 500°C; and complete calcination at 700°C.

A Munsell soil color book was used to analyze the color of the bone after burning. Each code in the Munsell soil color book refers to the hue, value, and chroma of a particular color, and each code also has a visual description that goes along with it. After initial observation, although there are differences in the assigned color code, there are multiple codes that all refer to the same color; therefore, it appears that there is no significant difference between the visual descriptions of the final discolorations of the fresh, immersed, and embalmed bones. Bones heated to 200°C result in a yellow-brown or brown color, bones heated to 350°C result in black or very dark gray, bones heated to 500°C result in variations of gray or bluish gray, and bones heated to 700°C result in white coloration. Both bone from embalmed pigs and bone immersed individually in formalin exhibit post-burning coloration that is consistent with that of fresh bone. When looking at the Munsell color codes, it can be seen that both the initial color and the final discoloration of the immersed bones were more homogenized. While the multiplications of fresh and embalmed bones revealed several different color codes for a particular temperature, the immersed bones only displayed two at most.

Embalming, Burnt Bone, Color Change

A27 Modeling Thermal Alterations on Burned Human Remains

Amanda Williams, MA, 2450 Lymbery Street, Apt 309, Reno, NV 89509; Elayne J. Pope, PhD, Tidewater OCME, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510; Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096; Mary E. Cablk, PhD, 2215 Raggio Parkway, Reno, NV 89512; and Alison Galloway, PhD, University of California, Chancellor's Office, Santa Cruz, CA 95064*

After attending this presentation, attendees will better understand the variation in thermal alterations on human remains and the variables that can contribute to these heat-related changes.

This presentation will impact the forensic science community by highlighting the limitations of current models and the need to create a new model that can be more broadly applicable to the forensic community.

Since its original publication in 1996, forensic anthropologists have used the Crow-Glassman Scale (CGS) to characterize heat-related damage to human remains.[1] The CGS was developed from a mass casualty fire in Waco, TX, where the remains exhibited advanced stages of heat-related damage. As a result, this scale progresses from blistering to fragmentation in only five stages, thus, limiting its utility. The CGS does not include descriptions of times or temperatures, nor does it quantify surface area or percentage of body affected. This scale is also not typically used by medical examiners, who instead use calculations of total burned surface area and the rule of nines to describe the extent of burn injuries. As such, there are inconsistencies in the reported descriptions of burned bodies from medical examiners from those provided by forensic anthropologists.[2-5] This research seeks to develop a method more applicable to and consistent with remains encountered in fires, thus bridging the work between the various forensic sciences.

This study involves observational experiments of the burning of 40 donated human cadavers between 2014 and 2016. Data were collected as part of the Fatal Fire Death Investigation Course by the San Luis Obispo Fire Investigation Strike Team Inc. Cadavers were placed in vehicle fires, structure fires, outdoor contexts, and in confined spaces. All physical alterations to both soft and skeletal tissues were documented with digital photography and thermocouples. The visual assessment of the burned bodies was guided by the existing CGS and supplemented with additional time and temperature data. Skin splits, subcutaneous fat exposure, muscle exposure, and presence or absence of soft tissue color banding were among the soft tissue variables recorded for each individual. Skeletal color banding, charring, calcination, fracturing, and fragmentation were among the skeletal changes recorded.

The amount of thermal damage to remains is correlated with maximum temperatures and exposure times in each fire environment. Individuals placed in the front seat of vehicles exhibited limited soft tissue loss and bone exposure, consistent with exposure to high temperatures (CGS score of 3). Individuals placed in trunks exhibited calcination and fragmentation, consistent with prolonged exposure to high temperatures (CGS score of 5). The individuals in outdoor fires exhibited calcination, fragmentation, and heat-related fracturing, consistent with prolonged exposure to high temperatures (CGS score of 5). Remains in structure fires exhibited partial soft tissue loss and soft tissue color banding, which is consistent with exposure to intermediate temperatures (CGS score of 2). Remains from confined space fires exhibited charring, muscle exposure, and limited presence of soft tissue, consistent with intermediate temperatures (CGS score of 3).

The results of this study demonstrate notable and patterned differences in physical alterations, making it possible to model heat-related damage. The presence of soft tissue, muscle exposure, and skin splits on some remains illustrates the need for refining the CGS to include these variables. As data collection progresses, a more robust model to describe heat-related damage in addition to temperature data will be created that can be more broadly applicable to remains encountered in fatal fires.

Burned Human Remains, Crow-Glassman Scale, Forensic Anthropology

A28 Scavengers at Real and Taxidermied Carrion

Lauren R. Pharr, PhD, 5709 Lyons View Pike, Apt 2208, Knoxville, TN 37919*

After attending this presentation, attendees will be aware of misconceptions regarding when and how scavengers locate carrion.

This presentation will impact the forensic science community by illustrating that forensically important animal scavengers appear early in the postmortem interval, regardless of whether the food is actually decomposing or simply appears to be decomposing.

Acceleration of decay by animal scavengers has been attributed to turkey vultures, which use smell to locate decay, and black vultures, which rely on sight. Once vultures hone in on a carrion source, they land and rapidly remove soft tissues from the body. Once skeletonization has been reached, terrestrial scavengers will then scatter and damage the bones.

Although researchers are aware that turkey vultures can locate food through smell, the ability of black vultures to use the sense of smell to locate food is debatable. New knowledge on vultures' ability to locate food via visual versus olfactory indicators will contribute to the understanding of both vulture scavenging behavior and the postmortem roles vultures have in forensic contexts involving buried or concealed remains.

To test the role of sight versus olfaction in vultures' ability to detect carrion, a taxidermied juvenile pig was placed seven times at three different site types where vultures had previously scavenged real juvenile pigs in the fresh stage of decay. The three site types included the Texas State Forensic Anthropology Research Facility (FARF), a cattle pasture located more than 1km from FARF, and rotating pig placement sites that changed locations with each trial. The Rotate Sites were located at least 7km from the other two site types.

On September 9, 2012, the project began by placing a juvenile pig in the fresh stage of decay at each of the three site types. This process was repeated every two weeks eight more times to determine if the site type affects vulture scavenging. Three real pigs were placed at the three sites during each of Trials 1-4. After the fourth placement of the decaying pigs, vultures had scavenged 11 of the 12.

Beginning on November 4, 2012 (Trial 5), both real pigs and the taxidermied pig were placed, and the taxidermied pig was placed at sites where the real pigs had been scavenged by vultures. As more real pigs were placed and scavenged by vultures, additional sites to place the taxidermied pig became available. During Trials 5-9, the taxidermied pig was placed biweekly at five of the Rotate Sites that had involved vulture scavenging of the real pigs. Following the conclusion of the ninth trial, the taxidermied pig was placed a sixth and seventh time at the cattle pasture and FARF sites, respectively. All pigs were monitored with a motion-activated game camera.

Results reveal that animal scavengers arrive early in the postmortem interval, regardless of whether the food source is dead or appears to be dead. Scavengers at the taxidermied pig included turkey vultures, a red-tailed hawk, a crow, coyotes, dogs, foxes, opossums, raccoons, and a bobcat. Other animal visitors included deer, cows, and rabbits. Surprisingly absent was the black vulture, a scavenger said to rely on sight. This is surprising because 121 black vultures were present at the real carrion placed during the nine trials.

In addition to advancing the discussion on how scavengers detect a carrion source, this research contributes to the discussion of the trauma scavengers inflict. During this study, scavengers removed an ear and the tail of the taxidermied pig and left linear scratch marks on the abdomen. This trauma is consistent with scavengers going for easily removable and accessible parts of the body as seen on real carrion.

The unexpected presence of forensically important scavengers at the taxidermied pig, a pig unable to decompose and unaffected by accumulated degrees, will promote a discussion on the need to include avian and terrestrial scavengers in future taphonomic studies.

Scavenging, Taphonomy, Taxidermy

A29 The Effect of Partial Wrapping of Buried Rabbit Cadavers on the Decomposition Rate: A Comparative Taphonomic Study

Robert A. Parkinson, BSc, 19 Hillside Road, Chorleywood, Hertfordshire WD3 5AP, UNITED KINGDOM*

A30 Robbed Burial Sites: A Comparative Investigative Approach Using Geographic Information Software (GIS) to Locate Secondary Burial Sites

Maria Mikellide, MA, International Committee of the Red Cross, 19 Avenue de la Paix, Forensic Unit, Geneva 1202, Switzerland; and Derek Congram, PhD, Munk School of Global Affairs, University of Toronto, 315 Bloor Street, W, Toronto, ON M5S 3K7, CANADA*

After attending this presentation, attendees will: (1) better understand the phenomenon of "robbed" mass graves in armed conflict contexts; (2) become familiar with examples from Spain, Bosnia, and Cyprus; and, (3) more thoroughly understand the motives behind the clandestine removal of bodies from graves, which can be studied to help determine the location of the secondary depositions. Attendees will also appreciate the negative consequences of this grave robbing for forensic professionals, who are called on to exhume residual remains from primary sites and reconstruct the sequence of events concerning the victims, and for the families of the missing, who are offered partial skeletal remains (possibly at different time intervals) for reburial.

This presentation will impact the forensic science community by demonstrating a new investigative approach which uses GIS to assist in the discovery of secondary deposition sites. This study builds on previous research, analyzing patterns of primary grave distribution, and examines whether a more specific analysis of similar patterns may assist in identifying secondary grave locations.

This study reviews a set of 130 graves in Cyprus, of which five were subject to the clandestine removal of bodies, and 403 graves in Bosnia, of which ten sites were robbed. Robbed bodies from sites in Bosnia were redeposited in 39 secondary graves, whereas secondary burial locations in Cyprus are unknown. Several examples of robbed graves from the Spanish Civil War, which relate to different motives and actors (i.e., by families of the victims or by the postwar government), are also used to assist in the analysis, albeit in a qualitative rather than quantitative way due to the limited number of confirmed sites and positive identifications from secondary sites.

This study examines the possible elements that set the robbed graves apart from others that were left intact. Observations from all three contexts indicate that bodies from robbed graves were of both civilians and military personnel; however, factors such as victim demographics (sex, age) and whether the victims were battle casualties, executed prisoners of war, or mass killings of civilians, have been identified as important factors influencing the decisions of those responsible for the robbing.

In order to assist in the search for secondary graves in Cyprus, GIS was used to analyze primary and secondary grave locations in Bosnia for spatial clustering and distances relative to settlements and territorial borders. The analyses indicate a 24% increase in distance from settlements between primary (mean of 1,049 meters) and secondary (mean of 1,303 meters) graves. The mean distance of secondary graves from their robbed primary graves is 14.85km with a standard deviation of 9.21km. Of particular interest is that the bodies robbed from primary graves closest to international borders and territory controlled by the military associated with the victim group were relocated farther than other robbed bodies. Consistent with previous studies, there is significant clustering of secondary graves. These results all indicate a coordinated effort to hide victim bodies in response to the threat of international investigations in Bosnia, which subsequently firmly established military responsibility for grave robbing.

This study hypothesized that, similar to Bosnia, high-level political developments — at an international scale — combined with considerations regarding the victim count and demographics, spurred the large-scale, organized, and costly operations of the clandestine removal of human remains from mass graves in Cyprus. Qualitative evidence and observations from Spain indicate that *internal* (rather than international) high- and low-level decisions also motivated grave robbing, but the spatial patterns between primary and secondary graves in Spain contrast with the case of Bosnia.

Through the analysis of data collected from all three contexts, this study is able to construct site location models to assist in the search for identifying secondary deposition sites, particularly in Cyprus, but with implications for other contexts as well. Such mechanisms offer the forensic community useful guidelines and insights to help manage expectations of the families of the missing. This will also help to work toward a more complete return of victim remains to families, honoring their fundamental right to know the fate of their loved ones.

A31 A Comparison of Skin Color Change in Terrestrial and Aquatic Decomposition and Its Potential Value as an Indicator of Postmortem Interval (PMI)

Sophie Iddamalgoda, MSc, Sedley, Gravesend, Kent DA13 9PE, UNITED KINGDOM; Charlene D. Swanborough, MSc, University of Huddersfield, Queensgate, Huddersfield HD1 3DH, UNITED KINGDOM; Kestutis Soblinskas, BSc, University of Huddersfield, Queensgate, Huddersfield, UNITED KINGDOM; Mark Tibbett, PhD, School of Agriculture, Policy & Devel, University of Reading, Whitenights, PO Box 237, Reading RG6 6AR, UNITED KINGDOM; and Anna Williams, PhD, University of Huddersfield, Applied Sciences, Queensgate, Huddersfield, West Yorkshire HD1 3DH, UNITED KINGDOM*

After attending this presentation, attendees will better understand how skin color changes during decomposition in terrestrial and aquatic (submerged) environments and how the use of reflectance spectrometry can allow objective quantification of skin color as a function of time.

This presentation will impact the forensic science community by providing results from three controlled porcine experiments in an area of very little previous research. This presentation will add to existing research in the field of forensic taphonomy by broadening understanding of porcine decomposition in terrestrial and aquatic conditions and by enabling a better appreciation of these processes in human decomposition. This research presents a novel in-field reference guide for estimating: (1) the PMI or Postmortem Submergence Interval (PMSI) of an unknown individual; and, (2) the original skin color of the unknown individual and, as such, adds to the existing armory of techniques for the identification of severely decomposed human remains.

Bodies found in aquatic environments show markedly different decomposition to those found in terrestrial situations.[1] One of the most obvious, visually arresting differences is in skin color. The processes of decomposition can change the original skin color of an individual dramatically, particularly in cases with long PMIs.[2] As skin color can be used to make a preliminary assessment of the ancestry of an individual, any skin color changes as a result of decomposition can cause misidentification of unknown remains, as was the case in the aftermath of the 2004 Asian tsunami.[3] In addition, skin color changes can cause confusion regarding the stage of decomposition reached, complicating PMI estimation.[4]

This presentation combines the results from three separate porcine decomposition experiments, conducted between 2013 and 2016 in outdoor decomposition facilities at Cranfield University and the University of Huddersfield in the United Kingdom. As such, it represents a substantial accumulation of knowledge on the visible alterations to skin color as a result of decomposition in terrestrial and aquatic environments and marks the first time such experiments have been attempted in a United Kingdom climate.

In the first experiment, the cadavers of two domestic pig (*Sus scrofa*) were left on the surface to decompose for 49 days, while skin color (represented by L*a*b* scores) was recorded across the torso and back using a hand-held Konica Minolta reflectance spectrophotometer. The second experiment utilized four domestic pig cadavers, two surface deposited and two submerged in tanks of tap water for a total of 56 days; skin color measurements were taken across the bodies using a hand-held HunterLab MiniScan EZ 4500L spectrophotometer. The third experiment focused on the color change of eight excised swatches of porcine skin, submerged in canal water (freshwater) at 5°C and 18°C for a total of 35 days.

In the data from both terrestrial and aquatic environments, preliminary statistical tests found a significant correlation ($p < 0.01$) between PMI and skin color, measured using L*a*b* scores. In the surface-deposited pigs, the skin visibly darkened as PMI increased, the correlation between PMI and L* reaching a peak at day 45 ($R^2 = 0.83$). In the submerged pigs and skin swatches, a significant correlation ($p < 0.05$) was found between PMSI and skin color, particularly in the a* scores, which represent hues on the red-green spectrum. The nature of the water in which the submersion occurs was found to influence the skin color change as well. The skin of the pigs submerged in tap water turned a peachy-pink color, whereas those in canal water lightened visibly and gained an obvious greenish hue.

The linear relationship and statistically significant correlation between L*a*b* scores and PMI and PMSI suggest that it may be possible to use quantifiable skin color change as a method for estimating PMI or post-submersion interval, particularly in originally light-skinned individuals.

A preliminary reference tool produced from combined L*a*b* scores for in-field use in time-sensitive forensic cases is presented here. The color swatches can be used: (1) to give an early indication of PMI or PMSI; and, (2) even to allow back extrapolation to estimate the original shade of an individual's skin color. This has important implications for the identification of unknown human cadavers found in terrestrial, surface depositions and those found submerged in freshwater aquatic environments.

Decomposition, Skin Color, Postmortem Interval

A32 Estimating the Postmortem Interval (PMI): A Metabolomics/Lipidomics Approach

Natalie R. Langley, PhD, Mayo Clinic College of Medicine, 13400 E Shea Boulevard, Scottsdale, AZ 85259; Paul Wood, PhD, LMU DeBusk, College of Osteopathic Medicine, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; Patrick Herling, MS, Lincoln Memorial University-DeBusk College of Oste, 6965 Cumberland Gap Parkway, Harrogate, TN 37752; and Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

The goal of this presentation is to explain the utility of Glycerophospholipids (GPLs) unique to the membranes and organelles of human skeletal muscle tissue cells in estimating Time Since Death (TSD).

This presentation will impact the forensic science community by demonstrating the use of targeted metabolomics and lipidomics assay platforms to provide more accurate and robust biomarkers of the PMI.

During the initial stages of decomposition (within 72 hours), body temperature is used to determine PMI. Prior to the onset of putrefaction, the potassium content of the vitreous humor is also a useful estimator. After this point, visual inspection of the body for color changes, the onset of bloat, and the stage of insect activity can be used to predict TSD; however, longer PMIs are more difficult to estimate with precision using visual inspection, especially if scavengers have consumed some of the soft tissues. Consequently, these estimates are often open-ended and limited in forensic utility (e.g., a minimum of number weeks or months). Biochemical analyses have shown promise, but the actualistic studies were conducted on small samples and lack extensive validation data. Furthermore, the analytical capabilities of mass spectrometers have increased exponentially since these studies were conducted.

This study utilizes high-resolution mass spectrometry analytical platforms to examine biomarkers of time-dependent postmortem tissue degradation. Twenty bodies were placed in protective cages at the University of Tennessee's Anthropological Research Facility. Daily samples (20mg-40mg) were collected from vastus lateralis muscle, four to six inches proximal to the patella and lateral to the femur using muscle tissue biopsy needles. If vastus lateralis muscle was not available, samples were obtained from other thigh muscles or from the leg. Temperature and humidity data were collected daily as well. Samples were stored in a -80°C freezer until transported to Lincoln Memorial University-DeBusk College of Osteopathic Medicine for mass spectrometer analyses. The muscle samples were placed into solution of 50ul standard, 1ml of deionized water and 1ml of methanol. The solution was sonicated with polytron, mixed with 1ml tert-butyl ether 99%, shaken for 30 minutes, and centrifuged for 15 minutes. A 1ml organic layer was extracted, vacufuged for four hours, and 150 ul ammonium acetate was added to sample for mass spectrometry.

The results obtained from the analytical platforms for sterol sulfates, short chain fatty acids, Very-Long-Chain Fatty Acids (VLCFA), Ethanolamine Plasmalogens (PlsEtn), Choline Plasmalogens (PlsCh), and phosphatidyl glycerophospholipids were analyzed with multiple linear regression analysis with stepwise variable selection using Accumulated Degree Days (ADD) as the dependent variable. An r-squared value of 0.81 indicates that these variables account for variation in temperature-related postmortem changes in a corpse. The equations are being tested on a separate validation sample of known-PMI tissues to provide the forensic community with validated equations to derive accurate postmortem interval estimates based on biomarkers of long PMIs.

This research was supported by the National Institute of Justice.

Time Since Death, Postmortem Interval, Mass Spectrometry

A33 The Growth and Development of Secondary Sex Characteristics in the Human Skull

Michala K. Stock, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610*

After attending this presentation, attendees will better understand the growth and development of sexual dimorphism in the human skull, including which sexually dimorphic craniofacial traits reach adult expression before skeletal maturity, and the implication that these traits may be useful for sex estimation from adolescent skeletal remains.

This presentation will impact the forensic science community by addressing the common assumption that sex cannot (and should not) be assessed from immature remains and by suggesting avenues for further research to improve sex estimation methods in adolescent populations.

Although high accuracy rates have been achieved for sex estimation from adult skeletal remains, estimating sex in subadults remains a vexing issue facing forensic anthropologists. Many previous studies have focused on measuring sexually dimorphic skeletal features that are commonly used to estimate sex in adults, such as pelvic morphology and cranial traits, and have applied these methods to juvenile humans. As these are sexually dimorphic features whose expression is either absent or incomplete until adolescence, these methods have enjoyed mixed success when applied to immature skeletal remains; however, the growth and development of these sexually dimorphic secondary sex characteristics have not been systematically studied. The timing of their sexually dimorphic expression therefore remains unknown, and practitioners frequently and perhaps erroneously assume that these traits are not fully developed until adulthood. To assess the value of these traits for diagnosing sex among subadults, their expression must be measured during the adolescent period when growth and development of the secondary sex characteristics occurs.

This study was performed on a longitudinal sample of lateral radiographs from the Denver Growth Study, which includes males and females of European ancestry (n=5 males; n=5 females; n=96 total scans). To assess the growth of secondary sex characteristics in the human skull, four linear distances were measured that approximate the areas commonly scored in non-metric sex assessment: the nuchal crest, mastoid process, glabella, and mental eminence. These four measurements were taken of each individual at multiple ages; the youngest age cohort is defined as prior to the eruption of the second permanent molars, which is correspondingly before the onset of sex-based differential growth of cranial secondary sex characteristics. Measurements were taken on every subsequent scan for each individual until the measurement in question reached full adult expression (i.e., maximum size). Skeletal maturity was defined as the age of alveolar eruption of the maxillary third molar, with all earlier radiographs being characterized as immature. The age of skeletal maturity was then compared to the age of adult expression for each measurement. One-tailed, paired Wilcoxon rank-sum tests were performed to compare the pooled-sex sample's age at full expression of each trait to the age at skeletal maturity. The age of adult expression of the mental eminence was significantly younger than the sample's age of skeletal maturity (p<0.001), while the age at adult expression of the nuchal crest was significantly older than the age of skeletal maturity (p=0.02). The mastoid process and glabella ages at adult attainment did not differ significantly from the sample's age of skeletal maturity (p=0.27; p=0.34, respectively).

The results indicate that the mental eminence matures in size relatively early in adolescence and suggest that this feature is suitable for further analysis and the development of sex estimation criteria in adolescent skeletal remains — effectively pushing back the age at which sex can be assessed from crania. These results also support the use of the mastoid process and glabellar regions for sex estimation at (and after) M^3 eruption, but indicate that caution should be exercised when scoring the nuchal crest in young adults, as this trait does not reach full expression until after skeletal maturity. None of the traits included in this study are routinely employed for sex estimation in subadults. Yet their utility in this context can be assessed through the use of a longitudinal database of radiographs that began 85 years ago at the Denver Growth Study. The novel insights into adolescent growth and development of sexually dimorphic traits provided by this study demonstrate how even evolving forensic methods rely upon past research efforts.

Sex Estimation, Growth and Development, Adolescence

A34 Sex Estimation: A Novel Protein-Based Sex Assignment Technique Using Human Tooth Enamel and Mass Spectrometry

Katelyn Mason, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Caleb Kiesow, United States Air Force Academy, Colorado Springs, CO; Laura A. Regan, PhD, Office of Net Assessment, 1920 Defense Pentagon, Rm 3A932, Washington, DC 20301-1920; Haagen D. Klaus, PhD, George Mason University, MSN 3G5, Dept of Sociology and Anthropology, George M Robinson Hall B, Rm 305, Fairfax, VA 22030; Bethany L. Turner-Livermore, PhD, Georgia State University, Dept of Anthropology, 33 Gilmer Street, Ste 335, Atlanta, GA 30303; Deon Anex, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Bradley Hart, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; and Glendon Parker, PhD, Protein-Based Identification Technology, 4421 Ashwood CMN, Fremont, CA 94538*

After attending this presentation, attendees will better understand a powerful new methodology in which proteinaceous sample sources such as tooth enamel can be used as an alternative to DNA for the forensic analysis of humans. This presentation will inform attendees that compromised samples lacking DNA can still be used to determine information about the identity of a subject. Specifically, sex estimation can be achieved by proteomic analysis of human tooth enamel proteins.

This presentation will impact the forensic science community by offering an alternative science-based forensic technique using proteins as a biological sample source to achieve human sex estimation from human tooth enamel.

Human sex-estimation provides a fundamental metric essential for human forensic and bioarchaeological practice. Compromised samples that are influenced by fire, explosions, extreme environments, and long periods of time often do not meet the quality standards necessary for success of current sexing techniques. These techniques rely on anatomical sexual dimorphisms, which are particularly problematic in subadult skeletons' DNA-based analysis of sex chromosomes. Protein is chemically more stable than DNA and has an increased resistance to deterioration in the environment. Tooth enamel is the hardest tissue in the human body and is an ideal sample source in this context due to its preservation in harsh conditions. Probing the sex-linked protein amelogenin that is found in tooth enamel offers a novel way to sex compromised or subadult skeletons that lack DNA.

Using Mass Spectrometry (MS) -based proteomic techniques, the sex-linked isoforms of amelogenin can be detected directly by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) peptide sequencing. Approximately 20mg-30mg blocks of enamel were resected from each tooth. Protein extractions were performed by a milling, acid-etching, disulfide reduction and alkylation steps. Peptides were generated by proteolysis in the presence of the surfactant with trypsin. The resulting peptides were separated by high-pressure LC and analyzed by a Thermo™ Q-Exactive™ plus hybrid orbitrap/linear ion trap MS. Mass spectra were then matched to peptide sequences and a subset of peptides containing amino acid sequences peptides unique to the X- and Y-isoforms of amelogenin was generated. In this study, five male, five female, and one archaeological sample from a male and a female were tested for amelogenin X/Y isoform peptides in their tooth enamel. After the initial detection of unique isoform peptides was achieved, specific mass-to-charge ratios of interest were chosen for additional data acquisition targeted to collect MS/MS data correspondingly. Synthetic peptides were purchased for validation of mass-to-charge ratios and retention times of the peptides identified within experimental data. Optimization of protein extraction from tooth material was achieved by testing different extraction conditions (different chelating agents and acid-etching time/temperatures) on a homogenized standard sample composed of eight different teeth. Dentin and cementum were also excised from teeth for amelogenin isoform detection.

X-isoform peptides were detected within every sample of the enamel dataset and peptides unique to the Y-isoform were consistently detected within all male samples of this group, yielding a positive predictive value of male and female sex-estimation of 100% in this cohort. These results reveal the potential of this technology for sexing of a given individual using a proteomic approach. By exploiting the durability of enamel in combination with the stability of protein, this technique provides a new pathway for analysis of compromised human remains in both forensic and bioarchaeological settings. Expansion of this research will likely establish that proteomic analysis of the isoforms of amelogenin in tooth enamel can be used for sex assignment when other established forensic and bioarchaeological techniques are ineffectual.

This work performed under the auspices of the United States Department of Energy by Lawrence Livermore National Laboratory under contract.

Sex Estimation, Proteomics, Tooth Enamel

A35 Sex Estimation Using Relative Pubis Length

Caitlynn Cole, 27 Princeton Drive, Delran, NJ 08075*

After attending this presentation, attendees will: (1) better understand how to estimate sex using relative pubis length; (2) be informed regarding a method that provides statistical analysis to support previous literature describing the pubis as longer in females than in males; and, (3) realize the importance of utilizing a replicable pubis length measurement.

This presentation will impact the forensic science community by providing a method of sex estimation using the pubis that is not reliant on morphological features. This research adds to the already existing methods of sex estimation and provides a method developed on a modern sample.

Sex estimation is an integral part of the biological profile. Other aspects of the biological profile require the estimation of sex before their evaluation can be considered. Both age at death and stature use sex-specific regression formulas. Estimations of sex are most accurate after the individual has reached adulthood, due to the emergence of secondary sex characteristics.[5] The pubis bone is continually used in sex estimation based upon its identification as the best indicator of sex due to childbirth; however, there are discrepancies on how to measure the pubis.[1]

In this presentation, an index to determine relative pubis length is proposed, using "the nearest border of the acetabulum to the superior point of the pubic symphysis" for measurement of pubis length and the "distance from the most superior point on the iliac crest to the most inferior point on the ischial tuberosity" for measurement of os coxa height.[2,3] Relative pubis length is proposed as a sex estimation method in order to provide metric assistance to the assessment that the pubis is more "stretched" in females.[4] Four hundred eighty-nine individuals of known age at death, sex, and ancestry from the W.M. Bass Collection at the University of Tennessee were measured to determine relative pubis length. Two hundred seventeen females and 272 males make up the 489 individuals measured from the W.M. Bass Collection. Relative pubis length is an index, created by dividing pubis length by os coxae height. This information was then applied in an Analysis of Variance (ANOVA) to determine the statistical significance of relative pubis length and sex estimation. In preliminary results, there is a significant relationship between sex and relative pubis length (p=2.2x10^{-16}) and in a two-way ANOVA, the only significant relationship found was between sex and relative pubis length; all other factors were not significant (ancestry and age at death). Additional measurements were taken using the Hamann-Todd Collection to assess the effect of secular trends on relative pubis length. Five hundred nineteen individuals were measured from the Hamann-Todd Collection; this data is currently undergoing evaluation.

Relative Pubis Length, Sex Estimation, Pelvis

A36 The Accuracy of Nutrient Foramen Versus Midshaft Measurements of the Tibia for Sex Determination

Ashley C. Dafoe, University of Wyoming, 11065 Dahlia Court, Thornton, CO 80233; and David R. Hunt, PhD, Smithsonian Institution, Dept of Anthropology/MRC112, 10th and Constitution Avenue/NMNH, Washington, DC 20013-7012*

After attending this presentation, attendees will understand the utility of nutrient foramen and midshaft measurements of the tibia for sexing by discriminant function analyses.

This presentation will impact the forensic science community by providing usable discriminant function analyses for sex determination using the tibia.

The postcranial skeleton has been used for sex determination of an individual for more than a century. These methods have been developed and re-assessed to find the most accurate methods. In the tibia, discriminant function analysis has been employed, including measurements of diameter taken at the nutrient foramen. The location of the nutrient foramen varies from person to person and can be located in different areas of the bone from the right to left tibia in the same individual. This inter- and intra-individual variation has led some standards to adopt midshaft measurements in place of, or in addition to, the existing nutrient foramen located measurements.

To understand the implications this variation may have on the accuracy in sex determination, comparative consideration of midshaft measurements in place of nutrient foramen level measurements were tested with the following questions: Is intra-person variation in the location of the nutrient foramen great enough to cause significant mismatching of tibias left applied to left, left applied to right? Is there a significant advantage to using measurements collected at the midshaft in addition to, or in place of, measurements collected at the level of the nutrient foramen? It is hypothesized that there will be no significant difference in correct sex classification between the two measurements.

A sample of 400 individuals were measured from the Robert Terry Anatomical Skeletal Collection. Measurements of the tibia were taken via standard osteometric protocols. Because of discrepancies in the standards, medial-lateral diameter at the nutrient foramen was collected both in a 90° rotation from the anterior posterior measurement and from the interosseous crest.

Data were randomly divided into a testing set and a training set, each consisting of 200 individuals. Discriminant function analyses were run in the statistical programming environment R, using only left measurements or left and right measurements from the training set. Initial tests of ancestry differences determined no significant differences, and thus ancestry groups were pooled. The resulting discriminant functions were applied to classify individuals from the testing set using left and right measurements combined. Three variables, maximum length and proximal and distal epiphyseal breadth, were tested.

Results indicate breadth measurements of the proximal and distal epiphyses were consistently good predictors with high loading values higher in all combinations. Of the medial lateral measurements of the diaphysis, the measurement taken from the crest to a point directly opposite was a better predictor of sex than measurements taken at a 90° rotation from the anterior posterior measurement (90% versus 91.5%). Of the measurements taken at the midshaft, minimum diameter and circumference were both considered good predictors (89% correct). In the combined analysis medial-lateral diameter at the nutrient foramen, minimum at the midshaft and circumference at the midshaft were the best predictors (89% correct). There is no significant difference in accuracy between a discriminant function created with only lefts and applied only to lefts and the same function applied to lefts and rights (always a <1% difference in accuracy).

This investigation identifies that there is no significant advantage of sex determination based on measurements taken at the nutrient foramen compared to those taken at the midshaft. In cases involving fragmented remains, measurements taken at the level of the nutrient foramen would, of course, have more utility. It would be most valuable to collect both midshaft- and nutrient foramen-based measurements.

Tibia, Discriminant Function Analysis, Sexing

A37 Skeletal DNA Preservation and Bone-Associated Microbes: The Implications for DNA Sampling Strategies in Forensic Identification

Alexandra L. Emmons, MA, University of Tennessee, 2831 Island Home Avenue, Knoxville, TN 37920; Sarah W. Keenan, PhD, University of Tennessee, Biosystems Engineering and Soil Science, Knoxville, TN 37996; Amy Z. Mundorff, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; Jon Davoren, MS, 10430 Furance Road, Ste 107, Lorton, VA 22079; and Jennifer M. DeBruyn, PhD, University of Tennessee, 2506 EJ Chapman Drive, Knoxville, TN 37996*

After attending this presentation, attendees will better understand microbe-mediated skeletal DNA degradation.

The results of this study provide novel insights into the diverse fungal and bacterial communities capable of colonizing and possibly influencing bone degradation. This presentation will impact the forensic science community by contributing to attendees' current understanding of microbe-mediated skeletal degradation and by informing attendees of current skeletal DNA sampling strategies for forensic identification.

Skeletal DNA degradation occurs at differential rates during human decomposition, and which elements are more susceptible to mechanisms of degradation is currently debated. Some research points to long bones as better reservoirs of high-quality DNA, while others point to small cancellous bones.[1-7] Mundorff and Davoren ranked skeletal elements from three individuals based on their overall DNA yield and ability to ascertain a full forensic profile.[6] This was the first study of its kind that looked at both intra-individual and inter-individual variation in human skeletal DNA yield. That study found that small cancellous bones, on average, yielded greater amounts of better-quality DNA than their larger, denser cortical bone counterparts, a pattern that held true over time in postmortem intervals of up to 21 years.

Yet, the mechanisms behind skeletal degradation and preservation remain largely unknown. Microbial colonization is likely a critical component, since bacteria and fungi readily degrade organic material, including DNA. Therefore, it was hypothesized that microbial intrusion and community composition will be related to human skeletal DNA preservation. While there have been several published reports on microbes associated with soft tissue decomposition, there is little information on the quantity and community composition of microbiota in human bone. The present study seeks to improve understanding of bone-associated microbes and skeletal DNA degradation by looking at bacterial DNA yields and microbial community composition across multiple bone types within and between three skeletons following natural (surface) decomposition.

Human skeletal DNA extracts previously generated and analyzed for Mundorff and Davoren were used to directly compare bone-microbial colonization with DNA quality and quantity.[6] Specifically, extract from 49 bones, from each of the three individuals, were characterized for microbial intrusion using Illumina® MiSeq®. Both 16S recombinant DNA (rRNA) and 18S rRNA gene sequences were obtained for characterization of bacterial and fungal communities co-extracted with human skeletal DNA. Additionally, total bacterial DNA was quantified using quantitative PCR (qPCR), targeting the 16S rRNA gene.

Preliminary results reveal major contributions from the phyla Proteobacteria (20-35%), Actinobacteria (2-11%), Bacteroidetes (2-11%), Firmicutes (1-10%), with additional contributions from Verrucomicrobia, Planctomyetes, Chlamydiae, and Deinococus-Thermus; however, the proportion of these phyla throughout the skeleton do not appear to be uniform and also show varying influences from rarer taxa. Of the fungal communities sequenced, Ascomycota (40-60%) and Chytridiomycota (15-40%) were highly representative, with lesser contributions by Basidiomycota.

Preliminary qPCR results are highly variable within and between individuals; mean 16S rRNA gene abundances range from 4.10×10^8 gene abundances per gram of bone powder in teeth to 1.58×10^{10} gene abundances per gram of bone powder in 1st proximal foot phalanges. The bones with the least amount of bacterial DNA were teeth, femora, humeri, ulnae, the 12th ribs, and occipital bones, respectively. Conversely, the highest quantities of bacterial DNA were found in the 1st proximal foot phalanges, 3rd metacarpals, 1st proximal hand phalanges, capitates, and sterna. When considering human DNA yield, the highest human DNA to bacterial DNA ratios were found in teeth, 3rd metatarsals, humeri, mandibles, femora, and the tibiae. Bones with a lower ratio of cortical to trabecular bone appear to be more readily colonized by microorganisms than those with a higher ratio of cortical to trabecular bone.

This is the first study to systematically examine microbial intrusion and microbial community composition throughout the human skeleton.

A38 A Morphometric Analysis of the Neurocranium in an Adult South African Sample

Jacqui Friedling, PhD, University of Cape Town, Dept of Human Biology, Faculty of Health Sciences, Observatory, Western Cape 7925, SOUTH AFRICA; and Petra Maass, MSc, University of Cape Town, Dept of Human Biology, Faculty of Health Sciences, Observatory 7925, SOUTH AFRICA*

After attending this presentation, attendees will better understand the human variation among modern Black, White, and mixed-ancestry South Africans and will understand the statistical framework used to describe similarities and differences among these groups.

This presentation will impact the forensic science community by not only contributing to the knowledge of human variation in modern South Africans, but also by revealing a more accurate method of estimating ancestry and sex from full and partial crania in different ancestral populations occupying the same geographical space.

Many questions in anthropology relate to variation in shape of anatomical structures. Geometric morphometrics allow evaluation of shape variation by "removing" the effect of size and has been applied to many fields within anthropology, primarily utilizing the cranium. The high crime rate in South Africa makes it important to develop methods to gain information such as sex and/or ancestry from skeletal material that is likely to be recovered in a forensic context. This study examined morphological variation in the crania of a South African sample in relation to the associated demographic information and assessed the accuracy with which such information could be estimated.

The purpose of this study was to use cranial morphometrics to evaluate ancestral variation and sexual dimorphism among White, Black, and mixed-ancestry groups as a means to explain current variation and more accurately identify unidentified remains.

A total of 774 crania of Black (160F, 123M), White (90F, 130M), and mixed ancestry (104F, 167M) were used from the Universities of Cape Town, Stellenbosch (Kirsten), Pretoria, and Witwatersrand (Raymond A. Dart) skeletal collections with ages ranging between 20 to 100 years at death. A total of 11 to 12 landmarks for each cranial element was digitized to generate various linear measures, angles and subtenses, and 14 landmarks for the whole cranium. Discriminant function analysis was employed and South African groups were tested against themselves to test classification accuracies. All accuracies were cross-validated. Multivariate analyses were used to assess differences between sex, ancestry, and sex-ancestry groups.

The analyses demonstrate that males have relatively and absolutely larger crania than females. Females tended to have a slightly larger medio-lateral dimension of the cranium, but an antero-posteriorly longer occipital region compared to males. This resulted in a more steeply sloped forehead but less steeply sloped occipital region in females. This revealed that the frontal bone had the best results for classifying each of the sexes with between 75.5%-83.7% accuracies

The most accurate identifiers for ancestry in Black individuals were found on the frontal bone (88%). This was similar for the mixed-ancestry individuals (83.7%); however, for White individuals, the whole cranium was best for ancestry identification (90.2%).

These results illustrate that morphometric analysis of the frontal bone alone could be used to estimate certain demographic parameters, which may be used in constructing a biological profile for forensic purposes. The accuracy of such analysis is similar to or exceeds that of traditional analyses.

Ancestral Variation, Sexual Dimorphism, Geometric Morphometrics

A39 Additional Information for Identification Purposes Via the Study of Cam-Type Deformity of the Hip

Laura Donato, Via Tripolitania 195, Rome 00199, ITALY; Marco Straccamore, MD, Sapienza University of Rome, viale Regina Elen 336, Rome 00100, ITALY; Alessandro Di Luca, MD, Via Domenico Chelini 7, Roma 00197, ITALY; and Costantino Ciallella, Viale Regina Elena 336, Rome, ITALY*

The goal of this presentation is to highlight the importance of a morphological variation, such as the cam-type deformity, as a useful tool for personal identification.

This presentation will impact the forensic science community by taking into account the cam-type deformity to gain important information in identifying unknown human remains by providing information about life style and possible pathologies.

The cam-type deformity of the hip is a morphological alteration of the femoral head neck junction. Such manifestation is considered part of the Femoral-Acetabular Impingement Syndrome (FAI). This disease develops consequently to hip flexion because of an abnormal contact between the acetabular cavity and femoral head neck junction. This causes the deformity and the loss of the round shape of the head of the femur, due to several and repeated traumas toward the upper labrum of the acetabular cup and the adjacent chondral structures, resulting in a deformity of the acetabulum of the pelvis. The cam-type deformity's main feature is the formation of extra bone in the upper segment of conjunction between the body and the head of the femur.

The presence of this clinical condition can either be painless or cause pain and functional limitation of the hip, due to the deformities of the acetabular labrum and articular cartilage. As a consequence of the FAI, the cam-type deformity can be linked to hip dysplasia, previous fracture of the pelvis and femur, childhood hip disorder, and septic arthritis. Scientific literature states that significant morphological variations of the femoral head-neck junction, due to physical activities and/or occupational stress, can be a possible manifestation. Sports such as soccer, hockey, and horseback riding may be the cause of this deformity of the head and body of the femur. In these cases, the peculiar stance of the subject, as in hockey for example, causes a morphological response of the bone structure of the proximal epiphysis of the femur. This feature is also typical in sports or in jobs in which the subject remains standing for long periods of time. In these cases, the deformity is caused by the normal and involuntary favoring of one of the legs.

By the anthropological examination of the bones of a subject, both of the femur and of the whole skeleton, it is possible to detect this type of modification of the physiological structure. This study compares two subjects, both affected by cam-type deformity due to different pathological and occupational conditions. Bones belonging to these individuals have been macroscopically examined with the goal of finding features leading to pathology or occupational stress. Particular physical activities or pathological conditions linked to cam-type deformity, such as limping, can provide additional and useful information for the reconstruction of identity in cases of recovered unidentified corpses.

International literature is not lacking information about the cam-type deformity, yet this feature has not yet been taken into account for identification purposes.

Cam-Type Deformity, Identification, Forensic Anthropology

A40 A Cranial-Postcranial Approach to Metric Ancestry Estimation Among Modern South Africans

Gabriele C. Kruger, MSc, 6 Casa Bari, 574 Jacobs Street, Gezina, Pretoria, Gauteng 0084, SOUTH AFRICA; Leandi Liebenberg, MS, 13 Andrehof, 211 Stead Avenue, Pretoria 0186, SOUTH AFRICA; Janice Lucinda Geel, BSc, University of Pretoria, 9 Bophelo Road, Pretoria 0007, SOUTH AFRICA; and Ericka N. L'Abbe, PhD, University of Pretoria, 9 Bophelo Road, Pretoria 0001, SOUTH AFRICA*

After attending this presentation, attendees will better understand the potential of employing a combined cranial-postcranial approach to estimate ancestry in modern South Africans. The combined approach will be compared to previous cranial and postcranial studies to highlight the improvement in accuracy over previous assessment methods.

This presentation will impact the forensic science community by contributing to knowledge on craniometric and postcraniometric variation observed among modern Black, Colored, and White South Africans and the potential of a combined methodology for estimating ancestry.

The cranium is recognized as the most reliable indicator of ancestry and is the preferred bone for assessing ancestry in South African anthropological casework. Recently a postcraniometric approach to ancestry on a South African sample yielded comparable results to accuracies achieved by previous craniometric studies, demonstrating the potential use of postcrania in ancestry estimation.[1] Despite high accuracies obtained with both cranial and postcranial data, large amounts of overlap between the three major South African groups limits the predictive accuracy of the elements in providing a definitive ancestry estimate.[2] A more holistic method assessing both cranial and postcranial measurements simultaneously would include the most discriminatory variables of the entire skeleton, resulting in better group separation than when crania and postcrania are evaluated separately.[1] The current research seeks to explore a combined cranial-postcranial approach to metric ancestry estimation in a modern South African sample.

A total of 38 standard measurements were taken from the cranium and ten postcranial bones. The sample consisted of 360 modern South African individuals (120 Black, 120 White, 120 Colored) from the Pretoria Bone and Kirsten Collections housed at the University of Pretoria and the University of Stellenbosch, respectively. Group differences were explored with Analysis of Variance (ANOVA) and Tukey's Honestly Significant Difference (HSD) test. Multivariate classification models were assessed using Linear Discriminant Analysis (LDA). Classification accuracies achieved for a variety of multivariate models were compared to previous cranial and postcranial studies to evaluate the potential of the holistic approach.

The results demonstrated variable patterns of group overlap. Consistent with previous studies, Black and Colored South Africans displayed overlap for the majority of the variables; however, 11 variables inclusive of all lengths of the distal limb segments, breadth measurements of the orbit and nasal aperture, interorbital breadth, mastoid height, and the femoral transverse subtrochanteric diameter were found to be significantly different between the two groups ($p<0.05$). White South Africans displayed larger measurement means for all postcranial variables, except the lengths of distal limb segments, whereas Black South Africans had the largest means. Cranially, White South Africans also displayed the largest measurement means for all variables, except inter- and bi-orbital, nasal and minimum frontal breadths, for which the measurements were the smallest of all three groups. For both crania and postcrania, Colored South Africans had either the smallest or intermediate measurement means. A series of multivariate subsets were created to present numerous different measurement combinations and achieved accuracies that ranged from 85% to 91% (using LDA), with only one to two misclassifications for White South Africans, creating almost complete separation of the group from Black and Colored South Africans. Overall, White South Africans had the highest correct classification rates, followed by Black and Colored South Africans, respectively.

Substantial heterogeneity among the three South African groups decreases the positive predictive power of the cranial and postcranial methods, making them of limited reliability in a forensic setting. The current research demonstrates that when used in combination, cranial and postcranial measurements have the potential to outperform the current standard methods for estimating ancestry in South Africa.[2] Combining the skeletal elements accounts for more between-group variation and decreases the amount of overlap observed among Black, Colored, and White

South Africans, ultimately yielding improved accuracies. Using a computer program, such as FORDISC® 3.1, that combines or selects the most discriminatory variables on a case-specific basis, may be the best approach to ancestry estimation.

Classification Models, LDA, Human Variation

A41 The Decomposition of Child-Sized Remains in Different Depositions

Ann H. Ross, PhD, North Carolina State University, Dept of Biological Sciences, Campus Box 7614, Raleigh, NC 27695-7614; and Amanda R. Hale, MA*, North Carolina State University, 127 David Clark Labs, Campus Box 7617, Raleigh, NC 27695*

After attending this presentation, attendees will be better acquainted with the specific environmental factors that influence seasonal decomposition.

This presentation will impact the forensic science community by presenting the significant environmental factors that affect decomposition during each season.

Thirty-seven *Sus scrofa* (16 juvenile and 21 fetal) remains were obtained fresh from the North Carolina State University (NCSU) swine farm in the summer, fall, winter, and spring months. The traditional calendar for the start of each season was used as the initial day of placement from summer 2013 to spring 2015. Juvenile pigs were used as a proxy for human children up to 9 years of age (35-50 pounds) and fetal pigs were used as a proxy for human neonatal remains (4-6 pounds). Two juvenile pigs were placed on the surface each season, one fetal pig was placed in a plastic bag, and the other fetal pig was wrapped in a baby blanket. From spring 2014 to spring 2015 (5 seasons), a third fetal pig was placed on the surface as a control. All remains were enclosed in cages to prevent scavenging.

Total Body Score (TBS) was used to record decompositional observations. Accumulated Degree Days (ADD) were calculated from daily maximum temperature with data obtained from the State Climate Office of North Carolina Lake Wheeler Road Field Lab weather station located one-half mile from the open-air site. In addition to daily temperature, daily precipitation, relative humidity, fly activity, soil temperature, and soil moisture were collected.

A mixed random coefficients model, which is useful for analyzing repeated measures, was used to examine the relationship between the dependent (ADD) and independent variables (TBS, daily temperature, daily precipitation, soil temperature, soil moisture, and deposition). All statistical analyses were performed using JMP® Pro 12.1. For the fall season, TBS, deposition, fly activity, and relative humidity were not significant effects in the fetal remains (*deposition* (bag, blanket) DFNum = 2, DFDen = 116, F ratio = 0.107, Prob >F = 0.956; *relative humidity* DFNum = 1, DFDen = 116, F ratio = 57.469, Prob > F = 0.470; *fly activity* DFNum = 1, DFDen = 116, F ratio = 0.086, Prob >F = 0.770; *TBS* DFNum = 1, DFDen = 116, F ratio = 1.99, Prob >F = 0.160;); however, daily precipitation, soil moisture, and soil temperature were significant at the <.0001 level. The juvenile remains followed the same pattern in the fall as the fetal pigs with the only significant effects being daily precipitation, soil moisture, and temperature. For the spring, all variables were significant (0.01-0.0001 level) with the exception of the fly activity for the fetal remains (p-value = 0.119). The juvenile remains displayed a different pattern with TBS, soil moisture and temperature as significant factors in the spring. Summer yielded a different pattern with only two significant effects for fetal remains (*soil temperature* DFNum =1, DFDen = 104, F ratio = 7.27, Prob >F = <.0082; *soil moisture* DFNum =1, DFDen = 104, F ratio = 19.69, Prob >F = <.0001) and only TBS (p-value = 0.05) for the juveniles. Winter also showed a different pattern with TBS, deposition, fly activity, and soil moisture having significant effects (*TBS* DFNum =1, DFDen = 140, F ratio = 90.20, Prob >F = <.0001; *Deposition* DFNum =2, DFDen = 140, F ratio = 4.77, Prob >F = <.0099; *fly activity* DFNum = 1, DFDen = 140, F Ratio = 9.77, Prob>F = 0.002; *soil moisture* DFNum =1, DFDen = 201, F ratio = 70.87, Prob >F = <.0001). For the juvenile remains, only TBS and soil temperature were significant effects in winter (*TBS* DFNum =1, DFDen = 54, F ratio = 42.03, Prob >F = <.0001; *soil temperature* DFNum =1, DFDen = 54, F ratio = 17.50, Prob >F = <.0001).

Results demonstrate that size has a significant impact on the pattern of decomposition and further support the importance of seasonal and geographic-specific indices for estimating the postmortem interval. This project was supported by a National Institute of Justice grant.

PMI, Decomposition, Seasonal

A42 Changing Impact Angles: The Mechanics Involved in Blunt Force Cranial Trauma and Their Importance in Investigating Curb-Stomping Cases

Carole A.L. Davenport, BSc, Liverpool John Moores University, C/O Rm 439A James Parsons Bldg, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM; James C. Ohman, PhD, School of Natural Science and Psychology, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Matteo Borrini, PhD, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will better understand how fracture types can differ as a result of blunt force trauma produced by differing angle strikes.

This presentation will impact the forensic science community by providing an experimental model that aids in the understanding of fracture mechanics produced when force is applied to the cranium from differing angles.

The majority of studies on the infliction of blunt force trauma to the cranium assess only the initial impact site. This method can therefore result in a loss of essential data relating to the circumstances in which the injury was sustained. The goal of this study was to create an experimental model that would provide a more realistic picture of the damage sustained during a violent attack to aid investigators.

Twenty adult pig heads (*Sus scrofa domesticus*) were placed on a solid base, resting on the mandible. The base could be angled so that the impact angle to the skull could be altered for each strike. Using a drop hammer rig, modified with a replica hammer head (modeled after a 16oz claw hammer), each pig head was struck once over the frontal bone from a height of one meter. A total of five angles were assessed in this preliminary study (0°, 9°, 18°, 27°, and 36°), with each angle tested a minimum of three times. It was not possible to strike the frontal region of the pig head at any angle greater than 36°. To monitor the acceleration, timing, and force of each strike, a piezoelectric accelerometer was attached to the drop hammer, with data recorded at a rate of 10,000 scans per second. Following maceration, the fractures present were compared with previously published images and descriptions, with measurements taken of the width, length, and depth of each depression fracture.[1]

It was noted that a number of mandibles had also fractured when struck using a more direct angle (0°, 9°, and 18°). To establish that this was a result of the impact study, a further set of pig heads were radiographed prior to the strikes. A further radiograph following the impact confirmed that the mandibular fractures had caused a transference of the force through the cranium when struck from above.

A total of 22 fractures were observed between the cranium and mandible. Depression fractures (n=10) demonstrated a decrease in size as the angle increased and radiating fractures (n=4) were present on angles from 18°. Mandibular fractures (n=8) were only present up to 18° in this study, with the severity ranging from complete break to partial fractures as the angle increased. It was also noted that the angle of the fracture on the mandible differs as the angles increase.

Presented here is a pilot study that exhibits the need to further investigate the issues surrounding violent assaults using blunt force trauma, such as bludgeoning with a hammer; however, an unexpected finding was the secondary trauma inflicted to the mandible as a result of resting on the solid base plate, which mimicked the scenario faced by curb-stomping victims. Although the traditional "biting the curb" posture is not exhibited in this experiment, it provides information on how the transference of force can travel through the skull and exhibit in fractures elsewhere.

There are increasing numbers of reports in the media of violent crimes involving blunt force trauma taking place that utilize everyday household objects.[2] It has also been highlighted in studies that blunt force trauma to the head is one of the most effective methods of murder, but that the weapons most commonly involved are hands and feet, also referred to as human strength.[3]

This study is limited by the small sample size, but has provided information that could direct further research into violent assaults using blunt force trauma. It would be beneficial to repeat the study using a larger sample size, bone substitutes to more directly simulate the cranial biomechanics of a human skull, and by modifying the drop hammer to investigate how increasing the surface area impact will affect the results.

Blunt Force Trauma, Cranial Fracture, Secondary Injuries

A43 Comparing the Decomposition of Partially Suspended (Semi-Recumbent) Pigs With Fully Suspended Hanging Pigs and Fully Recumbent Pigs in Direct Contact With the Ground

Jeanne Lynch-Aird, PhD, UCLAN, The Old Forge, Burnthouse Lane, Preston, Lancashire PR1 2HE, UNITED KINGDOM; Colin Moffatt, PhD, UCLAN, School of Forensic & Inv Sci, Preston, Lancashire PR1 2HE, UNITED KINGDOM; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will better understand the major differences in the decomposition patterns and rates between fully suspended hanging pigs, semi-recumbent pigs, and pigs decomposing on the ground.

This presentation will impact the forensic science community by adding to current knowledge concerning decomposition in hanging bodies and the appropriate decomposition scoring scales to use, which, when combined with Accumulated Degree Days (ADD), will allow for the calculation of time since death.

Establishing the Postmortem Interval (PMI) is an essential part of any death investigation. By using decomposition scoring and ADD, the PMI can be estimated. The findings of a decomposition study conducted under controlled conditions at the Taphonomic Research in Anthropology: Centre for Experimental Study (TRACES), University of Central Lancashire, United Kingdom, will be presented. Thirty freshly killed pigs (*Sus scrofa*) of the same age were used as human analogues. Twenty pigs were hung by the neck using nylon rope attached to hooks hung from A-frames built from scaffolding poles. Ten pigs were hung, fully suspended, with their hind feet approximately 100cm off the ground, with the remaining ten hung partially suspended, so that the flanks and hind legs were in direct contact with the ground. The animals were spaced 60cm-90cm apart. To protect the pigs from vertebrate and avian scavengers, each of the A-frames was surrounded with chicken wire up to a height of 60cm above ground and bird netting was stretched over the whole frame. A further ten control pigs were placed on the ground under scavenger-proof cages.

The pigs were observed and the patterns of decomposition recorded and photographed for head and neck, torso, and limbs at approximately 50 ADD intervals until 1,078 ADD. Ambient temperature was recorded by dataloggers every six hours. Total Body Scores were assigned to the control pigs (TBS_{surf}) at each visit using the Megyesi et al. decomposition scoring scale, adjusted to score from zero for fresh bodies.[1] Decomposition scores for the hanging pigs (TBS_{hang}) were obtained using the Lynch-Aird et al. hanging scale.[2] Initially, the semi-recumbent pigs were scored using both of these scales to assess the whole body until it became clear the upper and lower portions of the animals were displaying different decomposition patterns. The upper sections of the semi-recumbent pigs followed the same decomposition pattern as the hanging pigs and were scored using the hanging scale, covering the head, upper limbs, and upper torso, while the lower sections followed the same pattern as the control pigs and were scored using the surface scoring scale, covering the lower limbs and lower torso (the head was not scored), to give Partial Body Score Torso plus Limbs ($PBST_{surf} + PBSL_{surf}$).

The hanging and semi-recumbent upper bodies displayed the same levels of TBS response to ADD, with no statistically significant difference between the two groups (p=0.53, $F_{2,197}$=1,402). The TBS versus ADD responses for the lower sections of the semi-recumbent bodies were compared with the corresponding partial body scores for the controls; there was no statistically significant difference between these two groups either (p=0.8, $F_{2, 197}$=1,157).

Taphonomy, Hanging, Decomposition

A44 The Effects of Cranial and Pelvic Asymmetry on Accurate Sex Classification

Stephanie J. Cole, BA, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; Luis L. Cabo, MS, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; and Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621*

After attending this presentation, attendees will better understand how asymmetry impacts non-metric sex estimation methods.

This presentation will impact the forensic science community by examining the potential and actual impacts of the presence, frequency, and type of asymmetries on the classification accuracies of two methods based on cranial and pelvic markers: the original Walker and the Klales et al. methods.[1,2] This presentation will also provide recommendations for the application of these methods in asymmetrical individuals.

Sex estimation is one of the most important aspects of the biological profile, as a reliable estimation of this parameter allows for the application of more accurate sex-specific methods for the estimation of age, ancestry, and stature. Sex estimation still relies to a large extent on non-metric evaluation of the pelvis and skull, as these areas are both strongly dimorphic and geometrically complex, with subtle morphological traits and differences that are hard to capture metrically. By convention, forensic anthropological protocols typically suggest using the left side when estimating sex from bilateral traits; however, if asymmetry is common, this criterion could introduce fundamental biases and compromise accuracies. For example, if the population displays directional asymmetry, by preferentially selecting the left side, a systematic decrease in the classification accuracy for either females or males would occur, depending on whether that side is the one favored or disfavored by the directional trend. Even if the asymmetry does not consistently favor one of the sides, more asymmetrical individuals could be reflecting systemic effects, such as increased developmental stresses, affecting the accuracy of not only one, but both sides of the individual. In this case, the presence of asymmetry should be factored when reporting the corresponding sex estimates, as asymmetrical individuals would be expected to render lower accuracies than reported for the overall method.

An experienced observer blindly collected ordinal score data for the two bilateral cranial traits in the Walker method (Mastoid (M) and Supra-Orbital (SO) margin) as well as for the three bilateral pelvic traits in the Klales et al. method (Ventral Arc (VA), Subpubic Contour (SPC), and Medial Aspect (MA) of the ischio-pubic ramus). Data were also collected for the three unilateral Walker traits in order to test the classification accuracy of the method equations. The left and right sides were scored from a sample of 1,310 individuals (523 females, 787 males) from the Bass, Terry, and Hamann-Todd donated skeletal collections, as well as from the Texas State Operation ID collection.

Asymmetry was observed in 55.6% of individuals in at least one of the two cranial traits and in 59.8% of individuals in at least one of the three pelvic traits. With a frequency of 40.4%, the M was significantly more asymmetrical than the remaining traits ($p < 0.001$), well above SO and VA (31.0% in both cases; $p = 0.734$), while two of the Klales et al. traits, MA and SPC, were the least asymmetrical (27.2%; $p = 0.427$); although the difference between the two pairs SO-VA and MA-SPC ($p = 0.018$) is not significant after Bonferroni/Holms correction.

Even though asymmetries are common, the intra-class correlation coefficient revealed high levels of agreement between the left and right trait scores of individuals (M 0.849, SO 0.859, VA 0.952, SPC 0.984, and MA 0.932) with the vast majority of asymmetries consisting of only one score point difference. Directional asymmetries were detected, with males being right dominant for all traits ($p < 0.05$), while females only displayed directional asymmetries at the 0.05 α-level for the cranial variables, also exhibiting right dominance for the two traits.

As expected from the presence of directional asymmetries, selecting always the left side resulted in some cases in increased accuracies for females, at the expense of lower ones for males. Although, also as expected from the high intra-class correlations, the effect sizes of these between-sex discrepancies in accuracy were basically negligible in most cases (with the notable exception of Walker's equation 6). These results recommend reporting both the presence of asymmetries and the estimates for both sides when asymmetries are present.

Asymmetry, Sex Classification, Cranium and Pelvis

A45 Experimentally Derived Protocols for Generating 3D Cranial Surface Scans for Forensic Anthropological Applications

Taylor J. Rider, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546; Megan J. Rue, BA, Mercyhurst University, 1630 W Gore Road, Apt 1, Erie, PA 16509; and Heather M. Garvin, PhD, Mercyhurst University, Dept of Applied Forensic Sciences, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will be familiar with the utility and limitations of cranial 3D surface scans in forensic anthropological contexts, including the need for further development of standard operating procedures.

This presentation will impact the forensic science community by providing an experimentally derived protocol for the use of the NextEngine® Desktop Scanner in scanning cranial elements for forensic anthropological contexts.

The prevalence of 3D laser technologies employed in contemporary forensic anthropological research introduces the need for assessments of accuracy and systemic standardization of these techniques. The NextEngine® Desktop 3D Scanner is the most widely implemented 3D scanning technology within the discipline due to its user-friendly capabilities, relatively inexpensive cost, and resolution; however, at this time there are no published or implemented standard operating procedures for the collection and utilization of 3D scans for forensic purposes. This can have sizable consequences in forensic examinations, as the application of various settings chosen by the user ultimately affects the accuracy of the scan and 3D model. The purpose of this study was to systematically evaluate the effect of various scanning settings and determine the optimal settings for scanning the cranium. The cranium was selected due to its significance and frequented application in forensic anthropological estimations of the parameters of the biological profile, including age, sex, and ancestry.

Using the NextEngine® Desktop 3D Scanner, cranial scan trials were conducted using 8 divisions, 12 divisions, and 16 divisions for each of the following Points Per Inch (PPI) settings: Quick3, SD1, SD3, HD1, and HD3. In total, 15 scans were conducted. All scan post-processing was performed in the associated ScanStudio™ HDPro software. Following completion, the scans were coded to facilitate an unbiased evaluation and an observer was asked to perform a quality assessment by comparing the scans to the actual specimen and ranking a number of features on a scale of 1 to 10, 1 being terrible and 10 being a perfect representation of those features. Comparative analyses of average scan quality rankings, time requirements, and memory demands in relation to implemented scan settings were performed in order to determine those settings that produce optimal scans for forensic anthropological contexts.

The results of the comparative analyses indicate that the optimal settings for scanning the cranium include 12 divisions at the HD1 PPI setting. Time and memory demands for scan procurement proved to correspond highly, and ultimately determined that the HD3 PPI setting was inoperative, as the memory demands were too high for the scan to be reopened after obtained, even when using a high-end graphics computer. The representative accuracy of trial scans was assessed with regard to unique features, taphonomic qualities, and traits associated with evaluations of the biological profile. In none of the scans, regardless of employed settings, did the observer feel confident in assessing cranial suture closure by means of the Meindl and Lovejoy 1985 age estimation method; however, the observer felt comfortable applying non-metric sex and ancestry estimation methods to the cranial scans.[1] Using the optimal 12 divisions, HD1 settings, the observer felt the scan exhibited a suitable representation of surface coloration and suture representation (score 5). In addition, the observer felt able to discern cranial landmarks (score 5.3), muscle markings (score 5.7), nasal aperture shape (score 6), cranial foramina (score 7), and distinct skeletal markings (score 8).

To further evaluate the accuracy of scans produced using the proposed settings, 24 measurements taken on the cranium were compared to those taken virtually on the 3D scan. The average difference in measurements was 0.62mm (*SD* = 0.51mm), equating to an average percent difference of 1.17%. The highest deviation was found in measurement of the orbital height (1.7mm), which resulted in a 4.5% difference; however, the subjectivity in the definition of this measurement may have factored into this discrepancy. The next highest error was obtained with orbital breadth (2.9%). All other measurements had error rates less than 1.8%.

Once established, a standard operating procedure for the use of the NextEngine Desktop® 3D Scanner would

allow further documentation of known error rates in compliance with the *Daubert* ruling and the 2009 National Academy of Sciences (NAS) Report and render them operative practices within forensic anthropological contexts.[2,3]

A46 Testing Computational Age Estimation Methods Using Laser Scans of the Adult Pubic Symphysis on Modern Hispanic Populations

Cristina Figueroa-Soto, MA, The University of Tennessee, 254 S Stadium Drive, Knoxville, TN; Detelina Stoyanova, PhD*, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306; Jieun Kim, PhD*, 801 Sutters Mill Lane, Knoxville, TN 37909-9702; Dennis E. Slice, PhD*, Florida State University, Dept of Scientific Computing, 400 Dirac Science Library, Tallahassee, FL 32306-4120; and Bridget F.B. Algee-Hewitt, PhD*, Stanford University, Rosenberg Lab, Dept of Biology, Gilbert Bldg, Rm 109, 371 Serra Mall, Stanford, CA 94305-5020*

After attending this presentation, attendees will have a better understanding of the applicability and effectiveness of three newly published computational methods that focus on 3D laser scans of the pubic symphysis to estimate age at death for individuals of Hispanic identity.[1-3]

This presentation will impact the forensic science community by demonstrating how age at death can be estimated in a more accurate, precise, and objective manner by utilizing fully computational methods and 3D scans of the pubic symphysis on populations of Mexican and Puerto Rican descent. This presentation will also provide recommendations and best practice applications of these standards for forensic casework.

Age-at-death estimation techniques have received considerable attention within the anthropological community, especially among forensic anthropologists, as knowing age can narrow the list of potential missing persons in a forensic investigation. Even though the estimation of age is a crucial parameter of a biological profile, it is also one of the most challenging to attain as it greatly depends on the practitioner's ability to associate age changes with a set of population-specific criteria, usually represented by a series of pre-defined age phases. Along with this issue is the lack of population-specific standards for underrepresented populations in the United States, as the most established of the age-at-death techniques are based on individuals of European and, to a lesser degree, African ancestries from late 19th- and mid-20th-century anatomical collections. In order to address the lack of population-specific methods in age-at-death estimation for contemporary Hispanic casework, this study sourced data from individuals of Mexican and Puerto Rican origin with the goal of testing the newly published framework for age-at-death estimation of Slice and Algee-Hewitt and Stoyanova et al.[1-3]

Slice and Algee-Hewitt and Stoyanova et al. have recently developed objective, fully computational, and statistically robust techniques that offer several advantages over the conventional bone-to-phase matching methods.[1-3] These new techniques utilize coordinates obtained from 3D scans of the pubic symphysis. These data are subjected to numerical shape algorithms and multivariate regression analysis to produce age-at-death estimates. The goals of this study are: (1) to expand these new standards so they can be utilized in populations of Mexican and Puerto Rican origin; and, (2) to produce more accurate and precise estimates of age at death for these populations with reduced error and subjectivity than currently possible using the traditional macroscopic assessment methods.

Data for this study consists of laser scans for both sides of the pubic symphysis from skeletal collections with known age at death housed at the Universidad Nacional Autónoma de Mexico, Institute of Forensic Science in Puerto Rico, and Pima County Office of the Medical Examiner's in Arizona. For each pubic symphysis, 3D scans were created using the NextEngine® 3D Desktop Scanner, 2020i. The resulting scans were aligned and fused in order to generate a multidimensional model of the pubic symphysis. The 3D coordinates representing the symphyseal surface were extracted from each scan and subjected to the Slice Algee-Hewitt (SAH) -Score method, the thin plate splines/bending energy-based method, and the ventral curvature method.[1-3] Multivariate regression models were used to combine the resulting measures and obtain the final age estimate for each individual.

Preliminary results of match-paired *t*-tests find no significant differences between known age at death and inferred age when utilizing a combination of all three methods and when both left and right sides were pooled, such that $0.03 \leq p \leq 0.71$. Furthermore, when left and right sides of the pubic symphysis were tested separately, non-significant results are produced: SAH+curvature for left, p=0.28; BE+curvature for left, p=0.80; BE+curvature for right, p=0.47. Bonferroni corrections were imposed on α=0.05 for multiple comparisons. Pearson correlations between true and inferred ages for all methods and side configurations appeared consistently high (r >0.91), indicating good agreement among values. Results do suggest a tendency, though not significant, to overestimate

known age notably with the SAH+curvature method, generating the greatest mean difference, 9.3 years, for the right side. This study has confirmed that objective and reliable age-at-death estimation can be obtained for populations of Mexican and Puerto Rican descent by the use of computational methods and 3D laser scans of the pubic symphysis.

A47 Recording Total Skeletal Completeness: Introducing a New Approach

Samantha K. Rowbotham, MA, Monash University, Dept of Forensic Medicine, 65 Kavanagh Street, Southbank, Victoria 3006, AUSTRALIA; Soren Blau, PhD, 65 Kavanagh Street, Southbank, Melbourne, Victoria 3146, AUSTRALIA; and Jacqueline Hislop-Jambrich, PhD, Toshiba Medical, 12-24 Talavera Road, North Ryde 2113, AUSTRALIA*

After attending this presentation, attendees will better understand a new standardized and objective method for recording skeletal completeness.

This presentation will impact the forensic science community by providing an improved method for recording total skeletal completeness in osteological analyses of adult individuals. This presentation will also illustrate the value, and provide an example of one possible application, of Computed Tomography (CT) volume-rendering techniques for forensic anthropological research.

Recording the preservation (condition and completeness) of human skeletal remains is the foundation of osteological analyses for forensic and archaeological skeletal material. Guidelines for the recording of skeletal preservation typically include a statement on the total skeletal completeness; that is, how much of the total skeleton is present for analysis. This component of skeletal preservation recording is essential as the quantity of the skeleton preserved determines the extent to which it is possible to develop a biological profile and provide an interpretation about skeletal trauma; however, current osteological methods for recording the total skeletal completeness are non-standardized and subjective. In order to provide practitioners with an objective and standardized means to accurately quantify the total skeletal completeness preserved in an adult skeleton, percentage values for each skeletal element have been established and can be applied to the skeletal remains of any adult individual.

Percentage values for each skeletal element were calculated by establishing the proportion of the volume of each bone relative to the total volume of a complete skeleton. The postmortem CT scan of a young adult male (undertaken with a 128-row helical CT, the SOMATOM® Definition Flash, as part of the Victorian Institue of Forensic Medicine's routine autopsy process) was used. Volume measurements for each skeletal bone and the complete skeleton were generated using Philips IntelliSpace Portal, V7, CT visualization software. The proportion of each skeletal element relative to the complete skeleton, and their subsequent conversion into percentage values, was calculated using basic descriptive statistics.

Percentage values ranged from 0.01% (select hand and foot bones) to 10.83% (cranium). A variety of mediums (visual, written, and an application designed for mobile operating system devices) are provided to ensure the user-friendly calculating of percentages.

Results of this study will provide an accurate and objective means of calculating total skeletal completeness; a component of skeletal preservation recording that is important in medicolegal contexts (to guide recovery operations and provide information about the deceased to their family) and in archaeological contexts (influence the outcomes of research).

Total Skeletal Completeness, Percentages, Volume Rendering

A48 A Study of Modern Commingled Human Remains From a Korean War Recovery Site — Gum Riverside, Junla Province

Nahyok Im, PhD, 250 Hyeon Chung-Ro, Dong Jak - Gu, Seoul 06984, SOUTH KOREA; Youngsoon Shin, MS*, Republic of Korea MND Agency for KIA Recovery & ID, 250, Hyeonchung-ro, Dongjak-gu, Seoul, SOUTH KOREA; Hae Joung Cho*, Makri in Hyunchungwon, Dongjack-gu, Seoul, SOUTH KOREA; Minho Cha, MS*, Republic of Korea MND Agency for KIA Recovery & ID, 250, Hyeonchung-ro, Dongjak-gu, Seoul, SOUTH KOREA; and Yu Ryang Jang, PhD*, 65 Hyeonchung-ro Donggak-dong, Donggak-gu, Seoul 156-080, SOUTH KOREA*

After attending this presentation, attendees will better understand two of the most commonly used methods in pair-matching and segregation of commingled remains and their effectiveness when applied to Korean samples.

This presentation will impact the forensic science community by providing results that compare and validate two methods — visual pair-matching and osteometric sorting — as well as demonstrating that the osteometric sorting method can be reliably used as a basic guideline in segregating commingled remains in situations such as mass disasters or archeological sites.

In a situation in which commingled remains are recovered from mass disasters or mass burial, segregating the remains is one of the most fundamental and crucial processes.[1]

The purpose of this study is to analyze the effectiveness of the two widely used methods in pair-matching and segregation of individual remains — visual analysis and osteometric sorting. In this study, samples were collected from the commingled remains recovered from a Korean War recovery site.

Of the 1,969 samples recovered from Gum Riverside in Junla Province, four skeletal elements (femur, tibia, innominate, and humerus) were chosen and the two pair-matching methods were separately applied. Using the visual analysis method, the samples were evaluated by looking at the similarities in bone morphology and taphonomy, and the osteometric sorting, a quantitative method, was used to find possible matches through a statistical evaluation of size similarities between homologs.[2-4] The matched homologs were then compared to DNA analysis of the samples in order to confirm the validity of the methods.

As a result, the concordance rate of the samples pair-matched using the visual pair-matching method to the DNA analysis ranged between 58% and 94%. Specifically, 94% (29/30) of the pair-matched samples were in concordance with the DNA testing result for femurs, 88% for tibias (14/16), 100% for innominates (5/5), and 58% for humeri (7/12).

Using the osteometric sorting method, the pair-matching concordance rate ranged from 83% to 97%; 97% for femurs (29/30), 94% for tibias (16/17), 100% for innominates (5/5), and 83% for humeri (10/12).

The result showed a relatively high concordance rate (94%~100%) for both methods when applied to the femur and tibia; however, the rate was comparatively low (58%~83%) when applied to the humerus. The result indicates that both pair-matching methods are reliable when applied to the femur, tibia and innominate, but not for the humerus; however, the low rate of successful pair-matching of the humerus could be due to the small sample size as well as the samples being highly fragmented, which limited the analysis using the visual and osteometric methods.

Although it is difficult to be conclusive due to the small sample size, the result for the innominate was noteworthy as it exhibited a 100% concordance rate despite its highly fragmented condition. It is hypothesized that distinctive features of the samples, such as sciatic notch and auricular surface, contributed to the result.

Despite a recent study suggesting that the osteometric pair-matching method is unreliable, the conclusion reached through the results from this study is that the quantitative method is adequately utilizable in segregating commingled remains in situations such as mass burial or archeological sites.[5] Also, this study demonstrated that one can expect a positive result even for highly fragmented samples, especially if the samples have distinct features that can be visually evaluated and distinguished. Thus, in sum, the osteometric sorting method has its value in pair-matching commingled remains and would be even more so through some adjustments and when used in combination with the visual pair-matching method.[6]

In this study, the equation of regression using the size of bones and the *t*-score for the comparison of adjoining bones at joints could not calculated because the sample size of the Korean remains collected from Gum Riverside

was not significant enough to apply the statistical method. Through further studies, the calculation of the equation of regression that is suitable for the Korean data by accumulating Korean samples is expected, along with the establishment of a pair-matching method that can be used in combination with the visual analysis method to effectively analyze and segregate commingled remains in various situations.

Pair-Matching, Comminged Remains, Osteometric Sorting

A49 The New Method of Implementing 3D Scanners and X-Rays on Commingled Remains Recovered From a Korean War Recovery Site

Yu Ryang Jang, PhD, 65 Hyeonchung-ro Donggak-dong, Donggak-gu, Seoul 156-080, SOUTH KOREA; Jung Min Lim, PhD, MAKRI, ROK, 65 Hyunchungro, Donggakdong, Donggakgu, Seoul, SOUTH KOREA; Jeung Sang Park, MA, MAKRI, ROK, 65 Hyunchungro, Donggakdong, Donggakgu, Seoul, SOUTH KOREA; and Na-Hyok Im, PhD, MAKRI, ROK, 65 Hyunchungro, Donggakdong, Donggakgu, Seoul, SOUTH KOREA*

After attending this presentation, attendees will better understand how to approach the new method of implementing 3D scanners and X-rays in the calculation of Minimum Number of Individuals (MNI) for commingled remains.

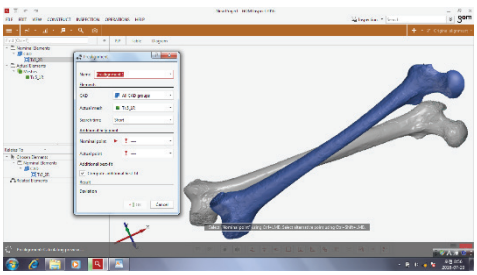
This presentation will impact the forensic science community by providing information on the challenges faced when calculating MNI for commingled remains in mass burial cases.

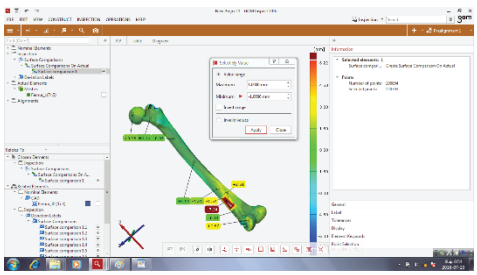
The pair-matching method has been a useful means of identifying each individual from commingled remains. Until this point, physical and metrical (osteometric sorting) analyses were commonly used for pair matching; however, both methods face certain limitations. As physical analysis is subjective in nature, results may differ depending on anthropologists' personal experiences. With metrical analysis, there may be difficulties in applying this method when the bones are either impaired or damaged.

This study will review the effectiveness of employing 3D scanners and X-ray images as part of pair matching to minimize the limitations faced by the more traditional methods. In this study, samples were collected by the Ministry of National Defense (MND) Agency for KIA Recovery and Identification (MAKRI) as a part of their mission to recover Korean War remains in Gum riverside in Junla province, Republic of Korea. The MNI calculation for the physical and metrical analyses of commingled remains recovered was 41 individuals; however, 49 individuals were identified through DNA analysis. The eight individuals who could not be matched using the traditional pair-matching methods were 3D scanned and X-rayed.

Once 3D scanning was completed, an analytic program was used to produce mirror images of the bone elements and compared: (1) to the same bone element of different individuals; (2) to the left and right bone elements of different individuals; and, (3) to the left and right bone elements of the same individual for the degree of superimposition, then deviation was calculated.

To compare the same bone element of different individuals through bone marrow cavity of extent and width, thickness of compact bone, and bone curvature and angle, the bone elements were X-rayed in anterior to posterior and lateral directions.





Through 3D scanning and X-ray analysis, five out of the eight individuals were pair matched, which could not be accomplished using only the physical and metrical analyses. Based on these results, it is possible to infer that X-ray and 3D scanners, when used in combination with the traditional methods such as physical or metrical analysis methods, are effective enough to enhance the accuracy from 84% to 94%. The mirroring technique of the 3D analysis method is especially effective in inferring or confirming the degree of superimposition on damaged or impaired bones, which cannot be seen by physical or metrical analysis methods. X-ray provides valuable information that cannot be gained by superficial examination as it allows for a comprehensive evaluation of internal structures of bone elements. Thus, using 3D scanners and X-ray with pair matching is highly recommended; however, it is necessary to collect additional samples in further studies to truly understand its effectiveness. In addition, the possibility of implementing Computed Tomography (CT) or Magnetic Resonance Imaging (MRI) in pair matching

commingled remains should also be considered.

This presentation will discuss the effectiveness of the use of 3D scanners and X-ray in pair matching commingled remains.

Commingled Remains, 3D, Mass Burial

A50 A Grading System to Assess the Sex and Parity Status for the Preauricular Sulcus: A Step Forward

Sarah E. Canty, BSc, Liverpool John Moores University, James Parsons Bldg, Byrom Street, Liverpool, Wiltshire L3 3AF, UNITED KINGDOM; Silvia Gonzalez, PhD, Liverpool John Moores University, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM; Constantine Eliopoulos, PhD, Liverpool John Moores Univ, School of Nat Science & Psych, James Parsons Bldg, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM; and Matteo Borrini, PhD*, Liverpool John Moores University, RCEAP-School of Natural Science & Psych, Byrom Street, Liverpool L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will better understand the sexual dimorphic variability of the preauricular sulcus in the human adult os coxae.

This presentation will impact the forensic science community by providing additional tests on a new grading system for the preauricular sulcus (p.s.) as a sexually dimorphic trait.

During the 68th AAFS Annual Scientific in Las Vegas, a new grading system for the p.s. to assess sex and parity status was presented. This scoring system provides grades from zero (no p.s. present) to four (large, well-defined p.s.) and was developed on two British Medieval populations. Even though the samples used were archaeological, the collections have been previously seriated (aged and sexed) by using multiple established methods and compared through inter-observer error with the estimations produced by other forensic anthropologists.

In the present research, the proposed scoring system was tested on a modern documented British collection. The samples (*n*=353) are from the St Bride's Church and curated through the Museum of London. For the entire collection, the sex (170 females; 183 males) and age at death of each individual was known. The parity status of 35 females was established by archive research and coffin plates data.

The results confirmed the findings of the previous study, exhibiting a significant difference in the occurrence rates of p.s. in males and females. A p.s. is present in 98% of females and not present in only 2%, while for males, p.s. is only present in 51.4% of cases and is absent in 48.6% of the samples. When the sulcus is detected in males, the grade is very low: 73% have grade one and 27% show grade two. No grade three or four sulcus have been found in males, supporting the hypothesis that the aspect and modifications related to these grades are reliable sexual dimorphic traits. The results also demonstrated that parity status had a significant correlation with the grades of the p.s. and an association with the highest grades (three and four) in the scale provided.

As an additional step forward in the analysis, the effect of pelvic shape on the p.s. morphology was observed. A selection of 68 pairs of coxae that was possible to anatomically articulate with the sacrum was made from the same documented collection. The diameters that describe both the greater and lesser pelvis as well as the measurements that describe the sacrum shape have been recorded with sliding callipers and analysed.

The results reveal that there is a significant correlation between some of the measurements and the morphology of the sulcus. In particular, the transverse diameter, the bispinous diameter in the pelvis, and the maximum sacral width seems to affect the development of a well-defined preauricular sulcus. An interesting finding indicates the direct correlation in females between the increasing of the transverse diameter and the increasing of the p.s. grade. This suggests the needs of future investigations on the link between the p.s. and the process of giving birth.

Considering that pelvic morphometric characteristics are related to both sex and parturition, this study suggests the validity of the new system proposed to describe the p.s. as a tool for the objective description of a trait that is not only a sex-indicator but also a possible parity marker.

With the new test performed on the preauricular sulcus grading system, this study demonstrates the reliability of this instrument as a useful tool for establishing a biological profile of unidentified skeletal remains.

Forensic Anthropology, Preauricular Sulcus, Sexual Dimorphism

A51 Biological Indicators of Aging and Their Application in Individualized Biological Anthropology

Ivana Kruzic, PhD, Rudjera Boskovica 33, Split 21000, CROATIA; Zeljana Basic, PhD, Rudjera Boskovica 33, Split 21000, CROATIA; Ivan Jerkovic, MSc, Rudera Boškovica 33, Split, CROATIA; Ozren Polašek, PhD, Šoltanska 2, Split, CROATIA; and Simun Andjelinovic, PhD, University of Split, Dept of Forensic Sciences, Rudera Boskovica, Split 21000, CROATIA*

After attending this presentation, attendees will better understand, and gain insight into, the application of biological indicators in age estimation of adult persons on skeletal remains and will become familiar with the limitations of anthropological age estimation techniques that could be expanded with a novel approach that uses biological indicators such as mineral bone density and mitochondrial DNA (mtDNA) for narrowing ranges for age estimation.

This presentation will impact the forensic science community by presenting a novel methodology of personalized biological anthropology that enables narrowing the intervals for age estimation on skeletal remains of adults.

Besides chronological age, biological indicators of aging such as telomeres or GlycanAge Index are often employed to enlighten the aging dynamics. Additionally, an important aging indicator is mineral bone density. The results of this research will be used for the development of this novel approach — personalized biological anthropology, which will use both morphological age indicators on skeletal and mitochondrial haplogroup data in order to more precisely estimate age. In the case of the positive correlation of mtDNA haplogroups and other aging indicators, the biological anthropologist could, after estimating age with traditional methods, use the results of the mtDNA analysis to additionally narrow down the estimated age range. One of the main aggravating factors of the reconstruction of person's biological profile is the fact that anthropologists estimate the age in a five-year range (often even wider) using morphological skeletal indicators. Thus, the main goal of this study is to investigate the correlation of mitochondrial genetic markers with mineral bone density and biological aging indicators.

This research was conducted on a sample that consisted of 969 adults from the island of Korčula, Croatia, as a part of the 10,001 Dalmatians project. Data used in research were basic data (such as age and sex) as well as data about behavioral risk factors previously known to be associated with mineral bone density, which were collected by questionnaire. Mineral bone density was measured on calcanei using a densitometry method with a mobile Dual-Energy-X-ray Absorptiometry (DEXA) Calcsan device. Measurements were conducted on standard bone sites to estimate the density of cortical and trabecular bone. Three additional data acquisition methods were employed: genotpisation, telomere length measuring, and the analysis of N-glycans. Genotipisation was conducted on a venous blood sample. After an isolation using a commercial QIAGEN® kit, the samples were genotyped using the Illumina® CNV370 chip. Telomere length was measured on amplified DNA by Polymerase Chain Reaction (PCR) and the relative ratio of telomere repeats to a single-copy gene was compared with a reference sample. The glycans from plasma were measured using Hydrophilic Interaction Chromatography (HILIC). Glycan analysis was based on solubility measured in glucose units and obtained data were compared to the reference values in Glyco-Base (available on: http://glycobase.nibrt.ie) due to structure determination. Glycans were separated by the number of sialic acid molecules using weak anion-exchange high-pressure liquid chromatography. The analysis was performed using a Prozyme GlycoSep™ C 75mm x 7.5mm column. Linear regression was employed to simultaneously examine the effect of multiple variables and their interaction in the same analytical model.

The results of the mitochondrial haplogroup analysis revealed a total of 120 different haplotypes that were afterward classified into seven haplogroups to facilitate computation. Association of mtDNA haplogroups and target outcomes was not found for the majority of variables, except for the mineral bone density that showed a statistically significant association. Results revealed that persons with haplogroup H have significantly higher mineral bone density values compared to the average, while people with haplogroup HV have significantly lower bone density. Overall, it is shown that there is statistically significant association between mtDNA haplogroups and mineral bone density (additionally controlled for the known factors that influence the mineral bone density — lifestyle, calcium intake, physical activity and sun exposure). On the other hand, a significant association of mtDNA with telomere shortening, N-glycan profile, and the association of the Single Nucleotide Polymorphisms (SNPs) with the named

markers of aging was not found.

Mineral bone density, considered as a valuable method for estimation of age at death on skeletal remains, stands out as a valuable indicator of the biological age of an individual, but also indicates the great potential for the application of personalized biological anthropology. The importance of mineral bone density and mtDNA analysis is even greater because, unlike glycans and telomere analysis, those methods can also be applied to dry bone.

Personalized Anthropology, mtDNA, Mineral Bone Density

A52 The Use of the Palate for Ancestry and Sex Estimation

Natalie L. Andras, Mercyhurst University, 501 E 38th Street, Erie, PA 16504; and Alexandra R. Klales, PhD, Washburn University, Forensic Anthropology Program, Soc & Anthro Dept, 1700 SW College Avenue, HLRC#218, Topeka, KS 66621*

After attending this presentation, attendees will better understand the use of the palate in the estimation of ancestry and sex for adult individuals.

This presentation will impact the forensic science community by providing insight into a method for ancestry and sex estimation in adult individuals using metrics of the palate. In addition, this presentation demonstrates the need for further research into the use of palate shape and depth for sex and ancestry estimation.

The estimation of ancestry remains the most difficult parameter of the biological profile and, due to the changing demographic structure within the United States, ancestry estimation is becoming increasingly difficult. Until recently, utilization of the palate for ancestry estimation focused on non-metric traits of palate shape and the dentition itself. In 2015, Maier and colleagues developed three landmarks to measure palate depth and found significant ancestry and sex differences.[1] The goal of the present research is to metrically examine size and shape differences between four groups using Maier et al.'s palate landmarks: (1) Black Males (BM); Black Females (BF); (2) White Males (WM); and, (4) White Females (WF).

A total of 519 dentulous adult individuals of known ancestry, sex, and age were sampled from the Hamann-Todd Osteological Collection housed at the Cleveland Museum of Natural History: 259 Blacks (130 females and 129 males) and 260 Whites (130 females and 130 males). Using a digitizer, one new coordinate was collected, the midpoint between the Central Incisors (CI), as well as three additional coordinates in accordance with Maier et al.: (1) the most posterior aspect of the Incisive Foramen (IF); (2) the Intersection of the median and transverse palatine Sutures (IS); and, (3) the most posterior aspect of the Palate/Posterior (PP) nasal spine.[1] Interlandmark Distances (ILDs) were calculated and subjected to jackknifed Linear Discriminant Function Analysis (LDFA) to explore size differences and classification accuracy between ancestry/sex groups. Next, Geometric Morphometric Analyses (GMA) were conducted to explore shape differences. Classification accuracy was again assessed using LDFA and the Procrustes Coordinates (PCoords) generated from the GMA, as well as the Principal Components (PCs) from the principal component analysis.

Using LDFA of the ILDs, correct classification among the four groups was 50.5%. With the exception of BF-WF (p=0.0106) and BF-WM (p=0.1528), the Mahalanobis Distance (D^2) between the groups was significant at the p<0.01 level. Correct classification between the two ancestral groups (pooled sexes) was 62.8% and between the sexes (pooled ancestry) was 72.3%. Blacks were significantly larger (p<0.05) than Whites for three ILDs except IF-PP and CI-IF, which were not significantly different between ancestry groups, and IS-PP, which was larger in Whites. Males were significantly larger (p<0.05) than females for all ILDs except CI-IF and IS-PP, which were not significantly different between the sexes. Classification between the four groups using LDFA of the PCoords was 52.79%, slightly higher than, but similar to, the size analysis. LDFA classification between the two ancestral groups was 72.5% (pooled sexes) and between the sexes was 82.3% (pooled ancestry). T he first six PCs explained 99.9% of the variance. Using LDFA and these six PCs produced 52.0% classification accuracy between the four ancestry/sex groups. Sex classification was 69.0% and ancestry classification was 62.2% using PCs one to six.

The results of this study show statistically significant differences among the palate of the four reference groups. Classification accuracy for the four groups was highest with the shape analyses; however, the results from the size analysis were comparable. Classification by sex and ancestry independently was highest using LDFA of the Procrustes coordinates. The results from this study are similar to the Maier et al. study examining palate depth in which significant differences existed between Whites and Blacks and between males and females. The combination of size and shape analyses from this preliminary study with the measurement of palate depth, as conducted by Maier et al., has the potential to produce even higher classification accuracies.

DiGangi, PhD*, Department of Anthropology, Binghamton University, PO Box 6000, Binghamton, NY 13902*

After attending this presentation, attendees will understand the ways in which subaerial weathering research can enhance estimates of the Postmortem Interval (PMI) in forensic anthropological contexts, particularly in the region of Algiers, Algeria.

This presentation will impact the forensic science community by providing new subaerial weathering data from the Mediterranean region of North Africa, specifically in the region of Algiers, Algeria.

Taphonomy is the study of all of the processes that occur after death until the recovery of an organism and is critical to the reconstruction of forensic anthropological contexts. The study of taphonomic effects on bones, particularly those related to subaerial weathering, sometimes allows for the estimation of the PMI in medicolegal contexts. Scholars have demonstrated that numerous variables, including solar radiation, heat, moisture, and freeze/thaw cycles, affect human skeletal remains over time.[1] Moreover, researchers have developed six Weathering Stages (WS) to describe the degree and extent of osseous changes linked to subaerial weathering.[1] While several studies representing diverse geographic contexts have been undertaken to document subaerial weathering, there have been no studies related to this topic in Algeria, despite the high frequency of forensic casework recovered from outdoor surface contexts there, particularly in urban zones located along the Mediterranean coastline. This study presents WS data generated from an actualistic study conducted in the Algerian capital of Algiers, located in the country's northernmost region along the Mediterranean coast. Algiers is characterized by a mild climate with moderate seasonality (Köppen climate classification (Csa). The mean annual temperature is approximately 18.3°C (65°F) and there is approximately 600mm (24 in) of precipitation annually.

The experiment consisted of depositing fresh, defleshed and fleshed ovine (*Ovis aries)* and bovine (*Bos taurus*) bones on the surface of the grounds of the Institut National de Criminalistique et de Criminologie de la Gendarmerie Nationale Algérienne (INCC/GN) (the National Institute of Criminalistics and Criminology of the National Gendarmerie) in Algiers. All skeletal elements were deposited in June 2014 and observed over a period of two years. Corresponding WS stages were recorded visually and documented with photography.

Regarding the defleshed skeletal elements, WS 0-2 were observed during the two-year observation period. Bones remained in WS 0 for nearly a year, with WS 1 reached after 11 months. WS 2 was reached after 23 months. These results are similar to other regions of the world where WS 1 and WS 2 have been observed 1-2 years after death. For example, on the African continent, scholars observed WS 1 two years after death in Zaire.[2] WS 2 has been observed beginning after two years in Kenya.[3]

Though these results provide some preliminary data on subaerial weathering in Algiers, this research is ongoing. There are plans to continue this study to better understand when and if WS 3-5 appear. Moreover, this study will hopefully be expanded to the southern region of Algeria to document differences in subaerial weathering caused by exposure to the Sahara Desert. Ultimately, this study will contribute to refining PMI estimates for Algerian forensic anthropological contexts.

A54 Metric Pair-Matching of Calcanei in Commingled Remains Cases: A Case Study From South Africa

Kayla L. Orr, BSc, Saint Mary's University, 923 Robie Street, Halifax, NS B3H 3C3, CANADA; Tanya R. Peckmann, PhD, Saint Mary's University, Dept of Anthropology, 923 Robie Street, Halifax, NS B3H 3C3, CANADA; Susan B. Meek, PhD, Saint Mary's University, Biology Dept, 923 Robie Street, Halifax, NS B3H 3C3, CANADA; and Claudia Garrido Varas, MSc, 19 av de la paix, Geneva 1202, SWITZERLAND*

The goal of this presentation is to highlight the use of osteometric sorting in commingled remains cases. After attending this presentation, attendees will understand the benefits of using metric analysis to assist in pair-matching elements before applying visual assessment.

This presentation will impact the forensic science community by expanding methods for resolving commingled remains cases, ensuring that the individuals are more complete and reducing the potential for mismatched elements. By utilizing osteometric sorting, the number of elements requiring visual pair-matching decreases; this is beneficial for improving time and costs for analyses in the field.[1]

Sorting commingled remains in order to re-associate skeletal elements of the individual has been investigated using both morphological and metric methods. Recent research has been conducted utilizing metric assessment to remove any subjectivity and increase the accuracy and repeatability. Pair matching a left element to its corresponding right element has traditionally been based on visual assessment and relies largely on the experience of the observer.[1-3] Pair matching using quantitative and statistical methods is known as osteometric sorting; this method relies on the ability to "formally characterize normal size and shape relationships" among skeletal elements.[1,2] Osteometric sorting of skeletal remains is possible for a number of long bones (e.g., the femur and humerus) and some smaller bones (e.g., metacarpals). Previous methods utilized for predicting element pairs has reduced the number of potential pairs requiring visual assessment.[1-3]

Research involving the pair matching of tarsal bones is scarce. This study tested the ability to pair match the calcaneus, similarly to Thomas' and colleagues' method, based on metric analysis and utilization of a statistic (M).3 The objectives were: (1) to investigate bilateral asymmetry of the left and right calcanei in the South African colored population for pairing unmatched human remains; (2) to investigate the degree of asymmetry between left and right calcanei within each individual; and, (3) to use the M-statistic to assess applicability for pair matching left and right calcanei.

In this experiment, left and right calcanei from 70 males and 70 females were measured (*N*=280) from the South African colored population group. Two additional re-samplings of the calcanei from 5 males and 5 females (*N*=20) were measured for inter- and intra-observer error analyses. Six measurements of the left and right calcaneus were assessed and the M statistics were calculated for each pair of measurements. The maximum value of M, and 90th and 95th percentiles of M for each variable, were tabulated for use in assessing possible pairs. When attempting to pair match calcanei, the value of M for the possible pair is compared with the tabulated values; if the value of M is greater than the 90th or 95th percentile of M, then the null hypothesis can be rejected. The values of M for males and females exhibited no statistically significant difference between the sexes, therefore pooled M statistics can be utilized to pair match. A test application was performed in which measurements of a left calcaneus were compared to a sample of 140 right calcanei (including the homolog). Values of M were compared to the 90th percentile of M, 95th percentile of M, and the maximum value of M; this resulted in a reduction in the number of potential pairs requiring visual pair matching up to 90%, 93%, and 74%, respectively. Further analyses will compare this data to other population groups and the use of pooled values of M will be explored. These results may have the potential to assist in the re-association of individuals from commingled remains cases, no matter the population group nor the level of admixture of the sample.

Forensic Anthropology, Osteometric Sorting, Commingled Remains

A55 A Validation Study of the Mandibular Canine Index Method of Sexual Assesment Using Two American Populations

Samantha W. Coberly, MS, 1530 NW 4th Avenue, Apt 19, Gainesville, FL 32603*

After attending this presentation, attendees will be informed concerning a dental sexing method developed from a South Indian population and its application to American populations. Attendees will understand that further investigation is needed in the application of this method.

This presentation will impact the forensic science community by acknowledging the idea that not all sexing techniques are useful for all populations, yet specific techniques are still applied too broadly. This presentation will present a validation study of a sexing technique on an American population in which the technique has not previously been implemented.

The analysis of biological sex is important to the forensic community during any investigation of an unknown decedent. Due to the fact that human remains and especially skeletal remains may be incomplete, it is important to create, and also test, sex assessment methods on as many skeletal elements as possible in case the more traditional methods cannot be used.

In 1989, Rao and colleagues studied canine measurements in South Indian male and female populations.[1] Using the data they gathered, the Mandibular Canine Index (MCI) was created: the mesio-distal length of the mandibular canine crown, which was then divided by the width of the mandibular canine arch length (that is, the distance between the left and right canine cusp tips measured at the midline). Males were found to have a significantly higher mandibular canine index than females.[1] Since the Rao article was published; more studies have been conducted in the South Asian populations. Some of these studies have come to the same conclusion as Rao and colleagues, while others have found no significance between males and females using this method.[2] Issues have been found with the mandibular canine index technique, including the fact that teeth that are not in correct occlusion can affect the results.[3] Further research on populations from different regions may clarify the benefits and issues of this method.

The purpose of this current study was to test the effectiveness of the mandibular canine index for sex discrimination in modern North American White and Black populations. Twenty-one individuals from the C.A. Pound Human Identification Laboratory archived collection were measured in addition to 24 individuals from the Wichita State University donated collection. The measured sample consists of 23 females and 22 males. The two ancestry groups were pooled due to the lack of significant differences between the two groups (p value of MCI = .64 for females and .34 for males). The individuals were chosen based on having a known identity and having full dentition that was in correct occlusion. Individuals with dental pathologies or missing teeth were excluded. The maximum mesio-distal lengths of both mandibular canines and the canine arch width were measured using sliding calipers. The MCI was calculated using the left canine. A two sample t-test was completed to determine if there were any significant differences between the male and female canine measurements.

On average, females had significantly smaller canine mesio-distal lengths than males (p = .04 for right and .002 for left). Female right canines averaged 6.68mm compared to the male canines that averaged 7.05mm. Left canines were slightly larger than right canines. Female left canines were 6.7mm while the men's were 7.18mm. Males also had large canine arch widths, with an average of 29.62mm to the females 27.32mm (p=.01)

The mandibular canine index showed no significant differences between males and females. Using either the right or left canine in the MCI ratio leads to females having a slightly larger mean of .25 compared to the males .24 (p=.48 for right and p=.83 for left.)

Due to the small sample size, only tentative conclusions can be made. From the above results it appears that the Mandibular Canine Index may not be an adequate tool for sex analysis. The mesio- distal lengths and the canine arch widths may be better tools. Further testing is needed.

A56 Identity by the Numbers: Cancerous Lesions and Likelihood Ratios

William D. Cawley, BA, University of Tennessee, 1611 Fremont Place, Knoxville, TN 37917; and Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will better understand how the frequency of skeletal cancerous lesions can contribute to a correct identification using a likelihood ratio framework drawn from Bayesian theory.

This presentation will impact the forensic science community by further demonstrating the utility of likelihood ratios when identifying an unknown individual. Additionally, the likelihood ratio generated in this study can be used multiplicatively with likelihood ratios derived from other parameters of the biological profile, thereby increasing the probability of a correct identification.[1]

The use of Bayesian theory has been gaining popularity within the forensic anthropology community for its ability to model the way in which decisions are made based upon varying levels of confidence. Through the evaluation of evidence in court, participants unknowingly utilize Bayesian reasoning when determining the weight of evidence while considering the legal proceedings and their personal biases.[1] As prior probabilities representing attitudes and effects of evidence on the jury's decision cannot be determined realistically, it is impossible to create posterior probabilities representing the weight of anthropological evidence. Therefore, this study instead focuses on the generation of a likelihood ratio representing the strength of macroscopic skeletal cancer when making an identification from a closed population of known antemortem records.

This project consists of skeletal analysis of a sample of adult individuals from the Bass Donated Skeletal Collection (BDSC) who self-reported as having cancer at the time of death or having had a previous cancer diagnosis (n=337). A preliminary randomized sample of these individuals (n=75) was initially analyzed for the presence/absence of macroscopic lesions and is the focus of this study. The BDSC was then used to represent the "population at large" (total n=1,432) from which the likelihood ratio numerator was drawn, this equation having been modeled using Steadman et al.'s likelihood ratio for skeletal pathology.[1]

Data collection involved physical examination of all skeletal elements for signs of primary bone cancer or secondary metastases. Of the 75 individuals in the preliminary sample, 16 exhibited macroscopic cancerous lesions (21.3%). Assuming this frequency remains constant to the subset of all individuals who reported having or having had cancer, 72 out of the 337 would be expected to show visible lesions in the skeleton. Thus, the expected likelihood ratio of visible cancerous lesions from the BDSC is 1,432/72, or 19.9. These results indicate that if a possible identification of an individual within a closed population matches the BDSC demographic, has a medical history indicative of cancer, and exhibits visible cancerous lesions, then it is 19.9 times more likely that they have been correctly identified than not. This preliminary likelihood ratio only represents a single category of pathology and is intended for combination via the product rule with other independent likelihood ratios representing additional parameters of the biological profile.

Although this study is limited by scope and composition of the BDSC (primarily middle-aged to elderly individuals), this presentation provides a further proof of concept for the generation of likelihood ratios representing pathological conditions and how they can be used to influence the quantitative probability of making a correct identification, even if DNA evidence is not available.

Forensic Anthropology, Identification, Cancer

A57 The Application and Accuracy of 3D Surface-Scanned Postcranial Bones

Victoria N. Harrington, MSc, Louisiana State University, 227 Howe-Russell-Kniffen Geoscience Complex, Baton Rouge, LA 70803; and Heather McKillop, PhD, Louisiana State University, 227 Howe-Russell-Kniffen Geoscience Complex, Baton Rouge, LA 70803*

The goal of this presentation is to provide attendees with an understanding of the complexity of 3D surface scanning of human remains, the principles of osteological scanning methods, the necessary considerations for successful scanning, and the current applications and limitations of a mid-range surface scanner.

This presentation will impact the forensic science community by highlighting current research assumptions and areas of necessary testing and by addressing the difficulties of osteology replication via surface scanning using the NextEngine®, a popular and economical tabletop scanner.

3D scanning provides forensic anthropologists with permanent records of human remains that can be shared globally and analyzed in innovative ways on 3D platforms with 3D tools. To utilize this growing technology in a scientifically meaningful way, set standards need to be implemented.

The objective of this research is to determine whether standardized surface scanning methods can accurately record skeletal characteristics for use in display, teaching, or research applications. Five categories of skeletal traits were selected: (1) gross morphology; (2) rugosity; (3) non-metric variation; (4) pathology; and, (5) trauma. These aspects were selected because of their effect on analyzing age, sex, and health. Parameters set to evaluate the scanning success for this study required 100% similarity in all categories to be used in research, 75% similarity to be used in teaching laboratories, and a 50% similarity to be used in display. The postcranial bones selected for this sample were from the ancient Maya trading site Moho Cay, Belize (AD 600-800), which was situated at the mouth of the Belize River. Although well-preserved, the human remains excavated from Moho Cay are fragile due to cyclic wet and dry seasons.

3D surface scanning the remains created a durable record of the Moho Cay Maya. Bones from nine adult males were selected for this study, including: (1) the sternal end of an unnumbered left rib; (2) a left ulna; (3) a lumbar vertebra; (4) a left clavicle; (5) a right scapula; (6-7) a left and right radius; and, (8-9) a left and right humerus. The selection included large, medium, and small sizes and complex and simple geometric shapes. All of the selected bones could be evaluated for rugosity, pathology, and trauma.

Scanning was carried out in the Louisiana State University (LSU) Digital Imaging and Visualization in Archaeology (DIVA) Lab. A trial scan was performed first, which began at the lowest division (lowest number of individual laser scans) and then increased in number of divisions until the complete geometry of the trial bone was captured. The method was then applied to all nine postcranial bones.

The bones and the 3D digital scans were separately evaluated according to the five categories of gross morphology, rugosity, non-metric variation, pathology, and trauma. Categorically, rugosity was the only trait with a 100% similarity. Gross morphology, non-metric variation, and trauma showed mid-range success but did not rate above 90% similarity. Pathology was the lowest categorical similarity, rating at only 11%. Using the parameters of similarity set up for this study, all of the 3D scanned bones could be used in display, approximately 50% of the bones could be used in teaching, and none of the digitized bones were precise enough to be used in research. Suggestions for improving precision in 3D surface scanning of skeletal material are discussed, including increasing the number of individual laser scans (rotations), increasing the point density for scanning, and adding macro-scans of bone features.

3D Scanning, Osteology, Digital

A58 An Exploration of the Variation in the Sternal Rib Ends of Infants

Julia R. Prince-Buitenhuys, MA, University of Notre Dame, Dept of Anthropology, 611 Flanner Hall, Notre Dame, IN 46556; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054; Sharon M. Derrick, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand the gross morphological variation of the developing human rib, in particular at the Costochondral Junction (CCJ) of infants up to one year of age.

This presentation will impact the forensic science community by providing insight into sternal rib morphological variation for infants between 0 and 12 months of age in order to improve the accuracy of fracture identification on the costal surface of the CCJ using macroscopic analysis.

While multiple studies have looked at fracture patterns in infants, little research has been conducted focusing on the topography of the anterior rib at the CCJ. Remote fractures at this location are difficult to identify due to the lack of data on morphological variation during development in normal infant ribs. This study examines the gross morphology of infant rib costal surface at the CCJ in order to establish what features are normal, likely the result of human development, and what may result from other factors, such as remote trauma and possibly pathological changes.

To address this goal, this study reviewed a total of 73 sternal rib ends from 39 individual cases ranging from the ages 0 to 12 months old at the Harris County Institute of Forensic Sciences (HCIFS). All cases but one received Cardiopulmonary Resuscitation (CPR). Case data on age and whether or not remote trauma was observed elsewhere on the skeleton was collected from the Infant Injury Database housed at the HCIFS. Traits on the costal face observed included pits, crevices, and bony spicules. Pits were defined as areas on the bone surface where there were holes or depressions with distinct, relatively sharp edges. Crevices were defined as areas on the costal surface where the bone folds over or into itself. Bony spicules were defined as outgrowths of bone on the costal face that were texturally distinct from the rest of the surface that disrupted the topography and protruded at sharp angles. All characteristics were scored according to presence or absence. Additionally, the number of pits present on the costal surface was tallied.

Pits were found on 57.5% of the ribs. The majority of ribs that had pits had more than one pit present on the surface (43.8% of the total cases). Most pits were found on ribs with ages of 0 to 3 months (76.2%). The correlation between age and the presence or absence of pits approached significance (X^2=16.479, *d.f.*=10, p=0.087); however, there was no correlation between presence of pits and the presence of remote trauma on the skeleton (X^2=0.190, *d.f.*=1, p=0.663). Crevices were found on only 37.0% of ribs. The presence of crevices was not correlated with age (X^2=14.174, *d.f.*=10, p=0.165). Crevice presence also did not correlate with the presence of remote trauma on the skeleton (X^2=0.220, *d.f.*=1, p=0.639). Finally, bone spicules were observed in 28.8% of the cases. The presence of bone spicules was also not correlated with age (X^2=12.157, *d.f.*=10, p=0.275) or with remote trauma on the skeleton (X^2=0.271, *d.f.*=1, p=0.602).

The results suggest that the presence of pits, crevices, and bone spicules are likely part of normal human developmental variation for this age group. The large amount of gross morphological variation observed on the costal face may limit the ability to diagnose subtle remote fractures or fracture healing on the costal surface of the CCJ macroscopically. This study therefore recommends the use of caution in diagnosing subtle remote fractures at the costal surface of the CCJ using macroscopic analysis based on these variants in topography when lacking other definitive indicators of trauma.

Infant Osteology, Rib Morphology, Trauma Analysis

A59 Reciprocating Saws as Tools of Dismemberment

Jacqueline M. Berger, Boston University School of Medicine, 90 Saint Mary's Street, BN #7, Boston, MA 02215; James Pokines, PhD, Boston University School of Medicine, Dept of Anatomy & Neurobiology, 72 E Concord Street, L1004, Boston, MA 02118; and Tara L. Moore, PhD, 700 Albany Street, W701, Boston, MA 02118*

After attending this presentation, attendees will be familiar with class characteristics of sharp force trauma caused by reciprocating saws, specifically those characteristics most affected by variations in blade type. The results of qualitative analysis of sharp force trauma inflicted by a reciprocating saw with interchangeable blades will be presented.

This presentation will impact the forensic science community by demonstrating the effects of reciprocating saws, which may be used in cases of dismemberment. This presentation will add to previous research by broadening the understanding of a different type of mechanical saw and its effects on bone.

The analysis of sharp force trauma characteristics to bone is undertaken to determine the class of implement used to inflict the trauma. Specific features of kerfs vary based upon saw blade properties, including the morphology of the blade teeth, how the saw is powered, and how it is wielded in reference to the bone. The present study focuses on the characteristics created by reciprocating saws, which previously have not been investigated in detail. The hypothesis tested is that reciprocating saws have unique class characteristics that can be used to differentiate them from other classes of saws, and that unique blade configurations used on reciprocating saws can be differentiated from each other.

Six saw blades were used in the study: five types of reciprocating saw blade with varying numbers of teeth-per-inch and one hacksaw blade for comparison with a common hand-powered saw. Partially fleshed hind and forelimbs of white-tailed deer (*Odocoileus virginianus*) were utilized as a proxy for human remains. A minimum of ten complete kerfs and two false-start kerfs were made using each saw blade on the remains. In addition, three partially fleshed cervical vertebrae segments of white-tailed deer were sawn a variable number of times by the reciprocating blades of the lowest and highest teeth-per-inch, as well as the hacksaw blade. Following sawing, the remains were further defleshed using scalpels, macerated, dried, and then placed in a dermestid colony to remove any residual soft tissue.

The remains were examined macroscopically and microscopically for a suite of class characteristics as denoted in Symes and Symes et al.[1,2] Features examined include: kerf floor shape, minimum kerf width, blade drift in kerf, cut surface drift, exit chipping, cut consistency, tooth imprint, entry flare, kerf flare, bone islands, entrance shaving, pull-out striae, energy transfer, harmonics, and striation regularity/visibility. The features were described qualitatively and/or scored as present/absent, with the exception of minimum kerf width, which was measured using digital calipers.

Qualitative analysis identified several key characteristics that varied based upon blade type and power source: size and location of exit chipping, cut surface drift, striation regularity/visibility, and energy transfer. Kerfs created by the hacksaw blade were readily differentiated from those made by the reciprocating saw blades. Hacksaw kerfs had minimal exit chipping and little cut surface drift, demonstrating a consistent blade path. The kerf walls were deeply etched, with readily visible striae that varied in regularity throughout the sawing event. The kerfs did not show any evidence of energy transfer (i.e., polishing of the cut surface).

The reciprocating saw kerfs varied based upon blade type but overall displayed lesser blade control and less visible kerf wall features. Kerfs showed relatively larger exit chipping and across a greater degree of the kerf edge. Chipping varied in size based on the Teeth Per Inch (TPI) of the blade but was found both externally and within the medullary cavity of the element. Interior exit chipping was not observed in the hacksawed bones. The reciprocating saw kerfs also displayed cut surface drift, as the path of the blade was not consistent. The striae were irregular and decreased in visibility with lower TPI blades. The kerf walls were highly polished, demonstrating extensive energy transfer.

In conclusion, while the degree of expression of these characteristics varied based upon blade, reciprocating blades can be confidently differentiated from hand saws. Furthermore, this research provides data regarding varied kerf characteristics for different reciprocating blades.

A60 Assessing the Accuracy of Historical Associations in a Commingled Assemblage

Carrie A. Brown, PhD, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Bldg 301, Offutt AFB, NE 68113; Carrie B. LeGarde, MA, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt AFB, NE 68113; Franklin E. Damann, PhD, DPAA CIL, 106 Peacekeeper Drive, Offutt AFB, NE 68113; and John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will understand the complexities associated with massively commingled historical assemblages of human remains.

This presentation will impact the forensic science community by identifying the extent of commingling that resulted from the application of legacy data and methods and how the Defense POW/MIA Accounting Agency (DPAA) laboratory is developing new strategies for resolving this issue.

Commingled assemblages present specific challenges for identification. In order for the medicolegal community to render individual identifications, remains must be segregated from the assemblage by medicolegal authorities into discrete units, representative of a single missing person. The complexity in achieving individual identifications from commingled settings is driven by the number of fatalities, the nature of the incident, and myriad postmortem processes that affect the provenience of recovered remains.

The commingled remains of the U.S.S. *Oklahoma* are believed to represent 388 individuals. These remains were recovered from the day following the attack on Pearl Harbor to May 10, 1944. After initial burial in two cemeteries on the island of Oahu, HI, the remains were disinterred in 1947 and attempts at individual identifications were made. Two years later, without successful individual identification for the majority of the remains, the American Graves Registration Service (AGRS) decided to consolidate the remains for a single group burial, and further commingled the remains by placing "like" elements together in caskets. When the group burial recommendation was denied by the United States Army Quartermaster Corps, the parent agency with oversight of the AGRS, an attempt was made to segregate the remains into individuals using articulation, morphology, age, color, texture, and/or proportion. Failing to segregate the remains adequately for identification, they were all reburied as unknowns, but this time individually divided into "bundles" of the most parsimonious associations.

Based on historical documentation, it is assumed that placement of skeletal elements in a single bundle was based on the belief that these elements represented a single individual. To test the accuracy of historical pair matches and associations, and to better understand the extent and patterning of commingling, a sample of 25 "paired" humeri and 28 "paired" tibiae were examined; followed by an assessment of 47 historical associations of upper (humerus) to lower (tibia) long bones. Only those complete or nearly complete humeri and tibiae that were placed together in a bundle and for which there is currently a mitochondrial DNA (mtDNA) sequence available were considered in this research. Mt DNA sequences were used to confirm or refute a potential pair match.

Of the 25 historically paired humeri in the test sample, 11 (44%) pairs were correctly determined and 13 (56%) pairs were incorrectly matched. For the 28 pairs of tibiae, 13 (46%) were correctly paired, and 15 (54%) were incorrectly paired. Comparing the association of humeri and tibiae within a single bundle, 3 (6%) were correctly associated to the same individual based on mtDNA sequence, while 44 (94%) were incorrectly associated. The total number of humeri and tibiae inventoried from segregated bundles are: left humeri, n=278; right humeri, n=282; left tibiae, n=296; and right tibiae n=304.

Testing the legacy assumptions provides insight to the extent of the problem to be addressed by the DPAA Laboratory today. If initial associations proved correct more often than chance, then more weight would be placed on the legacy association than not. As a result of this initial assessment, the bundles of most parsimonious associations made in 1949 appear to be better than chance alone, but there is enough error to warrant subsequent comparisons across the entire assemblage. Furthermore, it should be noted that correct associations of nearly 50% for pair matching, given the number of possible pairwise comparisons to be made with around 300 elements from each side, may represent a best-case scenario for pair matching in a historical sense.

These data indicate legacy pair matches and associations based on historical methods must be reexamined, and they highlight the need for incorporating osteometric and DNA data into the segregation process, particularly in large-scale commingling cases such as the U.S.S. *Oklahoma*. Further research is being conducted to incorporate

all available data types that will not only permit sorting and data-filtering capabilities, but will also permit front-end applications for applying algorithms to execute the complex computations required to cluster 10,000 skeletal elements into nearly 400 individuals.

Commingling, Historical Pair Matches, U.S.S. Oklahoma

A61 An Age-Based Approach to Establishing Minimum Number of Individuals (MNI) in Commingled Juvenile Skeletal Material

Maria L. Cox, BA, California State University, Chico, 400 W 1st Street, Chico, CA 95929; and Valerie Sgheiza, BS, California State University, Chico, 400 W 1st Street, Chico, CA 95929*

After attending this presentation, attendees will be informed of a step-by-step approach to constructing an age-based MNI from durable age-informative elements. Attendees will understand the situations in which the application of the method is warranted, as well as any limitations inherent in this approach.

This presentation will impact the forensic science community by providing an additional tool for assessing MNI in commingled assemblages, particularly in situations such as mass graves or mass disasters in which there may be an unknown number of young individuals of varying ages and states of skeletal preservation and recovery.

The goal of this presentation is to describe a systematic, replicable, and defensible approach to computing an age-informed MNI from commingled assemblages containing a large proportion of juvenile remains. This presentation will end with two case studies that demonstrate how this approach can provide a more accurate picture of burial demographics.

Incorporating age information into MNI is a common strategy for reducing the downward bias inherent to this estimator.[1] Such an approach is especially helpful with juvenile remains, as age estimation is more precise for younger individuals, but elements are more fragile and poor preservation may inhibit other approaches. The method presented here was developed during the analysis of two large archaeological burial features from the Lower Illinois River Valley, Helton 20-36 and Carter 2-15; however, this method is structured to be applicable and replicable in diverse situations, including modern mass graves or fatalities.

The goals of this method are replicability, utility in analyzing assemblages with poor preservation or recovery, flexible age categorization, and reduction of the downward bias of the traditional max(L, R) method of MNI calculation in which the MNI is computed as the largest number of a single element from the same side of the body.[2] The resulting procedure differs from many other age-based MNI approaches in that it focuses primarily on the dentition and uses flexible rather than fixed age categories. This approach could theoretically be useful for practitioners in legal settings as it produces a well-documented and supported MNI that can be presented in a way easily understood by laypeople.

The age-based MNI is calculated using the following procedure: (1) an age- and sex-informed MNI is calculated for all adult elements; (2) age at death is estimated for all maxilla and mandible fragments using associated teeth; (3) maxillae and mandibles are paired based on age matches; (4) age is estimated for each unassociated (loose) tooth; (5) unassociated teeth are placed with paired maxillae and mandibles based on age and absence of that tooth, tracking the age of each set of dentition as teeth are added; (6) any remaining teeth are grouped into as few units as possible based on age; and, (7) additional elements are used (e.g., the petrous pyramid) to ascertain any missing age categories, such as infant or fetal, as well as to provide support for the age ranges constructed from dentition.

For Helton 20-36, the max(L, R) MNI was 16 and the age-based MNI was 20. In Carter 2-15, the max(L, R) MNI was 10 and the age-based MNI was 13. Constructing an age-informed MNI made it possible to more accurately assess both the size and demography of the features by including age categories that would have otherwise been overlooked. In a forensic scenario, this would mean establishing the presence of more individuals whose remains could then be individuated through other means, such as DNA testing.

Commingling, Juvenile, Minimum Number of Individuals

A62 Accuracy in Osteometric Reassociation: Comparing Geometric Morphometric Landmark Data and Linear Measurements

Kyle A. McCormick, PhD, 1561 Wilhelmina Rise, Honolulu, HI 96816*

The goal of this presentation is to inform attendees regarding accuracy rates for resolving small-scale, closed-population commingled assemblages using either geometric morphometric landmark data or linear measurements.

This presentation will impact the forensic science community by comparing the performance of two forms of bone size/shape quantification in resolving commingling.

Commingled assemblages present a common situation in osteological analysis in which discrete sets of remains are not readily apparent, thereby hindering biological profile construction and the identification process. Of the methods available for resolving commingling, osteometric sorting is reliable and relatively objective.[1] Traditional osteometric sorting methodology is a decision-making, error-mitigation approach, in which possible matches are eliminated if the accompanying *p*-value exceeds an analyst-defined threshold.[1] Elements are reassociated if all other possibilities are eliminated and the assumption of a closed-population is met; however, recent research has demonstrated that commingled remains can be accurately reassociated in small-scale assemblages using geometric morphometric landmark data in a predictive framework.[2]

The primary goals of the current study are twofold: (1) examine the accuracy (as assessed through correct classification rates) of a predictive framework for reassociation; and, (2) compare two forms of data for quantifying long bone morphology — geometric morphometric landmark data and linear measurements.

To accomplish these goals, landmark data from 208 individuals and linear measurements from 435 individuals were analyzed from the William M. Bass donated skeletal collection. Raw landmark data were fit using generalized Procrustes analysis to extract log-centroid size and Procrustes coordinates. Procrustes coordinates were subjected to partial least squares analysis to extract relevant components. Ten individuals were randomly removed from the total sample, acting as a small-scale, closed-population commingled assemblage. One element was chosen from the commingled assemblage as the independent variable, with the ten possible matching elements representing the dependent variable. Using the remaining total sample, Bayesian regression via Hamiltonian Markov chain Monte Carlo was used to estimate a range of possible dependent variable values. These values were smoothed into a probability density function using kernel density estimation and the ten possible matches were evaluated against this distribution to calculate predictive probabilities. The element with the highest predictive probability was considered the best match. This process was repeated 1,000 times for femur antimere comparisons for both linear measurements and landmark data.

Matches were correctly classified for 78.2% and 93.2% of the commingled assemblages, using landmark data and linear measurements, respectively. These results suggest that bones can be accurately reassociated using the predictive framework, without the need to eliminate all possible matches. Linear measurements performed markedly better than landmark data for resolving commingling, demonstrating that linear measurements contain ample information for predicting correct matches. Furthermore, the ease of data acquisition and analysis of linear measurements in comparison to landmark data make the former a better choice for resolving commingling.

Commingling, Osteometrics, Bayesian Modeling

A63 Performance Assessment for Osteometric Pair-Matching

John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530; and Carrie B. LeGarde, MA, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt AFB, NE 68113*

After attending this presentation, attendees will understand how to measure the performance of a forensic test method and will understand what to expect from osteometric pair-matching.

This presentation will impact the forensic science community by providing attendees with error rates that can be used to understand results in the laboratory.

Byrd and Legarde provided osteometric methods for testing the association of paired bones when resolving a commingled assemblage.[1] The overall approach utilized a significance test with a null hypothesis which states that two bones are of a size to have originated from the same person. The reasoning is counterfactual in nature, as in: If one sampled left and right femora of individuals within a random sample of the relevant population and applied this test to each individual, the test would rarely reject the association. This approach does not provide a means to prove that two bones must have originated from the same person. To do that, one must employ a second line of counterfactual reasoning: If one sampled left and right femora of individuals within a random sample of the relevant population and applied the test to bones from different individuals, one would rarely accept the null hypothesis. The first line of reasoning is a straightforward significance test whose efficacy in future applications can be easily evaluated. The second line of reasoning is not straightforward — its veracity will be determined by the circumstances in which the method is applied. Specifically, the diversity of sizes among the commingled individuals will drive how rare it will be to accept the null hypothesis.

Byrd and Adams recommended using $p<0.10$ as a standard for rejecting an association of two bones.[2] This standard was intended to balance power against risk in applications. It is not intended to be a draconian cutoff, and analysts are encouraged to use the attained *p*-value to evaluate the association. As a rubric for evaluating performance, one can view a null hypothesis rejection ($P<0.10$) as a "positive" result and acceptance as a "negative." The False Positive Rate (FPR) is the rate at which associations that actually come from the same individual are rejected. When applying the Byrd-Legarde paired whole bone models (six bones) to DPAA reference data, the FPR ranges from 0.05 to 0.20, with a mean FPR of 0.10. Acknowledging that with $p<0.10$ as a standard, one can expect to attain variation in the FPR, these results largely meet expectations. One bone, the ulna, has an FPR (0.20) that is significantly higher than expected (one-sided binomial test $p=0.00083$). Vickers et al. applied the Byrd-Legarde models to the Forensic Databank (FDB) and attained very similar results (mean FPR=0.10) to include higher error with the ulna.[3] LeGarde applied a larger variety of models (12 models from three bones) to the Bass Collection and found the FPR to range from 0.07 to 0.13, with a mean FPR of 0.10.[4] She also applied the Byrd models to the collection at Chiba, Japan, and attained an FPR range 0.04 to 0.15, with a mean FPR of 0.09.

One cannot directly address the second counterfactual given above because it is difficult to project what variation in body sizes will hold in future forensic cases; however, one can use the size distribution of the reference sample as a proxy. A sample (N=1,000) of the right and left long bone measurements in the reference sample were randomly paired for comparison and any instances of the same individual removed from the analysis. This yielded a large number of random pairings of bones from different persons. These comparisons provided a basis for assessing false negatives along with other possible outcomes. With these random comparisons combined with the above metrics, the false discovery rate (Q_{actual}), sensitivity, specificity, positive predictive values, negative predictive values, and efficiency were estimated. The results from the six whole bone models (DPAA reference data) are in simple terms: Q_{actual} 0.01-0.03; sensitivity 0.67-0.84; specificity 0.80-0.95; positive predictive value 0.97-0.99; negative predictive value 0.17-0.52; and efficiency 0.69-0.86. The meaningfulness of these results will be determined by how representative the size distribution of the reference data is. Under strong assumptions about the size distributions of future cases, it is possible to project the future performance of these models.

Performance, Osteometric, Statistics

A64 Mentoring by Example: Lessons in Cremation Analysis From the Forensic Case Files of Walter H. Birkby, PhD

Thomas Michael Fink, MA, BioArch LLC, 2959 N 68th Place, #115, Scottsdale, AZ 85251-6872*

After attending this presentation, attendees will appreciate the skill and knowledge of Dr. Birkby in the field of cremation analysis and the example he set for his students.

This presentation will impact the forensic science community and the field of forensic cremation analysis by demonstrating that: (1) heavily fragmented cremains can still be identified, especially when examined by a highly skilled analyst such as Dr. Birkby; and, (2) when plying their skills in police cases, forensic anthropologists may have to contend with politically charged, high-profiles cases.

Attendees of this presentation will understand that the foundations of forensic anthropology lay, as with Dr. Walter H. Birkby, in "mentoring by example." Students learned by observation — not only the methods for studying human remains but the subsequent presentation of the results. This reliance on training by example, rather than on textbooks, epitomizes the formational stages of forensic anthropology.

Birkby often cautioned his students about making overreaching inferences from osteological data, saying, "Don't say anything in writing that you couldn't defend on the stand." Practical lessons in human osteology were often emphasized through similar, often humorous, sayings known as "Birkby-isms." These phrases captured the essence of the principles behind lessons taught by example.

While the presenter worked and studied with Dr. Birkby from 1975 to 1980, he learned from Birkby's emerging interest in the analysis of cremated and calcined bone. Birkby became an acknowledged expert in the study of human cremains and it was through him the presenter acquired a major interest in this mode of burial.

When it came to cremation analysis, Birkby said: "You get out of cremations what you put into them." His meticulous approach to cremains is well exemplified in one of his early forensic cases and represents a unique and important study. Unfortunately, it went unpublished.

The case dates to the late 1960s when a male member of the Black Panther Organization in the San Francisco Bay area was reportedly shot at a rural training facility. As the ground was rocky, the perpetrator(s) could not bury the body and, instead, burned the remains for several hours on a pile of redwood branches, repositioning the body parts to facilitate cremation. Once the fire had consumed the corpse, the calcined skeleton was broken up and the fragments were scattered on the side of a hill. The bony fragments remained *in situ* until 1971 when an informer, who may have assisted in the disposal, told local authorities what had happened and where the individual's remains could be located. A search of the scene revealed a number of personal items along with bone fragments.

The California authorities requested Birkby's help in examining the cremains and, in the summer of 1971, the calcined bone was sent to him for study. As the authorities knew the probable identity of the deceased, they also sent antemortem radiographs of his head and chest. After working for several weeks identifying and reconstructing fragments Birkby was able to identify several points of similarity between bony features in the cremains and those in the radiographs. The similarities included age and sex, mandibular and frontal sinus morphology, and a lambdoidal ossicle.; however, and most importantly, was the remnant of a healed surgical wound in the reconstructed fragments of the right temporal bone that matched a defect present in the decedent's radiographs. Birkby was able to extract from these burned and scattered bones the critical elements needed to cinch the case. Positive identification was later officially established by California authorities. The likely perpetrator was, himself, killed in 1972.

This case had significant impact on the direction of forensic anthropology. First, it proved that burning a body did not prevent identification when faced with someone of Birkby's skill and dedication. Second, this case showed that experts, like forensic anthropologists, often navigate dangerous waters around high-profile cases.

Similarly, Birkby's work on the Black Panther case also had an impact on the bioarchaeological study of cremains. The very same effort and attention he afforded forensic cases was given to prehistoric cremation burials. His work in the field of bioarchaeology likewise served as an example of what can be accomplished with fragmentary calcined bone.

The "Birkby-isms" hold true no matter what the year or what the nature of the case. By not over-reaching and

by devoting the time and effort, Birkby was able to advance a difficult and politically charged case long before most of the anthropological studies on cremation were conducted. These examples are those that guided his students and "mentoring by example" lies at the heart of forensic training.

Birkby, Mentorship, Cremains

A65 Walter H. Birkby's Influence on the Science of Mummy Studies

Karl J. Reinhard, PhD, School of Natural Resources, 719 Hardin Hall, University of Nebraska, Lincoln, NE 68583-0987*

After attending this presentation, attendees will gain an appreciation of Walter Birkby's influence on mummy studies. His own unpublished work, and fostering research on mummified remains by others, resulted in methods applied today in forensic studies.

This presentation will impact the forensic science community by increasing attendee awareness of the heretofore unknown contributions of Walter Birkby to forensic science.

For many decades, the Arizona State Museum at the University of Arizona curated one of the largest mummy collections in the United States. Walter Birkby was the curator of these collections. Several prominent archaeological sites were represented by the mummies. These included Ventana Cave, the excavations of which established the first chronology of extensive time depth and represented Archaic, Hohokam, and Tohono O'odham cultures. Mummies from Vandal Cave and Painted Cave represented Ancestral Pueblo peoples.[1] The mummies from Ventana Cave were reburied in 1992, representing the first major mummy collection reburied without full study.

Birkby's curatorial role was complicated by defleshing of mummies that occurred in the 1950s, long before his curatorship began. Birkby curated the resulting skeletal remains. He had the foresight to curate coprolites that were recovered when some Ventana Cave mummies were defleshed. The excavator of Ventana Cave, Emil Haury, mention two unpublished mummy studies.[2] It is noteworthy that these studies were relatively sophisticated approaches to mummy studies. Radiology was employed in an inclusive search for pathology related to valley fever (coccidioidomycosis). Also, the mummies were tested for ABO antigens. In this pioneering study, nine mummies were positive for type 0 and one for AB.

Birkby was perhaps the first paleopathologist to conduct studies of head lice (*Pediculus humanus capitis*) from mummies.[1] His work inspired the later paleoepidemiological approach to lice in large mummy collections.[3] This approach has expanded and now louse epidemiological studies are being based on analyses of large samples of mummies, especially in the Andes.

Significant for the forensic investigation of mummies, Birkby provided Ventana Cave coprolites for analysis.[4] The analyses of these laid the quantification method framework now used in the forensic analysis of mummy intestinal remains.[5] Analysis of parasites, pollen, starch, and other microscopic remains provided information relevant to diet and season of death. Macroscopic remains provided additional remains of diet. For the Ventana Cave prehistoric mummies, two dietary episodes were discerned. One was composed of mesquite and another of saguaro cactus seeds and pollen. The cactus reliance was especially interesting. The evidence conclusively demonstrated that buds of saguaro or organ pipe cactus were eaten. The use of buds from these cacti had never before been noted. These methods of analysis have since been applied to mummies of forensic relevance. These showed the location of death and last meals for a Nebraska homicide victim and of a starvation diet for a Korean War POW.[5]

The contribution of Birkby's direct research on mummies and his sponsorship of intestinal analysis laid a foundation for two important developments. Louse analysis of mummies has become a focus of paleoepidemiology. Importantly, the methods of coprolite analysis have been applied in the forensic setting, both in domestic homicide contexts and in military investigations.[5]

A66 Birkby, Bones, and Bodies: The Making of a Mentor

Madeleine J. Hinkes, PhD, San Diego Mesa College, Office of Institutional Effectiveness, 7250 Mesa College Drive, San Diego, CA 92111*

After attending this presentation, attendees will better appreciate the special mentoring role that Dr. Walter Birkby played in the lives of many forensic anthropologists in practice today.

This presentation will impact the forensic science community by reminding mentors of the key role they play in shaping their students and by urging students to learn as much as they can from their mentors.

Most people think of Walt Birkby as an exceptional forensic anthropologist, but his early career focused on archaeology and osteological analysis of the recovered human skeletal remains. Arriving at the University of Kansas in the late 1950s, by 1963 Walt had earned a BA and an MA under Bill Bass. During that time, he excavated sites in the Great Plains, worked his way up from crew member to crew chief to research assistant, and was Bill's Teaching Assistant (TA) for human osteology classes. Walt published on general skeletal identification, with forays into analysis of dentition, the suborbital fossa, non-metric traits, and craniometric assessment of race and sex.

Walt arrived at the University of Arizona (UA) in 1963 and completed his PhD in 1973. He rose from Instructor to Physical Anthropologist to Curator of Physical Anthropology at the Arizona State Museum. Just as Walt arrived in Tucson, AZ, the UA archaeological field school began work at Grasshopper Pueblo, a 500-room, 14th-century Mogollon pueblo located on the modern White Mountain Apache Indian reservation. Excavations continued there for 30 years and uncovered 672 burials (700 individuals). These remains were turned over to Walt at the Arizona State Museum for preservation, analysis, and curation.

That collection brought me to the UA in 1977 after I too had earned an MA at the University of Kansas. Because Walt curated that collection, I would be working with him. I became his first female graduate student, and for the next six years, my home was Birkby's Body Shoppe on the fourth floor of the Anthropology Building. My dissertation research focused on skeletal evidence of stress in subadults (a population of approximately 400) at Grasshopper. Walt helped me hone my osteological skills and taught me how to take and develop X-rays, since he was certificated in medical X-ray technology. I bought my first Single-Lens Reflex (SLR) camera, and he taught me how to take photos and the importance of documenting my work. He encouraged me to follow him into forensic anthropology, and I attended my first AAFS meeting in 1978.

During my time as his graduate student, Walt instilled many lessons in me and my colleagues, which have continued to influence our work today. He was always accessible and unselfish with his time. He taught us by example to take our work, but not ourselves, seriously; to take the time to do the job well (i.e., if forensic anthropology is the application of science to the law, you need to get the science right). Observing both his ease with law enforcement officers and his role as a forensic team member taught us how to conduct ourselves, too. His most important lesson: always take time for lunch.

Probably the best evidence of his influence on me begins with a 1980 incident in which 27 Salvadoran refugees fleeing a right-wing military regime decided to head north through the southwestern Arizona desert in July. After their smuggler abandoned them, only 14 were rescued. The other 13 were found dead — at that time, the deadliest incident involving migrants at the United States-Mexico border. Our team worked the case over the next few days. Just five-and-a-half years later, I was at Dover Air Force Base faced with a mass disaster of 248 fatalities from the crash of an airplane bringing the 101st Airborne Division back from the Persian Gulf. I was the only forensic anthropologist on the team with military pathologists and dentists, but I knew what to do and how to do it, thanks to Walt. Every one of the victims was identified.

Walter H. Birkby, PhD, Human Skeletal Remains, Forensic Anthropology

A67 The Birkby Paradox — Forensic Anthropology Participation and Gender

Alison Galloway, PhD, University of California, Chancellor's Office, Santa Cruz, CA 95064*

After attending this presentation, attendees will better understand the critical nature of support for diversity by gender in training programs in forensic anthropology and the current status of such diversity.

This presentation will impact the forensic science community by considering the current situation and discussing what levels of support are needed for the future in training and developing forensic anthropologists.

Walter H. Birkby was a superb osteologist and an excellent teacher, was dedicated to forensic anthropology, and possessed a great instinct for legal context. He and his program produced many students, both male and female; however, there was also a negative side. His laboratory featured pictures of women no longer considered acceptable and, from the perspective of his female students, his relationship with male and female students differed. He favored his male students in support, but he also gave rein to the women in his program, allowing us to move forward. His laboratory trained a significant number of female graduate students.

Women used a variety of strategies to survive and succeed: (1) alliances and support networks; (2) finding funding outside of Walt's laboratory and outside employment both factored into completion; (3) taking on the challenges; and, (4) focusing on the issues.

From the 1970s through 1990s, the Birkby laboratory epitomized the transitions in the discipline. The remainder of this presentation reviews the changes in participation by gender in forensic anthropology. Material is drawn from publicly available sites. Unfortunately, a binary separation into two genders had to be used, ignoring gender fluidity and those who may be gender queer.

Forensic science and forensic anthropology developed slowly, with the American Academy of Forensic Sciences being founded in 1948. Largely male for many decades, women were present and active, however, it was not until 1979 that a female served as president.

The Anthropology section has seen a steady growth of women. Membership lists as of 2016 show women at the Student Affiliate and Trainee Affiliate levels outnumber men by a 4:1 margin. At the Associate Member level, women outnumber men by almost 3:1. The margins are more balanced at Member level (3:2) but only reach equivalency at the level of Fellow.

At the Member and Fellow ranks, the numbers of men and women with doctorates are approximately the same; at the Associate Member level, the numbers are notably different with more women having a Master's degree (46.8%) than men (16.1%). There are suggestions that a number of women have found productive careers in forensic laboratories and coroners' offices with a Master's degree and have remained at that level for years.

The American Board of Forensic Anthropology has seen a similar transformation in the numbers of women. Begun by men in 1977, the Board gradually added a few females. Over the next two decades, the percentage of women gradually rose from 20% to more than 30%. Currently, the number of active male and female diplomates is approximately equal, having seen a noticeable upswing in the past few years.

Forensic anthropology has paralleled the trend of increasing the numbers of women in the forensic sciences. Universities report that forensic sciences program enrollments are 74%-90% female. Houck noted that forensic sciences constitute a marked departure from the gender gap in most of the Science, Technology, Engineering, and Math (STEM) fields.[1] There are many suggestions as to why this has occurred, including strong role models in popular media and a commitment to public service.

What is left of the "glass ceiling" is in leadership and in the pipeline to it. Women are common in state crime laboratories at the bench and leadership levels, they are rarely directors of the larger federal laboratories.

The increase in women in forensic sciences, and in forensic anthropology in particular, began in the mid-1980s, at the time that Walter Birkby and many of his generation of professors were at the height of their programmatic careers. Despite the often noticeable discrepancies in <u>how</u> they supported female students, they encouraged their entry into the field and provided opportunities for these women to gain field experience.

Career Development, Gender Diversity, Birkby

A68 The Recordkeeping of Walter H. Birkby, PhD

Bruce E. Anderson, PhD, PCOME, Forensic Science Center, 2825 E District Street, Tucson, AZ 85714*

After attending this presentation, attendees will better understand the advantages of keeping a parallel set of records derived from forensic anthropology examinations and the associated medicolegal death investigations.

This presentation will impact the forensic science community by illustrating the potential for augmenting current medicolegal case investigation data and for performing research into old and cold cases that can lead to case resolution.

The late Walter H. Birkby performed his first forensic anthropology examination in 1965 and continued from that date to keep a set of medicolegal death investigation records parallel to that of Law Enforcement Agencies (LEA) and Medical Examiners/Coroners (ME/C) for each of the more than 3500 forensic anthropology consultations that he performed over his illustrious career of over forty years. These records, arranged within a separate folder for each individual consultation, were a combination of original forensic anthropological notes, forms, sketches, chain-of-custody documents, photographs, radiographs, reports, and photocopies of law enforcement and ME/C reports. Many copies of court interviews and depositions, as well as a plethora of newspaper clippings from selected cases, are also included in this collection.

The vast majority of these records survive to date and are housed at the Pima County Office of the Medical Examiner (PCOME), where many of these are consulted on a regular basis by PCOME forensic anthropologists still attempting to identify unknown individuals or assisting LEA or family requests on resolved cases. The value of these records cannot be overstated for those cases in which governmental retention schedules have served to drastically reduce, or even destroy, the entire original governmental case file. More than 150 such files of currently unidentified individuals, including Dr. Birkby's first case from 1965, are the sole source of surviving archival records. Several identifications have been made over the past decade utilizing these records, with the existence of the original anthropological data and copies of ME/C data proving essential in establishing everything from chain-of-custody to explaining an identification to the family of the decedent. Because Dr. Birkby consulted in every county in Arizona and several counties in California over the course of his career, other forensic anthropologists in other jurisdictions have made inquiries to the PCOME regarding a few old cases with the hope that Dr. Birkby's records might clarify or establish that a suspected old case actually existed.

Examples of the diversity of the information contained within these 3,500 records will be highlighted and their importance to unresolved cases will be emphasized.

Forensic Anthropology, Case Reports, ME/C Case Records

A69 The Skeletal Trauma Casework of Walter H. Birkby, PhD: Setting a Standard for Future Generations

Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; Caitlin C.M. Vogelsberg, MS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; and Jennifer M. Vollner, PhD, Pima County Office of the Medical Examiner, 2825 E District Street, Tucson, AZ 85714*

After attending this presentation, attendees will understand the impressive scope of the skeletal trauma casework performed by Dr. Walter Birkby during his long and distinguished career.

This presentation will impact the forensic science community by discussing the influence Dr. Birkby's peri-mortem skeletal trauma casework had on his students, as well as on future generations of forensic anthropologists.

The distinguished career of the late Walter H. Birkby spanned more than 40 years and encompassed more than 2,300 forensic anthropology cases. From the years 1965 to 2008, Dr. Birkby consulted for medical examiner offices and law enforcement agencies across Arizona and the west. Approximately 15% of his total cases involved the analysis of peri-mortem skeletal trauma. Interestingly, his very first forensic case, on November 2, 1965, included a description of sharp force defects to the skeleton.

Of Dr. Birkby's 310 peri-mortem skeletal trauma cases, 169 cases were gunshot wounds (55%), 94 were blunt force trauma (30%), and 47 were sharp force trauma (15%). From 1965 to 1979, his number of trauma cases was modest, totaling approximately 40. Beginning in the 1980s, there was a sharp increase in trauma consultations, and this trend continued through the 1990s. Over the two-decade period from 1980 to 1999, Dr. Birkby worked 88% (272) of his total trauma cases. These ranged from the analyses of homicides and suicides to skeletonized undocumented border crossers to the re-evaluation of cause of death from exhumed remains. Indeed, the scope of casework performed by Dr. Birkby proves difficult to summarize as it encompasses so many aspects of forensic anthropology.

Despite not publishing extensively on skeletal trauma, his legacy involving trauma analysis is a powerful one, both through the large number of trauma cases he worked and through his keen analytical skills, careful descriptions paired with meticulous diagrammatic and high-quality photographic documentation, and the succinct, streamlined case report writing style he developed. Most importantly, at the foundation of his legacy is the impact he had on his graduate students; one that is squarely centered on his daily interactions with those who worked at his side on many of his cases.

In the days before the Scientific Working Group for Forensic Anthropology (SWGANTH), Dr. Birkby trained his students with his own best-practice guidelines on trauma analysis. Many students were given the opportunity to write first drafts and co-author reports with him, following successful assistance with trauma casework. His intensive case volume allowed for training in the recognition of the mechanisms of trauma, as well as distinguishing antemortem and peri-mortem trauma from the postmortem damage generated by the denizens of the Sonoran Desert. Above all, though, he trained his students to be conservative analysts, to front-load analyses with careful, clearly stated descriptions, and to follow up with interpretation only when appropriate.

Many of Dr. Birkby's students are now board-certified forensic anthropologists who have their own graduate students, direct their own laboratories, consult on trauma cases, and publish on skeletal trauma, including Alison Galloway who wrote *Broken Bones: Anthropological Analysis of Blunt Force Trauma*, the benchmark of blunt force trauma. [1]

Most certainly the presenting author's case experience and training under Dr. Birkby was the impetus for the ongoing interdisciplinary research initiative focused on pediatric and adult cranial and long bone fracture initiation and propagation at Michigan State University. In this collaborative research between forensic anthropologists and biomechanical engineers, a science of skeletal trauma is being built based on controlled biomechanical experiments that are performed in order to test hypotheses and establish relationships between fracture characteristics and variables related to the injury scenario. This application of the scientific method to skeletal trauma analyses follows in the footsteps of Dr. Birkby's objective of understanding the processes behind observations made during skeletal analyses. This, along with the involvement of graduate students in both casework and research, continues the

legacy set forth by Dr. Birkby to engage and train the next generation of young scholars interested in pursuing new directions in trauma interpretation and forensic anthropology.

Trauma Analysis, Walter H. Birkby, PhD, Forensic Anthropology

A70 Human Bone Taphonomy and the Use of Consolidants: An Example From Cyprus

Sherry C. Fox, PhD, Arizona State University, School of Human Evolution and Social Change, Tempe, AZ 85287; and Jessica S. Johnson, MA, Smithsonian Institution, Museum Conservation Institute, Museum Support Center, 4210 Silver Hill Road, Suitland, MD 20746*

After attending this presentation, attendees will better understand human bone taphonomy and the use of consolidants; Walter H. Birkby utilized bone consolidants both in forensic anthropology casework to preserve fire-damaged teeth and in bioarchaeology to prepare human skeletal remains for a museum display in Cyprus. This presentation will look historically at the use of consolidants commonly used for human bone and also note more recent work examining the analytical effects of these materials that may affect choices made in the field today.

This presentation will impact the forensic science community by examining the taphonomy of human bone and by making known Walter H. Birkby's contributions to conservation sciences.

Walter H. Birkby, in addition to devoting his career to teaching and practicing forensic anthropology, was a bioarchaeologist, often working on archaeological field projects during the summer months. His skills in the analysis of skeletal disease and trauma, as previously noted by Dr. Fenton in this session, were invaluable, both in the context of casework in forensic anthropology and in applications to archaeology. Walt's archaeological work in Arizona is noted in Dr. Hinkes's presentation on the human skeletal material from Grasshopper Pueblo and in Dr. Reinhard's presentation regarding Walt's research in mummy studies. In historical archaeology, Walt spent a field season excavating in the Rocky Mountains, where he and a team excavated and analyzed the victims of the first convicted cannibal in United States history, Alferd Packer.

In international endeavors, Walt consulted on at least one forensic case in Mexico, and in classical antiquity, Walt worked at both of the University of Arizona excavations, directed by David Soren, at the Roman sites of Lugnano in Italy, and at Kourion in Cyprus. As with casework in forensic anthropology, Walt took his students with him into the field, and Kourion was no exception. It was in Cyprus where victims of the AD 365 earthquake were recovered and prepared for a museum display.

Animal bone is highly mineralized and it is generally recovered from archaeological contexts in Cyprus in better condition than human bone. Unfortunately, human bone on the island often tends to be demineralized, with the organic component of the bone having been highly degraded through taphonomic processes. Human bone prefers a constant environment, such as in Egypt, for example, where it is hot and dry, or in the Russian tundra where the climate remains relatively cold. Both conditions tend to produce more well- preserved human bone.

The situation in Cyprus, though, is not one of stability, but rather one of flux, due to the constantly changing environmental conditions, alternating between hot and dry summers and cool and wet winters. Furthermore, bone prefers a neutral soil pH, and Cypriot soils tend to be either highly alkaline or highly acidic. To exacerbate the situation, Cypriots in the past, as they do today, often reused tombs and practiced secondary burial, thus commingling human skeletal remains and causing further damage to the bone in the process.

Walt worked in conjunction with archaeological conservators at Kourion, in both the consolidation of human skeletons and in block-lifting them as was required among two different contexts at the site by the Department of Antiquities of Cyprus. Walt understood the value of using consolidants in the field, both in forensic anthropology casework for the preservation of fire-damaged teeth and in archaeology for preserving human skeletal remains, in particular, for those destined for museum display.

This presentation will provide a historical view of the use of consolidants commonly used for human bone and also note more recent work examining the analytical effects of these materials that may affect choices made in the field today.

Human Bone Taphonomy, Bone Consolidants, Walter H. Birkby, PhD

A71 Standing on the Shoulders of Giants: The Evolving Legacy of Walter H. Birkby, PhD

Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending the presentation, attendees will better understand the importance of strong mentoring and reflecting backward as they progress forward.

This presentation will impact the forensic science community by elucidating the evolving role of forensic anthropology in medicolegal death investigations and the importance of relying on and providing strong mentoring.

Everyone stands on the shoulders of those who came before them: parents, grandparents, iconic and admired predecessors. Mentors wittingly and unwittingly shape the individuals they impact and, in doing so, drive the evolution of the professional discipline related to their mentorship. Forensic anthropology has evolved in just such a manner; mentors influencing students and students becoming mentors, all the while putting their particular stamp on the discipline.

Walt was a student of William Bass and his initial loves were skeletal biology and archaeology. As he moved into his own career at the University of Arizona, he was slowly drawn into the medicolegal community. He forged strong ties with the local medical examiner and personnel from local and regional law enforcement. Students gravitated toward him as knowledge of forensic science trickled out into the collegiate community. Eventually Walt became one of the founding members of the American Board of Forensic Anthropology (ABFA) and the Physical Anthropology (now Anthropology) section of the American Academy of Forensic Sciences (AAFS). He served as an officer for both entities and encouraged his students to be active participants in both.

Over time, Walt's interests shifted from skeletal biology to assessing traumas in bone. He became a recognized expert both in Arizona and nationally, and was known for his down-to-earth sensibility. As Walt honed his skill, Forensic Anthropology also began to expand nationally and internationally. Developing the biological profile for unidentified skeletons as a side line to an academic career morphed into full-time employment in medical examiners' offices and active engagement in human rights movements globally. Anthropologists have always been able to adapt their skill set as necessary and forensic anthropologists were no exception. The career path burgeoned and during the 1980s and early 1990s, Walt's student population exploded to more than 20. Many of those individuals left and turned their careers to different aspects of anthropology; indeed, many of them are presenting in this symposium.

Forensic anthropology has evolved from the weird old aunt that is at every family reunion to a respected mainstream science. Walt's students have emerged from the shadows to become leaders in the field, positioned around the country and even the world as engaged scientists who care passionately about their work and their contributions to the discipline. Those contributions include mentoring the next generation who, in turn, will put their own mark on forensic anthropology.

The 2009 National Academy of Sciences Report has changed forever the way forensic sciences will be viewed in the United States. Where before academicians like Walt could dabble in the medicolegal world, practitioners will now be required to earn a PhD in Anthropology and board certification will become the norm. Standards that have never before been applied universally will be developed by the National Institute of Standards and Technology (NIST) Scientific Area Committee (SAC) and forensic anthropologists will have to adhere to a more uniform code. Medical examiner and coroner offices will move toward accreditation and the anthropologists and odontologists will move with them. The forensic anthropologist will become part of a standard death investigation. Many of these changes are already being implemented internationally. The discipline is growing up and good mentorship will create the practitioners who will thrive in this new world. This presentation will discuss the changing roles of forensic anthropology domestically and internationally; using Walt as a focus to reflect back will project out to the future of the science in the next 20 years.

Walter H. Birkby, PhD, Legacy, Forensic Anthropology

A72 A New Application for Estimating Ancestry Based on Dental Morphology

Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096; G. Richard Scott, PhD, University of Nevada, Reno, 1664 N Virginia Street, MS 0096, Reno, NV 89557-0002; David Senhora Navega, MSc, Laboratory of Forensic Anthropology, University of Coimbra, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; João Pedro Valente de Oliveira Coelho, MSc, University of Coimbra, Dept of Life Sciences, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Eugenia Cunha, PhD, Universidade de Coimbra, Dept of Life Sciences, Forensic Anthropology Lab, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; and Joel D. Irish, PhD, John Moores University, Natural Sciences and Psychology, Byrom Street, Liverpool, Merseyside L3 3AF, UNITED KINGDOM*

After attending this presentation, attendees will better understand how dental morphological traits vary across the globe and how this variation can be used to estimate the ancestry of individuals in a forensic context.

This presentation will impact the forensic science community by providing an additional method for ancestry estimation that can be adopted by forensic anthropologists for use in the development of the biological profile.

A statistical application using R was developed to estimate the ancestry of unknown individuals using tooth crown and root morphology.[1] A global reference sample of 21 dental traits was created from the Christy G. Turner II database consisting of approximately 30,000 individuals. These individuals were subdivided into seven geographic regions (American Arctic and Northeast Asia; Australo-Melanesia and Micronesia; East Asia; American Indian; Southeast Asia and Polynesia; Sub-Saharan Africa; and Western Eurasia) for ancestry estimation. To classify an unknown individual, dental traits are scored according to the Arizona State University Dental Anthropology System and entered into the application as present, absent, or unobservable, according to predetermined breakpoints.[2] The statistical program first derives a Nei's distance matrix, followed by a hierarchical clustering tree using an Unweighted Pair Group Method with Arithmetic Mean (UPGMA) algorithm with complete linkage. Posterior probabilities are then assigned for the unknown set of remains to each of the seven biogeographic groups using a naïve Bayes classifier algorithm.

A web-based application of this program, called rASUDAS, was used to test the accuracy of the method. In an analysis of a test set of 150 individuals of known ancestry from all parts of the world, the application correctly assigned individuals to their geographic group between 57% and 92% of the time. When limited to the broader ancestry groups of European, African, and Asian, correct assignment increased to between 82% and 92%.

The rASUDAS program is extremely flexible; it is able to accommodate missing data and allows the user to choose which biogeographic groups to include in the model; however, in its current form, the reference sample for this program is based predominantly on individuals from archaeological sites with considerable temporal depth. More work is needed to understand the effects of secular change on dental morphology before the method can be broadly adopted in a medicolegal context. The ultimate goal is to grow the reference sample to include modern individuals to enhance the utility of the program.

This study identifies broad patterns in crown and root traits as related to ancestry. The efficacy of the method outlined here highlights the utility of these data as part of the biological profile. As dental traits are directed by different developmental processes than those traditionally analyzed for ancestry estimation (i.e., cranial metrics, cranial morphoscopics, and postcranial morphology), the inclusion of dental morphological data can provide a more robust view of population histories and improve the estimation of ancestry within forensic anthropology.

Dental Morphology, Ancestry Estimation, rASUDAS

A73 Molar Crenulation Trait Definition and Population Variation

Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096; Christopher A. Maier, MA, 350 Harbour Cove Drive, Apt 319, Sparks, NV 89434; and G. Richard Scott, PhD, University of Nevada, Reno, 1664 N Virginia Street, MS 0096, Reno, NV 89557-0002*

After attending this presentation, attendees will better understand how molar crenulations vary in modern human populations and how this variation can be used to estimate the ancestry of individuals in a forensic context.

This presentation will impact the forensic science community by providing a standardized scoring system for molar crenulations that can be adopted by forensic anthropologists for use in the development of the biological profile. Additionally, this presentation outlines frequency data on molar crenulations in various modern human samples — data that has been lacking within forensic anthropology.

The condition of crenulated (i.e., wrinkled) molars has been described extensively in the paleontological and anthropological literature. Within forensic anthropology, molar crenulations have often been identified as being encountered at higher frequencies among samples of individuals of African ancestry.[1,2] Despite the recognized importance of this trait to differentiate contemporary samples, very little data exist that document the distribution of molar crenulations. Part of the difficulty with implementing research programs investigating molar crenulations may stem from the fact that they are not well defined. In fact, they do not form a part of the standard suite of dental morphological characteristics that are described in the Arizona State University Dental Anthropology system.[3] In this work, a clear and operational definition and scoring system for the trait is provided, as well as inter- and intra-observer error rates. Frequencies for modern groups are documented and the use of the trait for differentiating between these populations is explored.

Molar crenulations are defined here as curved fissures and ridges that surround the primary ridges (i.e., cristids) of each main molar cusp. These crenulations are found on the occlusal surface of all three molars of both the mandible and maxilla. The scoring system is: 0 = no crenulation; 1 = crenulations are shallow and do not involve all cusps; and, 2 = crenulations are deep and involve all major cusps. Data were collected on several modern skeletal collections (n=420). These samples include individuals from Japan (n=98), Hispanic migrants (n=54), American Whites (n=111), American Blacks (n=17), and casts of South African Bantu-speaking peoples (n=140). To test inter- and intra-observer error, data were again collected on the same set of individuals (n=50).

Inter- and intra-observer error rates were assessed using Cohen's Kappa. Rater agreement was moderate to high (<0.41) for all teeth, indicating the reliability of this scoring system.[4] The frequency of molar crenulations was low among the Japanese, Hispanic, and American White samples. When the trait was observed, it was typically on the third molar and was a score of 1. Crenulation frequencies increased with the American Black sample and greatly increased with the South African sample. In these samples, the trait was present on all molars and scores of 2 were much more frequent. Univariate statistics (Chi-square) indicated a difference in crenulation presence between groups for all molars when raw scores were used. When data were dichotomized and the breakpoint set at one, this same pattern was found. When the breakpoint was set at two, all teeth show group differences except for the lower first molar.

Based on this research, it is argued that molar crenulations become part of a suite of traits that can be used to estimate ancestry. It is further advocated that crenulations (as well as other dental morphological traits) be included in statistical frameworks to improve accuracy rates of ancestry estimation as part of the biological profile.

A74 Observer Error and Its Impact on Ancestry Estimation Using Dental Morphology

Donovan M. Adams, MS, University of Nevada, Reno, 1664 N Virginia Street, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096; Heather J.H. Edgar, PhD, Maxwell Museum of Anthropology, MSC01 1050, 1 University of New Mexico, Albuquerque, NM 87131; and Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand how observer error impacts data collection on dental morphology and methods that use dental morphological data to estimate ancestry.

This presentation will impact the forensic science community by evaluating the utility of dental morphology in the estimation of ancestry as well as providing a comprehensive study on inter- and intra-observer rates for dental morphological data.

Traditionally, only a small set of dental morphological variants have been used as part of the "trait list" in the biological profile to estimate ancestry. As dental morphology has gained greater visibility within forensic anthropology, several methods have been developed to estimate ancestry that employ a range of traits; however, many forensic anthropologists have received limited training on the 36 dental traits that make up the Arizona State University Dental Anthropology system.[1-4] This study serves to explore how error can affect estimations of ancestry.

Data were collected on the same set of nine dental casts by ten different participants. The dental casts form part of the Economides Orthodontic collection housed at the University of New Mexico. Of these nine casts, three had an identified ancestry as European-American, three were Hispanic, and three were African American. Dental morphological data collected for each cast included 19 traits on multiple teeth. Volunteers were provided with extensive trait descriptions, dental cast exemplars, and scoring sheets. Participants supplied data on level of training in dental morphology, total time taken, as well as their highest degree and area of study. Data were collected on the same set of casts twice. Data from each observer for each cast were then evaluated for ancestry using the method proposed by Edgar.[2]

Intra-observer error on 636 data points using raw scores (not dichotomized) provided a Kappa statistic of 0.452, indicating moderate rater agreement. Inter-observer error varies by trait and observer experience. When data were input into the method of Edgar, results varied widely.[2] Correct ancestry assignment per individual ranged from two to seven (out of nine total), with an average of 3.5 correct. Total time spent on data collection ranged from 0.5 to 8 hours, with an average of 2.9 hours. There was a strong bias toward an ancestry assignment of Hispanic (74% of the results, 60/81). Two participants classified every single individual as Hispanic, and two more classified all but one individual as Hispanic. These researchers indicated moderate experience with dental morphology and took the least amount of time to collect the data (average 1.95 hours). Individuals who indicated low or high experience with dental morphology took more time to collect data (average 3.85 hours) and had higher rates of correct ancestry assignment (average 4.75 correct).

It is likely that the bias toward an estimate of Hispanic ancestry is related to improper recordation of the dental variation in these sets of casts. The Edgar method classifies individuals as Hispanic if any shoveling is present at a grade of one or higher, and/or the metacone/hypocone have a score of five.[2] Care must be taken to ensure that these traits are in fact present at these scores. Additionally, methods that employ breakpoints at the high and low ends of the variant scores appear to be more susceptible to observer error.

The results of this study indicate that ancestry estimation methods based on dental morphology have utility in forensic anthropology; however, they are only effective when the practitioner has proper training and care is taken in scoring traits.

Observer Error, Dental Morphology, Ancestry Estimation

A75 The Utility of Stable Isotope Ratios of Tap Water and Human Teeth as Predictors of Region of Origin in Central and Southern Mexico

Chelsey A. Juarez, PhD, Department of Soc & Anthro NCSU, 1911 Bldg, 10 Current Drive, Campus Box 8107, Raleigh, NC 27695-8107*

The goals of this presentation are to explore the relationship: (1) between oxygen and hydrogen isotopes in tap water sources available to Mexican populations from traditionally high immigrant sending areas; and, (2) between these water samples and tooth samples of known origin.

This presentation will impact the forensic science community by presenting data on the relationship between Mexican tap water and human tooth enamel and by examining the utility of this relationship to act as a predictor of region of origin.

The use of oxygen and hydrogen isotopes in human drinking water, hair, bone, fingernails, and teeth has demonstrated the ability to track movement and identify the region of origin for modern populations.[1] In this study, the ability of human tooth enamel to predict region of origin in modern Mexican populations by estimating drinking water from tooth enamel is tested.

The water samples consist of 224 samples of tap water collected from 13 contiguous states in Central and Southern Mexico. Hydrogen and oxygen water isotopes were measured for tap water samples for all locations using laser absorption spectroscopy at the University of Utah Stable Isotope Ratio Facility for Environmental Research (SIRFER) laboratory. Sixty-four human tooth samples were collected from four states (Yucatan, Michoacán, Oaxaca, and Mexico) and analyzed for ^{18}O and ^{13}C isotopes at the University of California Santa Cruz (UCSC) Keck isotope facility. All carbonate analysis was conducted for the tooth samples using a Thermo™ Finnegan Gas Bench II connected to a Thermo™ Delta Plus XL continuous flow mass spectrometer. Replicates of NBS-19 resulted in a reproducibility of 0.1‰ and 0.2‰ for $\delta^{18}O$ and $\delta^{13}C$. The results are reported here using delta notation and the Vienna Standard Mean Ocean Water (VSMOW) and Vienna Peedee Belemnite (VPDB) scale. Drinking water values from tooth enamel were estimated using the following equations by Iacumin et al. and Daux et al.[2-3]

All reported data has been calibrated to the VSMOW-Standard Light Antarctic Precipitation (SLAP) scale. Tap water values spanned a range from -12.7‰ to +0.4‰ and -91.7‰ to -4.2 ‰ for $\partial^{18}O$ and $\partial^{2}H$, respectively. The most ^{2}H and ^{18}O depleted tap water samples were distributed over the inland high-altitude regions of Puebla, Morelos, and Oaxaca. The local Meteoric Water Line (LMWL) for tap waters was $\partial^{2}H=7.78 * \partial^{18}O+7.0$, $r^2=0.96$. The slope of the LMWL for tap waters is similar to that of the Global Meteoric Water Line (GMWL), which has a slope of eight.

Oxygen values for tooth enamel ranged from 23.1‰ to 28.1‰. Estimated drinking water values ranged from -4.8‰ to -11.3‰, with the most depleted drinking water estimates coming from inland Michoacán and the most enriched drinking water estimates coming from Coastal Oaxaca. A one-way Analysis of Variance (ANOVA) was conducted to determine if the means of estimated drinking water values and measured drinking water values were different for four regions in Mexico. Means for measured and estimated drinking water were statistically significantly different between regions $F(7,104)=7.817$, ($p<0.05$). Tukey Kramer post hoc analysis revealed that estimated drinking water values from each of the four regions were not statistically significantly different from actual measured drinking water values from the regions; however, the test also revealed a substantial amount of overlap between estimated drinking water values and actual drinking water values between regions. In each case, estimated drinking water values were not significantly different from at least two alternate locations in addition to the region of origin. For example, estimated drinking water values for Mexico State were not significantly different from Michoacán actual drinking water values ($p=0.167$), nor Yucatan actual drinking water values ($p=0.162$).

Although clear patterns exist among measured water samples from different regions, there is also a significant amount of overlap. In order for patterns in measured water samples to provide useful information on provenance, products such as IsoMap or ArcGIS must be used to identify regional differences and identify areas of overlap based on estimated drinking water values.

A76 Cranial Non-Metric Variability and Ancestry Assessment in Modern Japanese and Thai Individuals

Sean D. Tallman, PhD, Boston University, Dept of Anatomy and Neurobiology, 72 E Concord Street, Boston, MA 02118*

After attending this presentation, attendees will better understand how cranial non-metric traits can be used within a statistical framework to identify Japanese and Thai individuals. Additionally, attendees will be more informed concerning several issues associated with using non-metric traits in forensic ancestry assessment.

This presentation will impact the forensic science community by identifying the non-metric traits that are the most useful in identifying Japanese and Thai individuals. This presentation will also provide forensic anthropologists with statistical models to differentiate between Japanese and Thai individuals using non-metric traits.

Effective biological profiles in forensic anthropology and bioarchaeology depend on the development, validation, and refinement of population-specific methods; however, most biological profile methods were developed in North America on individuals of African and European descent, and it is unlikely that such methods accurately determine biological profiles for Asian individuals. Further, Native Americans have served as biological proxies for Asians due to their distantly shared genetic history, resulting in the largely untested assumption that Native Americans and Asians share a unique suite of cranial traits that can be used to ascertain ancestry. The continued reliance on methods developed from non-Asian populations is especially problematic in forensic contexts in which Asian remains are likely to be recovered, including mass disaster contexts and large western United States cities where significant populations of East and Southeast Asians reside.

This study explores non-metric cranial trait variability in 1,397 Japanese and Thai individuals, 17 to 96 years of age. The Japanese sample is composed of 209 individuals from the late 19th to early 20th centuries (Chiba University) and 572 individuals from the modern era (Jikei University). The Thai sample is composed of 616 individuals from the modern era (Khon Kaen and Chiang Mai Universities). Trait frequencies and chi square analyses for 37 traditional and novel cranial and mandibular traits used in ancestry assessment were calculated to determine if the Japanese and Thai differ from each other and from Native Americans in trait expressions. Subsequently, binary logistic regression equations and Chi Square Automatic Interaction Detection (CHAID) decision trees were calculated to identify the traits that best differentiate Japanese and Thai individuals. Additional non-parametric statistical tests examined the affects of sex, age at death, inter-trait correlations, intra-observer error, and time period on the non-metric traits.

The results indicate that 32 (87%) of cranial and mandibular traits used in ancestry assessment significantly differ in frequency between the Japanese and Thai. Additionally, logistic regression equations and CHAID decision trees correctly classified 61%-91% of individuals, with the logistic regression equations performing the best and all classifications favoring the Japanese individuals. The traits that performed the best at differentiating the two groups include the inferior nasal aperture, nasal aperture shape, prognathism, occlusion, maxillary incisor orientation, gonial muscle attachment ridging, mandibular tori, and chin projection. Further, the Japanese and Thai differ from Native Americans in the frequency distributions for most non-metric traits; however, non-metric traits are influenced by several factors, including sex, age at death, inter-trait correlations, intra-observer error, and time period, thereby complicating their use in ancestry assessment.

This study demonstrates that the Japanese, Thai, and Native Americans are not skeletally homogenous, as they exhibit differences in the expression of cranial trait frequencies due to unique population histories. Thus, non-metric traits can be used within a statistical framework to identify Japanese and Thai individuals, despite the factors that influence the expression of non-metric traits. Moreover, the findings of this research underscore the importance of developing population-specific biological profile methods for diverse and understudied Asian populations.

This research was funded by the National Science Foundation, the Japanese Society for the Promotion of Science, and the National Institute of Justice.

Ancestry Assessment, Non-Metric Traits, Asia

A77 Population Classification Using Discriminant Function Analysis of Combined Mandibular Osteometrics and Non-Metric Traits

Paul D. Emanovsky, PhD, DPAA-Laboratory, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853; and Nicolette Parr, PhD, DPAA-Laboratory, 590 Moffet Street, Joint Base Pearl Harbor-Hickam, HI 96853*

The goal of this presentation is to evaluate various combinations of mandibular non-metric traits and osteometrics for their efficacy in classifying individuals based on ancestry.

This presentation will impact the forensic science community by demonstrating that classification rates using the mandible for ancestry assessment can be used accurately and reliably.

It is widely known that the cranium is the most diagnostic area of the skeleton for ancestry assessment; however, the cranium is often damaged or distorted by trauma or taphonomic processes, making accurate morphological and metric assessments difficult or even impossible. Thus, other skeletal elements must be evaluated for their usefulness in assigning ancestry to unknown skeletal remains. Widely available tools such as FORDISC® 3.0 allow one to make an assessment based on mandibular osteometrics, however, in practice, inclusion of mandibular variables tends to limit population sample sizes. When used in conjunction with other standard cranial measurements, their inclusion may confound some discriminant function model interpretations. Researchers have recently turned to analyzing non-metric traits of the mandible, yet these traits are rarely used in combination with the full suite of morphological characteristics utilized for ancestry assessment.

In the current study, non-metric traits previously found useful for population-based classifications (inversion of the ramus, eversion at the gonial angle, chin shape, shape of the mandibular border, and presence/absence of a mandibular torus) were combined with several standard mandibular osteometrics (mandible length, gonial width, bicondylar width, mandibular angle, and minimum ramus breadth) and tested for classification accuracy using Linear Discriminant Function (LDF) and canonical variates analysis. Scoring of these mandibular variables are different than those previously published by Berg.[1] A total of 963 individuals of European (205 male, 207 female), African (292 male, 195 female), and Asian (40 male, 24 female) ancestry, spanning three continents, were analyzed using the custom database feature in FORDISC® 3.0. These samples include individuals of European and African ancestry from South Africa as well as the United States, while the Asian sample derives from Thailand. Using the ten combined traits, this study seeks to discern whether correct classifications can be obtained and refined for various logical iterations of "lumping" and "splitting" the populations based on shared geographic ancestry and sex (e.g., pooled males and females of combined African, European, and Asian groups).

It is recognized that combining ordinal and continuous data violates some assumptions of LDF analysis; thus, the various iterations and variables are analyzed critically. Correct classification rates, positive predictive values, specificity, sensitivity, and efficiency are used as tests of efficacy. In a three-way test of European, African, and Asian males and females combined (n = 547), the model provides an overall cross-validated Correct Classification Rate (CCR) of 76.2% using ten variables. Two-way tests between African and European (n = 485), African and Asian (n =345), and Asian and European (n = 264), using the same ten variables, yield CCRs of 81.0%, 89.3%, and 85.2%, respectively. Results indicate that the classification rates based on these combinations are on par with Berg's discriminant functions for "forensically interesting groups," which have accuracies ranging from 58.1%-91.4%.[1] This further demonstrates the validity of "mandible only" ancestry determination methods as an accurate and reliable technique for ancestry assessment.

Ancestry, Mandible, Discriminant Function Analysis

A78 Forensic Age Estimation by Medial Clavicle Epiphysis Ossification Using Computed Tomography (CT)

Venkatesh Maled, MD, SDM College of Medical Sciences & Hospital, Sattur, Dharwad, Karnataka State 580009, INDIA*

After attending this presentation, attendees will better understand the principles of Forensic Age Estimation (FAE), its importance for law enforcement, how to increase the accuracy of FAE, the use of CT to enhance the precision of clavicular maturity, and CT's practical application.

This presentation will impact the forensic science community by providing knowledge about the role of maturation stages of the clavicle in FAE. In addition, this presentation will highlight the role of CT scan s in increasing the accuracy of FAE.

Age estimation is of paramount importance in assisting law enforcement.[1] In many countries, the relevant age limits in criminal laws for the existence of criminal responsibility are between 14 and 21 years. Maturation of sexual characteristics, dental and skeletal, have been used to determine age.[2] By 18 years of age, most developmental sites have completed their growth, except for the medial epiphysis of clavicles. Therefore, in some countries, radiography or CT scan of the clavicles is used to estimate age in persons presumed to be older than 16, 18, and 21 years.[2] For example, as per the Association of German Forensic Age Diagnostics (AGFAD) guidelines, X-ray examination of the clavicle to confirm the chronological age of 21 is mandatory.[3] Correlations between clavicle maturation and age have long been studied in dry bones and at autopsy.[4] Recent studies have revealed the utility of imaging tools and, among these, CT has particular advantages.[5]

A retrospective analysis of 556 CT scans of the neck or chest of patients aged between 10 and 30 years was performed. Medical records were reviewed for date of birth and date of performing the CT. All axial and coronal images of 1mm slice thickness were used in the evaluation. The clavicular maturation stages were scored separately by two radiologists without knowledge of the patient's age. The five stages of maturation described by Schmeling et al. and sub-stages of stage 2 and 3 by Kellinghaus were followed.[4,5]

The results of gender-based comparisons revealed statistically significant differences in mean age at the maturation stages of 1, 3b, and 5. The maturation at stage 1 and stage 3b occurred earlier in females by 16 and 17 months, respectively. In contrast, maturation at stage 5 occurred 12 months earlier in males compared to female counterparts. No statistically significant differences were noted in other maturation stages (2a, 2b, 2c, 3a, 3c, and 4). Maturation stage 3a was first presented at 16 years of age for both sexes. Maturation stage 3b was first presented at age 18 in females and age 16 in males. Maturation stage 3c was first presented at 21 years of age for both sexes.

In conclusion, the CT scan is a useful visualization tool for estimating chronological age. The Kellinghaus sub-stage classification criteria improved accuracy of age estimation, particularly in stage 3. Results suggest using stage 3a of maturation to represent ages >16 years, stage 3b of maturation to represent ages >18 years, and stage 3c to indicate ages >21 years in FAE.

Forensic Age Estimation, Clavicle Ossification, Computed Tomography

A79 The Role of Third Molar Impaction on Dental Development and Age Estimation in Males

Kelly Heim, MA, University of Nevada, Reno Anthropology Dept, 1664 N Virginia Street, Ansari Business Bldg, Rm 512, Reno, NV 89557; and Marin A. Pilloud, PhD, University of Nevada, Reno, 1664 N Virginia, Reno, NV 89557-0096*

After attending this presentation, attendees will understand how third molar impaction influences dental development and estimates of age as part of the biological profile.

This presentation will impact the forensic science community by evaluating the utility of impacted third molars in the age estimation of males.

Numerous dental development charts exist to aid in overall age estimation from the dentition.[1-3] These charts incorporate the third molar; however, this tooth is often treated separately to establish independent methods of age estimation. While there is substantial variation in third molar development, it is still a useful measure of age in late adolescence, when other teeth are fully developed. Third molar development may also prove effective in conjunction with other age indicators in determining if an individual has attained the age of majority, which could have legal ramifications.

While a clear relationship between chronological age and third molar development has been established, the effect of impaction on crown and root development is not well understood. The vast majority of impacted teeth are third molars, and a worldwide survey found that approximately 24.4% of the population has impacted third molars.[4] While prophylactic extraction of the third molars is exceedingly common in the United States, there is growing debate over the necessity of this procedure, and the presence of third molars may become more common in forensic casework. The goal of this study is to investigate the effect of third molar impaction on development and its concomitant impact on age estimation methods.

Data were collected on radiographs of individuals who were analyzed in the Central Identification Laboratory within the Defense POW/MIA Accounting Agency. Due to the unique mission of this agency, the vast majority of individuals recovered are males; therefore, this study is only comprised of males (n=90). Radiographs of skeletonized individuals were taken by forensic odontologists. These radiographs were then scored for dental development according to the stages defined by Demirjian et al.[5] Two cohorts were created from this sample, individuals with impacted third molars (n=38) and those without impacted third molars (n=52). Age was assigned based on the appropriate ancestry-based method.[6-7] Differences between identified age and predicted dental age in each group were assessed to determine if molar impaction affected root development and age estimations.

In the cohort with third molars that were not impacted, age was correctly assigned in 90.1% of third molars. In the cohort with third molar impaction, age was correctly assigned for 66% of impacted teeth and 61.5% of non-impacted teeth. In every case of incorrect age assignment, the individual was estimated to be younger than his identified age.

Based on this research, individuals with at least one impacted third molar tend to have underdeveloped third molars, even in those that are not impacted. Therefore, care should be taken in age estimates of individuals who display any impacted third molars; however, more work is needed to explore the effect of impacted molars and development among females and other ancestry groups.

Molar Impaction, Age Estimation, Dental Development

A80 The Challenges of Comparative Radiography in the Developing Skeleton

Carolyn V. Isaac, PhD, 1000 Oakland Drive, Kalamazoo, MI 49008-8074; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Dept of Pathology, 1000 Oakland Drive, Kalamazoo, MI 49008; and Joseph A. Prahlow, MD, Western Michigan University School of Medicine, 300 Portage Street, Kalamazoo, MI 49007*

After attending this presentation, attendees will recognize the ability to positively identify juvenile individuals by means of comparative radiography using radiographs taken years apart.

This presentation will impact the forensic science community by identifying comparative radiography as a method that can be used in the scientific identification of subadults. Specifically, strategies can be implemented to approximate postmortem radiographs by adapting radiographic techniques to accommodate changing growth.

Positive or scientific identifications are a common practice in medical examiner's offices when decedents are not visually identifiable. In Michigan, law also requires definitive identification when a death is the result of an incident involving two or more individuals of approximately the same age, sex, ancestry, height, weight, hair color, and eye color. Scientific identifications can be achieved using DNA, fingerprints, and dental and medical radiography. While each technique has its advantages and disadvantages, they each require the availability of antemortem and postmortem data for comparison. While these are commonly used for adult decedents, there are few reports or validation studies of appropriate identification methods for juveniles. Juveniles present a unique challenge in that they are growing and developing rapidly and may not have antemortem data, such as fingerprints, for comparison. Depending on their age, dental records may or may not be available. The first challenge in these cases is determining if there are radiographic features that retain morphological stability in the growing and maturing juvenile skeleton. An additional difficulty is the change of the gross morphology and orientation of skeletal elements with development requiring the adaptation of standardized techniques to approximate antemortem radiographs. Six cases in which antemortem radiographs from infancy or childhood were used in the scientific identifications of juveniles or young adults are presented.

One case concerned a motor vehicle accident involving two sisters who had the same skin, hair, and eye color and were approximately the same size since one was four years old and the other was five years old. One of the girls died as a result of the accident. The other girl survived but was unresponsive in the hospital. Footprints from birth had not been documented for the presumed decedent but were available for the decedent's sister. Unfortunately, there was not enough detail in these prints to confirm an identification. Antemortem chest radiographs of the decedent at eight months old were obtained and were able to be used for positive identification. Another case involved the discovery of subadult remains requiring identification. A postmortem vertebral radiograph of the 7-year-old decedent was compared to an antemortem chest/abdomen radiograph of the presumed decedent at three years of age to establish aid in identification. A multiple fatality house fire required the identification of two juveniles, a 12-year-old female and a 10-year-old male. The female was identified from a hand radiograph taken 4.5 years prior and the male was identified from chest and abdomen radiographs from between 2.5 and 3.5 years prior. The final cases resulted from a motor vehicle accident in which three young adults, two males and one female, died. One male had fingerprints on record taken 1.5 years prior, from which he was positively identified. The other male had dental records and dental radiographs from 8.5 years prior, when he was 11 years old. The 20-year-old female had an antemortem chest radiograph taken when she was 12 years of age. Using fingerprint comparison and comparative dental and medical radiography, each of these decedents was positively identified.

Comparative radiographic identification cases present unique challenges that require an understanding of radiographic techniques and positioning to approximate the antemortem radiograph. Juveniles can be especially difficult to positively identify due to growth changes and morphological changes to the skeleton. Although there are gross developmental and morphological changes to skeletal elements, these cases demonstrate that specific skeletal radiographic traits are maintained for long periods and can be used to make positive identification in the postmortem setting.

Identification, Radiography, Juvenile

A81 Examining the Effect of Region Of Interest (ROI) Size on the Ability to Accurately Estimate Age at Death From Osteon Population Density (OPD)

Megan E. Ingvoldstad, PhD, DPAA Laboratory, Joint Base Pearl Harbor-Hickam, HI 96853; Timothy P. Gocha, PhD, Texas State University, 601 University Drive, San Marcos, TX 78666; Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Victoria M. Dominguez, MA, The Ohio State University, Skeletal Biology Research Lab, Columbus, OH 43210*

After attending this presentation, attendees will understand the current issues concerning histological age estimation and the effect that ROI size has on the relationship between OPD and age-at-death estimation.

This presentation will impact the forensic science community by demonstrating that the amount of bone sampled/analyzed in histological age assessment can have a profound impact on the ability to accurately estimate age at death. This will inform future histological research, resulting in higher quality forensic research and practice.

As a complement to macroscopic aging methods, or when necessary macroscopic elements are damaged/absent, age can be estimated through histological examination of remodeling events in cortical bone. To date, the femoral midshaft has been the most commonly employed site for histological studies; however, a consensus is lacking on how much bone to analyze when quantifying remodeling, as existing methods employ ROIs that differ in size, number, and location.

Recently, histological research at the femoral midshaft has proliferated due to the revival of the Ericksen femur collection as an active resource. The current study is a meta-analysis of three recent studies that provide a unique opportunity to assess the effect of ROI size on the relationship between OPD and age. All three studies analyzed here (the Ingvoldstad, Crowder/Dominguez, and Gocha methods) primarily utilized the Ericksen collection, examined the anterior region of the femur, and quantified remodeling according to the same standard histological definitions.[1-3]

The Ingvoldstad method examined 200 individuals (97 males, 103 females), aged 30-97 years (average=71 years), all from the Ericksen collection; a fixed ROI size of 3.00mm^2 was used to quantify remodeling at eight anatomical and biomechanical locations around the femoral cortex, though only anterior data are analyzed here. The Crowder/Dominguez method examined 320 individuals (170 males, 150 females), aged 15-97 (average=66 years), 87% of whom were from the Ericksen collection. This method used a topographic sampling strategy, separating a 5mm-wide section of the anterior femur into ten columns and reading every other frame using a Merz reticule; this resulted in an average ROI size of 18.30mm^2, with an average of 9.52mm^2 of bone analyzed. The Gocha method examined only 30 individuals (15 male, 15 female), aged 21-97 years (average=59 years), 83% of whom were from the Ericksen collection. This method examined remodeling over the entirety of the femoral midshaft, though only anterior octant and quadrant data are analyzed here; average octant ROI size was 41.82mm^2, average quadrant ROI size was 89.93mm^2.

Statistical analyses were performed in SPSS 23. Kolmogorov-Smirnov tests demonstrated OPD values for all methods to be normally distributed (all p-values >0.070). The relationship between OPD and age was assessed through Pearson's correlation coefficients, as well as the adjusted R^2 value of linear regression predictive models; all of these statistical measures were statistically significant (all p-values <0.043). The person who collected the majority of the data for the Crowder/Dominguez method also performed inter-observer error measures for the Ingvoldstad and Gocha studies, neither of which demonstrated significant differences between observers.

The correlation coefficient for the Ingvoldstad method was R=0.143, and the adjusted R^2=0.016, indicating OPD explained only 1.6% of the variation in age at death. The correlation coefficient for the Crowder/Dominguez method was R=0.681, and the adjusted R^2=0.462, indicating OPD explained 46.2% of the variation in age-at-death. The correlation coefficient for the Gocha Octant method was R=0.907, and the adjusted R^2=0.817, indicating OPD explained 81.7% of the variation in in age at death. For the Gocha Quadrant method, the correlation coefficient was R=0.918 and the adjusted R^2=0.838, indicating OPD explained 83.8% of the variation in age at death.

Results indicate that ROI size has a significant effect on the ability to predict age at death from histological remodeling. Examination of small, isolated ROIs is not recommended, as such an approach is more susceptible to random variation in variable distribution and can negatively affect interpretation. Instead, future studies should examine larger ROIs to maximize histological remodeling's ability to predict age at death.

Age Estimation, Skeletal Histology, Forensic Anthropology

A82 Age Estimation Using the Development of the Foot and Ankle

Kelsey A. Carpenter, MS, Mercyhurst University, Dept of Applied Forensic Sciences, Erie, PA 16546; and Stephen D. Ousley, PhD, Mercyhurst University, Dept of Anthropology/Archaeology, 501 E 38th Street, Erie, PA 16546*

After attending this presentation, attendees will understand the changes that have occurred in the development of the foot and ankle in subadults since the 1930s as well as a new subadult aging technique utilizing radiographs of the foot and ankle. By using the presence or absence of ossification centers in the subadult foot and ankle along with new statistical methods, a new means of subadult age estimation will be discussed.

This presentation will impact the forensic science community by providing an improved subadult aging technique of the foot and ankle that can be used in forensic anthropology and pathology. Additionally, by using only radiographs, this study presents a less intrusive age estimation method for subadults.

Age estimation in subadults can assist with narrowing missing person searches substantially. The developmental timing of multiple areas of the skeleton, such as the wrist, knee, and elbow, have been researched thoroughly in recent years in relation to subadult age estimation; however, multiple areas of the skeleton should be used for age estimation when available.[1] The goal of this study is to first test for differences in age of appearance of ossification centers in the foot and ankle between historical and modern cohorts, and, if differences are noted, to develop a model using these modern data for subadult age estimation.

A total of 1,520 radiographs (871 males, 649 females) of the right foot and ankle from White individuals aged from birth to 13 years were analyzed from the Pediatric Radiology Interactive Atlas (PATRICIA) and funded by a National Institute of Justice grant. Eleven ossification centers were chosen to be scored based on their previously published predictive value for age.[2] Each ossification center was scored as either present, absent, or not able to be scored. Data from each ossification center were analyzed using logistic regression, which removes assumptions of a normal distribution and linearity. Most importantly, a logistic regression model produces probabilities for ossification center appearances at any age. There were two goals for using logistic regression to analyze these data. The first was to test for differences in each ossification center between the modern and historical samples; the 5th and 95th probabilities produced from the logistic regressions were used for one-sided confidence intervals for age. The second goal was to test for sexual dimorphism in ossification center appearance. The regression tree method was applied to these data in order to estimate age using explicit intervals based on the scores of multiple epiphyses.[3] Inter-observer and intra-observer studies were completed on 39 individuals to test the validity and reliability of the method. All statistical analyses were completed using R software.[4]

Results of the inter-observer and intra-observer studies demonstrate that this scoring method is both reliable and valid for 9 out of the 11 ossification centers, with the ossification centers of the ankle, tarsals, and metatarsals being more reliable and valid than ossification centers of the phalanges. Two ossification centers located on the phalanges were valid for estimating age but were very often difficult to score. For this reason, these two ossification centers had a limited amount of observations because they were rarely visible enough to score in the radiographs.

Seven out of the 11 ossification centers appear earlier in the modern males than they did in the historical males. In the modern females, 9 of 11 ossification centers developed later than the historical females. Sexual dimorphism was seen in 9 of the 11 ossification centers, with 8 of the 11 ossification centers appearing statistically significantly earlier in females. Noting these observed changes in the modern sample, this study explored two different methods for age estimation, the first being age estimates based on one-sided 5^{th} or 95^{th} probabilities of the ossification center scores for age, and the second being the application of regression trees. The results of this study prove that an updated age estimation method for the foot and ankle is necessary to use on modern populations, and that the application of regression trees in this type of study provides a valuable new age estimation technique.

A83 The Influence of a Pathological State on Fetal Biometric Age Estimation

Sarah Humez, MD, University Hospital of Lille, Biological and Pathological Department, Bd du Professeur J Leclercq, Lille, North CS 70001 59037, FRANCE; Mélissa Niel, MS, University of Aix-Marseille UMR7268 ADES(EFS-CNRS), Faculté de Médecine, bâtiment A- CS80011, Boulevard Pierre Dramard, Marseille Cedex 15, Bouches-du-Rhône 13344, FRANCE; Valéry C. Hedouin, MD, PhD, Iml-chu Lille, Rue Andre Verraeghe, Lille 59000, FRANCE; Pascal Adalian, Laboratoire ADES, Marseille, FRANCE; and Marie-Dominique Piercecchi-Marti, PhD, 264 Rue Saint Pierre, Marseille 13005, FRANCE*

The goal of this presentation is to highlight the influence of fetal growth-affecting diseases on the estimation of fetal biometric age calculated from conventional anthropometric tools. This presentation reveals the potential mistakes inherent in the estimation of fetal age in cases in which judicial consequences are crucial. This study challenges the anthropometric tools traditionally used for age estimation in healthy fetuses and suggests more relevant markers of fetal growth in pathologic conditions. With brain maturation being the most relevant marker of fetal maturation, skull base bony structures could be a useful witness of fetal growth.

This presentation will impact the forensic science community by providing diagnostic tools useful in all fetal diseases characterized by a short femur length.

Pars basilaris growth is not influenced by the diseases characterized by a short femur length; thus, the decoupling between pars basilaris growth and that of long bones is a diagnostic element for these diseases. Thirty-seven Computed Tomography (CT) fetal scans, *in utero* or postmortem, conducted after observing a short femur length were compared to a control population of 97 CT postmortem fetal scans. Twin pregnancies were excluded. The study population was divided into two groups: (1) a "skeletal anomalies" group involving fetuses suspected of, or that were carriers of, a constitutional bone disease or a chromosomal abnormality; and, (2) an "isolated short femur length" group involving fetuses without suspicion of syndromic context. A reconstruction of the long bones (humerus, radius, ulna, femur, and tibia) and the pars basilaris of each fetus allowed the calculation of the maximum long bones diaphyseal lengths and the dimensions of the pars basilaris (maximum width, maximum length, and sagittal length). For each fetus, the ratio of diaphyseal lengths to Femoral Length (FL) as well as that of FL to pars basilaris dimensions were calculated. Between study and control populations, a significant difference in the humeral, radial, femoral, and tibial lengths was observed ($p<0.05$), whereas no difference between the pars basilaris dimensions was found. Age estimation calculated from the FL underestimated the true age of the population. The FL/Maximum Width Basilaris ratio was the most relevant diagnostic tool of the diseases characterized by a short femur length, and the Humeral Length/FL ratio was useful for the differential diagnosis between intra-uterine growth retardation and constitutional bone disease.

A study associating both pars basilaris and long bones growth estimation allows: (1) reducing the risk of gestational age underestimation and, thus, its legal consequences; and, (2) making a diagnosis of disease affecting fetal growth, which is a challenge in anthropological practices.

Fetal Age, Short Femur Length, Anthropology

A84 Exploring the Gap Between Anthropological and Clinical Literature on Pediatric Fracture Healing

Diana L. Messer, MS, 2873 Neil Avenue, Apt 452B, Columbus, OH 43202; and Amanda M. Agnew, PhD, The Ohio State University, 306 Atwell Hall, 453 W 10th Avenue, Columbus, OH 43210*

After attending this presentation, attendees will understand the differences within and between anthropological and clinical literature regarding the interpretation of the time since injury of pediatric healing fractures.

This presentation will impact the forensic science community by serving as a resource for understanding the variability that exists within current literature and how this impacts the applicability of certain fracture healing timelines for use in forensic contexts. Further, inconsistencies across the literature and between fields call into question the appropriateness of published timelines for use in legal contexts.

Several methods to assess time since injury using radiographic signs of healing have been proposed specifically for identification of child physical abuse. The goal of this project is to present major gaps in these methods, compare clinical and anthropological literature, and define issues that warrant future research. Through a review of scientific literature, 18 published timelines of fracture healing were identified and compared. Of these, more than half were based solely on previous literature or clinical experience. In fact, little scientific data exist to support the understanding of the rate of pediatric fracture healing and only 8 of the 18 timelines examined were based on primary research.

The most significant discrepancy across the literature is a failure to take into account intrinsic variables that may influence fracture repair, including age, anatomical location, specific bone location, and within-bone fracture location. Of the nine timelines of fracture healing with an associated age range, the majority pool various age groups of different years together with little to no consideration given to the effect of age on fracture repair. Three timelines pool adults and teens with children. Given the definite differences between mature and immature skeletons, timelines derived from such samples should be treated with extreme caution. Even pooling smaller age ranges is questionable; age ranges of 0-5 years, while more appropriate to pool together than adults and children, still include pre-ambulatory and ambulatory children whose skeletons are distinct from one another structurally and morphologically.

Further, different bone functions likely influence the healing process between broad anatomical locations (upper vs. lower extremities). Half of the published timelines examined did not take into account anatomical location of the healing fracture, though it has been preliminarily suggested to influence fracture repair rate. Malone et al. found that upper extremity fractures heal more rapidly than lower extremity fractures, yet more than half (55%) of time-since-injury methods either do not cite the specific skeletal elements from which their research was derived or they combine skeletal elements of various anatomical regions (28%).[1] Further, there is significant overrepresentation of long bones (98% of the timelines examined), with 33% represented by radius fractures; however, fracture locations used in time-since-injury studies, such as the radius, do not necessarily overlap with fracture locations that are considered specific for abuse. Finally, published timelines do not take into account within-bone location and its influence on fracture repair, particularly in the early stages of healing. This is despite the fact that there are several clinical methods to assess radiographic union for specific within-bone locations.

Finally, stages, features, and timelines of fracture healing are inconsistent both within and between fields. There is a general lack of published timelines including early evidence of fracture healing, especially within anthropological literature. These early characteristics are of particular importance to identify occult healing fractures seen in child physical abuse. In anthropological literature, there is a tendency to use a stage system, while clinical literature tends to examine traits of specific radiographic characteristics of healing. Not only are the radiographic features of fracture healing inconsistent, the timelines presented in the literature vary significantly between one another, even for the same features.

In conclusion, time since injury of pediatric healing fractures is of great importance to the forensic field as evidence of child physical abuse; however, inconsistencies across the literature and between fields call into question the appropriateness of published timelines for use in legal contexts. This work identifies the gaps in current knowledge surrounding pediatric fracture healing. Further research is needed to determine the influence of certain

variables on fracture healing and to work toward incorporation of those variables into time-since-injury estimation methods and timelines.

Child Abuse, Fracture, Healing

A85 Skeletal Sun Bleaching and Weathering Patterns in Central Florida: An Approach for Estimating Time Since Death (TSD)

Michelle M. Hawkins, BSc, UCF Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816; John J. Schultz, PhD, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816; and Alexander T. Mitchell, 1045 Club Sylvan Drive, Apt H, Orlando, FL 75022*

After attending this presentation, attendees will better understand the progression of skeletal sun bleaching and weathering over time. This presentation will focus on patterns of bone sun bleaching and weathering in order to fill a gap in the literature regarding the time frame in which bones become bleached and weathered in the Central Florida environment during the Postmortem Interval (PMI).

This presentation will impact the forensic science community by discussing the timing and extent of skeletal sun bleaching and weathering. Factors influencing sun bleaching and weathering that will be discussed include the effect of microenvironments (full sun versus shade), length of the PMI, and bone type.

After soft tissue decomposition, taphonomic modifications to the remaining skeletal elements can provide valuable information to investigators regarding TSD. It is therefore important to investigate the timing of sun bleaching and weathering patterns observed during the PMI in order to understand how these taphonomic modifications can contribute to TSD estimations. Investigation into the timing and progression of sun bleaching and weathering was undertaken over six months in Central Florida. Four pig (*Sus scrofa*) carcasses were placed in two microenvironments: two in open, full sun and two in shade. After skeletonization occurred, ten bones from each pig carcass location were assessed weekly for sun bleaching and weathering changes and included cranial elements, mandibles, scapulae, vertebrae, ribs, os coxae, and long bones. The total sample was reduced to 37 bones due to animal scavenging. Bone sun bleaching was assessed once a week using the Munsell soil color charts, with the lightest coloration of the exposed bone scored.[1] A bone was considered to be sun bleached when the lightened color corresponded to the WHITE PAGE, and the extent of the sun bleaching was estimated as <25%, 25% to 50%, >50% to 75%, and >75% to 100%. Additionally, bone weathering was evaluated using the Behrensmeyer stages by scoring weather-related changes on a scale from 0 to 5.[2]

Analysis of sun-bleached skeletal elements demonstrated that microenvironment had the greatest influence for the presence or absence of sun bleaching. Overall, bones in full sun locations exhibited a greater rate of sun bleaching than bones in full shade locations. By month four of the investigation, skeletal elements in full sun locations exhibited approximately 25% more sun bleaching on the exposed bone surface than elements in full shade locations. Bones in full sun locations exhibited approximately 25% to 50% bleaching on the exposed bone surface by day 100 and approximately 50% to 75% bleaching on the exposed bone surface between day 100 and 135. Additionally, bones in full sun and partial sun locations exhibited initial signs of bleaching around day 22 and day 36 of the investigation, respectively; however, by day 135, bones in full shade still exhibited minimal signs of bleaching (<25% of the exposed bone surface).

Skeletal element types displaying sun bleaching earliest in the PMI included ribs and scapulae, whereas os coxae appeared to exhibit bleaching latest in the PMI out of all bone types studied. While the majority of the skeletal elements that were analyzed contained no soft tissue remnants, a few elements that were studied contained minimal desiccated and adhered soft tissue, including articular cartilage, which may have partially shielded the surface of the bone from sun bleaching. It is important to note that the most challenging issue with scoring sun bleaching was the periodic presence of moist bones from rainfall that affected bone surface coloration, as compared to dry bones. Overall, minimal weathering was noted on the remains after five months. While bones in full shade generally exhibited Stage 0, bones in partial shade and full sun exhibited Stage 1. In addition, one mandible and one scapula in full sun exhibited the beginning progression of Stage 2 on less than 25% of either bone. In conclusion, the combined utilization of sun bleaching and weathering as a taphonomic model that is regionally specific may aid standardization of future studies by increasing accuracy in estimating TSD.

Taphonomy, Sun Bleaching, Bone Weathering

A86 Optimization of a Protocol for Visualizing Vascular and Cellular Pore Networks in Human Bone Using Multiphoton Confocal Microscopy

Mary E. Cole, MA, Ohio State University, Dept of Anthropology, 4034 Smith Laboratory, 174 W 18th Avenue, Columbus, OH 43210-1106; and Sam D. Stout, PhD, Ohio State University, Dept of Anthropology, 4034 Smith Laboratory, Columbus, OH 43210-1106*

After attending this presentation, attendees will appreciate the potential of multiphoton confocal microscopy for 3D visualization of human bone loss at the histological level.

This presentation will impact the forensic science community by optimizing a protocol for 3D imaging of vascular and cellular spaces in bone tissue. Future forensic applications for imaging these pore structures include: (1) identifying bone tissue sites at high risk for spontaneous fracture; (2) distinguishing between different bone types at the tissue level based on pore geometry, which appears highly sensitive to mechanical loading environment; and, (3) demonstrating the advantages of multiphoton confocal microscopy for histomorphological analysis in general.

Throughout life, bone is remodeled to replace old tissue, repair microscopic damage, or resorb bone in response to decreasing mechanical strain. Osteoclasts tunnel into the old bone, and osteoblasts fill this resorption space with new bone, leaving a central Haversian canal to transmit a blood vessel. This "vascular porosity" increases with age as osteoblasts decline in their capacity for bone formation, while osteoclasts increasingly resorb bone in response to declining physical activity and muscle strength. Vascular pores are stress concentrators for microdamage, which can initiate and propagate into a spontaneous fracture within the highly interconnected pore network. Bone tissue also has a separate network of "cellular porosity," composed of the lacunae that house osteocyte cells and their connecting canaliculi. Porosity shows promise for distinguishing between bone regions and types based on mechanical loading environment. Regions of lower mechanical strain within a given bone have higher vascular porosity. Loaded bones have been found to have larger lacunar volumes and more branched canaliculi compared to the unloaded bones.

3D pore geometry is poorly characterized. Forensic scientists interested in associating pore geometry with different bone types (e.g., normal/osteoporotic, young/old, human/non-human, loaded/unloaded) need an effective protocol for imaging these pore structures. Ciani et al. stained rat tibiae with Fluorescein Isothiocyanate Isomer I (FITC) and imaged cellular pore networks with single-photon confocal laser scanning microscopy.[1]

The suitability of this protocol was tested for imaging both vascular and cellular pore networks in human bone. Multiphoton confocal microscopy was used as it can penetrate far deeper into a sample with infrared light. Ten cross sections, approximately 500µm to 600µm in thickness, were cut from the midshaft of a fresh cadaveric human rib. Each cross section was placed in a 15mL volume of freshly prepared 4% formaldehyde and fixed for 24 hours at room temperature under gentle rotation. Cross sections were dehydrated in ascending grade ethanol (75%, 95%, and 100% for five minutes each). FITC was diluted in 100% ethanol at concentrations of 1%, 0.9%, 0.8%, 0.7%, 0.6%, 0.5%, 0.4%, 0.2%, and 0.1%. Each 10mL solution was gently rotated for one hour, then filtered. Each cross section was placed in a different concentration of solution for four hours under gentle rotation. Each cross section was then rinsed in 15mL of 100% ethanol under gentle rotation for 30 minutes, then air dried. Small regions were imaged using an Olympus® FV1000 MPE Multiphoton Laser Scanning Confocal microscope with N.A. 1.05, 25x water immersion objective, 800nm laser excitation wavelength, resolution 1,024 x 1,024 pixels, step size 0.63µm, and 2x Kalman averaging. 3D vascular and cellular pore networks were analyzed for volume, orientation, and connectivity in the image analysis software FIJI.

Results were best for a concentration of 1% FITC, as resolution was lost as most features became indistinguishable at a depth of approximately 185µm into the sample. Vascular and cellular pores were clearest to a depth of approximately 100µm. Pores displayed fairly uniform brightness within a given depth. At concentrations of FITC <1%, the resolvable depth decreased, and pore structures became more variable in brightness within a given depth.

These results demonstrate that the method from Ciani et al. is suitable for 3D imaging of both vascular and cellular pore networks in human bone tissue. Multiphoton confocal microscopy facilitates deep penetrance into the sample to allow quantification of pore volume, orientation, and connectivity.

Skeletal Histology, Confocal Microscopy, 3D Imaging

A87 Reconstructing Personhood: A Historical Perspective on Fragmentary Remains, DNA Technology, and Family Acceptance of Positive Identifications of United States War Dead

Christine M. Pink, PhD, Metropolitan State University of Denver, Dept of Sociology and Anthropology, Campus Box 28, PO Box 173362, Denver, CO 80217-3362; and Allysha P. Winburn, MA*, University of New Hampshire, Dept of Anthropology, 310 Huddleston Hall, 73 Main Street, Durham, NH 03824*

After attending this presentation, attendees will better understand the historical evolution of identifications based on fragmentary remains as reconstituting the personhood of the decedent from the perspective of forensic practitioners and next of kin.

This presentation will impact the forensic science community by expanding the discussion regarding the identification of increasingly fragmentary remains consequent to improvements in scientific methodologies, including how those identifications may or may not reconstitute the "person" to the next of kin. A renewed awareness of the different meanings of "identification," "remains," and "person" to scientists and family members will positively impact attendees' abilities to practice a contextualized and empathetic form of forensic science.

The identification of remains from past United States conflicts is meant to provide answers for family members and contribute to a semblance of closure, despite the significant time depth often associated with these losses. The dead themselves — their bodies, their memories, their deaths — have agency. In some cases, a minute quantity of physical remains, accompanied by a report consisting of sequences of nucleotide bases and statistical probabilities, is willingly recognized as proof that a loved one was located, recovered, and identified. At first glance, this acceptance of very fragmentary remains appears to be a modern artifact of the genomic era; however, this presentation argues that the trend of accepting smaller and smaller portions of the body as representative of the whole "person" has deeper historical roots. Specifically, public acceptance for the identification of less-than-whole bodies appears to have begun during the Civil War, the first United States conflict in which families faced the realities of decomposition and fragmentation on a massive scale. Over time, the developing rhetoric around the recovery and repatriation of service members has increasingly made the possibility of receiving partial remains, or none at all, acceptable to the public.

Trends were analyzed among identification year, duration of identification process, completeness of remains, and use of mitochondrial DNA (mtDNA) analysis in a sample of remains identified at the Defense POW/MIA Accounting Agency-Central Identification Laboratory (DPAA-CIL).

Data were collected from the DPAA-CIL on a subset of identifications made from 1996-2015 and accessioned as early as 1982 (n=888). A subset of the cases accessioned after 1995 (n=621) was also analyzed (1995, the year in which the Defense Science Board Task Force released their *Report on The Use of DNA Technology for Identification of Ancient Remains*, represented a benchmark for DNA-led identifications of United States war losses). Positive identifications from cemetery disinterments were not considered, as these disproportionately targeted more complete cases for exhumation. Similarly, to counteract possible biasing effects, group identifications and additional portions from previously identified individuals were not considered.

The majority of cases in the sample were less than 50% complete. Results indicated that the completeness of remains had a significant relationship to the amount of time taken between initial accession and identification in both datasets (p<0.001 for both). The use of mtDNA as an identification method also had a significant relationship with completeness of remains (p<0.001) and the year the identification was made (p<0.001). The overall trend in the data is that more fragmentary remains take longer to identify, and those identifications tend to use mtDNA methodology.

As methods for sequencing degraded DNA improve (e.g., next generation sequencing), fragmentary remains, once unidentifiable, may become the basis for positive identifications and repatriations. The last entire year considered here (2014) includes the highest numbers of identified cases consisting of remains <50% complete. Yet, anecdotal evidence suggests that it is an existing historical foundation that facilitates the acceptance of incomplete remains identified through modern DNA-based methodologies. In 2015, for example, family members of a service member implied hesitance in accepting a recent positive identification, instead finding closure in witness testimony:

as *The Charlotte Observer* reported, "(They) still weren't convinced (of the DNA-based identification) until finally they heard what happened that day from the helicopter's co-pilot …."[1]

Loss, acceptance, and closure are part of a process that is individual; however, previous research across disciplines reveals some commonalities in this process with regard to war losses. As advocates for the dead, forensic anthropologists would do well to acknowledge the perspectives of the next of kin when making and presenting positive identifications.

Fragmentary Remains, Positive Identification, Mitochondrial DNA

A88 Changing the Mentorship Paradigm: Survey Data and Interpretations From Forensic Anthropology Practitioners

Allysha P. Winburn, MA, University of New Hampshire, Dept of Anthropology, 310 Huddleston Hall, 73 Main Street, Durham, NH 03824; Audrey L. Scott, PhD, Defense POW/MIA Accounting Agency, 590 Moffet Road; Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; Cate E. Bird, PhD, Anthropology, University of South Florida, 4202 E Fowler Avenue, Social Science Bldg 100, Tampa, FL 33620; and Sean D. Tallman, PhD, Boston University, Dept of Anatomy and Neurobiology, 72 E Concord Street, Boston, MA 02118*

After attending this presentation, attendees will understand current perceptions of the roles of mentors and protégés within the field of forensic anthropology.

This presentation will impact the forensic science community by informing future mentor-protégé interactions and guiding forensic scientists to focus on the positive influence that mentorship can have — not only on protégés' careers, but also on the personal development of the mentor and the overall well-being of the field.

The concept of mentorship originated in ancient Greek mythology and referred to a relationship between a knowledgeable person (mentor) and a less-experienced person (protégé). Today, mentorship can be conceptualized as the informal transmission of knowledge over a sustained period of time and in a domain in which the mentor and protégé have unequal knowledge. Traditionally, mentors are seen as older, wiser advisors who provide counsel to younger, less-experienced individuals in their professional or social sphere. Certainly, the role of this high-level mentor has been paramount in developing the field of forensic anthropology; however, anyone with greater knowledge in a specific domain who exerts a positive influence on another individual's professional or social development can be considered a mentor, regardless of age or experience. This presentation contends that peer-to-peer interactions (e.g., leading by example, sharing diverse work experiences, and dispensing advice) also qualify as important mentorship behaviors.

This research explores how the roles of mentors and protégés are perceived throughout the diverse academic and applied contexts of the field of forensic anthropology. All users of the American Academy of Forensic Sciences (AAFS) Anthropology Section listserv received a link to an anonymous, Institutional Review Board (IRB) -approved Qualtrics.com survey. Instructions encouraged participants to share the survey link with other practitioners of varying skill and experience levels, including students and other non-members. Consenting participants answered 23 multiple-choice and 12 open-answer questions regarding their demographic information, opinions about mentorship, and experiences as both mentors and protégés.

A total of 96 professional forensic anthropologists and anthropology graduate students participated in the survey. The majority of respondents specialized in biological anthropology, had completed a PhD, and worked in the academic or medical examiner setting. Most had been in the field for fewer than 21 years and were less than 45 years of age. The majority self-identified as being of female gender and European ancestry.

Respondents were nearly unanimous regarding the importance of mentorship in forensic anthropology, and many felt that being mentored directly contributed to their career success. Nearly all respondents had benefitted from the influence of multiple mentors, and many had also mentored multiple protégés. As expected, most respondents reported being mentored by a thesis/dissertation advisor; however, many respondents also reported peers as an important category of mentor (68%) and peers emerged as the most commonly reported category of protégé (75%). More respondents had received mentorship in career-related areas than they had in social interactions and social issues. Likewise, when asked in which areas they desired to provide and receive additional mentorship, more respondents selected these latter, social categories. Still, differences between distributions for mentorship provided/received and additional desired mentorship provided/received were not statistically significant (α=0.05; Wilcoxon rank-sum test; R). Further, the most commonly selected category for additional desired mentorship (both received and provided) was "none," implying overall satisfaction with the mentorship experience.

This study indicates that the traditional mentorship paradigm is already shifting. In forensic anthropology, the mentorship paradigm does not solely consist of vertical-level interactions, but often includes horizontally oriented interactions. If the future reflects the past, then forensic anthropologists must honor the long-valued (and still valuable) role of the traditional mentor, while emphasizing the non-traditional mentorship behaviors that can

enhance the careers and lives of both trainees and experienced practitioners.

Career, Professionalism, Mentor-Protégé Interactions

A89 Rethinking Adult Skeletal Age Estimation: An Expanded Approach to Transition Analysis Using Binary Traits

Sara M. Getz, MS, Penn State University, Dept of Anthropology, 409 Carpenter Bldg, University Park, PA 16802; George R. Milner, PhD, Pennsylvania State University, Dept of Anthropology, 409 Carpenter Bldg, University Park, PA 16802; and Jesper L. Boldsen, PhD, ADBOU, Institute of Forensic Medicine, Lucernemarken 20, 5260 Odense S , DENMARK*

After attending this presentation, attendees will understand that potentially useful variation exists in areas of the adult skeleton that are not traditionally used for age estimation.

This presentation will impact the forensic science community by demonstrating that age can be estimated when standard features, such as the sternal ribs, pubic symphyses, and auricular surfaces, are unavailable for analysis.

For more than 100 years, the development of age estimation methods for adult skeletons has been heavily weighted toward portions of the skeleton that experience numerous changes throughout life. Despite repeated testing and revisions of techniques based on the cranium, pelvis, and ribs, problems remain. The most notable of these is ubiquitous age estimation bias that worsens after approximately age 50.

This work, with collected data, is a proof of concept that low-information, binary features can be used to produce age estimates throughout adulthood. Five rounds of preliminary data collection, analysis, and trait revision at the W.M. Bass Donated Skeletal Collection were used to investigate more than 250 trait variants. In each iteration of data collection, traits with strong age-related patterns were retained, while those that provided little to no age information were revised for one or more rounds of analysis before being eliminated if useful age-related patterns failed to emerge. Fifty-three skeletal features were ultimately selected and investigated in a larger sample of individuals from the W.M. Bass Donated Skeletal Collection, the Maxwell Museum Documented Skeletal Collection, the University of Iowa-Stanford Collection, and the J.C.B. Grant Collection. These samples were intentionally chosen to represent as heterogeneous a group as possible within a single, broadly defined ancestry category (European/White). This is because in many forensic situations the most appropriate reference sample for an individual case is impossible to identify. Thus, a conservative, widely applicable method is desirable.

The combined sample of 1,010 individuals (677 males and 333 females) from the four skeletal collections was used to select a suite of features that collectively show age-related change throughout adulthood. These data were then used as a reference sample to estimate age for 350 modern and historic individuals from the Athens, Greece, collection and the St. Bride's crypt collection in London. Estimates generated using several dozen binary features are compared to those produced using the existing Transition Analysis procedure and other commonly used age-estimation methods for the pubic symphysis and auricular surface.[1] The Greek sample demonstrates how the selected traits perform on well-preserved modern remains. Individuals from St. Bride's crypt illustrate how the traits perform on individuals from a population with significantly different diet, activity level, and disease exposure than the reference sample. Because this sample is also less well-preserved than the Athens collection or the reference sample, it is a test of how well the procedure performs under less than optimal conditions, similar to those encountered in forensic settings when skeletal elements are often missing or damaged. The produced maximum likelihood estimates of age collectively exhibit less bias than estimates from other methods, even though no data from the cranial sutures, rib ends, pubic symphyses, or auricular surfaces were used.

A wider array of features similar to those used here is currently under investigation by a National Institute of Justice (NIJ) -funded research team using a diverse sample of modern populations from four continents. A reference manual and computer software are also under development as part of the larger project.

This research is supported by a National Science Foundation (NSF) Doctoral Dissertation Research Improvement Grant (DDRIG) award.

A90 Examining the Effectiveness of Mastoid Process Measurements in Estimating Sex

Sarah C. Kindschuh, PhD, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Offutt AFB, NE 68113*

After attending this presentation, attendees will understand the applicability of using mastoid process measurements to estimate sex of the fragmentary cranium.

This presentation will impact the forensic science community by examining the use of the "mastoid length" measurement, as described by Buikstra and Ubelaker, in determining sex of a fragmentary cranium using the mastoid process.[1] This presentation will also evaluate the inter-observer variability of the mastoid length measurement due to its wide use by forensic anthropologists.

Due to sexually dimorphic morphology, the skull is considered to be very useful when determining the sex of skeletal remains as part of the biological profile. The mastoid process is a feature typically cited as a good indicator of sex based on differences in length and volume between males and females. A system of scoring the mastoid process, and other cranial features, on a 1-to-5 scale has been developed to aid in sex estimation of cranial remains[1]. In addition, in recent years, attempts have been made to analyze the mastoid triangle region for sexual dimorphism with varying results; however, no attempt has been made to solely use the mastoid length measurement described by Buikstra and Ubelaker, which is likely the most common mastoid process measurement.[1] Nevertheless, there is a general consensus among forensic anthropologists that this measurement is difficult to take and inconsistent between analysts.

This research examines the usefulness of mastoid length and mastoid triangle area as an indicator of sex using a Southeast Asian sample. A total of 122 crania (47 female, 75 male) from the skeletal collection at Khon Kaen University in northeast Thailand were used in this study. Each mastoid process was scored on a 1-to-5 scale following Buikstra and Ubelaker, referred to as estimated sex, and the mastoid length measurement was taken.[1] Measurement of the mastoid triangle was conducted to obtain distances between porion, asterion, and mastoidale. The semi-perimeter of the triangle was computed and used to calculate the triangle's area using Heron's formula. Twenty crania were measured by a second researcher to test the level of inter-observer error.

Correlations between variables were measured using Pearson's correlation coefficient. As expected, significant correlations (p <0.05) were observed for both males and females between estimated sex and mastoid length, estimated sex and area, and mastoid length and area. A significant correlation was observed between estimated sex and age in females, the only significant correlation between age and other variables in females. No significant correlation was identified in males between age and remaining variables.

Discriminant function analysis was performed using several different combinations of variables to test whether mastoid length alone can be useful in determining sex. When all six measurements were used to discriminate between sexes, leave-one-out cross-validation reached an accuracy of approximately 80%, the highest level of accuracy reached of any analysis. When only mastoid length was used to discriminate between sexes, cross-validation accuracy was approximately 77.6%. This suggests that when presented with a fragmentary temporal bone, a single mastoid length measurement can be used with significant accuracy to estimate sex.

Inter-observer error was examined for estimated sex and mastoid length. Cohen's kappa was used to measure the level of agreement between observers. A Cohen's kappa value of 0.100 (p = 0.222) suggests a low level of agreement between observers. The percentage of difference between 40 mastoid length measurements (both left and right sides) was calculated with an overall average of 4% difference. Interestingly, in 18 of the 26 cases in which estimated sex differed between observers, the observer that scored the mastoid process highest also had the larger mastoid length measurement. Given that estimated sex was assessed prior to taking the mastoid length measurement, this suggests the estimated sex score may bias the researcher's measurement of mastoid length.

The results of this analysis are promising for the applicability of using the mastoid length measurement as a method for estimating sex of fragmentary crania; however, further testing on non-Asian samples should be conducted to corroborate these results.

Mastoid Process, Sex Estimation, Discriminant Function Analysis

A91 The Effect of Body Composition on Outdoor Human Decomposition

Saskia Ammer, MSc, Jestelstrasse 2, Munich, Bavaria 80999, GERMANY*

After attending this presentation, attendees will understand the phases of human decomposition and how they are affected by body composition. The underlying goals are to improve the determination of Postmortem Interval (PMI), provide information useful to the positive identification of remains, and to spark further research into the decomposition variables that show correlation to body composition.

This presentation will impact the forensic science community by providing results of a study regarding how body composition affects the association between human decomposition milestones/phases and Accumulated Degree Days (ADD). This presentation will add to the general understanding of PMI estimation, human decomposition, and one of its key variables, body composition.

This research examined the differences in the rate of decomposition in humans with reference to their Body Mass Index/body composition. For instance, Simmons and colleagues found no effect of body mass on the rate of decomposition, while Sutherland et al.'s study found that small pigs decomposed almost three times as rapidly as large carcasses and Meadows and colleagues study found that obese individuals "quickly loose body mass due to the liquefaction of the body fats," which was supported by Zhou and Byard's case studies.[1, 3-5]

For this study, it was predicted that the body composition will affect the length of various phases of decomposition. Furthermore, it was predicted that more or less ADD will be required to reach specific decomposition milestones depending on body mass. Additionally, body mass may have an effect on how long (ADD) it takes the body to transition from one phase to the next.

A modified version of Megyesi et al.'s total body scoring system was used to examine the influence of body composition on human decomposition using 35 study subjects at the Texas State University's Forensic Anthropology Research Facility (FARF).[2] A total of 32 phases/time periods were established for three anatomical regions. The phases and time periods of decomposition were examined daily until full mummification occurred and ADD were calculated. These results were further statistically analyzed using a Student's Slope *t*-test.

The milestones of decomposition were examined for each individual following Megyesi and colleagues' method every day until full mummification occurred.[2] The dates from the beginning and the end phases and when milestones were reached was recorded and ADD were calculated to measure the thermal units that were required for the subject to reach certain decomposition landmarks (discoloration, bloat, and mummification) and for the bodies to complete certain stages of decomposition (Fresh, Discoloration, Loss of Tissue, Maggot Activity, Bloating and Caving In of Abdominal Cavity, Purge, And Mummification).

The results exhibited a strong statistically significant correlation between ADD and BMI for 7 of the 32 phases and time periods. The Head's Loss of Tissue phase and the Limbs' Placement until Start of Mummification time period showed strong statistically significant correlations (R^2 = 0.70051 and R^2 = 0.77258, respectively). The strongest and most prominent correlations were seen in the Trunk:Purge (R^2 = 0.77396), Placement until End of Purge (R^2 = 0.73464), Caving In (R^2 = 0.77991), Placement until End of Caving In (R^2 = 0.6888), and Mummification (R^2 = 0.71958). The statistical analyses of how phases and time periods correlate to each other presented that the slopes of the Trunk Mummification and Trunk Placement until Mummification and Trunk Purge and Placement until Purge End phases and time periods do not reveal a significant difference and are therefore comparable.

Overall, the study demonstrated that body composition is a factor in human decomposition but is not always a statistically significant one. Therefore, the results should be further examined in order to establish exactly how the correlation works and how the correlation can be used to improve PMI estimation.

Body Composition, Human Decomposition, Forensic Anthropology

A92 The Accuracy of Estimating Ancestry in Undocumented Migrants Along the South Texas Border Using Dental Morphological Traits: A Comparison to Craniometrics

Chaunesey Clemmons, BA, Texas State University, 601 University Drive, San Marcos, TX 78666; Nandar Yukyi, BA, Texas State University - San Marcos, 1951 Aquarena Springs Drive, Apt 4104, San Marcos, TX 78666; and Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand the advantages and disadvantages of using dental morphological traits and craniometrics to estimate the ancestry of Hispanic individuals.

This presentation will impact the forensic science community by testing the validity of using dental morphology to estimate ancestry in Hispanic individuals and by comparing dental morphology to more traditional craniometric results.

Ancestry estimation is an essential factor of the biological profile, but accurately estimating ancestry in Hispanic individuals is difficult.[1] While it is customary to use craniometrics to quantitatively estimate ancestry of unknown individuals, the use of dental morphological traits for ancestry estimation is becoming more common. In this presentation, the accuracy of discriminant function equations using dental morphological traits established by Edgar and traditional craniometrics to differentiate between Hispanic and non-Hispanic individuals were compared.[2] The goal is to determine if these two accepted methods of ancestry estimation can accurately classify undocumented migrants discovered along the South Texas border.

The sample consists of ten individuals (nine male, one female) discovered along the South Texas border who are thought to be Hispanic based on anthropological analyses and cultural profile. A total of 13 dental traits were observed and scored on both antimeres, when present, using the Arizona State University Dental Anthropology System (ASUDAS) and the expression count method.[3] The expression count method uses the more complex or higher score of the antimeres to represent the scored trait for that individual.[4] Only permanent maxillary and mandibular teeth were observed and scored. Those teeth that exhibited wear, breakage, caries, modification, or calculus were observed to the extent possible. A discriminant function equation established in Edgar was used to differentiate between Hispanic and non-Hispanic. The rate of accurate Hispanic classification was then compared to the rate of accurate craniometric classification.

Standard craniometric landmarks were taken with a Microscribe® G2 3D digitizer and recorded using 3Skull. Twenty-four inter-landmark distances were then imported into FORDISC® 3.0 in order to estimate ancestry. FORDISC® is a program that uses discriminant function analysis to classify individuals into ancestral groups in reference to data from the Forensic Data Bank (FDB).[1] Each individual was compared to four ancestral groups in FORDISC®: White, Black, Hispanic, and Guatemalan. These four groups were chosen to be consistent with Edgar sample groups of Spanish-speaking regions that include South America, Cuba, Mexico, and Puerto Rico.[2]

Results from a sample of N=10 revealed that the two methods do not give similar ancestry estimations. According to the dental results, one out of ten individuals classified as Hispanic, while the craniometric results indicated that five out of ten individuals classified as Hispanic (one of which was Guatemalan). Further, of the ten individuals, ancestry estimations for only three individuals matched between both methods. A goodness of fit was used on the results and showed that there is a statistical significance between the two methods at the 95% confidence level; however, these results may be due to the small sample size of N=10.

Ancestry Estimation, Dental Morphology, Craniometrics

A93 What Stature and Weight Do We Actually Estimate?

Yangseung Jeong, PhD, 419A Atkinson Drive, 905, Honolulu, HI 96814; and Heli Maijanen, PhD*, University of Oulu, Lab of Archaeology, PO Box 1000, Oulun yliopisto 90014, FINLAND*

After attending this presentation, attendees will understand the type of body size (reported versus cadaver size) to which estimates by commonly used regression equations are most closely related.

This presentation will impact the forensic science community by investigating and quantifying the relationship between estimated body size and reported/cadaver size in contemporary Americans. This information will assist forensic investigators and researchers in selecting body size estimation methods appropriate for their casework and research.

In forensic anthropology, the primary purpose of body size estimation is identification of unknown skeletal remains. Thus, the emphasis is generally placed on estimating victims' body size *at the time of death*. Various estimation methods have been devised based on different types of body size (e.g., living stature/weight, cadaver-adjusted living stature, reported stature/weight), and they are frequently believed to be estimating living or reported size; however, how accurate or biased the results they produce are in terms of the reported and cadaver size, which are likely to represent one's body size at the time of death, have not been systematically tested. In this study, the estimates from the commonly used methods are compared to reported and cadaver size to see if they actually represent living stature/weight or other types of size.

Forty-three American White skeletons (23 males and 20 females) in the W.M. Bass Donated Skeletal Collection, University of Tennessee, were used. Statures of the donations were estimated using the anatomical method (Raxter et al., equation 1), Ousley (femur equation), and Trotter and Gleser (femur equation).[1-3] Weights were also estimated using the morphometric method (Ruff et al.), McHenry, and Grine et al.[4-7]. Then, the bias between estimates and reported/cadaver size (Σ(cadaver or reported size – estimated size/n)) was calculated.

Stature estimates tended to be closer to cadaver stature than reported stature. The only exception was the Ousley's female equation that yielded less-biased estimates for reported stature (bias of -0.24cm and -1.13cm for reported and cadaver stature, respectively).[2] As far as cadaver stature is concerned, the anatomical method and Ousleys equation produced least-biased results for females and males, respectively (bias of -0.38cm and -0.29cm, respectively).[2] Estimates closest to reported stature were obtained by Ousley's equations for both sexes (bias of -0.24cm and 1.93cm for females and males, respectively).[2] Trotter and Gleser tended to underestimate cadaver stature (bias of 3.12cm and 2.01cm for males and females, respectively).[3] Considering that cadaver stature is reportedly 2.5cm larger than living stature, Trotter and Gleser appear to estimate living stature with least bias.[3] All the weight equations underestimated both cadaver and reported weight. Like the stature equations, smaller bias was produced when cadaver weight was estimated compared to reported weight. The least-biased cadaver weights were obtained from the morphometric method and Ruff et al. for males and females, respectively (bias of 5.26kg and 4.33kg, respectively).[5] When estimating reported weight, Ruff et al.'s equations performed best for both sexes, but the bias reached up to 14.74kg and 6.78kg for males and females, respectively.[5] McHenry's equation turned out to produce most biased results among the weight equations.[6]

Stature and weight equations produce estimates of differential degree of bias depending on the type of body size (reported versus cadaver). Once forensic investigators and researchers decide the type of body size based on their purpose, the most appropriate equations should be chosen based on the degree of bias associated with the size type.

Body Size Estimates, Reported Size, Cadaver Size

A94 A Retrospective Analysis of FORDISC® Performance at the C.A. Pound Human Identification Laboratory (CAPHIL)

Amanda N. Friend, MA, C.A. Pound Human Identification Laboratory, 2033 Mowry Road, Gainesville, FL 32608; Janet E. Finlayson, MA, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610; Katie M. Rubin, MS, C.A. Pound Human Identification Laboratory, PO Box 103615, Gainesville, FL 32610; and Michala K. Stock, University of Florida, 2033 Mowry Road, Rm G-17, Gainesville, FL 32610*

After attending this presentation, attendees will better understand performance discrepancies between FORDISC® 2.0 and FORDISC® 3.1, as well as some causes for these differences.[1,2]

This presentation will impact the forensic science community by highlighting facets of ancestry assessment, particularly in metric analyses, that continue to be problematic for the identification of human remains.

The goal of this presentation is to evaluate the performance of FORDISC® and its use in analyses at the University of Florida CAPHIL.

Since its establishment in 1972, the CAPHIL has utilized cranial Discriminant Function Analyses (DFA) to help ascribe ancestral affiliations to skeletonized human remains, beginning with the DFA methods outlined by Giles and Elliot.[3] Despite the 1993 release of FORDISC® 1.0, the CAPHIL did not regularly employ this program until after the release of FORDISC® 2.0,[1,4] This study uses FORDISC® 3.1 to provide a retrospective analysis of metric ancestry assessment at the CAPHIL.[2]

Four CAPHIL analysts accessed cranial metric data from 60 individuals originally processed in FORDISC® 2.0 by the CAPHIL between 1997 and 2002.[1] All included individuals were positively or strongly tentatively identified by Medical Examiner's Offices (MEOs). For each individual, all measurements included in the original FORDISC® 2.0 assessment were entered into FORDISC® 3.1 and compared against all groups in the FORDISC® 3.1.309 Forensic Data Bank (FDB) using a forward mean percentage stepwise analysis.[1,2] The results of the FORDISC® 2.0 and FORDISC® 3.1 ancestry analyses were then compared to each other and to the individual's MEO-issued identification.[1,2] Results from each FORDISC® version were considered "correctly classified" if in agreement with the MEO identification.

FORDISC® 3.1 analyses agreed with the original FORDISC® 2.0 analyses for 40 cases (66.7%)[1,2] FORDISC® 2.0 did not provide a classification matching the MEO-provided demographics in ten cases (16.7%).[1] FORDISC® 3.1 did not provide a classification matching the MEO-provided demographics in 17 cases (28.3%); in four of these cases, FORDISC® 3.1 did not classify the individual into any group.[2] Importantly, for six cases (10%) the reference group selected by FORDISC® 3.1 was not included in the original FORDISC® 2.0 analysis, even though the reference group was available in the FDB at the time.[1,2] In five of these cases, the FORDISC® 2.0 result matched the MEO-issued identification; in the sixth case, a reference population representative of the decedent was not available in either FORDISC® version.[1] FORDISC® 3.1 results matched the MEO-provided data in none of these six cases.[2] In two additional cases, FORDISC® 3.1 selected a reference group that was not available in FORDISC® 2.0; in both cases the FORDISC® 3.1 classification was incorrect and the FORDISC® 2.0 classification correct.[1,2]

In this study, FORDISC® 3.1 showed no improvement over FORDISC® 2.0 in providing correct (i.e., matching MEO-issued identification) classifications of the Florida forensic sample.[1,2] These results may be influenced by discrepancies between the DFA options used by past CAPHIL analysts and those used in this study, including differences which may be chosen (e.g., by self-limiting reference groups based on *a priori* assumptions) or imposed (i.e., program updates between the two FORDISC® versions resulted in the addition of new reference groups and statistical functions). Nonetheless, the results prompt several interesting questions that will be discussed. Should forensic anthropologists expect updated versions of FORDISC® to increase discriminating power, or should researchers instead expect them to provide more realistic (and most likely lower) statistical probabilities? Is there a balance between increasing the amount of human variation captured by the program and maintaining practical classificatory efficacy? Further, as sample sizes increase and more comparative groups based on ethnic categories (e.g., Hispanic) are added, how confident are researchers that FORDISC® reference samples, though based on "known" identities, meaningfully reflect ancestry (or even self-identification, in cases where "known" ancestry is ascribed by the MEO)?

With the imminent release of FORDISC® 4.0, this comparative study provides important insight into DFA and its use in forensic anthropology. Understanding how updates to past FORDISC® versions and historical variation in analysts' use of FORDISC® have affected results through time may strengthen DFA implementation and interpretation as the field advances. In this manner, these reflections on the past can guide the continuing evolution of best practices in forensic anthropology into the future.

FORDISC®, Ancestry, Identification

A95 The Undergraduate Forensic Internship Experience: A Path to Employment for Anthropology Students

A. Joanne Curtin, PhD, University of West Florida, Dept of Anthropology, 11000 University Parkway, Pensacola, FL 32514*

After attending this presentation, attendees will understand the impact of forensic internships on employment opportunities for anthropology students.

This presentation will impact the forensic science community by identifying opportunities to enhance career development for undergraduate anthropology students.

The popularity of forensic-themed television shows focusing on aspects of forensic science (*Bones, CSI, Forensic Files,* etc.) has led to a concomitant increase in university enrollments in forensic-related fields, including forensic anthropology. Many of these undergraduate students lack the means or desire to pursue advanced degrees immediately upon matriculation, but employment opportunities in forensic-related fields for the graduate with an Anthropology BA are limited in Florida due to Florida Department of Law Enforcement (FDLE) regulations requiring a Bachelor of Science degree (in any field) prior to employment in all entry-level forensic science positons. Since 2006, the Department of Anthropology at the University of West Florida (UWF), in conjunction with the District One Medical Examiner's Office (MEO) in Pensacola, has offered forensic anthropology students the opportunity to intern at the MEO for academic credit, in the hopes of improving their employment prospects after graduation.

The forensic internship as developed at UWF is designed to allow students to clarify their career goals, to integrate theoretical concepts and knowledge obtained in the classroom with real-world employment situations, to gain practical on-the-job experience in a professional setting, and to gain work-related references and networking opportunities, which will enhance their marketability as professionals. Over the course of their internships, students have the opportunity to observe and assist with autopsies, attend and help document death scenes, assist in the field recovery of surface or buried skeletons, process/macerate decomposed bodies, familiarize themselves with Florida statutes governing the medical examiners system and the disposition of human remains, as well as to learn basic office management skills.

Over the past ten years, more than 30 anthropology students have participated in the internship program. The purpose of this presentation is to track the career trajectories of these students, and to evaluate the impact of the internships on the career prospects of undergraduate students in forensic anthropology. Of those interns whose post-graduate careers could be tracked, approximately 10% ultimately decided against a pursuing a career in the forensics field, 15% found employment immediately after graduation in an MEO, either locally or in another state, 27% were accepted into anthropology graduate programs, and 17% were accepted into forensic science graduate programs. The remaining students found employment in fields other than forensics or anthropology.

Internship, Medical Examiner's Office, Career Development

A96 The Detection of Genetic Information in the Enamel Proteome

Caleb Kiesow, United States Air Force Academy, Colorado Springs, CO; Katelyn Mason, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Deon Anex, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Bonnee Rubinfeld, MSc, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; Laura A. Regan, PhD, Office of Net Assessment, 1920 Defense Pentagon, Rm 3A932, Washington, DC 20301-1920; Bradley Hart, PhD, Lawrence Livermore National Laboratory, 7000 East Avenue, Livermore, CA 94550; and Glendon Parker, PhD*, Protein-Based Identification Technology, 4421 Ashwood CMN, Fremont, CA 94538*

After attending this presentation, attendees will better understand alternative scientific and statistical approaches for calculating measures of human identity from teeth.

This presentation will impact the forensic science community by informing attendees that genetically variant peptides from tooth enamel can potentially be used to infer the status of Single Nucleotide Polymorphism (SNP) loci in a subject's genome. The past few decades have seen the impact of nuclear and mitochondrial DNA typing on forensic science. The method discussed in this presentation introduces a third identifying method based on protein typing.

Human identification frequently depends on the ability to extract genetic information from human remains. In most cases, DNA typing is sufficient to statistically link an individual with biological material. In the event that DNA is absent or degraded, additional identification methods are required. Given the increased need for laboratory-based quantitative forensic methodologies, genetic variation in protein is an attractive alternative to develop novel identification technologies.

Enamel is the most robust human tissue and persists for long periods in the environment. The calcium apatite crystals encase and protect endogenous protein that contains genetic information in the form of single amino acid polymorphisms, the result of non-synonymous SNPs. This type of genetic variation is distributed across many populations and can be used to develop measures of human identification.

Blocks of enamel (20mg) were obtained from four subjects and were milled and dissolved in HCl for 1h at 56°C in the presence of reductant. The resulting supernatant was pH neutralized, carboxymethylated, and digested with trypsin protease in the presence of mass spectrometry-compatible surfactant. The resulting peptide mixtures were applied to a Thermo™ Q Exactive™ plus hybrid Orbitrap/linear ion trap mass spectrometry instrument. The resulting proteomic datasets were analyzed by using the "Global Proteome Machine" peptide spectra matching algorithm (www.thegpm.org). The peptide datasets were screened for previously characterized and genetically validated variant peptides. Six genetically variant peptides were observed in the enamel proteome across the four subjects and originated from five proteins, including COL1A2, one of the two major forms of collagen in teeth and bones.

This data indicates that genetically variant peptides in enamel are a potential and orthogonal means to develop statistical measures of human identification in the event of compromised, degraded, or absent DNA. This will have particular relevance for skeletal remains in which DNA is either degraded or absent. In the context of mixed skeletal assemblages, profiles of genetically variant peptides may also provide information about biodistance between different skeletal components.

This work was performed under the auspices of the United States Department of Energy by Lawrence Livermore National Laboratory under contract.

Enamel, Genetically Variant Peptide, Protein Typing

A97 Accumulated Decomposition Score (ADS): An Alternative Method to Total Body Score (TBS) for Quantifying Gross Morphological Changes Associated With Decomposition

Devora S. Gleiber, BA, Texas State University, 601 University Drive, San Marcos, TX 78666; Lauren A. Meckel, MA*, 1509 Marlton Street, San Marcos, TX 78666; Courtney C. Siegert, BA*, Texas State University, 7501 Whispering Winds Drive, Austin, TX 78745; Chloe P. McDaneld, MA*, Texas State University, 601 University Drive, San Marcos, TX 78666; Justin Alexander Pyle, BS, Texas State University - Anthropology, 601 University Drive, San Marcos, TX 78666; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will be aware of the foundation of a novel standardized method for quantifying human decomposition for the purpose of estimating the Postmortem Interval (PMI) based on gross morphological changes. Attendees will also have a better understanding of the pattern of decomposition in Central Texas as it relates to Accumulated Degree Days (ADD).

This presentation will impact the forensic science community by resolving issues anthropologists face when using the current TBS method to estimate PMI.[1]

Megyesi and colleagues presented a method for quantifying gross morphological changes during decomposition known as the TBS, as well as a regression equation for calculating the ADD since death based on the TBS; however, subsequent research has shown that the progression of descriptive traits used to calculate the TBS may not be universal.[1,2] Therefore, a new method of quantifying gross morphological changes associated with decomposition is needed.

In this presentation, the preliminary results of a new method of quantifying gross changes in the body during decomposition that resolves many of the issues associated with the progressive stages of the TBS are introduced. The proposed method, ADS, utilizes component scoring of traits, which allows for quantification of variability within and between regions. The ADS is calculated based on the appearance and progression of traits, including discoloration, skin slippage, marbling, bloat, purge, liquefaction, desiccation, mummification, and skeletonization. Although a sequence of decomposition is implied in this method, the ADS includes flexibility for adding the traits as they appear. For example, Megyesi and colleagues describes marbling and skin slippage in the trunk as occurring simultaneously; however, this is often not the case.[1] Additionally, because discoloration can be variable during decomposition, the ADS is designed not to emphasize coloration details, but to simply observe the initial appearance of this trait. Like the TBS, the ADS segments the body into regions for scoring; however, unlike the TBS, the ADS requires scoring the upper and lower limbs separately since they differentially decompose. Thus, the ADS observes the head and neck, torso, upper limbs, and lower limbs as four separate regions.

Four individuals from the Texas State University Willed Body Donation Program were scored throughout active decomposition using the ADS method. Observations were made both in the field and based on photographs taken throughout the decomposition process. ADD for each observation (n=138) was calculated using the average of the minimum and maximum temperature for the entire day. The ADS was then regressed against ADD, and the regression formula was tested using ten additional static observations at different stages of decomposition. Preliminary results indicate that the ADS correlates exponentially with ADD ($y= 25.574e^{0.0926x}$, R^2=0.84689), explaining a significant proportion of the variation observed in the rate of decomposition in Central Texas. This pilot study suggests the ADS method is a good predictor of PMI based on ADD.

This research introduces a new standardized method of collecting decomposition data that can be used to develop regionally specific regression formulas in order to more accurately estimate PMI. This will lead to a greater understanding of the PMI and the process of decomposition in forensic anthropology, may assist in condensing missing persons reports, and aid in generating a timeline for law enforcement investigation.

A98 To Group or Not to Group?

Carrie B. LeGarde, MA, Defense POW/MIA Accounting Agency, 106 Peacekeeper Drive, Bldg 301, Offutt AFB, NE 68113*

After attending this presentation, attendees will understand whether or not populations should be grouped in osteometric analyses.

This presentation will impact the forensic science community by describing which measurements exhibit statistically significant differences when comparing White, Black, and Asian (Japanese) groups and the implications for osteometric analyses, including osteometric sorting.

Osteometric sorting is a statistical tool utilized in cases of commingling to sort remains based on size. The reference dataset currently used for osteometric sorting uses multiple population groups and both sexes. This has primarily occurred to increase the sample size, but as the dataset increases, the need to pool groups may be unnecessary. In addition, differences in size between populations may decrease the performance of the method. The purpose of this study is to determine whether differences between groups exist and whether particular measurements should be utilized with a grouped sample.

Three populations were utilized in this analysis: American/European Whites, American Blacks, and Asian (Japanese). A total of 152 skeletal measurements (74 left, 74 right, and 4 midline), which includes standard and non-standard measurements (77 and 75, respectively), were compared via a two-tailed Student's *t*-test to determine whether a significant difference in group means exists ($p \leq 0.05$). White vs Black, White vs. Asian, and Black vs. Asian were compared with sexes pooled and separated by males and females, as well as males and females compared within each group, for a total of 12 comparisons per measurement. Because osteometric sorting utilizes the difference between left and right pairs (the "D" value), this value was calculated for each measurement and the same comparisons via *t*-tests were performed ($p \leq 0.05$). The mean, minimum, and maximum were also calculated for each measurement and D-value for every group.

The majority of the skeletal measurements were significantly different between the groups. When comparing Whites and Blacks, the number of statistically significant different measurements ranged from 33.8% to 38.8%, while the number of significant measurements ranged from 69.2% to 90.1% when comparing Whites and Asians. When comparing Blacks and Asians, there were between 63.8% and 75.0% significant.

The number of statistically significant tests was much lower when comparing the D-value between groups. When comparing Whites and Blacks, the number of statistically significant differences in D-values across elements ranged from 8.6% to 14.9%, while the number of significant D-value tests ranged from 2.9% to 17.6% when comparing Whites and Asians. When comparing Blacks and Asians, there were between 9.9% and 20.3% significant. The female group comparisons had the fewest number of significant results for all tests, which indicates a smaller difference in size between the females in these populations.

Overall, results of this study suggest that, although the majority of skeletal measurements are significantly different between groups, the difference between left and right elements when compared across groups is not significantly different. This suggests that the majority of measurements can be used with populations grouped in the reference dataset for osteometric sorting. Measurements with significant D-value tests for the majority of the between-group comparisons may need to be avoided in osteometric analyses when samples are grouped. These include the maximum length of the radius and ulna, the physiological length of the ulna, and the maximum distal epiphyseal breadth of the tibia.

Ancestry, Osteometry, Commingled Remains

A99 Disturbed Soil: Unexplored Variables and the Postmortem Interval (PMI) in Southwest Florida

Matthew D. Rolland, BS, 5795 SW 7th Court, Cape Coral, FL 33914; Shawn R. Dahl, BS, Florida Gulf Coast University, 10501 Florida Gulf Coast University Boulevard, S, Fort Myers, FL 33965; and Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Dept of Justice Studies, 10501 FGCU Boulevard, AB3, Fort Myers, FL 33965-6565*

After attending this presentation, attendees will understand how subsurface variables, such as soil moisture, temperature, and pH value, are influenced by the act of disturbing soil in the absence of human decomposition in Southwest Florida. The environment of Fort Myers, FL, will be delineated in an effort to determine how the simple act of agitating soil influences these ecological variables upon which well-established PMI estimation methods rely.

This presentation will impact the forensic science community by increasing the accuracy of PMI estimations.

Time-Since-Death (TSD) and Time-Since-Burial (TSB) estimation methods have grown from research conducted within the University of Tennessee–Knoxville's Forensic Anthropology Center. As a result of decades of research at this facility, Dr. Arpad Vass helped to establish two standardized equations to estimate the PMI associated with human body decomposition.[1] Of specific interest to this study was Dr. Vass' equation to estimate TSD. Key variables used in this equation are soil moisture and soil temperature. Similarly, other prominent PMI estimation methods, such as Megyesi's Accumulated Degree Days (ADD) system, also rely upon variables, such as average daily temperature and atmospheric humidity.[2] It is well established in the literature that these variables are proximal influences upon decomposition rates as: (1) warm temperatures increase in the rate of decomposition (per Van't Hoff's Law); and, (2) an increase in soil moisture slows body decay rate; however, this current study proposes that while the relationship of these variables to decomposition rates is well described, previous research has neglected to consider how the act of disturbing soil strata layers when a clandestine grave is dug without the addition of a body may influence these variables.[1]

Twice a year, as part of Florida Gulf Coast University's (FGCU's) forensic anthropology graduate and undergraduate course, five mock clandestine burials containing plastic skeletal specimens are uncovered from a pine flatwood ecosystem. The specimens are buried at a depth of 40 to 60 centimeters within an area of approximately 250 square meters.

From June 19 through July 1, 2016, a Science, Technology, Engineering, and Math (STEM) Student Research Opportunity (SRO) was conducted in conjunction with the Whitaker Center for STEM Education. This training included instruction in forensic anthropological field methods which allowed the SRO students to assist the FGCU Human Identification and Trauma Analysis (HITA) graduate students and faculty in large-scale data collection. Soil temperature, moisture, and pH readings were taken at surface level (0-3cm), the level of the skeletal specimen, and the grave bottom using Vernier probes. These same readings were also taken from the control test pits.

The statistical analysis revealed no significant differences in soil temperature (R = -0.053, t = 1.98, p = 0.08), skeleton level (R = 0.30, t = -0.039, p = 0.7), grave bottom (R = -0.36, t = -2.87, p = 0.34), or moisture (R = 0.22, t = 0.42, p = 0.68; pH (R = -0.53, t = 1.98, p = 0.08) between the undisturbed soil of the test pit and the previously disturbed soil of the mock graves. These findings therefore indicate that the agitation of soil does not significantly influence the soil temperature, moisture, or pH of a clandestine grave as compared to a control test pit. Caution must be used in the application of these findings because exogenous variables, such as insect activity and local floral species, may have an unaccounted-for impact upon these soil readings.

Accurate estimation of the PMI and TSB is imperative in forensic anthropology casework. A truly universal PMI formula would be an invaluable tool for forensic anthropologists. For this to be a future possibility, a complete understanding of the variables that influence decomposition rate is paramount; additionally, the calibration of environmental impact on those variables by using a control test pit in each experiment should be implemented as a standard.

Anthropology, PMI, Burials

A100 Mapping Surface Scatter of Scavenged Human Remains Using Drone Aerial Photography

Krystle Lewis, BS, 1350 N LBJ Drive, 1531, San Marcos, TX 78666; Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684; Eugene J. Robinson, RPFlight Systems, Inc, 209 Brunson Lane, Wimberley, TX 78676; John Buell, Drone Pilot, LLC, 715 E 8th Street, Austin, TX 78701; and Michael Josephs, Drone Pilot, LLC, 715 E 8th Street, Austin, TX 78701*

After attending this presentation, attendees will better appreciate the suitability of mapping the spatial distribution of major elements in outdoor surface remains using images collected by an Unmanned Aerial Vehicle (UAV).

This presentation will impact the forensic science community by demonstrating the accuracy, benefits, and drawbacks of aerial photography via UAV for mapping major skeletal elements present in outdoor crime scenes without disturbing the scene.

High-resolution aerial images collected from UAVs are more commonly being used by law enforcement to map crime scenes and to search for clandestine human remains.[1] Small UAVs can be rapidly deployed and photograph a scene in a fraction of the time required when using traditional methods. Computer software can stitch the multiple photographs to render a 3D map of the scene that can be viewed and measured from multiple positions; however, in outdoor scenes containing skeletonized human remains, scavengers often distribute the small bones over a relatively large area, making them difficult to identify in aerial photographs.

The purpose of this pilot study was to compare maps of outdoor human remains sites based on UAV-collected photographs to traditional baseline maps. Two scattered remains sites at the Forensic Anthropology Research Facility at Texas State University were used in the study. Both sites were more than two years old, in an open grassy area, and the bones had been scattered over an approximately 50-meter area by scavengers.

Prior to deployment of the UAV, each scatter was mapped utilizing traditional baseline mapping techniques used in archaeology. A 2'x2' black/white aerial target was then placed near the scattered remains for reference during the UAV flight. In addition, the baseline points were marked with pink flags to provide easier visibility in the photographs. A multi-rotor UAV was then deployed and a series of aerial photographs were taken at approximately 40 feet above ground surface for each site. Two images were also imported into the open-source software, ImageJ. The baseline was drawn and the scale was set using known distances. The measure tool was then used to measure the distance from the baseline to the bone that could be observed. Additionally, an ellipse was fitted around the areas of the scatters to measure the total distribution of the scatters.

Baseline measurements using traditional techniques were compared to baseline measurements acquired from the photographs. An analysis of the two methods exhibits an average percent error of less than 2% (1.5%) for major skeletal elements. The comparison of maps demonstrates that the major skeletal elements can be accurately mapped using aerial photographs collected from an UAV equipped with a high-resolution camera; however, mapping smaller elements is difficult. Though small elements can be seen in the photographs, they are not discernible enough to accurately measure. The advantage of the aerial photograph maps is that they can be rapidly produced without disturbing the scene, and the stitched map can be viewed three-dimensionally from any position.

As drones equipped with high-resolution cameras become more readily available, they have the potential to be used to develop accurate 3D maps of outdoor crime scenes. While aerial photographs collected from UAVs cannot replace the more detailed mapping necessary in forensic anthropological cases, they do provide a valuable additional tool. Furthermore, initial mapping can be conducted prior to any disturbance of the scene.

Surface Scatter, Drone Mapping, Spatial Distribution

A101 Assigning Region of Origin in the Southeastern United States Using Stable Oxygen Isotopes of Modern Human Enamel

Monica M. Warner, MA, Tennessee Valley Archaeological Research, 2211 Seminole Drive, Huntsville, AL 35805; Amber M. Plemons, MA, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; Nicholas P. Herrmann, PhD, Texas State University, Dept of Anthropology, 266 ELA, 601 University Drive, San Marcos, TX 78666; and Laura A. Regan, PhD, Office of Net Assessment, 1920 Defense Pentagon, Rm 3A932, Washington, DC 20301-1920*

After attending this presentation, attendees will understand the importance of developing regional stable oxygen isotope drinking water comparisons. Attendees will be informed of the application of assignment models to determine accurate predictions of region of origin in forensic investigations using isotopic signatures.

This presentation will impact the forensic science community by demonstrating the advantages of applying human enamel from individuals with known residential histories to tap water isoscapes for accurately predicting the decedent's region of origin in forensic investigations.

Isotope analysis has become increasingly popular for narrowing the region of origin for unidentified human remains in forensic investigations. Stable oxygen isotopes ($\delta^{18}O$) in enamel reflect early life residential history and stable hydrogen isotopes ($\delta^{2}H$) in hair keratin records later geographic movement, months before death. Skeletal preservation in the southeastern United States is typically poor due to the humid subtropical climate, sometimes limiting the isotope analysis package to $\delta^{18}O$ of enamel.

Distinct spatial $\delta^{18}O$ distributions in tap water assist in narrowing the decedent's region of origin in unidentified persons cases. Human oxygen isotope measurements are compared to the spatial tap water distributions using baseline tap water isoscapes. Furthermore, understanding the relationships of enamel and water isotopes improves the assignment prediction models in forensic investigations. The goals of this research were to investigate the relationship between enamel and tap water oxygen isotopes in the southeast and use the relationship to improve region of origin predictions for modern human enamel.

Enamel (n=11) samples obtained by the United States Air Force Academy (USAFA) from individuals whose third molars were extracted between 2004 and 2005 were processed.[1] Residential history information recorded for the participants included birth city and state, and residential history including the year and geographic information of relocations. The USAFA sample measurements ($\delta^{18}O$ carbonate) reported on the Vienna Peedee Belemnite (VPDB) scale were converted to $\delta^{18}O$ phosphate (Vienna Standard Mean Ocean Water (VSMOW)).[2,3] Tap water data were extracted from previously reported oxygen tap water values for the United States.[4,5] Converted AFA data, (i.e., $\delta^{18}O_{ep}$) from individuals with early southeastern United States residential origins were regressed against tap water isotope $\delta^{18}O_{tw}$ values.

To determine if the relationship would improve predictions for human enamel in the southeast, an assignment model based on likelihood predictions was used to estimate region of origin. Likelihood assignment methods based on probability are more accurate and may incorporate prior probability using Bayes' rule to directly estimate origin based on previous data. A likelihood assignment model was developed using Geographic Information Software (GIS) and the USAFA sample (AFA134) from Southaven, MS, was assigned to the calibrated isoscape.

The relationship between the southeastern individuals and the tap water was $\delta^{18}O_{ep} = 0.704 * \delta^{18}O_{tw} + 20.07$ ($R^2 = 0.89$) and was calibrated into the isoscape assignment model. The $\delta^{18}O_{ep}$ for the state of Mississippi ranged from 16.22‰ to 16.94‰, compared to AFA134 whose oxygen isotope value was 15.846‰. Sample AFA134 was an ideal participant for this study, being a local resident of Southaven, MS, from birth until the age of 20. The likelihood model predicted the region of origin for AFA134 from a geographical band spanning from southern Washington County to central Alcorn County on the northern Tennessee boundary. The Southaven area had a slightly lower predicted outcome than the 90% probability band just south of the actual residential origin of AFA134.

Since enamel reflects the $\delta^{18}O$ sources of body water, the human signature is enriched compared to the $\delta^{18}O$ of the tap water. Therefore, the tap water isoscape was calibrated to make it comparable when assigning region of origin for modern human dentition in the southeastern United States. Individuals sampled from Florida were omitted from the study due to disproportionate relationships with tap water. The relationship between tap water

and human enamel from this study ($\delta^{18}O_{tw}$ = 1.2704 * $\delta^{18}O_{ep}$ - 26.01) is similar to the relationship Daux et al. ($\delta^{18}O_{tw}$ = 1.54 * $\delta^{18}O_{ep}$ - 33.72) demonstrated for human $\delta^{18}O$ values.[6] The differences between the two conversion equations may relate to source water and sample availability, suggesting that specific human-to-drinking-water $\delta^{18}O$ conversions should be applied dependent upon the geographic region of the research study. Variability is expected as many factors complicate regional $\delta^{18}O$ values, especially in modern humans and globalization.

Isotope, Oxygen, Assignment Model

A102 The Differences in the Rate of Decomposition Between Frozen and Non-Frozen Human Remains

Shelby Garza, 7855 Kitty Hawk Road, Apt 8205, Converse, TX 78109; and Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684*

After attending this presentation, attendees will have a greater understanding of the differences in the decomposition rate between previously frozen and never-frozen human remains that have been allowed to decompose in an outdoor setting.

This presentation will impact the forensic science community by adding to the research being conducted involving decomposition of human remains and how freezing impacts the rate of decomposition.

There is a need to understand the effect of freezing on decomposition rates. In some cases, research facilities need to store human remains before they begin documenting decomposition in an outdoor setting. There are also instances when remains from a homicide victim may have frozen due to low external temperatures before decomposing or the remains are stored in a freezer prior to relocation.

Freezing slows bacterial growth and therefore greatly reduces the rate of decomposition while the body is in a frozen state; however, there have been mixed results in studies examining the effect of freezing on post-thaw decomposition rates. An experiment conducted examining the effect of freezing on muscle tissue found no significant difference between frozen and unfrozen samples.[1] A more recent study using domestic pigs (*Sus scrofa)* found that previously frozen subjects and non-frozen subjects differ in rates of decomposition, with decomposition rates being slower in previously frozen pigs.[2] There have been no studies that have used whole body human donations in an outdoor setting to examine differences in decomposition between previously frozen and never-frozen subjects.

In this experiment, a total of ten human remains were placed in an outdoor setting at the Forensic Anthropology Research Facility in San Marcos, TX. All of the remains were placed on the ground surface, with half of them having been previously frozen. Each subject was placed unclothed in a supine position under a wire cage to prevent scavenging. The frozen and unfrozen remains were pair matched for season of placement and body size. A Total Body Score (TBS) was calculated for each subject at approximately 100, 300, and 500 Accumulated Degree Days (ADD).[3]

Paired samples were compared using a scale of TBS <10, TBS 10-20, and TBS >20. There were no statistically significant differences in TBS between previously frozen and never-frozen remains at any ADD period; however, after 100 ADD, frozen remains consistently have higher TBS. At approximately 100 ADD, only 20% of the paired samples scored in the same TBS range. Forty percent of the paired samples demonstrated that never-frozen human remains decomposed at a slower rate than previously frozen remains, while the other 40% of the pairs displayed the opposite pattern. At approximately 300 ADD, 40% of the paired samples scored in the same range, while the previously frozen bodies decomposed more rapidly than the never-frozen bodies in 60% of the pairs. At approximately 500 ADD, 20% of the paired samples had the same TBS range, but the never-frozen bodies had a greater TBS in 60% of the pairs.

This research provides evidence that freezing does have an effect on the decomposition rate of human remains, especially after more than 100 ADD. These observations indicate that after approximately 100 ADD, previously frozen human remains decompose faster than their never-frozen counterparts. While the pattern observed in this study differs from the previous study using pigs, the conclusion is the same.[2] That is, the rate of decomposition between previously frozen and never-frozen remains should not be compared in taphonomic studies examining the relationship between TBS and ADD.

Research reported in this presentation was partially supported by a National Institute of Justice grant. The content is solely the responsibility of the author and does not necessarily represent the official views of the National Institute of Justice.

Decomposition, Frozen, Total Body Score

A103 The Use of Industrial Computed Tomography (CT) in Forensic Anthropology

Angi M. Christensen, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; Michael A. Smith, PhD, 2501 Investigation Parkway, Chemistry Unit, Quantico, VA 22135; Deborah L. Cunningham, PhD, Texas State University, 601 University Drive, San Marcos, TX; Daniel J. Wescott, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666-4684; and Devora S. Gleiber, BA, Texas State University, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will be familiar with the uses of industrial CT scanning in forensic anthropological examinations.

This presentation will impact the forensic science community by increasing awareness of alternative postmortem imaging approaches, as well as by demonstrating some of the uses of industrial CT technology in forensic anthropological casework and research.

The use of postmortem CT to examine skeletal remains is not new, but its use by forensic anthropologists is relatively rare. This may be due to limited resources for purchasing or accessing CT scanners, or unfamiliarity with CT options and their advantages. CT is used in a variety of industries, including not only medicine and dentistry, but also security, aerospace, automotive, manufacturing, and defense, among many others, and these industrial devices can be adjusted to parameters suitable for examining bone. Anthropologists may therefore be able to consider alternative technologies such as industrial CT, thereby increasing their potential access to it. Moreover, industrial CT scanners are highly versatile and offer several significant advantages over medical CT in the examination of skeletal remains.

For example, most industrial CT systems are self-contained and self-shielding, eliminating the need for specialized rooms for their operation, as well as individual shielding. Moreover, while medical CT systems are commonly limited to certain dosages (due to health concerns for living patients) or are tailored to specific diagnostic applications, industrial CT in postmortem imaging allows longer scan times and greater versatility in terms of the analytical parameters used. For example, the use of high intensity, micro-focus or nano-focus X-ray sources on industrial CT systems permit much greater magnification and resolution than a typical medical CT scanner. Industrial CT scanners are also capable of greater penetration of dense objects, such as dental fillings and surgical devices, than typical medical CT technology. If desired, most units can also be used for traditional 2D digital radiography. File formats generated from industrial CT scans are standard and compatible with most medical imaging viewers, analytical software platforms, and 3D printers.

Currently, the Federal Bureau of Investigation (FBI) Laboratory and the Forensic Anthropology Center at Texas State (FACTS) both utilize an industrial CT scanner in postmortem assessments of skeletal remains for forensic and research purposes. This unit is marketed primarily for non-medical, industrial applications but is readily adapted for use in anthropological investigations. Applications include documenting features for identification, analysis of skeletal trauma and disease, assessment and documentation of biological parameters, production of 3D printed replicas, and research on bone density and microstructure. Another significant advantage of this type of machine in a large forensic or academic laboratory is that, unlike a medical CT system, which is configured and dedicated to one or a few specific purposes, the machine has many forensic and research applications. In the FBI Laboratory, in addition to forensic anthropological applications, the device supports forensic examinations of manufactured products, explosive devices, electronics, and firearms. At FACTS, the system is used in forensic anthropological casework and research, as well as for imaging archaeological, paleontological, and geological specimens. This ensures a high utilization rate and more readily justifies the costs of its operation and maintenance.

CT is an extremely useful tool in postmortem forensic anthropological examinations, and the use of radiology for non-destructive documentation, examination, diagnosis, and preservation of skeletal remains is encouraged. Virtually any type of CT scanner can be adapted to effectively image skeletal material, so anthropologists are not limited to medical CT systems in their examinations. Laboratories can consider alternative CT scanners for purchase, but they may also be able to leverage resources that already exist in their community by developing relationships or partnerships with professionals in other offices or industries. The use of more versatile machines can result in greater imaging resolution and detail for skeletal examinations and may also be more cost effective for

a laboratory, especially in cases in which the device can serve multiple disciplines.

Forensic Anthropology, Forensic Radiology, Computed Tomography (CT)

A104 Prostheses and Medical Devices: Their Value in Forensic Anthropology

Eugenia Cunha, PhD, Universidade de Coimbra, Dept of Life Sciences, Forensic Anthropology Lab, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Maria Teresa Ferreira, PhD, University of Coimbra, Dept of Life Sciences, Laboratory of Forensic Anthropology, Calçada Martim de Freitas, Coimbra 3000-456 Coimbra, PORTUGAL; Catarina Coelho, MSc, University of Coimbra, Forensic Anthropology Dept Life Sciences, Coimbra, PORTUGAL; David Senhora Navega, MSc, Laboratory of Forensic Anthropology, University of Coimbra, Calçada Martim de Freitas, Coimbra 3000-456, PORTUGAL; Francisco Curate, PhD, Research Centre for Anthropology and Health, Rua Arco da Traição 7, Coimbra, Coimbra, PORTUGAL; David Gonçalves, PhD, Research Centre for Anthropology and Health, University of Coimbra, Coimbra, PORTUGAL; and Carlos Durão, Hospital Vila Franca de Xira, Lisbon, PORTUGAL*

After attending this presentation, attendees will better understand the value of prostheses for identification purposes.

This presentation will impact the forensic science community by providing relevant information on the multiple uses of prostheses and other medical devices.

Bodies in an advanced state of decomposition (e.g., skeletonized or burned) are a challenge for identification. Since identification of unknown human remains has major social, cultural, and economic implications, it is worthwhile to explore alternative means of identification. These can be particularly helpful in situations with multiple unidentified victims, such as mass disasters and human rights violations, or when the fragmentary nature or damage of the remains preclude the application of standardized methods. The primary techniques of identification may not always be applied in those contexts. The increase of life expectancy and the advances in medical knowledge are leading to a growing number of surgical implants that multiply the likelihood of finding a decedent with a surgical prosthetic device. Furthermore, manufacturers of these devices normally use a specific brand and serial number, which allow tracking of the individuals who possess them. Fortunately, these serial numbers are generally not affected by post-depositional processes, exposure to the environment, or heat-related events. In addition, several countries now possess national databases of implants. For forensic anthropology, the benefits of prostheses and other medical devices include: (1) they act as unique identity factors, disclosing information about a disease or injury afflicting the missing person, as well as his/her gait or posture, with which relatives and friends may be familiar; (2) in association with degenerative diseases such as osteoarthrosis or osteoporosis, they can supply data on age at death, primarily regarding elderly individuals; (3) since they imply the performance of surgery, they suggest that the victim may be from a socio-economic context or country that granted access to this type of procedure; (4) the type of material used as well as the technique performed can be relevant to assess ancestry and therefore be used as a biogeographical indicator as some cutting-edge techniques are only performed in developed countries; and, (5) they can provide an insight into the Postmortem Interval (PMI) since the device models are continuously being updated.

The goal of this presentation is to discuss these advantages through the medical devices found in the 21st Century Identified Skeletal Collection (CEI/XXI), housed at the Laboratory of Forensic Anthropology, University of Coimbra. A total of 43 cases of Portuguese-identified men and women, ages 29-98 years, with different types of prostheses and/or medical devices were analyzed.

The CEI/XXI collection is primarily composed of elderly individuals; as such, the prostheses found were useful to validate the biological profile, in particular age at death. Furthermore, all the analyzed prosthetic materials were applied in Portugal, corroborating the place at which the surgery was executed. In some cases, serial numbers and logos were found, leading to the identification of the individuals throughout the National Arthroplasty Observatory database, since it is obligatory to register all surgically added implants in Portugal. Materials used in the orthopedic prostheses were shown to be very resistant to time. Regarding PMI information, it was possible to detect a clear chronological sequence of prostheses utilization. For instance, while a Moore prosthesis points to an individual who underwent surgery a long time ago and who, most probably, died more than ten years ago, a ceramic prostheses points to individuals who died in the last 25 years.

In summary, the devices examined in this investigation proved to be of major value in providing key information regarding a positive identification or at least provided enough information regarding the individual to allow for a

narrowing of the list of potentially matchable missing persons. The prostheses and implants had severe consequences on the gait/locomotion and posture of the individuals under analysis, features identifiable by medical records and associates of the decedents.

Prostheses, Medical Devices, Identification

A105 Bones and Teeth as Osteological Signatures of the Identity of Human Remains Excavated From a 160-Year-Old Abandoned Well: A Forensic Anthropological Case Report From India

Jagmahender Singh Sehrawat, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160014, INDIA; and Raj Kamal, PhD, Panjab University, Dept of Anthropology, Sector 14, Chandigarh 160014, INDIA*

After attending this presentation, attendees will better understand the outcomes of unscientific excavations of human remains from a confined location such as an abandoned well, preliminary identifications of exhumed remains from a forensic anthropological context, and future challenges to be faced by experts in their positive identifications.

This presentation will impact the forensic science community by encouraging forensic anthropologists to be extra cautious when excavating human remains from pre-existing structures such as wells, natural ravines, pits, and sewage channels and to make efforts to preserve the challenged forensic sites with the utmost care.

Mankind has witnessed several crimes against humanity in which disposal of human cadavers becomes problematic for the perpetrators to avoid international human rights attentions. The pre-existing structures, such as abandoned wells, potholes, natural ravines, roadside trenches, sewage systems etc., have remained preferred sites for the clandestine burial of such human remains. Post-conflict recovery of human remains has been reported from a number of countries, including Spain, Guatemala, Croatia, and Iraq; however, no such recovery was been reported from Indian soil from such sites, although in one incident, there was a written record of the presence of human remains from 282 individuals buried in a well under a religious structure at Ajnala, India.[1] This ignited the ethical conscience of various local people to excavate any such remains to corroborate or negate this reported case of a crime against humanity. As the entire excavation process was executed by amateur excavators, the bones of multiple individuals were recovered badly damaged and commingled. This study's primary goal is to identify whether the recovered human remains belong to victims of a reported mass-killing incident or to dead bodies disposed of prior to or after the reported incident in an attempt to solve the mystery of alleged crimes against humanity or human rights violations. The other objectives include: (1) determining whether the remains were modern or archaeological in nature; (2) if archaeological, determining whether the bodies date back to the mentioned period, or are older or younger; (3) discovering the minimum number of individuals present in the well; (4) establishing whether the remains were from North India (the local area of the site) or from Bengal, Bihar, and Uttar Pradesh, where the victims reportedly originated; and, (5) identifying the sex, age, ethnicity, and probable stature of the victims.

The shape, size, morphology, and proportions of different skeletal elements revealed these remains belong to adult male individuals. The articular ends of the fragmented long bones had no signs of osteoarthritis, implying that the majority of victims were less than 60 years of age. The overlapping, disorganized, and diverse positioning of individual skeletons and their stratigraphic sequences indicated that bodies were thrown into the well from the top at the same time. The retrieval of well-preserved teeth, hand and foot bones, vertebrae, a few intact skulls, femur heads, etc., from the commingled remains demonstrate that the present human archaeological site could have been processed more scientifically had it been excavated by trained anthropologists and archaeologists with expert knowledge in human osteology and odontology.

All intact skulls have traumatic injuries in the same region (i.e., the forehead region of the frontal bone), implying that some blunt weapon was used to inflict the same type of injury to the frontal head of the victims. Associated ballistic evidence in the form of cone-shaped stone bullets (a few still intact) was also found with the remains. The majority of seriously damaged skeletal remains were found unsuitable for forensic examinations and hence were not analyzed. Only teeth were found in fairly good conditions and are expected to facilitate forensic anthropological identification regarding the provenance, geographic origin, disease and health status, dietary habits, minimum number of individuals inside the well, etc. from their anthropological, molecular, and elemental analyses. Numerous personal artifacts, including copper and iron wrist bracelets, gold necklace pieces, coins and medals (with the Queen's photograph and year), and beaded arm bands, were also recovered with the human remains inside the well. The systematic and expert-mediated recovery of human remains using advanced archaeological techniques and instruments may have proved fruitful, not only in their precise and safe excavation, but also in the identification of these human remains in the laboratory. This presentation will highlight the consequences of both

the unscientific excavation of human remains and preliminary forensic anthropological identifications.

Forensic Archaeology, Human Remains in a Well, India

A106 The First Case of a Mummified Face and Skull-Photo Superimposition in the United Arab Emirates

Khudooma S. Al Na'imi, MSc, Abu Dhabi Police General Directorate, Forensic Bio Sect, Forensic Evidence, PO Box 66722, Al Ain City - Abu Dhabi, UNITED ARAB EMIRATES*

After attending this presentation, attendees will better understand the first case of a mummified face and skull-photo superimposition in the United Arab Emirates and the importance of such a technique in the process of unknown person identification when there are no samples from relatives for DNA identification.

This presentation will impact the forensic science community by providing results from a mummified face and skull-photo superimposition case, which was possibly applied for the first time in the United Arab Emirates. This presentation will add to research being conducted in skull-photo superimposition by broadening the understanding of the usefulness and challenges of such techniques in connection with cultural differences, immigrant communities, unknown person identifications, intra-laboratory validations, and forensic investigations.

In 2012, an unknown mummified female body was discovered in salt marshes in the emirates of Abu Dhabi of the United Arab Emirates. Clothes located near the body were recovered. Documents found with the clothes indicated the unknown female was from a certain African nationality. Due to the effects of sea water, the photo in the document was unclear, damaged, and less useful in the identification process. The Criminal Identification department was successful in finding a passport of a missing female from nearby resident village. As it was not possible to reach the victim's relatives in their original country, a skull-photo superimposition examination was decided upon in order to check the connection between the passport photograph, the mummified face, and the skull X-ray photographs. One of the challenges was that the female's passport photograph had an Islamic hijab (a veil) covering the back the head, which can complicate the comparison process. In cooperation with Sheikh Khalifa Medical City in Abu Dhabi, a Computed Tomography (CT) scan of the unknown female skull was taken. The CT scan data was important in this technique to produce a 3D image of the skull to be used in skull-photo superimposition (in-house). To confirm and to adjust the in-house superimposition, the mummified face photographs, the CT scan Digital Imaging and Communications in Medicine (DICOM) data, and the passport photo were sent to the Center of Anatomy & Human Identification, the University of Dundee, for a separate mummified face and skull-photo superimposition report (intra-laboratories comparison and validation). The result of the in-house and intra-laboratories comparison confirm the presence of multi facial similarities between the mummified female face and skull and the passport photo.

In conclusion, this case study will be presented as the first case of a mummified face and skull-photo superimposition in the United Arab Emirates. Furthermore, the data and experiences gained from this case will be helpful for forensic experts faced with similar unknown person identifications that are due to cultural and technical challenges and limitations. This presentation also stresses the importance of intra-laboratory validation in such comparisons and superimposition techniques.

Mummified Body, Skull-Photo Superimposition, Unknown Person

A107 Documenting Fracture Time Since Injury (TSI) Through a National Archival Database of Antemortem Fracture Healing

Donna C. Boyd, PhD, Radford University, Forensic Science Institute, PO Box 6939, Radford, VA 24142; and Cliff Boyd, PhD, Radford University, Dept of Anthropological Science, Radford, VA 24142*

The goal of this presentation is to document anatomical variability in antemortem fracture healing to aid estimation of TSI in forensic abuse cases. This is accomplished through the creation and demonstration of a national archival database for antemortem fracture healing containing macroscopically, microscopically, and radiologically derived data.

This presentation will impact the forensic science community by providing forensic anthropologists and pathologists with an understanding of the variability inherent in antemortem fracture healing in relation to a number of key attributes. This presentation will aid in the determination of fracture TSI and ultimately provide evidence (and strengthen court testimony) relating to the determination of accidental vs. non-accidental etiology for peri-mortem fractures in forensic death investigations involving suspicions of pediatric, domestic, or elderly abuse.

Assessments of TSI for antemortem fractures heavily influence determinations of accidental vs. non-accidental origin of peri-mortem fractures in cases of suspected abuse. In this presentation, the anatomical basis for antemortem healing is reviewed, particularly in regard to dating of fractures and the factors that influence TSI determination.

Antemortem healing is a continuous process which does not lend itself well to rigid interpretation using a finite staging system.[1] Determining the timing of prior injury is difficult because bone repair is influenced by a number of important variables. These variables include an individual's age, sex, nutritional and disease status, fracture location, type, and severity as well as presence and nature of treatment and repetition of injury.[2,3]

This presentation illustrates the effect of these variables upon the healing rates of antemortem fractures. In this study, the antemortem healing process is chronicled through examination of a sample of more than 1,500 macroscopic, microscopic (from a digital light microscope at 5x-200x), and radiologic digital images representing 106 antemortem fractures from 11 forensic cases (six females, five males) involving pediatric, domestic, and elderly abuse.

These images are used in the creation of a digital archival database for antemortem fracture healing for use in forensic TSI estimation. This archive consists of a searchable, online (web-based) database of antemortem fracture imagery, including macroscopic, microscopic, and radiological modalities. The database is implemented as a web app through the Radford University Forensic Science Institute website, developed in python using a Flask microframework and a MySQL™ database; both the database and website are hosted on a single Linux® platform. This website allows users to search for antemortem fracture images across the three modalities and the variables discussed above (e.g., age, sex, bone, fracture location and type, healing status, and estimated TSI).

The database includes individuals ranging in age from 27 days to 79 years; 58% of all fractures derive from subadults. Fracture location overwhelmingly involves ribs (88%), but also long bones (primarily the diaphysis) and the clavicle. Fracture timing reflects the range of the healing process (early to late) and is categorized in terms of healing status based on criteria developed by Boyd et al.[1] In at least three cases, fairly precise healing times are known or inferred.

These macroscopic, microscopic, and radiological images and their associated metadata are used to illustrate differences in the healing process across the variables examined. It is noted, for example, that metaphyseal lesions, though less visible, manifest quicker healing times. Faster healing times are also documented in the younger subadults.

The database also provides users with the ability to upload additional antemortem fractures cases, including histology images. Future additions to the antemortem fracture database from the forensic anthropology and pathology community will result in larger, more diverse samples, enabling better understanding of fracture healing variability and more precise estimates of TSI in forensic abuse investigations.

Antemortem, Fracture, Database

A108 Rediscovering the Unknowns of South Jersey: The Long-Term Initiative to Develop a Standard Methodology for Unidentified Remains at the Southern Regional Medical Examiner Office (SRMEO)

Evonne Turner-Byfield, MA, Southern Regional Medical Examiners Office, 1175 Dehirsch Avenue, Woodbine, NJ 08270; and Bobbi-Jean Brooks, BSc*, Southern Regional Medical Examiner Office, 1175 Dehirsch Avenue, Woodbine, NJ 08270*

After attending this presentation, attendees will have an understanding of the challenges involved with identifying cold unidentified cases without a standard methodology and how Rediscovering the Unknowns of South Jersey (RUSJ) is making an effort to allay these challenges for the SRMEO.

This presentation will impact the forensic science community by providing examples of the use of a formal qualitative algorithm on all unidentified cases. These examples will also highlight the importance of applying best forensic practices to cold cases.

RUSJ is a project that was undertaken by personnel at the SRMEO in 2010. The project's main goal was to better determine how forensic anthropology-related cases were handled by this office, historically and currently. RUSJ has evolved to include all unidentified cases within three county jurisdictions, the current oldest case being from 1972. RUSJ has encountered, and is likely to continue to encounter, a wide range of challenges. The challenges tend to focus primarily on gathering the missing information on the historical cases. Best forensic practices and technology have evolved immensely in the 40 years since many cold cases in the current database were investigated. Creating a comprehensive database of these cases revealed gaps in knowledge and documentation. These gaps ranged from DNA information to reports and photographs to the current locations of the actual remains. Research is still ongoing to ascertain any missing information. With the assistance of local law enforcement agencies, funeral homes, and various other state offices, this data is being gathered and verified when available.

This project is based on the premise that SRMEO is rediscovering cases that have not been actively investigated in more than 40 years and applying current forensic practice to them. RUSJ will work toward ensuring that best forensic practices, including, but not limited to, DNA testing and forensic anthropology consultation, are applied to historical data. The same testing and scrutiny will be applied to current and future unidentified cases. Creating a standardized method for handling unidentified remains and individuals can streamline the process. By adopting similar procedures, cooperating medical examiners offices could operate on a single reliable algorithm, making it possible to cross reference documentation for unidentified cases more efficiently. The implementation of best forensic practices in every office would be imperative to accommodating the standardized system. The hope is that a standard methodology can ensure consistency in all cases, unidentified and anthropological.

Since the creation of the database, the processes suggested in RUSJ have been applied to numerous cases. The results of this fact-finding mission have led to the positive of identification three individuals from 2001, 2010, and 2013. These previously unidentified individuals have since been reunited with family members, and the intention is for more identifications to follow.

The long-term goal is that implementation of this algorithm on current cases will mitigate the research time, costs, and manpower incurred by identifying historical cases. Utilizing a standardized procedure will ensure best forensic practices are used at the start of any case, thus improving the probability of identification in the future.

Outside the scientific community, the benefits of RUSJ are numerous and long term. The project provides the opportunity for more unidentified individuals to be identified and their remains returned to family members. It can also decrease the strain on county offices to process unclaimed individuals and give closure to loved ones long waiting for answers.

Unidentified, Identification, Cold Cases

A109 The Identify Indiana Initiative: A Collaborative Approach to Reinvestigating Cold Cases of Human Remains in the State of Indiana

Krista E. Latham, PhD, University of Indianapolis, Biology Dept, 1400 E Hanna Avenue, Indianapolis, IN 46227; Stephen P. Nawrocki, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227-3697; Justin R. Maiers, BS, 5941 Westbury Drive, N, Apt D, Indianapolis, IN 46224; and Eric J. Bartelink, PhD, California State University, Chico, Dept of Anthropology, Butte 311, 400 W First Street, Chico, CA 95929-0400*

The goals of this presentation are for attendees to appreciate: (1) how these investigations require cooperation between multiple agencies; (2) how new technologies can be employed to further identification efforts; and, (3) the challenges faced in these reinvestigations within the context of an elected coroner system.

This presentation will impact the forensic science community by serving as an introduction to the coordination of multiple agencies and resources required for the reinvestigation of cold cases for those who may soon embark on a similar mission.

The Identify Indiana Initiative grew from the proposition that many unidentified cold cases in Indiana could benefit from the application of new technologies, such as missing persons databases, DNA profiling, and isotope analysis. A team of volunteer specialists, including forensic anthropologists, law enforcement personnel, DNA laboratory technicians, coroners, and National Missing Persons Data System (NamUs) administrators, was assembled to reopen these cases, which date back to 1974. The first step in this process was inventorying the unidentified cases in the state. Locating some of the unidentified individuals was straightforward since they are curated at the University of Indianapolis, while others require exhumation from cemeteries across the state. Osteological analyses were conducted on the exhumed remains that were buried before forensic anthropologists were practicing in the state. The information from the skeletal examination was combined with data from law enforcement records to create an entry in the Unidentified Persons section of the NamUs database. Skeletal samples were then collected for molecular investigations, including DNA profile generation and isotope analysis.

While locating the unidentified skeletal cases and implementing new technologies to aid in identification may seem rather straightforward, the team faces a number of practical challenges. For example, Indiana is a coroner system state, and the 92 coroners (who are usually not formally trained in either law enforcement or forensic science) are elected via the political process to six-year terms. According to state law, the coroner has the ultimate authority over found human remains and must therefore give advance permission for exhumations, analyses, database entry, and the release of case information to the press or public; however, many coroners operate in rural counties without formal office or morgue space in which files or evidence can be curated long-term. With the inevitable turnover in coroners over time, the team has encountered difficulty in obtaining basic case information and associating different case numbers from the various agencies that may have been involved in an investigation. This problem extends to the acquisition of family reference DNA samples; missing law enforcement reports may have included the names and addresses of possible relatives that were interviewed in missing persons cases. The ability to locate case files and case numbers is an instrumental step in furthering the identification of these individuals.

The collaboration process, utilization of new technologies, and challenges faced by the team will be discussed within the context of several examples in which unidentified remains were exhumed and reanalyzed for this initiative. Additionally, stable isotope analysis has been integrated into the Initiative to determine whether unidentified individuals are likely local or non-local to the location where their remains were discovered. Stable isotope analysis on one of these cases demonstrated that a deceased female, discovered in 1992 in central Indiana, was most likely from the Southwest (Arizona or New Mexico) but may have spent several months in western Indiana prior to her death. This information serves as an investigative tool to aid in narrowing search parameters for missing persons cases. As the scientific tools and technologies of forensic investigation evolve, unidentified human remains should be reinvestigated to increase the chance of identification.

Unidentified Individuals, NamUs, Isotopes

A110 Are They Full Siblings? The Distribution of the Sibship Index and Its Application in Forensic Identification

Jennie J. Jin, PhD, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853; Michael O'Rourke, BS, Armed Forces DNA Identification Laboratory (AFDIL), 115 Purple Heart Drive, Dover, DE 19902; and John E. Byrd, PhD, 95-033 Hokuiwa Street, #51, Mililani, HI 96853-5530*

After attending this presentation, attendees will understand the basic concepts of DNA profiling and the significance and challenges of using autosomal Short Tandem Repeat (STR) DNA in forensic identification.

This presentation will impact the forensic science community by providing a baseline dataset to assist in the interpretation of the sibship index to increase the chances of identifying missing people with no self-DNA references.

The Department of Defense has collected DNA samples for all American service members since 1992 to ensure reliable self DNA samples are obtained. Due to the absence of self DNA reference for the missing servicemen from the conflicts prior to 1992, the DNA sequences from bone samples are compared to the missing person's Family Reference Samples (FRSs). Mitochondrial DNA (mtDNA) has been most commonly used as the missing person shares the same mtDNA with his/her maternal relatives; however, an mtDNA sequence is not individual specific and can be shared by thousands of unrelated people. If the missing person has an mtDNA sequence common in a population, additional evidence may be required to establish identification. One such evidence is nuclear DNA, both Y-chromosome Short Tandem Repeat (Y-STR) and autosomal-STR (auto-STR). If the missing person is a male and has brother FRSs, the paternally inherited Y-STR is used for comparison. If the missing person is a male and has sister FRSs, auto-STR analysis is used. Unlike mtDNA or Y-STR, auto-STR is unique to an individual. The individual specific nature of the auto-STR poses a challenge for comparison because even full siblings do not have the same auto-STR profile. This is where the sibship index comes into play.

The sibship index is the likelihood that the auto-STR results obtained from a sample support the hypothesis that the sample and the included reference sample are biological siblings, rather than if the sample is a full sibling of an unrelated individual. For example, a sibship index of 100 means that it is 100 times more likely that the bone sample and the FRS are biological siblings, rather than if the bone is a full sibling of a random person. If the sibship index is in the millions, a full sibling relationship can convincingly be established as it is highly unlikely that two unrelated individuals have significant overlap in their auto-STR profile; however, a low sibship index may not necessarily indicate that the two individuals are unrelated due to the chance of two full siblings inheriting two complete different sets of auto-STR from their parents. The sibship index frequently falls into a gray area that neither supports nor refutes full sibling relationship. This is a problem because auto-STR is often the only way to identify a missing serviceman. The goal of this study is to document the distribution of the sibship index for: (1) full siblings; and, (2) unrelated individuals. The focus is on discovering the degree of overlap of the tales of these two distributions.

In this study, the auto-STR comparison data obtained from the following four scenarios were used to generate sibship index distributions (N = 1,000): (1) the bone of an identified soldier to the full siblings of the identified soldier; (2) the bone of an identified soldier to the excluded soldiers (unrelated individuals); (3) two known full siblings in the FRS database; and, (4) two unrelated individuals in the FRS database. The number of obtained auto-STR loci was also documented to see how significantly the sibship index can change based on the quality of the auto-STR data. The study found that when two samples are full siblings, the average sibship index was in the millions but indices lower than 0.05 were also observed (Negatively skewed curve; Mean 5,073,370; Median 10,635). When two samples are unrelated individuals, the average sibship index was in the hundredths but indices between zero and ten were also observed (Normal distribution curve; Mean 0.0598; Median 0.0005755). There was minimal overlap between the two curves. As predicted, the number of obtained auto-STR loci affected the sibship index significantly: the higher the number of loci, the stronger the sibship index to confirm/refute the sibling relationship. The current research will be expanded to increase the sample size as additional results are obtained from more bones and FRS samples.

Sibship Index, Autosomal STR, DNA Profiling

A111 A New Complex Investigation Model for Searching, Mapping, and Identifying Disappeared Persons in Argentina

Delida I. Caridi, PhD, Virrey Cevallos, 986, 2do, Buenos Aires, Capital Federal 1077, ARGENTINA; Carlos Somigliana, MS, Av Rivadavia 2443, Piso 2, dep. 4, Buenos Aires, ARGENTINA; Enrique Enrique Alvarez, PhD, Instituto de Cálculo, UBA, CONICET, Ciudad Universitaria, Pabellon 2, Buenos Aires, ARGENTINA; and Mercedes Salado Puerto, PhD, Equipo Argentino Antropologia, Av Rivadavia 2443 2-4, Buenos Aires 1034, ARGENTINA*

After attending this presentation, attendees will better understand the problems related to the identification of human remains of disappeared persons and, in particular, the importance of applying innovative frameworks of research such as, in this case, the combination of complex networks, Bayesian inference, and statistical evaluation tests in the systematization and analysis of the data.

This presentation will impact the forensic science community by providing a framework of complex networks and Bayesian inference to be applied to the identification of human remains belonging to disappeared persons during the last military dictatorship in Argentina (1976-1983).

During the past 32 years, the Argentine forensic anthropology team, Equipo Argentino de Antropología Forense (EAAF), has been using a multidisciplinary approach (archaeology, anthropology, dentistry, pathology, and genetics) to recover and identify the remains of thousands of disappeared in the country.[1] Typically, after their kidnapping, people were taken to illegal detention centers, tortured, and killed. Their unidentified bodies were buried in individual or common graves in official cemeteries or clandestine mass graves at military/police compounds.

The need to generate hypotheses of identity for the recovered remains triggered interest in applying an alternative model for the analysis of the information.

This new model has mathematically systematized non-genetic variables, resulting from information obtained by already solved identifications in specific events, in such a way that they can be used in the search, GIS mapping, and a generation of new hypotheses of identity for unsolved related cases. In other words, this dynamic model based on complex networks and Bayesian inference is able to "learn" from identified cases by generating a probabilistic ranking of candidates for unidentified related cases. The geographical and temporal systematized variables, using georeferenced data and image processing techniques, from the identified skeletal remains are analyzed within a Bayesian framework.[2] In a second stage, the data are included on a complex network, where connections are established between related cases by using rules based on the individuals' attributes.[3,4] Previous to this, the most effective rules in defining the network are evaluated. Once the network has been formalized, a ranking of candidates for unsolved cases (recovered skeletal remains) is produced.

The advantage of this complex model is, among others, to minimize bias in the investigation of related cases, providing probabilistic values to connected cases. This model has a high applicability in the mapping and search of burial sites, identification of human remains, and systematization of information, essential in the investigation of massive numbers of victims, as in crimes again humanity, conflict, or migration cases.

The developed software, which includes processing of raw data, calculations, and visualization, uses R language, a free software and open source environment for statistical computing and graphics.[5-7]

Human Remains, Geographic Information, Complex Network

A112 Antemortem vs. Postmortem Measured Statures of Korean War Casualties

Alexander F. Christensen, PhD, DPAA, 590 Moffet Street, Bldg 1077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will better understand the relationship between antemortem and postmortem measurements of stature and how this impacts the reference samples used in the anthropological calculation of stature.

This presentation will impact the forensic science community by further illuminating the relationship between antemortem and postmortem stature measurements.

Forensic anthropologists estimate the stature of skeletal remains using regression models based upon various data sets. Some data sets include measured antemortem statures for individuals, while others include postmortem cadaver lengths; rarely are both available. Two of the largest data sets available are those collected by Mildred Trotter from United States casualties from World War II and the Korean War, for whom living, measured statures were recorded. Other data sets, such as many anatomical collections, lack antemortem measurements and substitute postmortem stature, or cadaver length. These two measurements are not the same. The stature of any living individual is not a constant: recorded statures can vary based upon when they were taken, the methods used, and how they were transcribed. Postmortem measurements exhibit similar methodological and transcription variation, but are generally longer than antemortem measurements, presumably because curvature of the spine relaxes to some degree.

The Individual Deceased Personnel Files of historically identified Korean War casualties provide a data set of postmortem lengths that can be compared with antemortem measured statures. Stature was an essential component of the wartime identification process and was recorded at different stages. Form 1042 (Report of Interment) was completed when remains were initially processed and interred in a temporary cemetery. Early in the war, the height field was generally only completed for unknown remains; later on, its completion came to be more standardized. These measurements were taken by Army Graves Registration personnel at the cemetery. Form 1044 (Identification Data) was completed when the remains were later exhumed for identification processing by a team that generally included an anthropologist. Per the Central Identification Unit Standard Operating Procedures (SOP), these teams recorded "table measurements" of all flesh-covered remains, and long bone measurements from all skeletal and semi-skeletal remains. While bone lengths were recorded in centimeters (cm), all heights were measured in inches.

What is the relationship between these two postmortem measured statures and the casualties' antemortem statures? Multiple studies indicate that postmortem measurements should be approximately 1" higher than antemortem. Furthermore, the table measurements recorded on Form 1044 should be more accurate than the cadaver lengths recorded on Form 1042, given the conditions under which each was taken. In fact, the cadaver lengths were subject to more rounding error than the 1042 or 1044 measures: of 239 cadaver lengths in the dataset, 7 (2.9%) ended in fractions, while 205/481 antemortem statures (42.6%) and 137/290 table measurements (47.2%) ended in fractions.

Comparing 235 cadaver lengths to antemortem statures, 10.6% were identical, 58.7% larger, and 30.6% smaller, and the mean difference was 0.73"; 49.4% of the cadaver lengths were less than 1" different from the antemortem heights, placing them within rounding error. Another 16.2% were at least 1" but less than 2" greater, placing them within the expected range for postmortem measures; 34.5% were from 2" or 8" larger. Some of these may well be the result of growth after enlistment, given that many of the men enlisted at 18 or even 17 years of age, but much is presumably the result of measurement or recording error in either the antemortem or postmortem measures.

Comparing 289 table measurements to antemortem heights, 17.3% were identical, 55.0% larger, and 27.7% smaller, and the mean difference was 0.45"; 57.1% were less than 1" different from the antemortem heights, 10.4% were 1" or more shorter than antemortem heights (with a maximum discrepancy of 4"), while 29.4% were between 1" and 2.75" taller, and 3.1% were between 3" and 5.5" taller.

Only 48 cases had both cadaver lengths and table measurements recorded. The mean difference between them was -0.37", with half of the cadaver lengths larger and 37.5% smaller; 55.3% of the table measurements were closer to the antemortem height than the cadaver length was. Several cases demonstrate clear error in the recorded cadaver length, such as an antemortem height of 74" with a table measurement of 73.5" and a cadaver length of 67".

A113 Stature Determination From the Adult Human Clavicle: A Medicolegal Autopsy Study on the Indian Population of the Northwest Region of India

Jasbir Singh, MD, AIIMS, New Delhi, Vill-Kajlan, Tehsil-Buhana, Jhunjhunu, Rajasthan 333034, INDIA*

The goals of this presentation are to explore the relationships of the mean length of the clavicle and stature in the Indian population of the northwest region and to formulate regression equations for stature estimation from clavicular length for both sexes.

This presentation will impact the forensic science community by exploring methods to estimate stature from fragmentary remains of mutilated bodies to help establish individuality of a person in cases of terrorist attacks, war causalities, and train and airplane accidents in which body mutilation is likely. At times, criminals may intentionally destroy the remains of their victims to make their identification difficult or they may be destroyed by animals after death.

Left and right clavicular lengths from 256 adult cadavers (44 female and 212 male) without trauma-related fractures and mass lesions or deformities were collected between Jan 1, 2011, and December 31, 2012, at the Department of Forensic Medicine, Government Medical College Amritsar, Punjab, India. The cadaver stature was measured as distance from the vertex to the sole using a special osteometric board. The maximum clavicular length of both sides was measured using sliding digital Vernier calipers and the average length of bilateral clavicles was also calculated for each case.

The mean length of the clavicle in females on the right side was 139.68mm and 140.21mm on the left side. For males, the mean length of the clavicle on the right side was 150.71mm and for the left was 151.89mm. The mean stature of females was 157.47cm and was 168.51cm for males. Separate regression equations were calculated for both sexes in respect to the length of the right clavicle, left clavicle, and average length of bilateral clavicles.

In terms of gender, the male length of the clavicle was more correlated to the stature of a person as compared to females. In males, the average length of the bilateral clavicle (r=0.938) was more closely correlated to stature, followed by the mean length of the right clavicle (r=0.846). In females, the average length of bilateral clavicles (r=0.761) was also correlated with a comparatively fair degree as compared to the mean lengths of right (r=0.477) or left (r=0.424) clavicles. The standard of error was least for the average length of the bilateral clavicle.

In northwest India, in the same population, Singh and Sohal worked out a multiplication factor for the calculation of stature in the male population and concluded that it was possible to calculate stature from the length of the clavicle.[1] Jit and Singh, utilizing the same population, concluded that neither a multiplication factor nor a regression formula can be adopted that will estimate the height of an individual with a reasonable degree of accuracy.[2] Yashoda et al. also devised regression equations in a study on a population of north India and found that clavicle length was a good parameter for stature estimation. Per this presentation's research, the sample size in this particular study far exceeds those of other studies conducted on the similar population of northwest India. Together, this population-specific formula will provide an easy tool for stature estimation and can aid forensic research.

Stature, Northwest Region, Clavicle

A114 The Role of Stigma in the Medicolegal Investigation of Unidentified Persons

Cate E. Bird, PhD, Anthropology, University of South Florida, 4202 E Fowler Avenue, Social Science Bldg 100, Tampa, FL 33620; Jaime D. Sykes, BA, University of South Florida, 4202 E Fowler Avenue, SOC 107, Tampa, FL 33620; and Jason D.P. Bird, PhD, Rutgers University, Dept of Social Work, Hill Hall, 360 Dr Martin Luther King Jr Boulevard, Newark, NJ 07102*

After attending this presentation, attendees will better understand factors that contribute to the persistence of unidentified persons in domestic casework, focusing on the role that stigma can play in the identification process.

This presentation will impact the forensic science community by illustrating how particular groups become devalued in death through the use of pejorative language in medicolegal reports and how this stigmatization can affect resources dedicated to identifying these people.

Forensic anthropologists are increasingly called upon to assist in the identification of decedents lacking name associations (or tentative names). The forensic science community and the public have benefited from the development of sophisticated tools (e.g., National Missing and Unidentified Persons System (NamUs)) to address this country's "silent mass disaster," which help investigators bypass jurisdictional boundaries and create central, accessible, and easily comparable repositories for antemortem and postmortem data. Still, unidentified persons cases persist. Previous research has noted that particular groups (e.g., the homeless, foreign nationals, etc.) are disproportionally represented among unidentified persons in the United States, the reasons for which are likely multifactorial. These may include deficiencies in the reporting of missing persons (e.g., due to social alienation, fear of legal retribution, lack of available antemortem data, lack of public awareness, incompetence of investigators, etc.) or deficiencies in the reporting of unidentified decedents (e.g., due to lack of available postmortem data, lack of investigator education, lack of funding for sophisticated methods, incompetence of investigators, etc.). One contributing factor that has received limited attention is the role of stigma, or the process by which certain populations are devalued in society.

Macro-level identity of decedents is frequently evaluated as a tool for generating new investigative leads. In forensic anthropology, this "biocultural approach" considers biological, cultural, and contextual indicators as a means to assess group affiliation of unidentified persons. In turn, recognition of group affiliation can help anthropologists cater their route of identification to a specific community. This approach has proven particularly effective in resolving cases of unidentified decedents suspected of being foreign nationals who die while clandestinely crossing the United States-Mexico border; however, the categorization of unknown decedents is not new, nor is it unique to anthropology. Those involved in the medicolegal investigation of death frequently (albeit informally) categorize decedent's macro-level identity, observable in written descriptions from medicolegal (e.g., police, investigative, and autopsy) reports.

While the recognition of group affiliation can be useful, the language used in investigations can both reflect and continue to construct particular groups as "deviant" or less valued in society. This study discusses case examples of written descriptions of unidentified decedents from medicolegal reports, focusing on various types of pejorative language used to describe decedents from particular groups (i.e., homeless, foreign nationals, sex workers, and Lesbian, Gay, Bisexual, Transgender, Questioning (LGBTQ) members). Through this review, the manner in which the construction of these individuals in death as "deviant" can negatively affect the outcome of identification attempts through the prioritization of casework and the unequal distribution of resources is analyzed. Structural inequalities that certain groups encounter in life can continue to marginalize them in death, and depreciatory language employed as descriptors of group affiliation reinforce the devalued nature of these decedents.

In conclusion, the assessment of a decedent's macro-level identity is inherently political. When considerately applied, this approach may provide incredibly useful investigative leads and innovative routes for identification; however, when objective assessments of decedents are replaced by subjective, morally weighted judgments of an individual's value in society, this can negatively affect the outcome of the investigation. As forensic anthropologists employed to help contribute to identifying unknown persons, it is the responsibility of professionals to recognize this process of stigmatization and devaluation in medicolegal settings and to prevent the continued marginalization of vulnerable populations.

A115 The Applications and Practicality of Dental 3D Scanning in Forensic Anthropology

Teresa V. Wilson, PhD, Louisiana State University, 227 Howe-Russell Geoscience Complex, Baton Rouge, LA 70803*

After attending this presentation, attendees will better understand how and if consumer-grade 3D scanning of teeth can be used to aid medicolegal investigations involving skeletal remains and assist in the teaching of forensic anthropology students.

This presentation will impact the forensic science community by demonstrating the possible advantages and disadvantages of incorporating the 3D scanning of teeth into forensic anthropological analyses, research, and teaching. This presentation will provide results pertaining to the accuracy and resolution of scans, minimization of scanning anomalies and artifacts, and ways in which scans can be displayed for demonstration and teaching.

The use of 3D scanning in macroscopic analyses is becoming more affordable and attainable by researchers and practitioners in forensic anthropology. The non-destructive nature of 3D scanners allows for the scanning of fragile and important specimens; however, consumer-grade scanners can create several logistical and quality problems, including excess noise and gaps in the scans. Teeth in particular are difficult to scan because of the glossy texture of the enamel interfering with the reflective angles of the lasers employed by 3D scanners. This research focuses on dentition because of the importance of teeth in positive identification of remains as well as the analysis of age, trauma, and overall health.

Twenty modern isolated teeth, four isolated teeth from a historic population, and five mandibles (teeth: n=24; mandibles: n =5) were chosen for this study. The teeth from the modern population were selected to represent all tooth types and various states of dental health (i.e., carious lesions, amalgam fillings, resin fillings, and natural). Each specimen was scanned using a NextEngine® 3D Ultra HD scanner and processed using the NextEngine® ScanStudio™ ProScan software. Each specimen was scanned using different resolution settings, lighting conditions, and scanning techniques. Each scan was compared for measurement accuracy and the precision in which the lesions or restorations were captured. Scans using the highest resolution (16k points/inch^2) showed a grainier texture to the surface and displayed large amounts of noise that created inconsistent measurements of the teeth. Scans could not be accurately replicated at the high resolution due to the noise and textured surface. Scans at low resolution (~2k points/inch^2) proved to be accurate in dimensional measurement; however, all of the details of the tooth surface were lost. Scans at the middle resolutions (~4.2k points/inch^2) provided an acceptable balance between measurement accuracy and surface detail retention. Scan resolution and noise reduction were achieved through manipulation of the ambient light during scans and the reduction of enamel shine through the use of surface powders and sprays.

Although inexpensive consumer-grade 3D scanners are not without their difficulties, 3D scanning of dentition can be useful to forensic anthropologists in both the laboratory and the classroom. Choosing the appropriate scan resolution and noise reduction techniques is dependent on the purpose of the scan. When the goal is to preserve accurate dimensions and surface detail of the teeth for presentation during trial or continued examination of the dentition after skeletal remains have been released, choosing a mid-level resolution and controlling for all lighting problems that may affect the surface integrity is imperative. Accuracy is less important when using these scans in a classroom or training setting and lower resolutions can be used. Although it is unlikely that 3D scanning of dentition would be utilized in every forensic case, this technology can be useful in the preservation of anomalous features (i.e., trauma, dental pathologies, and unique occlusal patterns) for use in the future or when another look at the teeth will be useful later.

3D Scanning, Dental Anthropology, Teeth

A116 The Curious Case of Cranial Dysraphism: How a Cranial Variant Appears as Trauma or Trephination

Christine L. Halling, MS, Louisiana Department of Justice, 1885 N 3rd Street, Livingston Bldg, 6th Fl, Baton Rouge, LA 70820; and Ryan M. Seidemann, MA, Louisiana Department of Justice, 1885 N Third Street, Baton Rouge, LA 70802*

After attending this presentation, attendees will be aware of a natural cranial variant rarely reported in archaeological or forensic literature. This presentation will describe the detail of the cranial variant, present supporting information from the clinical literature, and describe how to discern the variant from trauma or pathology. In particular, this presentation emphasizes the scope of knowledge required by skeletal anatomists and how the inclusion of clinical literature into skeletal analyses can broaden the understanding of natural cranial variation.

This presentation will impact the forensic science community by demonstrating the need for broad studies of pathology and normal skeletal variation. Highlighted is a rare case of cranial variation, known as cranial dysraphism, reported in clinical literature, but rarely reported in archaeological or forensic literature. This presentation, based on a case study of cranial dysraphism, provides fellow researchers the opportunity to observe and learn about this rare anomaly.

In order to locate a specific individual's remains from within a multiple interment in an indigent cemetery, human skeletal remains were recovered from a pauper's grave in Louisiana in 2015. Although the individual passed away in 2000 and should, theoretically, have been easy to locate, the destruction of records by Hurricane Katrina and other mismanagement by cemetery caretakers made this a complex recovery effort, requiring a combination of forensic archaeology, historical research, legal maneuvering, and some luck. Despite difficult recovery conditions owing to New Orleans' high water table, commingled remains, and the lack of meaningful documentation, the remains were well preserved.

Upon exhumation, an oddity was noted on the autopsied calvarium of a single individual. Initial speculation consisted of trauma or a pathological condition due to the position on the calvarium occurring at bregma. Only after cleaning of the skeletal material was it clear that the resulting defect at bregma was not the result of trauma, but rather appeared to be an unexplained cranial pathology or morphological variant.

The cranial defect was visible as a large perforating foramen occurring at bregma. Distinguishing the defect from trauma are the smooth borders and intact sutural lines — the coronal and sagittal sutures were completely present and descended the thinning bone into the foramen. The defect was widest on the external table and tapered to a five millimeter foramen, circular in shape, perforating the inner table of the cranium. Due to the perforation into the cranial cavity and the defect's smooth borders, trephination was considered as a cause; however, in this case, there was no exposure of the diploë and, based on the location at bregma, the expectation would be that a trephined section of the cranium would not retain the presence of the sutures.

This case study is proposed as an ideal example of cranial dysraphism, a relatively unknown morphological cranial variant. The detailed analysis of the defect, when researched and supported with clinical data, supports the diagnosis of cranial dysraphism and highlights the need to look beyond traditional sources of archaeological/anthropological and forensics literature when confronted with a seemingly unique morphological trait.

Skeletal Remains, Forensic Archaeology, Cranial Variation

A117 The Relationship of Palatal Suture Complexity and Fusion

Carrie A. Brown, PhD, Defense POW/MIA Accounting Agency Laboratory, 106 Peacekeeper Drive, Bldg 301, Offutt AFB, NE 68113*

After attending this presentation, attendees will better understand how palatal suture complexity, palatal suture fusion, age, sex, and ancestry are interrelated.

This presentation will impact the forensic science community by demonstrating that sutural complexity and fusion are linked in such a way that complexity cannot be overlooked when producing an age estimate from the sutures of the hard palate.

Age estimation from the palatal sutures is based on the age-progressive synostosis of the incisive, median palatine (the Anterior Median Palatine (AMP) and Posterior Median Palantine (PMP)), and Transverse Palatine (TP) sutures. While closure of the palatal sutures is useful in categorizing unidentified skeletal remains into broad age categories, methods employing palatal sutures suffer from a lack of precision and exhibit only moderate correlations with known age-at-death. An investigation of other variables that potentially contribute to palatal suture fusion is important in order to better understand variation in suture closure and to improve current methods.

The palatal sutures are part of a complex biomechanical environment and play an important role in permitting strength and flexibility of the palate during mastication. Complex sutures, those with many interdigitations, have increased surface area along the sutural margin. These sutures thus have greater energy-absorption potential and strength in bending and are usually found where loading is predominantly compressive. Simple sutures signify a largely tensile loading environment, and they may resist fusion to a certain extent due to the continuous separation at the margins brought about by tensile forces.

Data on palatal suture fusion and complexity were collected from 762 male and female individuals of African, Asian, and European ancestry. The sample was stratified prior to data collection so that each sex, ancestry, and age group was evenly represented. The palate was photographed, and fusion, total sutural length, and suture chords were digitally measured for the TP, PMP, and AMP sutures using ImageJ and standardized landmarks; error introduced from digital measurement is believed to be negligible. Sutural complexity is the total suture length divided by the suture chord (suture length ratio; values at or close to 1 = simple suture; values increasing from 1 = greater complexity). The total amount of fusion along a given suture was measured, even if discontinuous, and this amount was divided by the total length of the suture (fusion ratio; 0 = absence of fusion; 1 = complete fusion). The relationship of sutural complexity and fusion was tested using Pearson's *r* and linear regression, and the relationships of complexity, fusion, and demographic group (e.g., age, sex, and ancestry) were tested using linear regression and Analysis of Variance (ANOVA).

Overall, the sutures of the palate in this sample are not complex (mean complexity values: TP suture = 1.53; PMP suture = 1.24; AMP suture = 1.25), and the correlation of fusion and suture complexity ratios is always negative (TP $r = -0.39$; PMP $r = -0.37$; AMP $r = -0.17$). The adjusted R^2 for regression of fusion on sutural complexity is 0.187, and TP and PMP suture complexity have significant effects on fusion while AMP complexity does not (TP, PMP $p < 0.001$; AMP $p = 0.292$). Sutural complexity shows little to no relationship with age (R^2 values from 0.001 to 0.006). Sutural complexity for all three sutures was significantly different between the sexes and among the ancestral groups ($p < 0.001$). Males show decreased complexity as compared to females. Asians have the most complex sutures for the median palatine suture, while Europeans are the most complex for the transverse palatine suture.

The negative correlation of sutural complexity and fusion indicates that sutures displaying increased complexity have a tendency to exhibit less fusion, while sutures that are less complex are more likely to display fusion. Since palatal sutures in this sample are simple, this indicates a largely tensile environment in the palate, which may explain the patency of palatal sutures even into late adulthood. These results also are interesting in light of sex and ancestral differences in fusion. Males have higher fusion ratios than females, but are less complex. Asian individuals have the most complex sutures for the median palatine but also the lowest fusion ratios. Future research will focus on including complexity data in age estimation methods.

Adult Age Estimation, Palatal Sutures, Sutural Complexity

A118 Elliptical Fourier Analysis of the Human Nasal Aperture

Justin R. Maiers, BS, 5941 Westbury Drive, N, Apt D, Indianapolis, IN 46224; and Stephen P. Nawrocki, PhD, University of Indianapolis, Dept of Biology, 1400 E Hanna Avenue, Indianapolis, IN 46227-3697*

After attending this presentation, attendees will appreciate the various biological and environmental factors that contribute to normal variation in human nasal aperture shape. The goals of this presentation are: (1) to discuss how age, sex, ancestry, and geography differentially contribute to the overall shape and size of the human nasal aperture; and, (2) to discuss how this information could be applied to modern forensic investigations.

This presentation will impact the forensic science community by quantifying and describing differences in shape of the nasal aperture across different population groups. Previous studies have focused on the nasal aperture as a qualitative trait. By quantifying the shape of the aperture, more rigorous statistical analyses can be applied to the data.

In the analysis of human skeletal remains, the nasal aperture is often used in discrete, non-metric analyses, especially in regard to ancestry assessment. The shape itself is complex, so the final assessment of the shape has traditionally been based largely on the subjective judgment of the observer. This means the final decision of the qualities of that shape are subject to the Gestalt of the observer, and do not necessarily accurately describe actual shape. Elliptical Fourier analysis can transform the complex shape of the nasal aperture into a numeric variable. Once transformed, not only can the complex shape be consistently and precisely recreated, but it can be quickly and easily compared against data from other nasal apertures.

A sample of 868 individuals from the Pretoria Bone Collection and the W.M. Bass Donated Skeletal Collection were utilized in this study. Data was collected only on individuals with a known age, sex, and ancestry. This study utilized both males and females, with ages ranging from 18 to 100 years, but only collected data on individuals identified as White or Black. Individuals were not included in the sample if there was any damage to the contour of the nasal aperture. Data was collected by photographing the nasal aperture on a standardized plane at a focal length of 55mm with the camera set to aperture priority with an f-stop of eight. All photos were taken from a distance of 30cm directly above nasion. After photography, all images were uploaded into Adobe® Photoshop® v 11. The outline of the nasal aperture was traced along the internal margin using the Magic Wand Tool. The shape was then filled using the Paint Bucket Tool. Traced and filled images were resized to 500 x 332 pixels and saved as a 24-bitmap file. Those files were subsequently uploaded into SHAPE v. 1.3 for elliptical Fourier analysis. Four principal components were identified using the SHAPE program. Univariate analyses were performed to evaluate which variables (age, sex, and/or ancestry) were contributing the most to the shape differences. An Analysis of Variance (ANOVA) test was performed to test for significant differences between group means. Even though four principal components were identified, only the first two significantly contributed to the overall shape of the nasal aperture. In this study, ancestry was the most powerful contributor to the overall shape and was found to be significant in Principle Component Analysis 1 (PCA1) (height-to-width ratio, p=.000) and PCA2 (inferior margin contour, I=.004). Sex contributed significantly to PCA1 (height-to-width ratio, p=.001) but also appeared to exhibit significant interaction with ancestry, which may confound significance. The biggest difference between the sexes is overall size, but the differences in the actual shape are minimal. Age did not contribute significantly to any principal component, suggesting that it does not systematically affect the shape of the nasal aperture.

Elliptical Fourier analysis was instrumental in quantifying a complex shape, which allowed this study to focus on statistical comparisons instead of qualitative descriptions. These results reify that ancestry is the strongest contributor to the shape of the nasal aperture. Although age and sex somewhat contribute to the differences in aperture shape, their effects are not systematic and therefore do not influence the overall mean.

Nasal Aperture, Elliptical Fourier Analysis, Shape Analysis

A119 Is Quantitative Ultrasound (QUS) a Useful Tool for Evaluating the Mechanical Properties of Infant Cortical Bone?

Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Christian Crowder, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Catherine G. Ambrose, PhD, UT Health and Science Center, 6431 Fannin, Rm 6 154, Houston, TX 77030; and Juantia M. Deaver, UT Health and Science Center, 6431 Fannin, Houston, TX 77030*

The goal of this presentation is to compare Speed Of Sound (SOS) values measured from pediatric bone with mechanical properties derived from tibial specimens to determine whether SOS reflects bone strength.

This presentation will impact the forensic science community by introducing pilot data for biomechanical properties of infant bone, which is absent from clinical and anthropological literature, and by discussing the assessment of QUS as a technique for evaluating infant bone quality.

In pediatric cases with suspected non-accidental injury, bone quality/strength is of prime interest. Defense attorneys often argue that skeletal injuries in these cases could result from normal handling due to inherent bone fragility caused by various non-confirmed diagnoses (i.e., temporary brittle bone disease, osteogenesis imperfecta, etc.). These arguments are disputed using medical findings and opinions of expert witnesses; however, opinions regarding bone quality and fracture susceptibility are typically based on qualitative assessments. Currently, there are no validated quantitative methods available for the assessment of infant bone quality; however, QUS is a validated technique for osteoporosis diagnosis in adults.

This research tests the efficacy of QUS in assessing infant bone quality through the comparison of tibial SOS values with the mechanical properties of tibial bone planks. It was hypothesized that SOS would exhibit a significant positive relationship to ultimate strength and elastic modulus and a significant negative relationship to plastic toughness. These hypotheses were deduced from two research-based assertions: (1) bone mineralization increases with age in children and SOS is positively correlated with mineralization in adult studies; and, (2) degree of mineralization affects the mechanical behavior of bone.

This study sample consists of 19 decedents ranging from 0 to 10 months of age. For each individual, SOS was measured on the antero-medial aspect of the tibial midshaft with QUS. Subsequently, a 10mm x 2mm section of bone was excised from the tibia using a Dremel® tool, placed in 70% ethanol, and refrigerated at 3°C-4°C. In preparation for mechanical testing, the specimens were cut into planks using an IsoMet® wafering saw, rehydrated in phosphate-buffered saline prior to mechanical testing, and tested wet at room temperature. The specimens were loaded in 3-point bending according to the following protocol: specimens were preloaded to 0.2N for two seconds and loaded at a displacement rate of 0.1mm/s until fracture or until a strain of 20% was reached. Load and displacement data were captured at a rate of 40Hz using Bluehill® software. Statistical analyses were performed using SPSS 22.

Results reveal no significant associations between SOS and the intrinsic material properties of the tibial specimens. Age was significantly correlated with ultimate strength ($r = 0.48$, $p = .036$) and elastic modulus ($r_S = 0.48$, $p = .038$). There was no significant correlation between SOS and age in the pooled sample; however, SOS was significantly correlated with age ($r = 0.62$, $p = .017$) after removing infants less than one month of age from the analysis.

Results indicate a complex relationship between age and SOS. SOS did not significantly correlate with age during the first month of life nor did it significantly correlate with biomechanical variables. During the first month of life, there was notable variation in SOS, which was likely related to variability in bone composition and porosity. In contrast, the comparison between age and biomechanical factors performed as expected. Cortical bone stiffness increases with age along with the amount of stress the cortical bone could withstand prior to failure. Owing to the bone elasticity, mechanical loading to the point of fracture was difficult to achieve in some specimens requiring the predetermined total strain (20%) value as the failure point. Potential explanations for these findings include: small sample size; samples with substantial subperiosteal new bone formation, which may influence the acoustic impedance of SOS and the mechanical behavior (i.e., more crushing than bending); and the endosteal trabeculae were trimmed from the second batch, which was not performed on the first batch. The presence of trabeculae may

have introduced noise into the biomechanical data. Although the hypotheses were not accepted, these finding are preliminary. With additional data, a more definitive statement regarding the relationship between SOS and biomechanical properties in infants can be presented.

Speed of Sound (SOS), Biomechanical Properties, Infant Cortical Bone

A120 A Histomorphological Analysis on the Variability of the Entire Human Skeleton: Implications for Differentiating Human From Non-Human

Annalisa Cappella, BS, Via Mangiagalli 37, Milano 20133, ITALY; Marco Cummaudo, MSc, LABANOF, Via Mangiagalli #37, Milan 20133, ITALY; Miranda Biraghi, BSc, LABANOF, Via Luigi Mangiagalli, #37, Milan, ITALY; Caterina Raffone, BSc, LABANOF, Via Luigi Mangiagalli #37, Milan 20133, ITALY; Nicholas Márquez-Grant, PhD, Cranfield University, Cranfield Forensic Institute, Defence Academy of the United Kingdom, Shrivenham SN6 8LA, UNITED KINGDOM; and Cristina Cattaneo, PhD, LABANOF, Via Luigi Mangiagalli, n.37, Milan 20133, ITALY*

After attending this presentation, attendees will be better informed regarding bone histology of the entire human skeleton, not only the compact bones widely presented in literature. In addition, attendees will also understand the useful role bone histology may cover in forensics in general, specifically regarding species diagnosis.

This presentation will impact the forensic science community by informing attendees of the importance of continuing to investigate this particular field, which has become increasingly more important in anthropology for a variety of purposes.

Bone histology has always proven to be of great importance in anthropology, especially when dealing with age estimation, postmortem alterations, trauma analysis, and species identification. The latter (differentiating human from non-human) has acquired an essential value in forensics, and anthropologists often have to undertake species diagnosis conducted with very small bone fragments. Although bone histology has been deeply explored, there is not yet a full consensus regarding classifications and terminologies of bone microscopic structures. In addition, even if the literature provides numerous studies reporting the histological bone characterization within different species, it primarily regards the compact bones; thus, there is still a need for in-depth investigation of the variability of the bone tissue appearance within the entire skeleton and/or on the same bone.

This study seeks to histologically map the entire human skeleton in order to clarify the histomorphological variability by determining and comparing the diverse tissue typologies that can possibly belong to the human skeleton and to different portions of a same bone.

The histomorphological analysis conducted on 50 cross-sections from a human adult skeleton (comprising long, flat, and short bones) revealed the prevalence of secondary bone characterized by secondary osteons immersed in a lamellar matrix.

As per the literature, no histological sections exhibited fibrous bone, which is instead typical of initial growth (fetus and infant), bone healing, and response to pathological conditions. Regarding the Haversian tissue, the most frequent pattern was characterized by scattered secondary osteons with no organization.

Generally, excluding the trabecular bone (characterized by avascular or poorly vascularized lamellar tissue), long bones displayed a higher variability (alternation of tightly packed secondary osteons and scattered Haversian systems immersed in a lamellar matrix). On the contrary, flat and short bones seemed characterized by a greater uniformity, namely scattered osteons with no organization. In general, flat bones are formed by scattered secondary osteons and smaller Haversian systems with abundant interstitial lamellae; the occipital, rib, sternum, the superior border of scapula, and ileo-pubic ramus also exhibit a greater osteon density. The only exceptions regarding short bones are the middle portion of the metatarsal, in which the osteons are tightly packed without organization, and the middle portion and the distal end of the metacarpal, in which Haversian systems are organized in circular rows.

The difference in the Haversian system density between long bones confirms what has been reported in previous research regarding the relationship between the physical properties of bone and its histological structure. The femur and tibia displayed a higher osteon density when compared to the fibula, in which the Haversian systems are smaller with higher amounts of interstitial lamellae. A large number of small osteons and fragments make the tensile strength of a given amount of bone smaller if compared to areas with few large osteons and fragments. On one hand, Haversian systems reduce the tensile strength and increase the tensile strain of cortical bone; on the other hand, interstitial lamellae reduce the tensile strain while increasing the tensile strength. This results in a greater tensile strength and elasticity of the fibula as compared to the femur and tibia.

The observation of the histological sections by polarized light allowed identification of the presence of several

drifting osteons in the diaphysis of the ulna, clavicles, and rib's heads.

The finding of drifting osteons in the study sample is in accordance with literature since, although they are typical of young individuals, their presence in adult individuals is also verified.

Further research on the histomorphometric variability of human and non-human bones is paramount in order to have a complete understanding of bone histology and to improve all its application fields, such as the differentiation between human and non-human species.

Bone Histology, Human vs. Non-Human, Forensic Anthropology

A121 Introducing the Macromorphoscopic Databank (MaMD): A Data Collection and Analytical Tool for the Analysis of Macromorphoscopic Trait Data

Joseph T. Hefner, PhD, Michigan State University, Dept of Anthropology, 355 Baker Hall, East Lansing, MI 48824; and Amber M. Plemons, MA, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with the newly created MaMD, a data storage repository attached to a data collection and analytical tool for the analysis of macromorphoscopic trait data. Attendees will be better informed concerning the development of this project, the current state of the database, data contributors, and the research/analytical potential of these data.

This presentation will impact the forensic science community by addressing a significant gap in best practice in the forensic anthropological approaches to macromorphoscopic trait data, particularly as those data relate to the estimation of ancestry.

An integral part of the biological profile constructed by forensic anthropologists for unknown human skeletal remains is an estimation of the peer-perceived ancestry for that individual. This estimation is usually accomplished through visual inspection of morphological variants of the cranium and mandible (i.e., cranial non-metric, or macromorphoscopic, traits) and/or through an analysis of measurements of the cranial and postcranial skeleton; however, estimating ancestry using macromorphoscopic traits is not straightforward and often relies on a considerable number of years of experience and an extraordinary understanding of human variation.

The purpose of this presentation is to address this substantial gap in best practice in forensic anthropology. Very little reference data exist — and are publicly available — for the objective analysis of macromorphoscopic trait data. Consequently, forensic anthropologists rely on their own experience or outdated methods having very little empirical support. The fundamental flaw with these two approaches is that they offer no way of estimating error nor are they verifiable as a method. The result is *post hoc* trait selection, experience-based justifications, and anecdotal expert judgement with no empirical support.

This presentation addresses the gap in best practice through the introduction of the MaMD. The purpose of any databank is to serve as a repository of data and to make those data accessible to many end users, or practitioners. To that end, the MaMD serves as a repository for macromorphoscopic trait data obtained primarily from recent and well-documented forensic cases or donated skeletal material. To facilitate data sharing and to maximize analytical output, the databank comprises relational databases housing not only macromorphoscopic trait scores, but also demographic data on each decedent. These include but are not be limited to: age at death, sex, stature, ancestry, place of birth, occupation, self-identified ancestry (social race), etc. All data are maintained in these relational databases on a central server, using a database platform to perform the essential managerial and analytical functions necessary for data management.

The MaMD is populated using Macromorphoscopic Traits (v. 1.61), a newly developed data collection program for 17 macromorphoscopic traits. The end user provides provenience information after data are collected, retaining trait scores to a sample-specific database for subsequent submission to the MaMD. The MaMD currently contains macromorphoscopic trait data for 6,670 individuals. Examples of populations for which data are available include samples of modern American Black and White, Hispanic, Guatemalan, Colombian, Fijian, Thai, Japanese, Pacific Islander, and Peruvian.

The MaMD and a forthcoming analytical program utilizing classification algorithms appropriate for categorical data will be available for wider use following extensive beta testing, method validation, and inter- and intra-observer error tests. Forensic anthropology laboratories (applied and academic) are encouraged to assist in the validation and beta testing phase of this research through a data-sharing model similar in scope and function to the Forensic Anthropology Databank.[1] Further refinement of several classification algorithms and the user interface for the analytical program will be completed within the next year.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect the views of the Department of Justice.

Macromorphoscopic Databank, Ancestry, Macromorphoscopic Traits

A122 Postmortem Interval Estimation Using the Blackened Osteocyte Method

Sarah Long, BS, 811 IH 30, Apt 625, Mesquite, TX 75150; Lynne S. Bell, PhD, Simon Fraser University, Dept of Criminology, 8888 University Drive, Burnaby, BC V5A 1S6, CANADA; and Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296*

After attending this presentation, attendees will be informed concerning the histological changes that occur in human bone during the decomposition process.

This presentation will impact the forensic science community by introducing a possible new method that may be further developed to estimate postmortem interval.

The ecology of human decomposition is a series of complex occurrences that are driven by biological and physiochemical processes and over the past decade has been at the forefront of forensic interest. The processes are responsible for leaving specific signatures in the landscape near a body, and in the body itself, including both soft tissue and bone. The documentation and identification of postmortem microstructural changes in bone are important and provide insight into both the peri-mortem and postmortem history of the body. Past histological studies focused on the microstructural changes that occur post-skeletonization but limited or no research has focused on pre-skeletonization conditions.

The focus of this study was to identify any histological changes in bone during the stages of decomposition, exploring any trends that could help estimate postmortem interval. Emphasis was placed on bones that have traditionally been used in past histological methods. The study was conducted at the Southeast Texas Applied Forensic Science (STAFS) facility, Sam Houston State University, Huntsville, TX.

Sixteen bone samples from the femur, tibia, humerus, and fourth rib were taken from human cadavers at each of the four stages of decomposition: fresh, early, advanced, and skeletonization. The samples were split into two sample groups: decalcified and undecalcified. The undecalcified samples were unaltered and had no chemical treatments. The decalcified samples were treated with decalcification reagents and stained. Thin sections of each bone were examined using light microscopy and submitted for analysis. The number of blackened osteocytes were counted and compared to the stages of decomposition. The fourth rib was ruled out due to difficulty acquiring clear imagery.

Preliminary results demonstrated a significant increase in the number of blackened osteocytes as the body progressed through the decomposition stages, not only in the stages of decomposition but also by bone type. For example, the femur exhibited an increasing number of blackened osteocytes, with the biggest changes occurring during the early and advanced stages. This method has the potential to be used in estimation of the postmortem interval. Blackened osteocytes were not visible in the decalcified samples. This may have been the result of the staining process or, more likely, that decalcification has removed part of the organic/mineral composition of the blackened osteocytes themselves. Additional research is underway, including increasing the sample size and collecting samples on bodies placed during various seasons of the year. If in these future studies the results continue to be reliable, the blackened osteocyte method may be a valuable tool for estimating the postmortem interval when skeletal remains are found in an advanced stage of decomposition and insect activity has long since ceased.

Forensic Science, Forensic Anthropology, Postmortem Interval

A123 A New Approach to Estimating Accumulated Degree Days (ADD): Using Binary Observations From Various Regions of the Body With Random Forest Modeling (RFM) and Geographic Information Systems (GIS)

Michael W. Kenyhercz, PhD, Department of Defense POW/MIA Accounting Agency, 590 Moffet Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96816; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996; and Annemarie C. Gundel, BA, University of Tennessee, Dept of Anthropology, 250 S Stadium Hall, Knoxville, TN 37996*

After attending this presentation, attendees will understand a new approach to estimating ADD to more accurately estimate the Postmortem Interval (PMI) by using binary observations from several regions of the body in conjunction with RFM and GIS.

This presentation will impact the forensic science community by offering an alternative approach to estimating ADD that will result in less-biased estimates by examining discrete features as opposed to components or arbitrarily weighted suites of characteristics, which leads to more accurate estimates of ADD.

Estimating PMI has long been a focus within the medicolegal community, particularly once rigor and algor mortis have passed as potential indicators of PMI. Currently, the most prominent method for estimating ADD is Megyesi and colleagues' Total Body Score (TBS).[1] Megyesi et al. have provided qualitative observations for three anatomical regions (head and neck; trunk; and limbs) that are assigned weighted scores and summed together to provide a quasi-continuous score that can be used to estimate ADD.[1] The model provided by Megyesi et al. resulted in an r^2 value of 0.84 for log 10 transformed ADD and squared total body score.[1] The current study seeks to improve ADD estimates by incorporating information from more anatomical regions and by using discrete binary (presence or absence) traits and advanced statistical models.

Ten donors received at the Forensic Anthropology Center were selected for the current study. For inclusion in the study, a donor must have had a known time of death, had not been subjected to an autopsy, and did not possess any overt trauma that might disrupt normal decomposition. Each donor was placed in a freezer for at least 24 hours before placement to ensure each donor was at the same temperature before placement. The ten donors were placed in a transect at the Anthropology Research Facility in a section designated for research. Donors were kept in body bags until they had reached ambient temperature.

A binary scoring list was developed for 16 regions of the body to be scored independently of one another. The 16 regions of the body scored include: (1) head and neck; (2) left upper arm; (3) right upper arm; (4) left lower arm; (5) right lower arm; (6) left hand; (7) right hand; (8) left upper leg; (9) right upper leg; (10) left lower leg; (11) right lower leg; (12) left foot; (13) right foot; (14) chest; (15) abdomen; and, (16) genitals. Each region was scored with the same list of 39 binary observations that examined bloating (6 observations), skin coloration (2 observations), purge (4 observations), skin appearance (14 observations), and insect activity (13 observations). Additionally, the head and neck region included two additional observations relating to retention of the scalp. In sum, each body was evaluated for the presence or absence of 626 traits each day from placement (at ambient temperature) through 2,000-averaged ADD.

Data were subjected to RFM regression using 1,000 trees and a maximum of five random variables tested at each node. The data were partitioned into a 70% training set, 15% validation set, and 15% test set. Each region was tested individually in addition to the entire body.

Known ADD was plotted against estimated ADD from the RFM regression, resulting in r^2values ranging from 0.74 (right foot) to 0.96 (all regions). Additionally, estimated ADD scores, from the regression, for each region were used in GIS to display heat maps showing the decomposition of each region for each donor and also to conduct hot spot analysis. Further, the individual heat maps were summed to create a general model displaying overarching trends in decomposition progression, which was also subjected to hot spot analysis. The heat maps reveal that the abdomen, genitalia, and upper leg decompose more rapidly than the rest of the body. Additionally, the right upper limb, chest, and feet exhibit significantly different hot or cold spots as compared to contiguous body regions.

Results indicate that using discrete observations from anatomical regions in conjunction with RFM provide excellent estimates of ADD that can be used to confidently estimate PMI.

Forensic Science, Forensic Anthropology, Time-Since-Death Estimation

A124 Validation of the Total Body Score/Accumulated Degree Days (TBS/ADD) Equation at 100, 300, 500, and 1,000 ADD on 30 Human Subjects With a Known Postmortem Interval (PMI) From Three Human Decomposition Facilities

Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296; Nichole Miller, Sam Houston State University, Box 2296, Huntsville, TX 77341-2296; Dawnie W. Meckel, MA, 1509 Marlton Street, San Marcos, TX 78666*

After attending this presentation, attendees will understand that the equation associated with the TBS method using ADD is ineffective as a means to estimate the PMI and becomes progressively less accurate as the decomposition process proceeds.

This presentation will impact the forensic science community by demonstrating the need for new regional-specific equations for calculating ADD from TBS.

Beginning in March, 2015, a validation study of the TBS and regression equation for calculating ADD to estimate the PMI was conducted at three human decomposition research facilities, each having different climates (subtropical-sub-humid, temperate, and subtropical-humid).[1] The study was conducted at the Forensic Anthropology Center at Texas State (FACTS) at Texas State University in San Marcos, TX, the Anthropology Research Facility (ARF) at the University of Tennessee, Knoxville, TN, and the Southeast Texas Applied Forensic Science Facility (STAFS) at Sam Houston State University, Huntsville, TX. From March 2015 to June 2016, a total of 24 bodies were placed at each facility (total 72) during the spring, summer, fall, and winter seasons. Four subjects were placed on the ground surface at each facility each season; two in a shaded environment and two in the sun. Observations with TBS documentation and digital images were recorded daily. Data loggers captured daily temperatures and ADD was calculated.

The purpose of this study is to test inter-observer variability in the TBS and to examine the accuracy of the TBS/ADD equation developed by Megyesi and colleagues in the three environments.[1] A 30-subject subsample (ten subjects per facility) was selected for the validation study. The 30 subjects represent individuals placed in all four seasons and in both sun and shade. For the inter-observer test, photographs of ten subjects at different stages of decomposition were examined and researchers from each facility independently calculated the TBS. An Interclass Correlation (ICC) statistic test was used to assess the inter-observer error for the TBS as well as the score for each body portion. For the test of the TBS/ADD equation, photographs corresponding to 100, 300, 500, and 1,000 ADD were selected from each of the 30 subjects. Using the TBS/ADD equation ($ADD = 10^{(0.002*TBS*TBS+1.81)} \pm 388.16$), the mean and range of ADD for each subject was compared to actual ADD.

The inter-observer test exhibited no statistically significant differences between researchers. The average measures for absolute ICC for the head presented near perfect agreement between observers (.959). The trunk displayed even greater agreement (.975) and the limbs demonstrated the least agreement (.940), but still was not statistically different ($p<0.001$). Based on this study and a recent study conducted by Dabbs and colleagues, it is clear that assessment of TBS from digital images is reliable and consistent between observers.[2]

The results of the calculated ADD exhibited significant variation between actual and estimated ADD. The difference between the actual and estimated mean ADD increases as ADD increases. For example, at 100 ADD (TBS 7), the TBS/ADD equation mean for all 30 subjects is 80.9 with a range of 0 to 475 ADD. At 300 ADD (TBS 26), the estimated mean is 1,452 with a range of 1,064 to 1,840 ADD. In addition, there was a significant overlap of ADD ranges in more advanced stages of decomposition when TBS increased. Numerous individuals remained at the same advanced TBS for more than 1,000 ADD at each of the three facilities.

This validation study demonstrates that TBS can be reliably calculated for human remains, but the equation for

estimating ADD provided by Megyesi and colleagues is insufficient, especially as PMI increases, regardless of the decomposition environment.[1] Other means of estimating PMI have been suggested and are also being.[3] The current study is two years and validation of revised equations pertinent to each unique climate or a new PMI method will be performed in the second year.

This study was funded by the National Institute of Justice.

Total Body Score, Validation Study, ADD Regression Equation

A125 Vulture Scavenging of Small-Sized Pig Carcasses in Central Florida: Utilizing Geographic Information Systems (GIS) to Analyze Site Variables Affecting Skeletal Dispersal

John J. Schultz, PhD, University of Central Florida, Dept of Anthropology, 4000 Central Florida Boulevard, HPH 309, Orlando, FL 32816; and Alexander T. Mitchell, 1045 Club Sylvan Drive, Apt H, Orlando, FL 75022*

After attending this presentation, attendees will have a better understanding of vulture scavenging of the Central Florida region and its impact on the scavenging of small-sized carcasses. This presentation will focus on vulture consumption, disarticulation, and dispersal of remains in two micro-environments (shaded and unshaded) in order to discuss regionally specific taphonomic modifications of carcasses and deposition sites.

This presentation will impact the forensic science community by describing how vultures scavenge small-sized carcasses in Central Florida and their collective ability to modify deposition sites and destroy forensic contexts in the process. The dispersal of remains will be analyzed using arcGIS® spatial analysis tools.

Scavengers can significantly alter a forensic scene and consume, modify, disarticulate, and disperse bodies. These scavengers can differ greatly between different geographic regions. In recent years, there have been a number of important vulture studies; however, little research exists regarding scavenging in Central Florida, specifically scavenging involving black and turkey vultures (*Coragyps atratus* and *Cathartes aura*).

The research site was located on the University of Central Florida (UCF) campus at the Deep Foundations Geotechnical Research Site, which consists of approximately two acres surrounded by a six-foot chain-link fence. The tall fence was optimal to primarily select for avian scavengers. The research sample consisted of four pig (*Sus scrofa*) carcasses weighing between 25kgs and 29.5kgs that were deposited individually during the month of March in two distinct micro-environments: two in shaded and two in unshaded locations. The shaded micro-environment consisted of a grove of long-leaf pines with a layer of pine needles over the ground surface. The unshaded micro-environment consisted of vegetation on the ground surface and was surrounded by taller vegetation and bushes. Two field cameras were placed at each site to record both video and time-lapse photography. The dispersal data was mapped in the field using the azimuth control method and analyzed using arcGIS® v. 10.2.2 spatial analysis tools.

A mass vulture scavenging event occurred over two days, beginning during the evening of the sixth day of the postmortem time period and ceasing at dusk. Scavenging then continued during the morning of the seventh day. The vultures reduced the small-sized carcasses to primarily skeletal elements, with large sections of skin containing adhered small bones of the lower limbs, in approximately eight to nine hours of feeding time combined over these two days. This mass scavenging event was accomplished by large numbers of vultures simultaneously feeding at each carcass, with a maximum total number of 43 observed on video at one time at a single carcass. While two bald eagles were also recorded contributing to consumption of the carcasses, they participated minimally. Vultures disarticulated the carcasses, usually by entering through the orifices of the caudal and cranial ends. It is important to note that as the vultures consumed soft tissue, the large bones were scattered away from the initial deposition site of the carcass, while the smallest bones (including epiphyses) were sometimes consumed. It was after the initial mass scavenging event that opossums began scavenging the remains at night, particularly any remaining sections of skin, including skin with attached skeletal elements from the lower limbs.

The spatial analysis results indicated a number of site ground variables impacted vulture dispersal, such as the site perimeter fence and the tall ground surface foliage. Vultures primarily dispersed skeletal elements in open areas, and the majority of elements were dispersed within 6m of the initial carcass deposition site, with a maximum distance of approximately 15m. Conversely, opossums dispersed remains directly into denser foliage, most likely to consume the remains in more secure locations, including modifying a number of bones. Additionally, the ground surface and foliage of the carcass locations were further modified by the mass vulture frenzy, including scratching the ground surface with talons and digging with beaks to consume all remnants of the carcasses. The scavenging observed in the current study illustrates the capability of vultures to consume, disarticulate, and disperse remains and to modify depositional sites in Central Florida. This study can hopefully provide a standard format for more appropriate comparisons among future vulture studies.

Avian Scavenging, Vulture Scavenging, arcGIS®

A126 Differential Temperatures of the Human Body and Fire

Elayne J. Pope, PhD, Tidewater OCME, 830 Southampton Avenue, Ste 100, Norfolk, VA 23510; Amanda Williams, MA, 2450 Lymbery Street, Apt 309, Reno, NV 89509; and Alison Galloway, PhD, University of California, Chancellor's Office, Santa Cruz, CA 95064*

After attending this presentation, attendees will better understand how temperatures external to the body in a fire can be more than 1,000°F-1,600°F, but the internal core temperature of the body does not rise by a single degree until a later interval of the fire (20-30 minutes).

This presentation will impact the forensic science community by providing documented time and temperature ranges in relation to heat-related changes of the body.

In taphonomic research, ambient temperatures are considered a key variable that affects the body's rate of decompositional changes over time. Temperature is also highly important in fire research since heat produces the burn patterns that are observed on the body at the crime scene or morgue. Aside from industry standard crematorium temperatures, there is scant data on temperatures at which the human body burns externally and internally.

Experimental fire research captured the temperatures around and inside the body using data loggers, Type K thermocouples, and digital photography. Three adult cadavers were placed inside of two structures and one outdoor fire with wood and ignitable liquids. Small incisions were made in the abdomen and a thermocouple wire was inserted a couple of inches into the liver. External temperatures of the interior structure along with internal liver temperatures were recorded. Fires burned for 8 to 50 minutes. For the structures, fire went through the stages of: incipient growth, development, fully developed, flash over, post flashover, and decay. Each of the stages has the capacity to inflict burn injury to the skin, fat, muscle, and later, bone. During the first five minutes of growth and development of the fire, temperatures increased to 1,500°F inside the structures with full involvement of the fire. The internal body temperature did not raise a single degree in less than ten minutes of burning.

The first structure fire (S1) burned for eight minutes with flashover occurring at four to five minutes and maintaining temperature for an additional three minutes prior to water extinguishment by the San Luis Obispo Fire Department in California. Temperatures climbed after three minutes up to 1,500°F at the floor and ceiling. Ignitable liquids were used to start the fire on the body as a suicide-by-gasoline in a room with a corner origin. After an eight-minute structure fire, the body was transformed into a charred mass of shrunken muscles with bone exposure of the extremities. The wrist fractured and the ankles broke away at the distal tibia and fibula. Exposed bones were charred and calcined for the feet, ankles, lower legs, distal arms, hands, face, and head. The internal body temperature did not change.

The second structure (S2) burned for 25 minutes with flashover occurring by three to four minutes with floor temperatures that peaked at 750°F and remained below 600°F for ten minutes until water suppression. Ignitable liquids were used to start the fire with a body inside of a shed full of combustible materials. At 22 minutes, the body had visible calcination of the face, head, and ribs during the fire. The suppression crew hit the body directly with a straight stream of water, which caused displacement and fragmentation of the fragile burned bones and superficial soft tissues. Sections of the calcined face, skull, and ribs were blasted off of the body, thus altering the final condition. There were no significant temperature changes in the internal body.

The outdoor fire (O1) burned for 50 minutes with temperatures peaking at 1,700°F after the first ten minutes, then hovered around 800°F for the duration of the fire. The body was on top of wood pallets, with more pallets placed on top along with other brush and started with ignitable liquids. The lower arms and legs were calcined, with charred and calcined bones of the head. The internal body temperature rose above 200°F after 18 minutes of burning and increased to 380°F by the end of the 50 minutes. By this point, the liver and other internal organs were exposed and charred. Bones of the head and extremities were exposed with patterned charring and calcination.

The results demonstrate that the external temperatures can reach 1,200°F-1,600°F or higher in the fire environment, but that the internal temperatures of the organs and soft tissues remain unaffected until after the first 20-30 minutes of burning. It also illustrates the variation in temperature for structure (ventilation-controlled) and outdoor (ventilation-driven) fire environments responsible for creating the burn patterns to bone that are examined by medical examiners and forensic anthropologists.

A127 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: An Overview of the Procedures of the Hosts of the Triennial Meeting of the International Association of Forensic Sciences, 2017, the Ontario Forensic Pathology Service (OFPS)

Kathy L. Gruspier, JD, PhD, Ontario Forensic Pathology Services, 25 Morton Shulman Avenue, North York, ON M3M 0B1, CANADA*

After attending this presentation, attendees will learn about the host institution of the triennial International Association of Forensic Sciences 2017 meeting, the OFPS. The OFPS is housed in a new complex in Toronto that was purposely built to manage a multiple fatality response — up to a Chemical, Biological, Radiological, Nuclear, and Explosives (CBRNE) Level II. The OFPS has a multiple fatality implementation plan for its physical plant and is an integral part of the Provincial Mass Fatality Plan. The OFPS' response to a multiple fatality event occurring on a remote indigenous reserve will be shared.

This presentation will impact the forensic science community by illustrating that a death investigation system must draw upon its daily practices in order to successfully address a multiple fatality in its jurisdiction. If those regular practices do not include appropriate experts (or at least an established network of expert consultants) and good communication, then there is a real probability that an agency's response will be problematic. The use of inexperienced experts, the lack of a teamwork attitude, and the use of unfamiliar Disaster Victim Identification (DVI) tools would all have created problems with this multiple fatality response and would have delayed returning the decedents to the community.

A multiple fatality is defined as a single event in which two or more people die. A multiple fatality can occur with little or no warning and vary in its scope and nature. In Ontario, all death investigations fall under the jurisdiction of the coroner, regardless of the cause of the death, although there are often parallel investigations, most commonly criminal. The guiding principle for the implementation of the plan is: "Business as usual, just more business than usual." The OFPS provides qualified expertise in the areas of anthropology, pathology, odontology, medical imaging, and photography. For many years, anthropologists and sometimes pathologists have been integral members of scene examination and recovery teams when needed. This is business as usual. In addition to daily casework, a partnership with the Ontario Provincial Police (OPP) called the Resolve Initiative is maintained by the researchers. This is the vehicle used for comparing missing persons with unidentified remains. In the event of a multiple fatality, the OFPS has access to a clean copy of this functional relational database, in order to compare cases for DVI.

In the early morning of March 30, 2016, the OFPS forensic anthropologist was notified of a house fire on the Pikangikum Reserve. As the person responsible for the OFPS multiple fatality implementation plan, the anthropologist opened communications with partners in the Office of the Chief Coroner (OCC), the OPP, and the Office of the Fire Marshall (OFM) and also began planning responses with the staff of the OFPS, as well as expert consultants in anthropology and odontology. As the scene processing continued, she liaised with team members with regard to timing and records to accompany the bodies. Communication was often hampered by the lack of cell phone and internet access in the community. Communication with the OCC was also maintained with regard to transport of the remains to Toronto. The scene work was completed and the bodies were transported by April 2. Postmortems took place on April 3 and the identifications were completed and the bodies flown back to the community on April 4.

Multiple Fatality/DVI, IAFS 2017, ON Forensic Pathology Service

A128 A Mass Fatality Response and the Indigenous Community: The Intersection Between Science, Death, and Culture

Kona Williams, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA*

After attending this presentation, attendees will better understand the approach to death investigation in remote communities, the challenges faced by the death investigation team, and the indigenous people from socioeconomic, historical, and current viewpoints, as well as how to identify culturally appropriate and respectful outcomes when dealing with deaths in these communities.

This presentation will impact the forensic science community by examining how this coordinated effort can be used as an example for other members of the forensic community to build better relationships with indigenous people by fostering mutual understanding and respect and facilitating the process of death investigation. The outcomes of these investigations can also identify root causes affecting deaths in these communities and point toward preventative solutions.

Nine people of the Pikangikum First Nation were recovered from a house fire in March of 2016. There was a swift multi-agency and multi-disciplinary approach to the scene, identification of the bodies, postmortem examination, and analysis of the findings. All nine individuals were positively identified using scientific methods and the cause of death for all family members was "smoke inhalation." Despite the success of the death investigation team response, many challenges exist when deaths of this nature occur in indigenous communities.

Pikangikum is a remote reserve located in northwestern Ontario, Canada. It has a population of approximately 2,500 people of the Ojibwe First Nation. Historically, the interaction between the government, the health care system, and the police force with indigenous people in Canada has been fraught with racism, discrimination, and neglect. The death investigation system in Ontario encompasses all three institutions, leading to unique challenges when investigating deaths in indigenous communities. Combined with the remote location of many northern First Nation reserves, the lack of resources, such as running water, proper housing or adequate fire services, multiple socioeconomic factors as a result of intergeneration trauma, and the lasting effects of assimilation policies, tragedies such as these continue to occur; however, improved communication with families and community members, positive relationship-building, and mutual understanding between the death investigation team, the scientific community, and the indigenous population can serve to increase timely and culturally appropriate responses to these situations.

Multiple Fatality/DVI, Indigenous, Socioeconomic Impacts

A129 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: The Scene and Its Challenges

Renee C. Kosalka, MA, Ontario Forensic Pathology Service, 25 Morton Shulman, Toronto, ON M3M 0B1, CANADA*

After attending this presentation, attendees will be informed concerning a house fire in a remote, indigenous community located in Pikangikum, Ontario, Canada, that resulted in nine fatalities and the subsequent forensic response at the scene. The response consisted of a multiagency provincial team who employed interdisciplinary methods to the background and witness investigations, including antemortem records collection, as well as to the search, recovery, and documentation of the scene, sets of human remains, and evidence of forensic interest. The agencies included representatives from the Office of the Chief Coroner (OCC), the Ontario Forensic Pathology Services (OFPS), the Ontario Provincial Police (OPP), and the Office of the Fire Marshall (OFM). This presentation is being presented as an illustration of the work that the hosts of the International Association of Forensic Sciences 2017 triennial meeting, the OFPS, undertake in a multiple fatality event.

This presentation will impact the forensic science community by explaining how a well-coordinated response with appropriate experts working systematically via a standard, interdisciplinary approach — implemented at the scene — serves to achieve a successful and expedient multiple fatality investigation of a significantly burned group of human remains.

The scene was located on the Pikangikum 14 Reserve in northwestern, Ontario, which was populated by ~2,500 members of the Ojibwe First Nation. Within the Canadian Shield, the Reserve was ~1,808 hectares in area, at an elevation of ~335m. In a rural neighborhood, the scene involved a private residence consisting of a one-story, six-room, wooden structure with side paneling. The fire was witnessed by neighbors at approximately 11:44 p.m. on March 29, 2016, and burned unsuppressed until at least 9:00 a.m. Multiple witness accounts, including police patrols, reported that the property owners were a married couple who were hosting a house party with extended family. The missing included six adults and three children who were each less than five years of age.

Forensic experts onsite included three OPP forensic identification officers, two OFM fire investigators, one OFM forensic engineer, and one OFPS forensic anthropologist. The ruins were such that there was significant thermal alteration to, and structural collapse of, approximately 95% of the structure. Systematic processing of the ruins took three working days, with the first 11 hours dedicated specifically to the exposure, documentation, and recovery of nine sets of human remains and associated artifacts. The cause of the fire could not be determined.

The main challenges included the remoteness of the location (more than 1,400km from Toronto) and the variable, cold weather (periods of snow with temperatures ranging from -15.5ºC to +3.8ºC and winds gusting up to 35km/h). These challenges affected general logistics, the initial response time by the forensic team, technical aspects of scene processing (e.g., the operability of an Unmanned Aerial Vehicle (UAV) and 3D site scanner in addition to the amount of time an expert could physically work), as well as the transport of cases, records, and information to the laboratory in Toronto for examination.

Multiple Fatality/DVI, Forensic Anthropology, Scene Recovery

A130 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: Postmortem Investigations

Rebekah Jacques, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Kona Williams, MD, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Jayantha Herath, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Kris Cunningham, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Drive, Toronto, ON M3M0B1, CANADA*

After attending this presentation, attendees will be informed concerning the approach to postmortem examination, the collection of information for identification, and how medical information from the dead can improve the quality of life for surviving family members in the event of a multiple fatality, presented by the hosts of the Triennial International Association of Forensic Sciences 2107 meeting, the Ontario Forensic Pathology Service (OFPS).

This presentation will impact the forensic science community by illustrating how a well-coordinated postmortem response with appropriate experts working systematically and as part of an interdisciplinary team in the morgue results in a successful and expedient multiple fatality investigation of a significantly burned group of human remains, as well as providing important information which may impact the health of surviving family members.

Nine family members were recovered from the rubble of a heavily damaged home following a fire on the Pikangikum Reserve, a remote Ojibwe community in Northern Ontario. A team of three forensic pathologists, two forensic anthropologists, six pathology assistants, two radiology technicians, and one forensic science technician worked alongside three forensic identification officers and three fire investigators to undertake the task of performing the postmortem examinations of this family in a single day. Communication and pre-planning for the postmortem examination of this multiple fatality allowed regular morgue business to continue uninterrupted. That the physical plant of the OFPS was designed to handle multiple fatalities also contributed to this successful single-day endeavor.

The purpose of the postmortem examinations was to collect information which would aid in identification and determination of the cause of death. The day began with a presentation from the scene forensic anthropologist that was attended by the entire team. Postmortems were assigned so any bodies with unresolved commingling would be autopsied concurrently. During the autopsies, there was ongoing communication among all members of the team, which was facilitated by the close proximity of the autopsy tables. The nine postmortems were divided among three teams with each forensic pathologist performing three autopsies and the forensic anthropologists circulating amongst cases that required their expertise.

All of the decedents had fire-related injuries and were in variable states of completeness. In particular, one of the children had extensive destruction to the pelvic organs that interfered with the recognition of the internal sex organs versus urinary bladder. The confirmation of the organ as a bladder was made by frozen histological section prior to the identification committee meeting the following morning. One adult had antemortem trauma and this was easily interpreted with the assistance of the scene forensic anthropologist. Samples for ancillary investigations included: blood collection for toxicological analysis, small tissue samples for histology, and samples for DNA. All nine individuals died from smoke inhalation. Biological information, such as approximate age and sex as well as natural diseases and other identifying features, were communicated to the identification committee. Any unexpected findings in the ancillary investigations were communicated to the other forensic pathologists prior to signing out the autopsy reports. All of the autopsy reports were audited by another forensic pathologist on the team to ensure completeness and similar content.

Two of the adult individuals were diagnosed with hypertrophic cardiomyopathy and referred to the cardiac pathologist for further examination. Genetic testing is currently underway in order to determine if a genetic mutation exists. Hypertrophic cardiomyopathy is typically an autosomal dominant condition and can therefore affect multiple members of a family and their extended families. The finding of this disease on postmortem remains allows for surviving family members to be screened, examined, and treated for this condition.

Multiple Fatality/DVI, Postmortem Examination, Hypertrophic Cardiomyopathy

A131 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: The Interdisciplinary Approach to Dental Identification

Yolanda Nerkowski, BA, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Taylor L. Gardner, BFSc*, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Robert E. Wood, DDS, PhD*, Ontario Forensic Pathology Service, 610 University Avenue, Toronto, ON M5G 2M9, CANADA*

After attending this presentation, attendees will be informed concerning the approach to dental identification of the Ontario Forensic Pathology Service (OFPS) in the event of a multiple fatality.

This presentation will impact the forensic science community by demonstrating the limits of the use of antemortem dental records for identification. This presentation will also illustrate how a team approach utilizing forensic anthropology from scene to dental assessment ensures that the most information possible is available to the odontologist and is not lost through mishandling by non-experts. In addition, this presentation will disclose how other skills, such as age stratification, can be useful in the final identification of decedents of a multiple fatality.

The OFPS and the Office of the Chief Coroner were engaged to investigate a single house fire in the remote Ojibwe community on the Pikangikum Reserve. A team including a forensic anthropologist, the Ontario Provincial Police, and the Office of the Fire Marshall were dispatched to the isolated community to recover the fire-damaged remains of nine family members, which included six adults and three children of known and differing ages. The decedents were transported to the Provincial mortuary facility for the purposes of conducting postmortem examinations and establishing identifications. The dental identification team consisted of a forensic odontologist and two pathologists' assistants. Upon examination, the remains were noted to have extensive fire-related injuries, were heavily fragmented, and, in some cases, incomplete. The lack of material available for examination posed a challenge to dental identification despite having a closed population of individuals to identify in a multiple fatality incident.

The dental identification team was provided with antemortem records for the six adults and two of the children by the local community nursing station. The records received were in varying states of completeness and quality. Typically, these remote areas are served by a series of itinerant dentists that leave after a short time; thus, continuity of antemortem dental records can be problematic. Further, as it is rare for these records to be audited, there is little impetus to maintain them. Additionally, most of the individuals from these remote areas attend school outside of their communities for a time, so assembling a complete antemortem data set may require contacting multiple dentists. As a result, it was a requirement that the dental identification team cautiously review the entire antemortem record, including odontograms, billings, and chart notes from the past to the present, then recheck some of the records from the present to the past to verify that an accurate record of the dental conditions at the time of death was available for comparison. Following this review, the team developed a list of identifiable conditions and created an antemortem odontogram for each individual.

The available dentition of each decedent was recovered, restored, and reapproximated by the forensic anthropologists during the postmortem examinations. The dental identification team then positioned and exposed numerous intraoral radiographs of the teeth and jaws; however, the incinerated, fragmented, and incomplete nature of the available tissue made it impossible to create complete postmortem dental charts and odontograms for each individual.

The dental team had to determine points of concordance and no points of discordance between the partial or complete antemortem records and the partial postmortem records. Identifying features that differentiated between people were used as much as were unique identifiers. A total of six positive dental identifications were provided to the Identification Committee as well as three dental age-at-death estimates for the children. Although antemortem dental records were not available for one of the children, investigators had accounted for every person in the community; therefore, having a closed population of the missing allowed the use of age stratification techniques to assist in the final identification of the three children.

Multiple Fatality/DVI, Forensic Odontology, Dental Identification

A132 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: Forensic Anthropology

Renee C. Kosalka, MA, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Kathy L. Gruspier, JD, PhD, Ontario Forensic Pathology Services, 25 Morton Shulman Avenue, North York, ON M3M 0B1, CANADA*

After attending this presentation, attendees will better understand the contributions of forensic anthropology in a multiple fatality response to a house fire in a remote Ojibwe First Nation community located on the Pikangikum 14 Reserve in northwestern Ontario, Canada. This presentation serves as a demonstration of the work of the Ontario Forensic Pathology Service (OFPS), the hosts of the International Association of Forensic Sciences 2017 triennial meeting.

This presentation will impact the forensic science community by illustrating how integrating forensic anthropologists into daily practice, as well as into multiple fatality responses, serves to achieve successful and expedient death investigations of significantly burned human remains by maximizing recovery, minimizing commingling, and preserving context. This presentation will also demonstrate how Computed Tomography (CT) scans can be useful for osteological age-at-death estimations.

In the OFPS, forensic anthropology is part of the daily business of death investigation. Since the 1980s, forensic anthropologists have been utilized in ever-expanding roles in death investigation. There is one full-time Forensic Anthropologist (FA) at the OFPS, and five fee-for-service FAs who can be called upon as necessary. In daily practice, OFPS FAs are involved in most death investigations in which bones are found and the species is unknown and/or human remains are visually unrecognizable and/or fragmentary, partial, or burned. In addition, the full-time FA manages long-term unidentified remains and is responsible for the OFPS Multiple Fatality Plan. Forensic anthropology is always utilized at scenes of found remains that are not fresh or intact. Forensic anthropology is an expected and integrated discipline at the scene of such found remains where the anthropologist most often leads the recovery of human remains. Forensic anthropology is also engaged in postmortem examinations, ancillary testing (such as tool mark analysis), and human identification. Forensic anthropology is considered an essential service in the Ontario government.

During the evening of March 29, 2016, a single-story home on the Pikangikum 14 Reserve burned unsuppressed into the morning, taking the lives of an extended family, including six adults and three children. Forensic anthropologists played principle roles in the multiple fatality response throughout the duration of the investigation, from March 30 to April 4. Initially, at the laboratory, the full-time FA coordinated the effort and deployed a consultant FA to the scene to integrate into the field team and be responsible for the search, exposure, documentation, and recovery of human remains and associated artifacts, as well as antemortem records collection and transport.

Specifically relating to the laboratory setting during April 3-4, the FAs integrated with every discipline while contributing to the postmortem examinations and identifications. Prior to any laboratory work, the FA interpreted preliminary scene findings and photos and created maps in order to lead a briefing to nearly 40 at-the-ready staff (no other field team members attended the postmortems). During the postmortems, which were held three at a time by three forensic teams, contributions by the FAs included: the interpretation of postmortem CT scans; removal of debris; anatomical positioning and skeletal inventory; dental reconstructions; burn-pattern interpretation; traumatic injury interpretation; estimation of biological profile (age at death and sex); analysis of unique skeletal features for identification purposes via antemortem radiographs; 3D virtual reconstruction (for skeletal inventory and juvenile age-at-death estimation); and the resolution of commingling.

Both FAs sat on the Identification Committee and collated summary findings from the antemortem and postmortem records. The full-time anthropologist led the reconciliation meeting through the comparison of antemortem/postmortem case profiles for final identification. The consultant anthropologist wrote the final forensic anthropology report, which was comprehensive, from scene recoveries to identifications.

Multiple Fatality/DVI, Forensic Anthropology, Recovery/Postmortem

A133 A Multiple Fatality Response to Nine Indigenous Deaths in a Burned House in Pikangikum, Ontario: Disaster Victim Identification (DVI)

Kathy L. Gruspier, JD, PhD, Ontario Forensic Pathology Services, 25 Morton Shulman Avenue, North York, ON M3M 0B1, CANADA; Renee C. Kosalka, MA, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Reuven R. Jhirad, MD, Forensic Services and Coroners Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Yolanda Nerkowski, BA, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Taylor L. Gardner, BFSc, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Rebekah Jacques, Forensic Services and Coroner's Complex, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; Robert E. Wood, DDS, PhD, Ontario Forensic Pathology Service, 610 University Avenue, Toronto, ON M5G 2M9, CANADA; Kona Williams, MD, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA; and Jayantha Herath, MD, Ontario Forensic Pathology Service, 25 Morton Shulman Avenue, Toronto, ON M3M 0B1, CANADA*

After attending this presentation, attendees will be better informed concerning the approach to DVI in a multiple fatality and will be aware of lessons learned from its application to a specific event from the hosts of the Triennial International Association of Forensic Sciences 2107 meeting, the Ontario Forensic Pathology Service (OFPS).

This presentation will impact the forensic science community by illustrating that a team or committee approach to identification in multiple fatalities utilizing evidence-based methods can be accomplished in a short timeframe. Early communication with all members of the team will ensure that the appropriate antemortem information is collected as soon as possible after the event. Finally, blinding of the postmortem team to existing antemortem information ensures that unbiased information is collected.

Nine family members died in a house fire on the Pikangikum Reserve, a remote Ojibwe community in Northern Ontario. While commingling of the remains at the scene was minimal, and what commingling existed was resolved by the forensic anthropologist at the scene and at postmortems, the remains were extensively thermally damaged and fragmented. Antemortem medical and dental records were only available at the reserve's nursing station on the reserve and had to be collected while the scene was being processed in order to be transported with the remains to Toronto for the purposes of identification.

The OFPS maintains a Multiple Fatality Plan with a section devoted to undertaking DVI. In large multiple fatalities, a clean copy of the Resolve Initiative database will be used. This database is used on a daily basis to compare unidentified remains and missing persons in Ontario and is a shared relational database used by members of the Resolve Initiative team at the OFPS and the Ontario Provincial Police (OPP). In smaller multiple fatalities, it has been practice to utilize Excel® spreadsheets, one each for antemortem and postmortem information. The spreadsheets contain available information and identifications are confirmed by a meeting of an Identification Committee prior to the release of the bodies to the families.

In this multiple fatality case, the anthropologists and pathologists provided information on age, sex, and antemortem medical findings to populate the postmortem spreadsheet. Another team carefully examined all of the medical records for each presumed decedent and populated another spreadsheet with pertinent information for identification. Police investigation in the community prior to removal of the bodies from the scene had confirmed that the decedent group was a closed population, as all other community members were accounted for. Although there was an attempt to blind the collectors of the postmortem information to the antemortem information, some was shared, which resulted in an interesting case of confirmation bias. This was easily resolved, but it illustrated that it is a good practice to separate the antemortem information team findings from the postmortem team findings until they are formally reconciled by the Identification Committee.

When all of the postmortem and antemortem information had been compiled, the Identification Committee, which consisted of all members of the team, met to determine the final identifications. A combination of dental, medical, group biological, and exclusionary criteria was utilized for the evidence-based final positive identifications. Having a closed population permitted the use of exclusion criteria based on age so the decedents could be returned to the community in a timely manner without having to await DNA identification results.

Multiple Fatality/DVI, Identification Committee, Confirmation Bias

A134 The Use of Laser Scanning Confocal Microscopy in Distinguishing Between Peri-Mortem Trauma and Postmortem Damage Using Histotaphonomic and Histochemical Techniques

Ashley C. Smith, MSc, University of Toronto, 19 Russell Street, Apt 402, Toronto, ON M5S 2S2, CANADA*

After attending this presentation, attendees will better understand the techniques used to implement laser scanning confocal microscopy in assessing whether bone damage occurred peri- or postmortem. While this pilot project used bone damaged approximately 24 hours after death and five years after death, this presentation will demonstrate that the methods introduced can be used to distinguish peri-mortem from early postmortem damage occurring just days after death.

This presentation will impact the forensic science community by adding to the body of knowledge on modern histological techniques used in forensic science and anthropology. This study will also add to the body of knowledge used in timing bone damage as either peri-mortem or postmortem. Present techniques in timing bone damage relies on macroscopic variations, particularly with regard to break margin morphology and color variation. By understanding the microstructural and histochemical variation between bone fractured at the time of death and bone damaged after death, one can better reconstruct the death and depositional events pertaining to human remains.

The purpose of this research was to determine if it is possible to distinguish bone damaged peri-mortem from damage occurring five years postmortem using microstructural and histochemical techniques. This research used laser-scanning confocal microscopy to quantify the degradation of two non-collagenous proteins, osteocalcin and osteopontin, as well as the presence of osteoclasts at margins of peri-mortem fractures and postmortem breaks. Additionally, this project analyzed the microstructural aspect of the fracture and break margins using qualitative and semi-quantitative methods and further quantified the natural autofluorescence.

The peri-mortem sample for this research derived from bone sections excised from commercially reared domestic pig (*Sus scrofa*), while the postmortem sample originated from elements from purpose-bred *S. scrofa* left over from a decompositional research study conducted five years ago with a known date and time of death, and documented environmental factors. The break margins were excised and sectioned to 10µm using a Buehler® IsoMet® low-speed saw. After sectioning, the samples were divided into three approximately equal sections and differentially stained for visualization of the specific proteins and the osteoclasts. The "protein sections" were stained using basic fuchsin as a base stain and specific Enzyme-Linked Immuno-Sorbent Assay (ELISA) kits to quantify their differential presence. The osteoclast sections were stained using Alexa Fluor® 488 and an osteoclast antibody kit. Imaging was conducted using a Carl Zeiss™ LSM-510 META® Laser Scanning Confocal and Multi-Photon Microscope with a 4',6-Diamidino-2-Phenylindole/Green Fluorescent Protein (DAPI/GFP) base setting and an Argon 2 and Helium/Neon (HeNe) 1 and 2 lasers. Image acquisition was achieved using the Carl Zeiss™ Zen 2009® Image software that was tied to the microscope, with image analyses conducted using ImageJ v1.50i, and Volocity® v6.3. A one-way Analysis of Variance (ANOVA) was conducted, with the levels of osteopontin, osteocalcin, and the ratio between the two set as the dependent variable, and the subject class as the independent variable. Further, a linear regression analysis was conducted to determine the relationship of osteopontin:osteocalcin ratio to time. A one-way ANOVA was conducted to evaluate the variance between the levels of osteoclasts present in the "peri-mortem" and postmortem samples. Lastly, a 3D analysis was conducted from the z-stack results in order to ascertain the surface structural variation between the two sample groups.

The results of this study found that laser scanning confocal microscopy can be used to distinguish between the peri-mortem trauma group and the postmortem group. In particular, higher protein levels were seen in the peri-mortem trauma group as opposed to the postmortem, and a higher osteoclast level was also observed. Additionally, the postmortem group generated a higher amount of natural autofluorescence. Lastly, the margin of the peri-mortem group appeared more jagged than the postmortem group.

Laser Scanning Confocal Micros, Taphonomy, Skeletal Trauma

A135 Skeletal Trauma Resulting From Falls Involving Stairs: An Analysis of Fracture Patterns and Morphologies Using Postmortem Computed Tomography (PMCT)

Samantha K. Rowbotham, MA, Monash University, Dept of Forensic Medicine, 65 Kavanagh Street, Southbank, Victoria 3006, AUSTRALIA; Soren Blau, PhD, 65 Kavanagh Street, Southbank, Melbourne, Victoria 3146, AUSTRALIA; and Jacqueline Hislop-Jambrich, PhD, Toshiba Medical, 12-24 Talavera Road, North Ryde 2113, AUSTRALIA*

After attending this presentation, attendees will better understand the skeletal fracture patterns and fracture morphologies that result from fatal falls involving stairs.

This presentation will impact the forensic science community by providing forensic anthropologists with an improved evaluation of skeletal fractures resulting from falls involving stairs. This presentation will also demonstrate the value of PMCT analyses in the context of detailed National Coronial Information System (NCIS) documentation for providing comprehensive, contextual, and accurate analyses and interpretations of skeletal trauma.

Falls are the second-leading global cause of unintentional injury and death.[1] Understanding the skeletal Blunt Force Trauma (BFT) resulting from falls, both in terms of the resulting facture patterns and morphologies, is of value to forensic anthropologists when interpreting circumstances of death in medicolegal cases involving skeletal BFT; however, the skeletal BFT resulting from falls involving stairs in particular is poorly understood. Currently, a small number of forensic pathology and clinical medicine studies have investigated trauma patterns following falls involving stairs and have illustrated that all areas of the skeleton are susceptible to skeletal fracturing, given the "tumbling" nature of this mechanism.[2] As these disciplines are predominantly focused on the soft tissues as well as the skeletal structure, unfortunately the level of skeletal trauma detail is typically not sufficient for forensic anthropologists to use when forming interpretations regarding the circumstances of death from only the skeletal material. To address this deficit, this study has investigated the skeletal fracture patterns and morphologies (size and shape) resulting from falls involving stairs using PMCT data in the context of detailed NCIS data.

A search of the NCIS database for fatal falls involving stairs in Victoria, Australia, between 2005 and 2014, identified 89 cases. For each case, the variables known to influence an indivdiual's fall, and to subsquently influence how his/her skeleton fractured, were recorded. These variables were comprised of sex, age, body mass index, number of stairs, landing/stair surface, manner of fall, and the presence of psychoactive drugs and preconditions (medical and/or physical). Skeletal trauma for each case was analyzed using the associated full-body PMCT scan (undertaken as part of the routine autopsy process at the Victorian Institue of Forensic Medicine using a 128-row helical CT – SOMATOM® Definition Flash). The data were analyzed using the *syngo*.via imaging software. Skeletal trauma recording for each indivdiual was comprised of the skeletal element and anatomical location traumatized, fracture/s classfication, descriptions of the fracture/s (including measurements and angles where appropriate), and a schematic of the fractures. The skeletal fracture patterns and morphologies were investigated in the context of the NCIS variables.

The 89 cases of fatal falls involving stairs was comprised of indivdiuals between the ages of 42 and 103 years (mean 78±11 years) with a relatively equal sex distribution of 47% females and 53% males. Almost all falls were mechanical, the location of the stairs were a combination of indoor and outdoor environments, and the number of stairs involved varied from 1 to 15 steps. Preliminary results indicate all regions of the skeleton, except for the hands and feet, were susceptible to fracturing following falls involving stairs, and that the fracture pattern resulting from the fall is largely determined by the associated variables. Skeletal trauma was present in 62% of individuals (55 cases) and within those cases, 75% exhibited trauma to one skeletal region while the remaining 25% exhibited poly trauma. Fracturing was primarily associated with the skull (45%) with the majority of these fractures sited to the vault, and typically comprised single linear fractures, depressed fractures, and/or hinge fractures. The cervical vertebrae (25%), ribs (20%), and femora (13%) were also frequently fractured. Almost all cases of rib fractures were associated with trauma to other skeletal regions.

This research will provide improved qualitative evaluations of skeletal fractures resulting from falls involving stairs and, subsequently, augment forensic anthropologists' interpretations of circumstances of fatal falls in medicolegal contexts.

Stair Falls, Computed Tomography, Skeletal Trauma

A136 Concentrated Four-Point Bending and Fracture Behavior in the Human Femora

Mariyam I. Isa, BS, Michigan State University, Dept of Anthropology, 354 Baker Hall, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, Dept of Anthropology, 655 Auditorium Drive, East Lansing, MI 48824; Patrick E. Vaughan, BS, Michigan State University, Orthopaedic Biomechanics Laboratories, E Fee Hall, Rm 407, East Lansing, MI 48824; Feng Wei, PhD, Michigan State University, 965 Fee Road, Rm A-414B, East Lansing, MI 48824; and Roger C. Haut, PhD, Michigan State University, Orthopaedic Biomechanics, A407 E Fee Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be aware of fracture outcomes in controlled, four-point bending tests on fresh human femora.

This presentation will impact the forensic science community by linking a known set of loading conditions with an expected range of bone behavior and fracture morphology.

Case studies and medical literature associate long bones failed in bending with butterfly fractures. It is expected these occur in a tension wedge configuration, with fracture initiating as a transverse crack at the tensile surface of a bent bone and branching toward the compressed or impact surface. Wedge configuration is forensically significant because analysts often cite the presence and orientation of butterfly fractures as diagnostic of impact direction.

Experimental research indicates this practice is problematic. Wedge fragments are not always produced in long bones failed in bending.[1-3] Furthermore, butterfly fractures may occur in a compression wedge configuration, with the transverse crack on the impact surface.[1,4]

Recently, researchers have reported on specific fracture characteristics better suited for reconstructing bending direction. Fenton et al. documented a consistent suite of incomplete fractures in dry human femora failed under three-point bending.[2] Isa et al. confirmed these features and documented consistent fracture surface features in experiments with fresh human femora.[3] These features could be used to reliably reconstruct failure in tension and compression and subsequently determine impact direction (anterior or posterior) within an experimental bending set.

Most experimental forensic research focuses on a three-point model of bending. Though compression wedges have been reported, they are observed less frequently than tension wedge-type fractures; however, Martens' engineering research team reported near-exclusive production of compression wedges in posteriorly loaded femora failed under a concentrated four-point bending configuration.[1,4] It is forensically relevant to understand if this type of bending produces a different range of fracture characteristics than three-point bending.

The objectives of the current study were: (1) to execute controlled, Martens-type four-point bending tests of fresh human femora; (2) to identify fracture outcomes, including characteristics of the complete and incomplete fractures and fracture surfaces; and, (3) to compare these fracture outcomes with those of three-point bending experiments.

Four unembalmed human femora were failed under four-point bending, with the supports at 60% bone length and the inner probes set at 10% bone length, using a servo-hydraulic testing machine. Failure was achieved via controlled displacement at a rate of 1Hz over a 20mm displacement of the inner probes, loading the posterior bone surface. All impacts were filmed with a high-speed camera at 40,000 frames per second. Following each experiment, specimens were examined for complete and incomplete fractures and fracture surface morphology.

Controlled bending tests produced compression wedge-type fractures in two specimens and distally oriented oblique fractures in two specimens. In all impacts, video footage confirmed fracture initiation on the bone's tensile side. Failure loads were 6,567N ± 1,323N. The displacement of the bone to failure was 7.99mm ± 1.80mm, and the energy input into the system until failure was 31.10J ± 15.77J.

Incomplete fracture characteristics observed in previous three-point bending impacts were not observed in long bones failed under this four-point bending configuration; however, for the two specimens with compression wedges, fracture surface characteristics were consistent with those described in previous 3-point bending impact experiments.[3] The fracture surface of the non-impact (tension) side was billowy with shallow topography. The surface of the impact (compression) side was jagged with steep topography.

The experimental results indicate there may be some differences in fracture characteristics of long bones failed under three-point and concentrated four-point bending. Regardless of the specific bending conditions, when wedge fractures are present, fracture surface characteristics are most useful for assessing failure in tension and compression and thus reconstructing impact direction.

Supporting the work of Martens et al., compression wedges and distally oriented oblique fractures were noted in this study. In all four experiments, fracture initiated on the tensile side and propagated to the compression side.

This presentation communicates the outcomes of experimentally controlled loading conditions in fresh/unembalmed human femora. The data contributed here provides a set of fracture characteristics observed in "known" cases of blunt trauma that may help experts better reconstruct the specific loading conditions in an injury scenario.

Trauma Analysis, Fracture Patterns, Biomechanics

A137 Differentiating Between Sharp Force Trauma (SFT) Defects and Insect Invasion of the Skin of Human Cadavers Throughout the Decomposition Process in a Terrestrial and Fluvial Environment

Sierra Smith, BA, Sam Houston State University, Box 2296, Huntsville, TX 77341-2296; Kevin R. Derr, 28601 Shawnee Court, 192 Waterwood, Huntsville, TX 77320; and Joan A. Bytheway, PhD, Sam Houston State University, College of Criminal Justice, Box 2296, Huntsville, TX 77341-2296*

After attending this presentation, attendees will understand that SFT skin defects, induced by a variety of sharp instruments, can be recognizable and distinguished from insect invasion defects throughout the human decomposition process into the late phases of the advanced stage. Issues that affect the margins of SFT will also be addressed.

This presentation will impact the forensic science community by providing results of SFT to skin from two controlled but natural environments where no current human taphonomic research exists. This presentation will acknowledge the need for the collaboration of human decomposition studies with trauma studies on both hard and soft tissue and will also broaden the forensic taphonomy research arena.

SFT in bone and cartilage is well documented in forensic literature and recent literature documents SFT evidence on hair and fabric; however, there is no literature on the effects of taphonomy on SFT of the skin and whether it is identifiable and distinguishable from insect activity throughout the decomposition process.[1-11] It is not known whether particular sharp instruments that produce a certain pattern on the body in the fresh stage of decomposition will maintain that pattern in the late stages of decomposition in either a terrestrial or fluvial environment. In addition, do sharp instruments produce a particular pattern when used in any area of the body, and is the pattern visible throughout decomposition? If the patterns are recognizable, can they be distinguished from insect activity?

This study was conducted at the Physical Anthropology Skeletal and Soft Tissue Trauma (PAST) Institute at Sam Houston State University.

SFT defects of human skin, how those defects changed through decomposition in a terrestrial and fluvial environment, and how they were distinguished from insect defects were examined. Eight sharp instruments were used to induce SFT on six human subjects at ten areas of the body. Each subject was in a fresh stage of decomposition and unclothed at the time of the SFT induction. Subjects were protected from scavenging by wire cages. Subjects in the fluvial environment were placed in a fiberglass mortuary vault filled with well water and local soil to simulate a regional water environment. Bodies were accessible to the outdoor environment, including insects. Instruments used included a Ryobi® reciprocating saw, a Marshalltown® trowel, an Estwing® axe, a Condor® Crocodilian machete, an HDX® clawed hammer, a Dexter Russell® knife, a Cold Steel® serrated edge knife, an Ace® shovel, and an HDX® screwdriver.

Length and width measurements of each wound were taken each day until advanced decomposition was reached. As expected, SFT wounds increased in length and width as decomposition progressed. For SFT measurements that could be taken at both the fresh and advanced stages for each instrument, percentage length increase ranged from 2% to 83%, with the clawed hammer having the largest average percentage length increase (57%). Percentage width increase ranged from 14 – 88% with the axe having the largest average percentage width increase (76%). All SFT wounds on terrestrial subjects were still evident into the advanced stage of decomposition and distinct from insect activity defects. Insect defects were predominantly circular in appearance and measured 1mm-4mm in diameter.

Human Decomposition, Sharp Force Trauma, Entomology

A138 Constricting Structures: A Critical Analysis of a Past Forensic Anthropology Case Through the Systematic Examination of a Neck Organ Block Traumatic Injury in the Present

Austin L. Polonitza, BS, Florida Gulf Coast University, 20628 Westgolden Elm Drive, Estero, FL 33928; and Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Dept of Justice Studies, 10501 FGCU Boulevard, AB3, Fort Myers, FL 33965-6565*

After attending this presentation, attendees will understand the frequency of trauma to the hyoid, thyroid cartilage, and cricoid cartilage that results from hanging, with special consideration paid to the age, sex, and ancestry of the decedent as well as the type of ligature used. In addition, this presentation reinforces observations made by forensic anthropologist William R. Maples, PhD, concerning a controversial international 1991 case involving neck trauma.

This presentation will impact the forensic science community by demonstrating how the intellectual merit of this study is grounded in the knowledge that the medical examiner's determination of cause and manner of death may not be reliably determined when the influences of the variables mentioned above are not taken into account.

With these analysis needs in mind, this study conducted macroscopic and radiographic forensic anthropological examinations of trauma at the request of the medical examiners from three medical examiner districts in Florida.

Over the past two years, 52 medical examiner cases (25 = with evidence of peri-mortem trauma; 27 = no evidence of peri-mortem trauma) were macroscopically (with a 300x dissecting scope) and radiographically (AGFA CR30-X machine at 40kvp and 1/30 exposure) examined in each medical examiner's facility. Each medical examiner removed the neck organ block from the decedent without cracking the thyroid cartilage along the midline. Cartilage and bone traumatic discontinuities (complete or greenstick fractures) were photographed and mapped (to scale) onto anatomical figures. The sample comprised 37 males and 15 females between the ages of 16 and 99 years (mean age = 42 years) who were of European (42), African (4), Asian (1), and Hispanic (5) ancestries, with statures ranging from 4'4" to 6'2". These cases involved 28 ligatures (rope, electrical cord, belt, etc.) and one instance of manual strangulation. Most of the hangings involved partial suspension while only two evidenced full suspension.

The analyses revealed that 25 individuals (48%) presented with fractures and that greenstick fractures (60%) predominated. Interestingly, 53% of the individuals presented with thyroid cartilage fractures, a finding that was statistically significant ($x^2 = 22.354$, $p < .001$). There was no significant association between ligature type and frequency of thyroid fracture ($x^2 = 10.69$, $p > 0.05$); however, there is a significant association between ligature type and the frequency of hyoid fracture ($x^2 = 23.69$, $p < 0.05$). No statistically significant difference in the fracture frequency of males and females was noted ($t = -0.876$, $p = 0.385$). These findings helped in the heuristic validation of a forensic anthropology case analyzed by Dr. William R. Maples that was part of more than 7,000 slides, notes, books, bones, and casts comprising the William and Margaret Maples Special Collection at Florida Gulf Coast University.

During Dr. Maples' 29-year career, which involved 1,000 forensic anthropology cases, one international case brought public emotions to the forefront. Ms. Flor Contemplacion's family and Filipino human rights activists fought to have her death sentence by judicial hanging overturned. Ms. Contemplacion, a housekeeper in Singapore, was found guilty of the homicides of Master Nicholas Huang (the 4-year-old son of their employer) and Ms. Della Maga (the 34-year-old Filipino coworker). On May 4, 1991, Master Huang's father came home to find his son's head in a pail of water and Ms. Maga strangled in the bathroom. Ms. Contemplacion was hanged on March 17, 1995 for her crimes. The incident triggered an emotional outrage by some who indicated that Contemplacion was denied a fair trial and that new evidence was off-handedly dismissed. Two years later, the Philippine National Bureau of Investigation put together a team of forensic scientists from United States, which included Maples, to review the exhumation records and reports in order to provide opinions on the validity of the new evidence, cause, and manner of death. Maples and his colleagues found Della Maga died as a result of asphyxiation due to ligature strangulation; thereby supporting the original autopsy while asserting that the evidence of the exhumation was fundamentally flawed.

Peri-Mortem Trauma, Hyoid, William R. Maples

A139 Searching for the Unidentified in South Texas: The Forensic Border Coalition (FBC) Cemetery Survey Project

Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Mercedes Doretti, EAAF, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Christine M. Kovic, PhD, University of Houston-Clear Lake, 2700 Bay Area Boulevard, Houston, TX 77058; Eduardo Canales, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Molly Miranker, MA, The Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Rachel Daniell, MPhil, Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Timothy P. Gocha, PhD, Texas State University, 601 University Drive, San Marcos, TX 78666; Ryan Strand, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; and Alberto Giordano, PhD, Texas State University, Dept of Geography, 601 University Drive, San Marcos, TX 78666*

After attending this presentation, attendees will understand the difficult task of locating burials of unidentified human remains along the South Texas border.

This presentation will impact the forensic science community by providing methods for locating burials of unidentified human remains for identification purposes.

In 1995, Texas passed laws specifying explicit procedures for processing unidentified human remains found within a forensic context. In 2005, additional state laws concerning missing and unidentified persons were passed, based on new technological advances using federal databases and DNA to help identify missing and unidentified persons. Currently, many counties in Texas follow these state laws. Unidentified human remains that are part of a medicolegal investigation and are processed through a medical examiner's office have a final disposition that is carefully tracked; however, the majority of Texas counties do not have a medical examiner's office and human remains found in these counties have historically been less carefully tracked.

Prior to 2005, most unidentified human remains found in South Texas representing presumed migrant deaths were buried without identification efforts. In Texas, there is no centralized recordkeeping system to address how many unidentified human remains have been found and buried statewide or along the South Texas border. Knowing the number of unidentified remains likely to correspond to migrants would allow for a better understanding of the humanitarian crisis at the South Texas border and across the United States-Mexico border region. Further, knowing the number of deaths and burial locations would allow for strategic planning for exhumation, analyses, and identification efforts of the long-term dead.

In an effort to count the number of migrants who have died crossing the Texas/Mexico border, the FBC conducted a cemetery survey project to address the following questions: (1) How many migrants have died crossing the Texas/Mexico border per county per year?; (2) Where are they buried?; and, (3) What are the county protocols regarding unidentified deceased persons? The FBC employed several different methodologies, including searching county records, soliciting public information from funeral homes, cemeteries, law enforcement, and medicolegal agencies, and surveying cemeteries for unidentified burials. A total of seven counties were targeted based on their close proximity to the border and accounts from journalistic sources detailing high numbers of migrant deaths.

Based on a lack of county records, even with two counties having an indigent burial program, it is difficult to address the question of how many unidentified deaths have occurred per county per year for the past 20 years. Unidentified remains buried in counties without a medical examiner (n=5) or indigent burial service (n=5) had little-to-no records regarding the number of unidentified deaths or locations of burials. A total of 70 burials were located through pedestrian survey of cemeteries, and an additional 62 burials were located through conversations with medicolegal death investigators, funeral homes, and cemetery directors. Burials with associated information were mapped using the Global Positioning System (GPS). Through information obtained from funeral homes, additional potential burial sites were located; however, these potential burials are unmarked with no existing records. Each of the seven counties had different approaches to processing unidentified human remains and not all complied with Texas state laws. Only one county, with a medical examiner, tracked the exact burial location and associated case information.

Since the survey for these seven counties is now complete, strategically planned, funded exhumations will take

place. Further, collectively the FBC will work toward identification of the exhumed remains. It is crucial that local jurisdictions secure pathology and/or anthropology exams, submit DNA samples, and track the final disposition of unidentified human remains and all associated case information. Without tracking final disposition or associated case numbers, unidentified remains will be difficult to locate and identification may never take place.

Forensic Anthropology, Identification, Migrant Deaths

A140 The Forensic Border Coalition (FBC): Collaborations in Forensic Sciences, Human Rights, and Public Policy

Christine M. Kovic, PhD, University of Houston-Clear Lake, 2700 Bay Area Boulevard, Houston, TX 77058; Mercedes Doretti, EAAF, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Eduardo Canales, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Molly Miranker, MA, The Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Rachel Daniell, MPhil, Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Ryan Strand, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Timothy P. Gocha, PhD, Texas State University, 601 University Drive, San Marcos, TX 78666; Robin C. Reineke, PhD, University of Arizona, 1009 E South Campus Drive, Tucson, AZ 85721; and Chelsea Halstead, BA, Colibri Center, 3849 E Broadway Boulevard, #206, Tucson, AZ 85716*

After attending this presentation, attendees will understand: (1) the multiple barriers to identifying and repatriating the remains of migrant border crossers; (2) the benefits of collaboration between forensic scientists, human rights organizations, cultural anthropologists, geographers, and others to address these barriers; and, (3) the need for changes in public policy to improve outcomes.

This presentation will impact the forensic science community by introducing the FBC and its strategies to count the number of migrants who have died or disappeared crossing the United States-Mexico border, to locate burials of unidentified remains, to identify the dead, and to improve practices and protocols for future identifications of the dead.

The mission of the FBC is to support families of missing migrants searching for their loved ones and to address myriad barriers related to the identification of human remains found near the United States-Mexico border. The FBC formed in the summer of 2013 following the high number of border deaths in 2012. According to official data from the United States Customs and Border Patrol, the number of border deaths reached 471 in 2012. The coalition is comprised of forensic scientists and other scholars together with human rights activists to comprehensively address the significant barriers to identifying the remains of border crossers. This presentation will focus on the work of the FBC in Texas to provide one example of the benefits of collaborations.

Border deaths in Texas occur in more than 20 counties at or near the U.S.-Mexico border, some of which are among the poorest counties in the nation. The majority of these counties lack medical examiners or forensic pathologists, some have failed to collect DNA on unidentified remains as required by state law, and many cases of unidentified remains fail to be entered into databases such as the National Missing and Unidentified Persons System (NamUs) that allow them to be compared against missing persons reports. Because many remains are severely decomposed or skeletonized, family reference samples are often required to make identifications via DNA. Some family members of migrant border crossers reside outside the United States (primarily in Mexico and Central America) and others are undocumented individuals who hesitate to visit law enforcement offices to file a missing persons report. In either case, families may be prevented from presenting missing persons reports or from entering their family reference sample into the Combined DNA Index System (CODIS).

Even locating the site of burials of unidentified remains in many South Texas counties is difficult due to lack of standardized recordkeeping, the lack of coordination between county officials, the large number of burials sites and funeral homes that process remains, the failure to clearly label unidentified remains in many cemeteries, and the failure of cemeteries to keep and share records.

In order to address barriers related to locating and identifying human remains, the FBC relied on the methodology of requesting and analyzing public records regarding migrant deaths and unidentified remains and accessing death certificates and indigent burial records to locate the final disposition of the death. In addition, the FBC collaborated with Missing in Harris County Day so migrant families could safely present cases and submit family reference samples, resulting in a number of identifications.

Non-governmental organizations and other FBC collaborators have been key in making recommendations and meeting with policymakers to improve protocols to identify, locate, and repatriate the dead in both Texas and

Arizona. The multidisciplinary nature of these collaborations is instrumental in exposing the gaps within these protocols and thus in making them a powerful humanitarian voice for pushing forward policy change at the local, state, national, and international levels.

Migrant Deaths, Human Rights, Policy Reform

A141 The Role of the Anthropologist in the Identification and Repatriation of Deceased Migrants Along the United States-Mexico Border

Timothy P. Gocha, PhD, Texas State University, 601 University Drive, San Marcos, TX 78666; Kate Spradley, PhD, Texas State University, Dept of Anthropology, 601 University Drive, San Marcos, TX 78666; Ryan Strand, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Bruce E. Anderson, PhD, PCOME, Forensic Science Center, 2825 E District Street, Tucson, AZ 85714; and Alicia Lusiardo, Argentine Forensic Anthropology Team (EAAF), 578A Halsey Street, Ground Fl, Brooklyn, NY 11236*

After attending this presentation, attendees will better understand the role of the anthropologist in the identification and repatriation processes of deceased migrants located along the United States-Mexico border.

This presentation will impact the forensic science community by highlighting how the role of an anthropologist varies in identification and repatriation processes depending on local and state laws and how this role may extend well beyond skeletal analysis.

Often law enforcement may be responsible for identification efforts while an anthropologist provides a report to a medical examiner, law enforcement agency, coroner, or Justice of the Peace (JP); however, in other circumstances, responsibility for identification may fall to the anthropologist. Depending on jurisdiction, these responsibilities vary, with the anthropologist taking on new roles.

These varied roles will be examined through a survey of three partner organizations of the Forensic Border Coalition (FBC): the Argentine forensic anthropology team, Equipo Argentino de Antropología Forense (EAAF), the Pima County Office of the Medical Examiner (PCOME), and the Forensic Anthropology Center at Texas State (FACTS). A generalized description of identification and repatriation processes is given for migrant deaths in Arizona, while case studies will be discussed to illustrate the complexities of these processes in Texas.

The EAAF investigates migrant deaths along both sides of the United States-Mexico border. Regarding cases of unidentified remains recovered in the United States, EAAF facilitates the collection of family reference sample DNA for comparison to DNA samples from remains likely to correspond to migrants. When DNA analysis suggests an identification, the EAAF works with forensic data banks on missing migrants or other mechanisms within the migrant's country of origin to compare all antemortem and postmortem records to confirm an identification. The EAAF writes an identification report and works with the appropriate local United States officials to legally recognize the identification. In recent years, EAAF has helped identify 65 migrants who perished within the United States. Repatriation is then handled by a Consulate's office, overseen by the Foreign Affairs Ministry from the decedent's home county.

In Arizona, forensic anthropological investigations of presumed migrants take place at the PCOME. Between 2001 and 2013, the PCOME received the remains of 2,203 presumed migrants and successfully identified 1,463. For cases requiring skeletal analysis, anthropologists at the PCOME construct both a biological and cultural profile. Once an identification hypothesis is made, the anthropologist compares all antemortem and postmortem data, writes an identification report, and briefs the medical examiner, who legally signs off on an identification. If the decedent is to be returned to their country of origin, the local Consulate's office manages the repatriation of the remains, a process that can take weeks to months.

Since 2013, Operation Identification (OpID), housed within FACTS, has received the remains of 87 presumed migrants, many through exhumation efforts carried out by Baylor University and the University of Indianapolis. DNA analysis, in addition to anthropological analyses of the skeletal remains and personal effects, are the primary sources for identification hypotheses. Once a DNA association is reported, anthropologists associated with OpID compare all antemortem and postmortem data, write an identification report, and brief the appropriate JP, who legally approves the identification. Since 2014, OpID has helped facilitate nine identifications; however, only five of those individuals have been successfully repatriated. The repatriation process for counties without a medical examiner requires the coordinated efforts of Consulate offices, the funeral home handling the repatriation, the funeral home that originally filed the death certificate, and the JP, which can all vary by case. Unlike the Arizona model in which these efforts are centralized, in Texas, these parties can be vastly separated by geography, culture, and available resources, which can result in a breakdown of communication and stagnation of the repatriation process. In the

most egregious example, an individual identified by OpID in August 2014 has still not been repatriated as of July 2016.

This unfortunate reality has led to anthropologists in Texas adopting new roles as de facto case managers and stewards of identification and repatriation processes. Anthropologists associated with OpID, with help from other FBC partners, are now facilitating/mediating communication between funeral homes, law enforcement, JPs, medical examiners, and the decedent's family members. It is believed these expanded roles of the anthropologist will help streamline and hasten the repatriation of remains.

Migrant Deaths, Identification, Repatriation

A142 Addressing the Challenges of Migrant Death Investigations Through Non-Governmental Organization (NGO) and Government Agency Collaborations

Ryan Strand, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Eduardo Canales, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; Molly Miranker, MA, The Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; and Robin C. Reineke, PhD, University of Arizona, 1009 E South Campus Drive, Tucson, AZ 85721*

After attending this presentation, attendees will better understand how collaborations between NGOs and government agencies are essential to unidentified human remains investigations throughout Central and North America, particularly along the United States-Mexico border.

This presentation will impact the forensic science community by highlighting challenges that medicolegal systems face along the United States-Mexico border and by presenting how those challenges are often overcome through collaborations with NGOs.

The purpose of this study is to: (1) explore how three NGOs have partnered with different government agencies in unique ways to facilitate investigations of deceased migrants in specific regions; (2) compare the similarities and differences between the different strategies they have employed; and, (3) discuss how collaborations between these NGOs create a unified model for addressing a humanitarian crisis. Data analyzed include: the protocols for each NGO/government agency collaboration, the number of cases investigated, the number of family reference DNA samples collected, and the number of identifications through collaborations. Additionally, case studies will illustrate general challenges and how these obstacles are overcome.

Migration across Central America and the United States-Mexico border is a dangerous and often deadly process. Investigations of migrant deaths are complicated by sociopolitical and geographical factors, resulting in challenges for the government agencies responsible for properly investigating these deaths. For example, many families live in countries far from the location of the death of their loved one, making it difficult for investigating agencies to obtain family reference DNA samples for comparisons to unidentified human remains. Furthermore, many families are afraid to meet with law enforcement, let alone submit a biological sample to a feared agency. Consequently, many of these investigations are incomplete.

In Central America and Mexico, the Argentine forensic anthropology team, Equipo Argentino de Antropología Forense (EAAF), facilitates the creation of forensic data banks on missing migrants, with case files containing all background and antemortem data, as well as DNA profiles from direct relatives for genetic comparisons. These forensic data banks are composed of governmental and non-governmental institutions, an unprecedented development in the region, allowing direct participation from the NGO sector, particularly committees of relatives, to monitor and inform work of government officials. Forensic data banks currently exist in Honduras, El Salvador, and Chiapas and Oaxaca in Mexico. As of July 2016, EAAF has 929 missing migrant cases, 2,520 family reference DNA samples, and has made 117 identifications through these data banks.

In Pima County, AZ, the Colibrí Center for Human Rights' process relies on building strong relationships with both families of the missing and the officials tasked with the investigation of unidentified remains. Colibrí is based in Arizona and works most closely with the PCOME, which has provided in-kind support to Colibrí in the form of office space and equipment, allowing the collaboration to be a regular part of the daily investigation process at this county office. Colibrí supports the investigation of migrant cases in Pima County by managing all incoming inquiries from families of missing migrants, providing detailed antemortem data to forensic practitioners, and producing identification hypotheses that can then be followed up scientifically. Colibrí has assisted with the investigation of hundreds of cases at the PCOME and several cases in Texas and in California. Colibrí's database includes records for more than 2,000 missing migrants last seen crossing the United States-Mexico border.

In Brooks County, TX, the South Texas Human Rights Center (STHRC) has established a Memorandum of Understanding (MOU) with the Brooks County Sheriff's Office (BCSO) that allows the STHRC to investigate both missing persons and unidentified human remains cases on behalf of the BCSO. As a result, the STHRC, in collaboration with other organizations, has assisted with the investigation of more than 200 missing persons cases, the collection of family reference samples from more than 40 families, the identifications of more than 10 deceased

individuals, and the finding of more than 40 missing individuals, some whose lives were saved by search and rescue efforts.

Collaborations between NGOs and government agencies are essential to the investigations of missing migrants and unidentified human remains found throughout Central and North America. Both reported statistics and presented case studies illustrate the strengths of involving NGOs in these investigations, as they combine diverse, multidisciplinary perspectives while working with families to resolve these investigations.

Migrant Deaths, Regional Collaborations, Non-Government Organizations

A143 Missing Migrant Data Managed by the Forensic Border Coalition (FBC)

Robin C. Reineke, PhD, University of Arizona, 1009 E South Campus Drive, Tucson, AZ 85721; Carmen E. Osorno Solís, 10 Jay Street, Ste 502, Brooklyn, NY 11201; Mercedes Doretti, EAAF, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Rachel Daniell, MPhil, Argentine Forensic Anthropology Team, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; Ryan Strand, BS, South Texas Human Rights Center, 117 E Miller Street, Falfurrias, TX 78355; and Chelsea Halstead, BA, Colibri Center, 3849 E Broadway Boulevard, #206, Tucson, AZ 85716*

After attending this presentation, attendees will understand the current state of the data regarding missing migrants managed by members of the FBC as well as strategies in data comparison and the latest figures on the minimum number of missing migrant cases in the United States-Mexico border area.

This presentation will impact the forensic science community by highlighting the unique challenges in collecting and sharing data about missing migrants along the United States-Mexico border and by providing a methodology for the collaborative management of such data as developed by the FBC.

The transnational nature of migration in the Americas poses unique challenges to the tracing of missing persons. Migrants may pass through multiple countries or states before reaching their final destination, facing extreme vulnerability at all points during their journey. Migrants are dying and disappearing at alarming rates throughout Mexico as well as along the United States-Mexico border. Relatives of the missing may live in Central American countries, Mexico, or the United States and reach out to a variety of governmental and non-governmental organizations in their search for information. These organizations in turn may or may not have access to comprehensive and accurate data about unidentified human remains discovered along migrant routes. The United States has a public, non-genetic, national database, the National Missing and Unidentified Persons System (NamUs), that is intended to centralize information regarding missing persons and unidentified remains, as well as a separate DNA-index system, the Combined DNA Index System (CODIS), operating at local, national, and state levels that has the potential to facilitate genetic comparisons; however, families of missing migrants face significant obstacles to participation in either system for a variety of reasons, particularly when family members reside outside of the United States and/or are living in the United States without official documentation. The consequence is that data regarding missing migrants is scattered throughout the Americas, with both duplication of efforts between organizations and inconsistency of responsiveness to relatives. In turn, experts trying to identify the dead struggle to obtain antemortem information about missing migrants that is accurate, organized, and complete.

Three non-governmental organizations within the FBC manage missing migrant data: (1) the Argentine forensic anthropology team, Equipo Argentino de Antropología Forense (EAAF); (2) the Colibrí Center for Human Rights; and, (3) the South Texas Human Rights Center (STHRC). Each organization differs slightly in geographical focus, with EAAF covering regions throughout Central America, Mexico, and the United States, Colibrí encompassing the entire United States-Mexico border, and STHRC focusing on those who disappear crossing into Texas. Despite these differences in geographical focus, there is overlap between these organizations' databases.

To compile a complete and non-overlapping list of missing migrant reports, cases were compared based on name, age, country of origin, and last known whereabouts. Common cases (appearing in two or more databases) were counted only once, and the organization with the most complete data was assigned the status of main point of contact, with the other organization(s) serving as secondary contacts. Between the three organizations, there is a total of 3,332 missing migrant cases, 929 of which are managed by EAAF, 2,118 by Colibrí, and 285 by STHRC. Matching cases is a crucial component in the prevention of duplicating efforts as well as clarifying who is responsible for a case, thus ensuring that all the necessary documentation, from antemortem to postmortem data, reaches the proper organization.

Obtaining reliable and comprehensive information regarding minimum numbers of migrants likely to have gone missing in the United States-Mexico border region has traditionally been a challenge. The FBC has addressed this need through case data collection and case data comparison processes that respect the unique needs of each organization's mandate while still facilitating large-scale comparison of case data to determine minimum numbers. These numbers represent the first comprehensive effort to obtain an estimate of those who have disappeared crossing the United States-Mexico border.

A144 Identification Notifications and Their Applicability to Families of Missing Migrants

Carmen E. Osorno Solís, 10 Jay Street, Ste 502, Brooklyn, NY 11201; Mercedes Doretti, EAAF, 578A Halsey Street, Ground Fl, Brooklyn, NY 11233; and Karla Hernandez, BA, Argentine Forensic Anthropology Team, 578 A Halsey Street, Ground Fl, Brooklyn, NY 11233*

After attending this presentation, attendees will understand the relevance of the protocol designed and successfully applied by the Argentine forensic anthropology team, Equipo Argentino de Antropología Forense (EAAF), for identification notifications to families of missing or disappeared people, particularly in missing migrant cases.

This presentation will impact the forensic science community by: (1) highlighting the gaps in documentation and communication that have led to insufficient or inappropriate notifications; (2) offering suggestions to improve this critical moment for families receiving information; and, (3) discussing considerations of a wider role for forensic scientists in the notification process. The goal of EAAF's notification protocol utilized in cases of disappeared people and missing migrants is to significantly improve the information, documentation, and circumstances in which notifications of remains identifications take place so family members can end their uncertainty regarding the fate of their loved ones.

In many countries, forensic specialists are typically not involved in the notification of identifications to the respective family. Further, in EAAF's experience with families of victims of human rights violations and, more recently, with families of missing migrants, it has been apparent that in numerous countries, whether forensic experts are involved or not, there are no specific protocols regarding how to conduct notifications. Yet, the notification of identification is a critical moment that may jeopardize excellent forensic work if not performed properly. In the migrant context, the absence of an identification report, the communication to families over the phone of identification from one country to another, the delivery of sealed coffins with the instruction to not open them, among other practices reported by families of missing migrants, often leave them with an open, severely painful doubt regarding identification results instead of the identification ending their uncertainty.

The Border Project, coordinated by the EAAF beginning in 2009, seeks to create a regional forensic mechanism throughout the Central America, Mexico, and United States migrant corridor to significantly improve both the identifications of missing migrants among unidentified remains in the region and the response of governments to families searching for missing migrant relatives. As part of this initiative, the project addresses the need to alleviate the doubts regarding an identification; such doubts are increased in the context experienced by families of missing migrants due to death occurring in a foreign country where they typically cannot afford to travel and often occurring in unknown circumstances. To truly evaluate the effectiveness of the work of forensic scientists on the impact of identifications on affected families, the significance of the notification process must also be evaluated, particularly the importance of forensic specialists' involvement. The Forensic Data Banks on missing migrants and related mechanisms that are currently part of the Border Project in El Salvador, Honduras, and parts of Mexico and Guatemala are applying a notification protocol that derives largely from EAAF's experience in other types of cases, such as enforced disappearances, to the migrant context.

EAAF's notification protocol involves several phases, including: the compilation, data verification, and review of all case materials prior to scheduling a notification; the completion of an integrated, multidisciplinary identification report in the family's language; risk assessment of the family receiving a notification, be it health related or threat from other persons; conducting the notification in person with the family; providing psychological and medical support; and explaining the repatriation process, among others.

Collaborative and centralized efforts involving forensic, governmental, and non-governmental institutions internationally are crucial to reaching the point of identification notification with all available information in place and to facilitating its delivery in the best way possible. The benefit of EAAF's protocol model is that it affords families clear and accessible forensic and circumstantial information on the death of their loved ones, assisting directly in their mourning process; it helps to standardize a critical moment in the identification of remains process and can be widely adapted in ongoing humanitarian efforts. It is through this tested mechanism that families can be ensured of their right to information, truth, and reparation. Conducting forensic work involves responsibilities not

only to the dead but also to the living and, as a result, requires that the Border Project serve the families of missing migrants by ending their uncertainty in cases in which their missing relatives have died.

Forensic Anthropology, Identification Notifications, Migrant Deaths

A145 The Evolution of Forensic Anthropology and the Influence of Court Rulings, Legislative Actions, and Social Trends

Jennifer C. Love, PhD, OCME, 401 E Street, SW, Washington, DC 20024; and Laura C. Fulginiti, PhD, Forensic Science Center, 701 W Jefferson, Phoenix, AZ 85007*

After attending this presentation, attendees will better understand the impact of court rulings, legislative actions, and social trends on the evolution of forensic anthropology. Several recent Supreme Court rulings, legislative actions, and social trends will be reviewed and the ways in which each impacts the field of forensic anthropology will be investigated.

This presentation will impact the forensic science community by emphasizing the importance of awareness of court rulings, legislative actions, and social trends that influence the practice of forensic science. Some of these influences may appear ancillary, but each has the potential to directly impact laboratory policy, admission of forensic testimony, and available funding.

Forensic anthropology has experienced significant growth during its relatively short history. In the past 45 years, since the first meeting of the Physical Anthropology section of the American Academy of Forensic Sciences, the field has experienced great change often driven not by forensic anthropological research and technical development, but by court rulings, legislative actions, and social trends. Some external influences are well known by practitioners (e.g., *Daubert v. Merrell Dow Pharmaceuticals, Inc,* the 2009 National Academy of Science Report *Strengthening Forensic Science in the United States: A Path Forward* (NAS Report), and The Innocence Project), yet others are less familiar (e.g., *Bullcoming v. New Mexico*).[1-3] Despite the low level of awareness, each of these influences affects the practice of forensic anthropology.

The NAS Report showcased systemic weaknesses in the field of forensic sciences. The Report emphasized the fact that few forensic science methods adequately measured inherent uncertainty or accuracy of inferences made by forensic scientists. Further, the Report presented concerns for contextual bias, drawing into question what "working in the blind" means for forensic science and how it can strengthen or limit analyses. As a response to the Report, anthropologists have focused research on defining method error rates, with specific attention on non-metric methods. Yet, the field has done little to explore error rates associated with analyst inference. Further, the trending concern for contextual bias has influenced some anthropology laboratories to require their analysts to perform analyses without contextual information; however, the field has not responded by investigating errors stemming from this approach.

Bullcoming v. New Mexico focused on the Sixth Amendment Confrontation Clause giving the accused the right to confront the witnesses against him. During the trial, the forensic analyst who completed, signed, and certified the toxicology report was on unpaid leave and unavailable. The State called another analyst to validate the report. Bullcoming's counsel objected, asserting that introducing the report without the opportunity to cross-examine the analyst was in violation of the Confrontation Clause. Ultimately, the Supreme Court ruled that the laboratory report was out-of-court testimony; therefore, it could not be introduced unless the analyst was available at trial or the accused had prior opportunity to confront the witness. This ruling should directly impact a laboratory's policy for co-signing reports.

Recent media coverage of court cases has brought forensic science under increased public scrutiny. For example, ProPublica, collaborating with PBS's *Frontline* and NPR, reported on the conviction of a Texas man for the homicide and sexual assault of a 6-month-old child. During the trial, the medical examiner and hospital workers provided testimony describing the injuries the child sustained. The Texas Court of Criminal Appeals overturned the conviction after hearing testimony from a different pathologist who concluded the child had been afflicted by a severe blood-clotting disorder. This type of media coverage increases the public's scrutiny of forensic science, in return causing prosecutors to seek more analyses, leading to a trickle-down effect as pathologists reach out to anthropologists for consultation on difficult cases. Popular culture has also affected the public's opinion of forensic scientists. Juries now disregard arguments not based on solid forensic evidence or they believe that the information provided on television shows (e.g., *Bones*) and in films accurately depicts the work of forensic scientists; therefore, conflicting information can be legitimately (in their minds) disavowed.

The NAS Report, *Bullcoming v. New Mexico,* and the ProPublica report are three of many examples of external influences that impact the direction of change in forensic anthropology. Understanding these influences is important to ensure the field's responses are appropriate and deliberate. Without such an understanding, forensic anthropologists may follow practices and develop policies that are detrimental to the field.

Forensic Anthropology, Court Rulings, Legislation

A146 Virtual Skeletal Data — The Ethical, Technical, and Legal Questions Anthropology Faces When Working With Virtual Skeletal Remains

Roland Wessling, MSc, Cranfield Univeristy, Cranfield Forensic Institute, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM*

After attending this presentation, attendees will better understand the challenges the anthropological community is facing and will be facing in the future concerning ethical and legal questions regarding virtual skeletal remains data. Currently, there is no legal framework anywhere in the world that governs the gathering and storing of analysis or the storage of data that represents virtual skeletal remains. There are also no ethical guidelines or technical standards for setting up a virtual skeletal collection. Attendees will be presented with the open questions, the issues caused by a lack of answers, and possible solutions to a number of the issues.

This presentation will impact the forensic science community by starting a discussion about several of the numerous questions that need to be addressed if virtual skeletal analysis is to have a productive place in anthropology. Ethical, technical, and legal question regarding virtual skeletal remains need to be addressed soon or anthropological research and forensic anthropological casework will soon suffer from a lack of answers. Virtual skeletal anthropology cannot exist in an ethical, technical, or legal vacuum.

For more than a century, anthropologists have collected skeletal remains and built up collections. These collections have helped develop and test numerous methods in physical anthropology and without them, forensic anthropology would not be where it is today. In recent years, a new type of skeletal collection began to emerge: the virtual skeletal collection. Here, electronic 3D models of bones are stored, rather than the physical original. Such virtual data can be tomographic or topographic, can come with "skins" or without, and can be produced in various file formats, sizes, and resolutions. This is a very promising new research area, but one that is more or less entirely void of rules, regulations, guidelines, and laws.

There are three areas in which a multitude of questions need to be addressed: ethical, technical, and legal. The legal questions concentrate primarily on the issue of anonymity and on intellectual property rights. While the first of these two issues is familiar to anthropology and fairly easily dealt with, the second becomes more difficult. Who owns a virtual skeletal bone? The person whose bone it is if the person is alive, their family if the person is dead, the institution that is housing a physical skeletal collection that is being scanned, or the institution that put all the time, work, and effort into scanning and/or processing the bones? Can one institution share the bones with one or more third parties? There are many questions and so far very few answers.

The ethical questions may turn out to be more easily answered. It is likely that, in many ways, virtual bones can be treated just like physical bones; however, while in many parts of the world physical remains are being reburied, there appears to be no need for that to happen with virtual bones. Should communities that request the burial of physical remains have the right to have virtual ones deleted? Does anthropology have the right to keep the data? Such questions can be ethical ones, but they can quickly turn into legal ones as well.

Finally, there are technical issues to address. One of the greatest arguments for those in favor of virtual skeletal collections is their potential size. I f the legal/ethical issues of sharing data can be solved and enough institutions cooperate, virtual skeletal collections could be thousands or tens of thousands of individuals large. If medial Computed Tomography (CT) scans are included, there could be millions of samples and the size would increase steadily; however, numerous technical standards for 3D model files exist and there is no specific technical standard agreement among those anthropologists who work with them. Should one of the existing file standards be used or should there be a particular anthropological file standard that can contain information on pathologies, trauma, etc. on top of the already existing xyz coordinates, texture, etc.? If so, detailed standards would have to be developed and that is a very considerable task.

Some of these questions can be solved by the international anthropological community, if they are willing to address them. Others questions need to be addressed by governments or international organizations but anthropologists will still need to lobby for change.

Virtual Skeletal Data, Ethics, Standards

A147 A Review of Statutes in Place to Stem the Commodification of Human Skeletal Remains in the United States

Ryan M. Seidemann, MA, Louisiana Department of Justice, 1885 N Third Street, Baton Rouge, LA 70802; and Christine L. Halling, MS, Louisiana Department of Justice, 1885 N 3rd Street, Livingston Bldg, 6th Fl, Baton Rouge, LA 70820*

After attending this presentation, attendees will better understand the laws in place relating to the commodification of human skeletal remains. This presentation categorizes and compiles all of the current legal statutes in order to provide a review of the protection of human skeletal remains from commodification in the United States. In particular, this presentation considers how the law protects cemeteries, archaeological sites, and even criminal sites, and further considers the extent to which the laws may protect human skeletal remains when removed from their final disposition.

This presentation will impact the forensic science community by demonstrating the need for statutory language that can stem the trade in human skeletal remains commodification. Highlighted is the unique problem with the commodification of human skeletal remains that may result from a modern version of grave robbing. This presentation provides an opening platform for the discussion regarding the commodification of human skeletal remains, regardless of the context from which the remains are derived (i.e., anatomical specimens, archaeological sites, sites of forensic significance, or cemeteries).

Damage to cemeteries, particularly above-ground vaults or unmarked cemeteries so common in the Southeastern United States, is inevitable in most locations. In South Louisiana, where bodies are often entombed in above-ground vaults, the effects of both natural events and intentional damage result in relatively easy access to human skeletal remains. Below-ground interments and archaeological sites are equally vulnerable, particularly when located on private lands. Legal protection at the state level varies greatly, not only in scope but in language. The language that addresses the law concerning the dead as it relates to interment spaces is of particular concern in Louisiana; however, each state has its own specific challenges.

Because federal law (aside from the Native American Graves Protection and Repatriation Act) regarding the protection of human skeletal remains is incomplete at best and negligible at worst, it is up to each state to put that legislation in place and to monitor the sales of human skeletal remains; otherwise, the commodification of human skeletal remains is ignored. Because highly visible platforms for human skeletal remains sales are dwindling (in particular, eBay® shut down the sale of human remains in 2016), it will become increasingly difficult to track the location of remains. To swiftly intercept human skeletal remains, state officials need laws in place as well as working protocols to implement rapid responses to recover such threatened remains. Louisiana serves as one example of working to fill in gaps in the legislation, which involves multi-agency cooperation to ensure swift action and proper documentation/investigation of the human skeletal remains.

While enforcement is presently lacking, researchers should be made aware of what is illegal for human skeletal remains trade in their respective states. Cooperation among local forensic anthropologists, legal entities, state archaeologists, and law enforcement is important in identifying and creating protocols for human skeletal remains trafficking.

Skeletal Remains, Forensic Archaeology, Commodification

B1 The Development and Initial Evaluation of a MicroRNA (miRNA) System for Forensically Relevant Body Fluids Using Capillary Electrophoresis

Carrie Mayes, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340*

After attending this presentation, attendees will better understand the utility of miRNAs for Body Fluid Identification (BFID) in a forensic setting. Recently, the development of molecular-based assays has shown some improvement over conventional biological screening methods through increased body fluid specificity, sensitivity, the identification of a greater number of body fluids, and less consumption of the evidentiary sample.

This presentation will impact the forensic science community by demonstrating a possible confirmatory method of BFID for venous blood, menstrual blood, semen, vaginal material, and saliva using miRNAs that utilizes similar techniques and instrumentation already in place in crime laboratories.

BFID can be of great importance during the course of an investigation and in the courtroom. Determining the body fluid origin of a stain may provide probative information about the events that took place during the commission of a crime. Current methods for BFID, such as chemical tests, microscopy, enzymatic activity, and immunological tests, do not offer the level of specificity the forensic field requires. In recent years, miRNAs have been suggested as a viable biomarker for BFID and have shown considerable body fluid specificity. MiRNAs are small, typically 18-25 nucleotides in length, which makes them ideal for analyzing highly degraded forensic samples. In addition, miRNA interrogation allows for the co-analysis of DNA for individualization and miRNA for BFID from a single sample.

A common strategy for miRNA profiling systems is to analyze relative expression (delta Cycle Threshold (ΔCT)) values of various miRNAs compared to an endogenous reference gene using Real-Time quantitative Polymerase Chain Reaction (RT-qPCR); however, most instrumentation for qPCR can only detect up to five different fluorescent dyes, which would limit the amount of markers that can be amplified simultaneously. Additional reactions would be required to analyze multiple markers, which increases sample consumption, the risk of contamination, cost of reagents, and time of analysis. To address these issues, a previously reported linear primer system was expanded in order to incorporate additional miRNA markers by forming a comprehensive four-dye multiplex system using capillary electrophoresis.

In this study, a new ten-marker system for BFID was designed to differentiate between venous blood (miR-451 and miR-142-3), menstrual blood (miR-144 and miR-412), semen (miR-891 and miR-10), vaginal material (miR-124 and miR-617), and saliva (miR-205 and miR-658). Each marker was tested in singleplex reactions to assess marker viability in the multiplex as well as evaluate cross-reactivity. It was observed that the vaginal markers interacted during reverse transcription and were removed from the multiplex at this time. All other primers amplified the correct miRNA targets. Five samples each of venous blood, menstrual blood, semen, vaginal material, and saliva were evaluated with the multiplex. Although further work is needed, the miRNA system was able to generate an STR profile (from the DNA extract) and distinguish between venous blood, menstrual blood, and semen (RNA extract) from a single sample.

microRNA, Body Fluid Identification, Capillary Electrophoresis

B2 The Development and Evaluation of Real-Time Polymerase Chain Reaction (PCR) Methods for DNA Methylation-Based Identification of Semen and Blood

Ken Watanabe, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Ayari Takamura, MS, National Research Institute of Police Science, 6 3 1 Kashiwanoha, Kashiwa, JAPAN; and Tomoko Akutsu, PhD, National Research Institute of Police Science, 6 3 1 Kashiwanoha, Kashiwa, JAPAN*

After attending this presentation, attendees will understand how the methylation status of the semen-specific unmethylated DNA region and the blood-specific methylated DNA region are analyzed using a real-time PCR technology. Attendees will also understand the usefulness of these methods for semen and blood identification.

This presentation will impact the forensic science community by demonstrating methods that can accurately and sensitively identify semen and blood from various samples, including highly aged body fluid stains. In addition, these methods can be readily established in forensic laboratories and are simple to perform.

The identification of body fluids provides important evidence in forensic investigation to prove the existence of criminal events, such as murder, injury, and sexual assault. Recently, DNA regions that are specifically methylated or unmethylated in different types of body fluid have been reported as novel markers for body fluid identification. The stable nature of DNA offers an advantage for forensic use because forensic samples have often been exposed to severe conditions before laboratory analysis.

Previous preliminary work reported the development of a MethyLight-based-method for analyzing the —C—phosphate—G— (CpG) sites in the DACT1 gene, which was previously reported as a semen-specific unmethylated region.[1,2] MethyLight is a method for quantitating the methylation ratio of a targeted region using a real-time PCR device and a pair of TaqMan® probes that are designed for methylated or unmethylated status.

In this presentation, further evaluations of the method are described to enable detection of the DACT1 region for semen identification. A MethyLight-based method was also developed and evaluated for detecting the methylation ratio of cg06379435 and its neighboring CpGs, which were previously reported to be specifically methylated in blood. To set the threshold methylation ratios for semen or blood identification, DNA from various body fluid samples (blood, semen, saliva, and vaginal fluid), which were bisulfite-converted using an EpiTect Bisulfite Kit, were analyzed by the two methods, each using a pair of TaqMan® probes, the EpiTect MethyLight PCR Kit and the Smart Cycler II system. The results revealed almost exclusive non-methylation of the DACT1 region in semen and high methylation levels of the cg06379435 region in blood, which is consistent with previous studies. Based on these data, the threshold methylation ratios were set for semen and blood identification. For semen identification, another threshold ratio to detect semen mixed with other tissues could be set near the average methylation ratio of DACT1 in non-semen samples, because the DACT1 region was almost fully methylated in non-semen samples. Use of these thresholds can accurately identify semen or blood from other samples, including highly aged (29-year-old) semen, blood stains, and mixture samples containing a smaller amount (20%) of semen DNA. The sensitivity of these methods was evaluated by analyzing pooled samples of semen and blood DNA and demonstrated the necessary amounts of DNA for bisulfite conversion to be 1ng for both methods.

In conclusion, these methods can accurately and sensitively identify semen and blood. Because a real-time PCR device is common in forensic laboratories, this method can easily be introduced without the purchase of further equipment. Moreover, because a real-time PCR-based method requires no substantial work beyond preparing the PCR reaction mixture, simple and quick analysis may be realized with a reduced risk of contamination. Therefore, these methods could be better suited to forensic work compared with other methods of methylation analysis, such as bisulfite sequencing methods.

Body Fluid Identification, DNA Methylation, Real-Time PCR

B3 Investigating the Identification of Vaginal Material Using Histological, Spectroscopic, and Molecular Methods

Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516; and Justine Kawa, BS, 95 Rockdale Road, West Haven, CT 06516*

The goal of this presentation is to inform attendees of the recent advancements in three emerging techniques for the identification of vaginal material in a forensic context.

This presentation will impact the forensic science community by providing insight into multiple techniques — histological, spectroscopic, and molecular — to identify and distinguish vaginal material from other biological fluids. Vaginal material does not yet have its own validated, specific, and reliable test for identification.

Body fluid identification is a crucial component in the forensic investigations of sexual assault. The recovery and identification of vaginal material has been a significant challenge for forensic scientists for decades. Forensic Short Tandem Repeat (STR) DNA profiles can be used to identify the donor; however, a crucial facet is to identifying the body fluid source of that DNA, thereby elucidating the circumstances of the case. The identification of vaginal material present on penile swabs, hand swabs, or foreign objects can be used to confirm or refute a victim's or suspect's statement. Several methods have previously been proposed, but none have garnered widespread acceptance. Traditional methods such as histological staining face challenges due to similarities in the cellular makeup of vaginal, buccal, and skin epithelial cells. In recent years, Raman spectroscopy has gained much attention for its use in the identification of body fluids; however, vaginal material has to date been overlooked. Finally, microbial profiling of vaginal material has most recently been proposed as a potential molecular biomarker; however, this work is still very much in its infancy. Further investigation of both traditional and emerging techniques to identify vaginal material is absolutely necessary to address the challenges faced in the industry today.

Following informed consent, this study investigated three techniques: histological, spectroscopic, and molecular methods. Histological methods involved staining skin (n=10), buccal (n=10), and vaginal (n=10) epithelial smears with six histological stains: hematoxylin and eosin, crystal violet, Lugol's iodine stain, Csaba stain, Dane stain, and the Ayoub-Shklar stain. While some of these stains are not considered novel, the last three have recently been identified as having the potential to identify vaginal epithelium. The DXR Raman microscope was used to analyze the spectra for vaginal material, buccal cells, skin epithelial cells, venous blood, menstrual blood, saliva, and semen (n=10 for each). Molecular methods involved relatively quantifying the expression of *Lactobacillus gasseri* and *Lactobacillus crispatus*, two common vaginal bacterial species. Real-time Polymerase Chain Reaction (PCR) was used with TaqMan® Universal PCR MasterMix and a primer-probe pair designed for each bacterial species. Cycle threshold values were used to determine expression levels.

For the histology test, skin cells were easily distinguished from vaginal and buccal cells when stained using any method due to the contrast in morphology; however, the Dane stain was found to be superior for the differentiation of all three cell types, as each cell type resulted in a different color, thereby reducing subjectivity. Using Raman spectroscopy, averaged spectra for each body fluid were taken and significant peaks were noted and identified. The resulting peaks from the previously researched body fluids such as venous/menstrual blood, semen, and saliva, were as expected, while the resulting spectra from the vaginal, buccal, and skin epithelial cells showed variation in peak presence and intensity. Preliminary results obtained from the molecular investigation of the vaginal bacteria indicate higher expression levels in vaginal material when compared to other body fluids; however, further experimental investigation and data analysis is required.

This research has highlighted the value of traditional methods as well as the merit of emerging methods for the identification of vaginal material in forensic investigations. Each method has been shown to have potential for use in casework, albeit each with their own shortcomings, thereby reinforcing the need for continued research and validation in this field.

Vaginal Material, Body Fluids, Sexual Assault

B4 The Use of Proximity Ligation Assays Coupled With Real-Time Polymerase Chain Reaction (PCR) as a Detection Method for Proteins Within Blood for Forensic Analysis

Katherine Hargett, BS, 2103 N Scott Street, Apt 83, Arlington, VA 22209; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will better understand how Proximity Ligation Real-Time PCR (PLiRT-PCR) can be utilized as a rapid confirmatory assay for the presence of blood in a biological sample.

This presentation will impact the forensic science community by demonstrating that PLiRT-PCR can be a very effective tool for throughput body fluid identification. Furthermore, the assay utilizes technology already present in forensic laboratories; thus, no new equipment is necessary. This research effort focuses on the identification of blood and is meant to complement, eventually in a single assay, PLiRT-PCR-based confirmatory assay for sperm/semen and saliva.

Blood evidence can be found at the scene of many different types of violent crime, including murder, rape/sexual assault, robbery, assault, domestic and stranger violence, and crimes involving injuries. Presumptive tests for the presence of blood performed at the crime scene are often followed by confirmatory tests in the laboratory, not only to confirm the sample is blood, but also that the blood is human. Presumptive tests are generally very sensitive but lack in specificity, while confirmatory tests, although very specific, are generally less sensitive. PLiRT-PCR possesses both characteristics.

PLiRT-PCR combines the specificity of an immunological reaction with the sensitivity of PCR and only requires a minimal amount of sample in order to be effective. A small cutting of the sample or small drop of diluted sample can be utilized for the assay, minimizing sample consumption for downstream processes (i.e., generating a DNA profile) should it prove to be human blood. An additional advantage of PLiRT-PCR is the potential for high throughput sample processing. In fact, this can be performed on a 96-well plate format and plate set up could potentially be performed by an automated liquid handling platform.

Samples are first cut from a swab or diluted from a sample of neat suspected human blood and lysed in a prepared lysis buffer to expose the proteins within the cells. Once lysed, the sample is exposed to specific antibodies that are targeting the proteins of interest. This binding reaction allows the antibodies to bind with the desired proteins for detection. The antibodies have different DNA segments attached to them to create proximity probes. After the binding step, the sample goes through a ligation period. Probes close to each other and with the complementary oligonucleotide strand will be hybridized. This new DNA strand is then amplified and can be measured by quantitative PCR (qPCR).

This presentation will demonstrate how PLiRT-PCR has the potential to be successfully implemented in the laboratory workflow of forensic laboratories for the identification of human blood. This presentation will reveal how sensitive and human specific PLiRT-PCR can be through the analysis of known samples provided by The George Washington University. This method can be used with samples that have a mixture of fluids or only the suspected blood.

Although there are other confirmatory tests for the presence of blood, PLiRT-PCR is a powerful alternative as it can be performed in as little as a few hours and with such sensitivity and specificity that it can replace other methods of detection. PLiRT-PCR consumes only a small amount of the original sample and can utilize many instruments already in use in forensic laboratories.

Blood, Proximity Ligation PCR, Hemoglobin

B5 The Effect of Washing and Blood-Enhancement Reagents on the Use of Raman Spectroscopy for Human Blood Identification

Tyler J. Schlagetter, University of New Haven, 300 Boston Post Road, West Haven, CT 06516; and Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will gain insight into both the advantages and disadvantages of Raman spectroscopy in reference to its use in the identification of human bloodstains under a variety of conditions frequently encountered in a forensic setting. These conditions include blood present on a number of fabrics, varying dilutions of blood, and the effect of washing and enhancement reagents on the analysis.

This presentation will impact the forensic science community by disseminating results of novel research regarding the effect of washing and subsequent enhancement of bloodstains, which according to this study has not yet been reported. This research also highlights alternative approaches to the methodology and the importance of investigating the effect of variables.

In forensic investigations, determining the identity of an unknown biological stain can aid both in reconstruction and identification of an individual. Human blood is commonly found at crime scenes, which is first presumptively identified at the scene, then confirmed in a laboratory setting; however, many of the tests used, both presumptive and confirmatory, consume the sample in question, preventing further analysis, namely DNA profiling. Raman spectroscopy has been gaining interest as a new method of body fluid identification, partly due to its non-destructive nature. Prior research has demonstrated that Raman spectroscopy provides a unique spectrum for blood, while also preserving the sample for DNA analysis. The goal of this study was to further investigate the use of Raman spectroscopy for human blood identification in simulated crime scene samples, including bloodstains on a variety of fabrics, at varying dilutions, following washing, and finally post-enhancement.

After obtaining informed consent from volunteers, venous blood was collected in sterile vacutainer EDTA vials. Using a 780nm wavelength laser and a controlled laboratory setting, Raman spectroscopy was performed on samples of blood under various conditions. These conditions included five fabrics (black and white cotton, black and white polyester, and denim), a series of dilutions (1:10 to 1:10^6, both wet and dry), and after washing and treatment with three enhancement reagents (Leuco Crystal Violet (LCV), Coomassie blue, and luminol).

A method of extraction of the stain from the fabrics was also tested. Baseline corrections for fluorescence were performed as necessary.

The results obtained from the bloodstains on a variety of fabrics illustrated that by using spectral subtraction, a signal similar to blood could only be recovered from the white cotton and white polyester samples. The results obtained from the diluted bloodstains revealed that only the neat blood gave a signal while wet. When dried, the neat blood, as well as the 1:10 and 1:100 dilutions, gave a signal with peak shapes similar to the blood reference; however, the peaks became significantly less intense after each successive dilution. The results obtained from the bloodstains that were washed and subsequently enhanced revealed luminol to have no effect or interference on the ability to obtain a clear blood spectrum following spectral subtraction; however, LCV and Coomassie blue introduced interference, giving indeterminate results. The results obtained by utilizing an extraction method of the stain from the fabric revealed a spectrum with similar peak shape and location, but lower intensity, resulting in a weak match to a library reference for blood, regardless of the substrate from which the stain was extracted.

This study demonstrated the capabilities of Raman spectroscopy as a means of identifying human blood in a variety of situations common to forensic investigations. The impact of washing and blood enhancement reagents reveals the importance of the choice of method and its bearing on subsequent Raman analysis.

Raman Spectroscopy, Blood, Enhancement

B6 A Comparative Analysis of Commercially Available Protein and Peroxidase Reagents for Blood Detection and Enhancement on Laundered Clothing of Varying Fabric Types

Gabrielle A. Hartley, 64 Indian River Road, Milford, CT 06460; and Claire Glynn, PhD, Henry C. Lee College of Forensic Science, University of New Haven, West Haven, CT 06516*

After attending this presentation, attendees will better understand the use of a variety of protein and peroxidase reagents that are commercially available to forensic professionals. Attendees will also gain insight into the advantages and disadvantages of these reagents, particularly when used with a variety of colored fabrics and following laundering.

This presentation will impact the forensic science community by providing a comprehensive comparative analysis of various blood detection reagents, their sensitivities on laundered fabrics, and their best use with particular fabric types, thereby providing a useful resource for forensic professionals.

Human blood is commonly encountered in forensic investigations, particularly on clothing following a violent incident. In certain circumstances, clothing may have been laundered prior to seizing to eliminate any traces of human blood. A number of methods and commercially available products have been introduced in recent years for the detection and enhancement of dilute bloodstains, including both protein- and peroxidase-based reagents. While each product has been researched individually in the literature, to date, these products have not yet been simultaneously and comparatively analyzed on a variety of laundered fabric types. The aim of this study was to investigate six commonly used protein and peroxidase reagents, which are commercially available from crime scene supply companies, and determine their sensitivities and most appropriate utilization on varying colored fabric types post-laundering.

Following informed consent from volunteers, venous blood was collected in sterile vacutainer EDTA vials. Five fabric types were selected: white cotton, black cotton, white polyester, black polyester, and blue denim. Three protein-based reagents and three peroxidase-based reagents were selected and purchased from Sirchie®: Hungarian red, Coomassie blue, amido black, luminol, Leuco Crustal Violet (LCV), and Bluestar® Forensic Magnum. One hundred microliters (µL) of human blood was deposited onto each fabric type in a range of seven dilutions from neat to 1:1 million. Each sample was performed in triplicate and photographed prior to laundering and enhancement. Following laundering, each sample was photographed and subsequently enhanced following the manufacturer's instructions provided with each of the six reagents. The results of each reagent, dilution, and fabric type were compared, using a scale from 0-4 (0 = no reaction; 4 = strong positive reaction).

The results of the post-laundering enhancement of neat blood and blood dilutions on the varying fabric types revealed the peroxidase-based reagents (luminol, LCV, and Bluestar® Forensic Magnum) to have the greatest sensitivities on the natural fabric types (white cotton, black cotton, and denim) as they all reacted positively on these fabrics down to 1:1,000; however, when the protein reagents were tested on the dilutions and varying fabric types, they revealed the greatest sensitivities (1:10) on the white polyester when compared to the peroxidase reagents, which only produced positive reactions on the laundered neat blood. As the protein-based reagents are color reactions and are not based on chemiluminescence, their use on dark fabrics revealed indeterminate results. The results of this study suggest peroxidase-based reagents to be the superior method for use on natural fabrics and all dark fabrics. Protein-based reagents have previously been shown to have merit for the enhancement of blood detail on non-absorbent surfaces, while in this study, their use, albeit inferior in most cases to peroxidase-based reagents, was shown on absorbent fabrics.

This study highlights the variety of commercially available blood detection and enhancement reagents offered and reveals their advantages and disadvantages in certain settings and on difficult types of evidence. The results of this research provide a much-needed comparative analysis of these reagents and could be used in the decision-making process for forensic investigators evaluating fabric evidence.

Blood Enhancement, Laundered, Fabric

B7 Rapid and Reliable Validation of Body Fluids Using Paper Microfluidic Device (µPAD) Chips

Rosa L. Cromartie, BS, 16800 SW 137th Avenue, Apt 1124, Miami, FL 33177; Ashley T. Wardlow, 11253 N Kendall Drive, Apt G106, Miami, FL 33176; George T. Duncan, PhD, Broward County Crime Lab, 201 SE 6th Street, Rm 1799, Fort Lauderdale, FL 33301; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the development of a new procedure for the determination of the presence of body fluids at crime scenes using µPADs. Paper microfluidics permit the simultaneous analysis of multiple sources of body fluids from a variety of substrates using multiplexed colorimetric detection. The result is a fast, simple, and reliable analytical tool for screening body fluids found at a crime scene.

This presentation will impact the forensic science community by demonstrating the practical application of µPADs in forensic serology. The design and developmental validation of the system will be discussed, including sensitivity, specificity, and long-term stability.

In recent years, there have been a number of new developments in the field of forensic serology; however, these methods involve lengthy laboratory testing (genomics, proteomics) and are not applicable to direct measurements at the crime scene. In contrast, field tests are simple, fast, and presumptive. Unfortunately, these analyses generally involve multiple testing procedures for each body fluid and are inherently destructive (with the exception of Raman and alternate light sources), wasting precious samples. With the advent of genetic testing, it becomes critical to determine all potential sources of human DNA at the scene to assist collection and sample analysis. These include blood, semen, saliva, vaginal fluids, urine, and sweat. To test each suspected body fluid with all these different procedures clearly would be uneconomical. Thus, a multiplexed presumptive body fluid screening procedure was proposed using paper microfluidics.

The µPADs utilize sheets of chromatographic paper and thermal wax to create hydrophilic channels that are bounded by hydrophobic barriers that direct a liquid sample to multiple test wells, each with a different sensor. In this project, various bodily fluids have been detected through the development of a µPAD chip. The device is designed like a tree. A single sample is placed at the base of the device and the sample flow is divided into several branches. A different colorimetric reagent is placed at the terminus end of each branch, each of which is capable of detecting a different body fluid. Currently, four different fluids can be simultaneously detected on a single device.

In this project, a variety of colorimetric sensing systems have been developed and modified for the presumptive determination of blood, urine, saliva, and semen. Reagents for detecting blood were prepared using sodium perborate as a longer-lasting oxidizing agent for the phenolphthalein-based Kastle-Meyer test. This compound becomes oxidized when sodium perborate comes in contact with water, generating hydrogen peroxide. A colorimetric change is produced in a minimum of ten seconds. To detect urine, a second test site utilizes the hydrolysis of urea via urease. The ammonia that is released interacts with the Nessler's reagent (mercuric iodide) and produces a color change in less than a minute. The reagents used for saliva detection utilize the amylase-based hydrolysis of the a-1,4 glyosidic linkages in starch/iodine, resulting in the loss of the initial colored complex. Reagents used for semen involve the reaction of sodium a- naphthyl phosphate with acid phosphatase. Upon analysis, the paper microfluidic chip permits the determination of sub-microliter volumes of samples.

Test results with mixtures and single-source samples demonstrate clear and distinct signals for the presence of each body fluid type. Further interference testing and validation is currently underway. Overall, this paper microfluidic presumptive testing method can serve as a cost-effective and field-able analytical method for screening unknown fluids found at crime scenes.

Colorimetric, Microfluidic, Serology

B8 The Detection of MicroRNAs (miRNAs) in DNA Extraction Methods Commonly Used for Forensic Casework

Carolyn Lewis, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Rm 2004, Box 843079, Richmond, VA 23284; Tiffany R. Layne, MS, University of Virginia, 3906 Grovewood Road, Hopewell, VA 23860; and Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will understand how miRNAs function and why they can be of significant value in forensic analyses. Recent forensic literature has focused on molecular markers for forensic body fluid identification, including miRNAs, messenger RNAs, methylation, and proteomics. Each has been proposed as a supplement to or replacement of the current serological methods. The miRNA and RNA work for forensic body fluid identification thus far has been performed using RNA extraction of samples, which requires an additional step in the evidence analysis process. Not only is analyst time lost in the secondary extraction process, but it could also consume additional sample, which is problematic when the sample is of limited size. Although two reports have shown that miRNAs can potentially be detected within silica column-based DNA extracts, only one type of silica column isolation method was tested and other extraction methodologies have not been explored for miRNA co-isolation and detection. Attendees will understand the importance and limitations of miRNA detection using common forensic DNA extraction methods and be encouraged to promote the necessary research for implementing miRNAs into forensic casework.

This presentation will impact the forensic science community by illustrating how forensic research on miRNAs continues to build evidence for their utility in forensic casework.

MiRNAs are small non-coding RNAs that regulate gene expression by binding to messenger RNA in the cytosol to prevent further translation. Their short length of 18-22 nucleotides, cellular function, and resistance to degradation allow for easy detection in highly degraded samples, as is often the case in forensic casework samples. This study was conducted to explore detection of miRNAs in a variety of DNA extraction methods. Liquid donations of semen, blood, and saliva were collected from three individuals, and 100µL was aliquoted onto cotton swabs. Seven of the most common DNA extraction methods used by forensic laboratories were performed on all samples, with a total RNA isolation method for each sample as a control. A portion of all DNA and RNA extracts were DNase-treated to ensure that the data was a reflection of miRNA detection rather than genomic DNA contamination. MiRNA presence was evaluated using Real-Time quantitative Polymerase Chain Reaction (RT-qPCR) analysis of miRNAs let-7g and let-7i because research has shown that they have relatively similar expression levels across multiple body fluids and between individuals. DNase treatment of extracts had little effect on miRNA expression levels between untreated and DNase-treated samples. Subsequent work revealed that multiple silica columns as well as other non-silica-based DNA isolation methods yielded detectable miRNA levels consistent with those found in the RNA extracts of the same samples. Based on these data, miRNAs are present at detectable levels in DNA extracts when using common DNA extraction methods. Co-extracting miRNAs with DNA would be beneficial for forensic investigations since it could provide probative information about an evidence sample without a separate RNA isolation, thus consuming less sample and reducing the amount of hands-on time for biological evidence analysis.

microRNAs, DNA Extraction, RT-qPCR

B9 Y-Screening and Direct Amplification of Casework Samples

Jeanne Bourdeau-Heller, PhD, Promega, 2800 Woods Hollow Road, Madison, WI 53711; Robert McLaren, PhD, Promega, 2800 Woods Hollow Road, Madison, WI 53711; Amy McGuckian, MSFS, Palm Beach County SO, Crime Laboratory, 3228 Gun Club Road, West Palm Beach, FL 33406-3001; Jerome G. Remm, MFS, Palm Beach County Sheriff's Office, 3228 Gun Club Road, West Palm Beach, FL 33406; Julie Conover Sikorsky, MS, Palm Beach County SO, Forensic Biology Unit, 3228 Gun Club Road, West Palm Beach, FL 33406; Anupama Gopalakrishnan, PhD, 2800 Woods Hollow Road, Madison, WI 53711; Lotte Downey, MSc, 2800 Woods Hollow Road, Madison, WI 53711; and Douglas R. Storts, PhD, Promega Corporation, 2800 Woods Hollow Road, Madison, WI 53711*

After attending this presentation, attendees will be able to evaluate and implement both a Y-screening protocol for processing sexual assault samples and a direct amplification process of casework samples in their laboratories.

This presentation will impact the forensic science community by streamlining and simplifying the processing of DNA casework samples.

Current serological screening of sexual assault samples is time consuming and limited in sensitivity, especially when compared to amplification-based methods for the detection of male DNA. Current quantitative Polymerase Chain Reaction (qPCR) and Short Tandem Repeat (STR) amplification chemistries display significant improvements over previous chemistries due to the robust performance in the presence of PCR inhibitors commonly found in casework samples. This makes it possible to perform direct amplification from such samples without the need for a DNA purification step. Elimination of this purification step reduces both cost and the potential for loss of DNA during purification, especially with low-level DNA samples, and it streamlines the laboratory workflow.

The Casework Direct Kit provides a method for the rapid generation of lysates from casework samples, which may be subsequently used in amplification-based assays, such as the PowerQuant® System, to quantify the abundance of human DNA, determine the male/female DNA ratio, predict PCR inhibition, and assess degradation of the DNA. If preferred, the lysate can be used directly in an STR amplification assay to generate an STR profile.

In the case of sexual assault samples, the lysates are used in the PowerQuant® System to screen for the presence of male DNA. Based on this information, the analyst can decide to either perform a differential extraction of the sample, take the lysate directly into an STR amplification reaction, or choose to stop processing the sample.

Unlike direct amplification from a punch, quantification results from the lysate can be used to normalize template DNA in downstream STR amplification reactions. Processing samples with the Casework Direct Kit facilitates the generation of high-quality laboratory results by directing workflow decisions and minimizing repeat assays and/or sampling. The method is fast (less than one hour) and requires minimal hands-on manipulation due to the use of new and improved spin baskets during the incubation step. Data will be presented from Y-screening and mock casework applications, including touch DNA samples, an example of the ability to detect the presence of male DNA, and a full PowerPlex® Y23 System profile in a 96-hour post-coital sample.

Y-Screening, Sexual Assault Samples, Direct Amplification

B10 Evaluating the Success of DNA Analysis and Latent Print Examinations on Submitted Firearms

Karlee Rock, BA, 1328 Neel Street, Huntington, WV 25701; Victor Murillo, BA, Iowa DCI Criminalistics Laboratory, 2240 S Ankeny Boulevard, Ankeny, IA 50023; Season E. Seferyn, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be informed regarding statistical data compiled from casework performed at the Iowa Division of Criminal Investigations Criminalistics Laboratory involving latent print examinations and DNA analysis of firearms evidence.

This presentation will impact the forensic science community by encouraging attendees to draw conclusions from the presented data that may alter or change methods and/or procedures regarding submitted firearms evidence at their laboratories across the country.

A request for multiple examinations on firearms evidence has become more and more common across the country. The development of latent prints has been a reliable method of human identification for decades, while touch DNA is a newer investigative tool that is employed in forensic casework. Latent print examinations date back to the early 20th century, while touch DNA dates back to 1999 in the United Kingdom and 2003 in the United States. Nationwide, laboratories have seen approximately a 10%-15% success rate with both latent print examinations and touch DNA analysis on firearms. Other studies have confirmed that latent print and DNA methods have even lower success rates on ammunition.

This presentation analyzes the types of cases that were submitted to the Iowa Division of Criminal Investigation Criminalistics Laboratory. Included are 104 closed cases from 2015 in which firearms evidence was submitted in addition to requests for analyses other than traditional firearms testing. First, cases were sorted into the type of crime that was committed (crimes against a person, weapon offenses, drug related crime, and property crime) and the type of request (latent print examination, DNA analysis, or both) beyond the firearms examination. Of the 104 cases, it was found that 58% were subjected to latent prints only, 26% to DNA only, and 16% had both examinations performed. Crimes against people constituted 45% of the total cases; property crimes had the least amount of case submissions.

One hundred pieces of firearms-related evidence were sent for latent print examination. The majority of the evidence was either a pistol or a magazine from a pistol. Fifty latent prints were developed, and 39 were considered suitable for identification on 24 firearms. This resulted in a 24% success rate. Blood was found on eight firearms and one bullet; the DNA analysis resulted in nine complete profiles suitable for identification, resulting in a 100% success rate for DNA analysis on blood-related firearms evidence. Sixty-seven swabs from 41 firearms and four ammunition types were analyzed for touch DNA. Of these 67 swabs, 11 profiles resulted in the identification of a person, providing a 16% success rate for touch DNA analysis. The most common outcome was a mixed DNA profile that was too weak to interpret. This result was seen nearly 50% of the time.

This research suggests that similar studies be performed over several years to determine if the rate of success is maintained and also to determine if the percentages are consistent in a larger data set. Studies like these are imperative since there is an increasing demand nationwide regarding turnaround time due to backlogs; therefore, laboratories need to be aware of and use the most efficient identification methods available.

Latent Prints, DNA, Firearms

B11 The Persistence of Ignitable Liquids on Laundered T-Shirts

Michelle Corbally, MS, University of California, Davis Forensic Science, 1909 Galileo Court, Ste B, Davis, CA 95618; and Katherine D. Hutches, PhD, ATF, 355 N Wiget Lane, Walnut Creek, CA 94598*

The goal of this presentation is to illustrate the patterns of ignitable liquids on clothing (a commonly collected item in suspected arson cases) that has been washed and dried.

This presentation will impact the forensic science community by presenting samples to demonstrate the importance of noting whether or not clothing has been washed and dried prior to analysis.

When attempting to set fire to a material that is relatively difficult to ignite, a perpetrator may turn to an ignitable liquid to accelerate the growth of the fire. These ignitable liquids may potentially be spilled onto the clothes of the person who is pouring it. It has been questioned whether or not these ignitable liquid residues could be washed off in the course of laundering, as would be the case if someone was trying to eliminate evidence of having committed arson. This study sought to determine if ignitable liquids could be detected on cotton, polyester, and nylon T-shirts after they have been cleaned in a conventional residential washing machine.

Different volumes ranging from 10mL to 100mL of a 1:1 mixture of gasoline and diesel fuel, a Heavy Petroleum Distillate (HPD), were added to one-half of a T-shirt. This T-shirt fragment was inserted into the washing machine with another T-shirt fragment without ignitable liquids to test how efficiently ignitable liquids would transfer from one shirt to another. One detergent was investigated to determine if detergent has an effect on the retention of ignitable liquids on the T-shirts, relative to simple water immersion and agitation. A subsection of the test shirts was dried in a dryer to evaluate the extent to which any ignitable liquids remaining after washing with detergent would evaporate during the drying process. The presence of ignitable liquids was determined using passive headspace extraction with activated charcoal strips and Gas Chromatography/Mass Spectrometry (GC/MS).

Gasoline and/or an HPD could be identified on all of the samples spiked with 10 mL of the Standard Accelerant Mixture (SAM) for all washing conditions (water only, detergent added, and detergent with subsequent drying). At the 1mL spike level, at least one of the ignitable liquids in the SAM was potentially identifiable for the different washing conditions, but the fabric type had an observable effect on which ignitable liquid was identified. At 100µL, there were some indications of ignitable liquids on the cotton and nylon fabrics; however, for the polyester samples, ignitable liquids could not be identified once detergent was used and were detected at an even lower abundance once drying was incorporated.

The different fabric types, use of detergent, and volume of ignitable liquid each had an observable impact on the final appearance and identifiability of the ignitable liquids. These variables also affected the extent to which the components of the ignitable liquids transferred to secondary pieces of fabric. The transfer to secondary pieces of fabric and the surprising retention of ignitable liquids through laundering has potentially important implications.

This research was funded by the University of California, Davis Forensic Science Program and the Bureau of Alcohol, Tobacco, Firearms, and Explosives.

Ignitable Liquids, Laundry, GC/MS

B12 Trace Chemical Analysis of Potassium Permanganate Hypergolic Mixtures Analyzed With Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES)

Waldon Chen, BSc, 2970 Sugar Maple Drive, Virginia Beach, VA 23453; Joseph B. McGee Turner, PhD, Virginia Commonwealth University, 1001 W Main Street, PO Box 842006, Richmond, VA 23284; Eric Hazelrigg, MS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; and Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284*

After attending this presentation, attendees will understand the types of chemical variation among commercial sources of potassium permanganate that can be used to create incendiary mixtures. Attendees will also be introduced to the utility of trace element differences and their potential to determine the source of arson or explosive residues recovered as evidence.

This presentation will impact the forensic science community by presenting a new chemical signature system based on elemental profiles that may be used for the attribution of arson/explosive residues.

Hypergolic mixtures are self-igniting reactions that have been used for various types of criminal mischief as well as higher-profile terrorism-related incidents. They are a particular concern for law enforcement and the forensic science community as the ingredients are easily accessible and the reactions are simple to execute. Many current forensic techniques for analyzing hypergolic residues can identify the primary components, but provide little other information pertaining to their source. Few strategies exist for differentiating mixtures that have the same bulk chemical composition but are derived from different source ingredients (i.e., brands, commercial sources of the same product).

Therefore, the goal of this research was to characterize variations in trace element concentrations in the post-reaction residues of hypergolic reactions made with potassium permanganate and test whether different commercial sources of permanganate yielded distinct elemental profiles. Four different commercial sources of potassium permanganate were examined as well as three different mixing ratios of potassium permanganate with automotive brake fluid or glycerin as the fuel: 1:1; 2:1; and, 3:1 (grams:milliliter). Four replicate reactions were produced for each source-mixing ratio combination. The residues were then extracted using 2% trace metal-free nitric acid and analyzed using Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES) to determine the concentration of 24 different elements. The quantitation range was between 5ppb and 100ppm. Discriminant Function Analysis (DFA) was used to analyze the resulting chemical profile for each mixture sample and identify a subset of variables that optimized multivariate differentiation of each sample group. These included Na, Mg, Zn, Pb, Ca, Al, and Ba.

Results show that ICP/OES profiles of the two post-reaction residues from the analytical-grade permanganate sources could be differentiated by the concentrations of magnesium and calcium (~10 ± 0.1 ppb vs. ~6 ± 0.1 ppb and ~100 ± 2 ppb vs. ~50 ± 1 ppb, respectively). DFA of the trace metal profiles also exhibited clear separation between the two analytical-grade sources. Standardized function coefficients indicate that the elements that had the highest contribution to the differences were magnesium and calcium and, to a lesser extent, aluminum and sodium. The abundance of many elements decreased as the permanganate ratio increased. For example, the concentration of magnesium varied between ~14ppb ± 0.1ppb, ~8.6ppb ± 0.1ppb, and ~5.8ppb ± 0.1ppb for 1:1, 2:1, and 3:1 mixture samples, respectively. Furthermore, each mixing ratio group was resolved with two discriminant functions. This indicates that trace elemental profiles may be influenced by the source of oxidant as well as other individualizing aspects of the reaction, such as the mixing ratio. This research suggests that various brands of potassium permanganate can be differentiated by their trace elemental variations and that elemental profiles may be useful for characterizing the source of hypergolic mixture residues recovered during an investigation.

Hypergolic Mixtures, ICP/OES, Trace Metals

B13 Updates From the Drug Enforcement Administration National Forensic Laboratory Information System (NFLIS): Benzodiazepines Reported in the NFLIS — 2009-2015

DeMia P. Pressley, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Artisha Polk, MS, Drug Enforcement Administration, Office of Diversion Control, 8701 Morrissette Drive, Springfield, VA 22152; Liqun Wong, MS, 8701 Morrissette Drive, Springfield, VA 22152; Kevin Strom, PhD, 3040 Cornwallis Road, Research Triangle Park, NC 27709; Katherine N. Moore, MS, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; David Heller, BS, RTI International, 3040 E Cornwallis Road, RTP, NC 27709; Jeffrey M. Ancheta, BS, 3040 Cornwallis Road, Research Triangle Park, NC 27709; BeLinda J. Weimer, MA, 3040 Cornwallis Road, Research Triangle Park, NC 27709; Hope Smiley-McDonald, PhD, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709; and Jeri D. Ropero-Miller, PhD, RTI International, 3040 Cornwallis Road, PO Box 12194, Bldg 7, Rm 211, Research Triangle Park, NC 27709*

After attending this presentation, attendees will understand the breadth of information the NFLIS provides to the forensic science community.

This presentation will impact the forensic science community by providing specific knowledge of national and regional trends for selected benzodiazepines reported to the NFLIS between January 1, 2009, and December 31, 2015.

The NFLIS is a program of the Drug Enforcement Administration (DEA), Office of Diversion Control, that collects drug identification results from cases analyzed by federal, state, and local laboratories. The NFLIS participation rate, defined as the percentage of the national drug caseload represented by laboratories that have joined NFLIS, is currently more than 97%. Presently, the NFLIS includes 50 state systems and 101 local or municipal laboratories/laboratory systems, representing a total of 277 individual laboratories. The NFLIS database also includes federal data from DEA and United States Customs and Border Protection (CBP) laboratories. Results from the NFLIS are regularly used to support drug scheduling efforts and to aid drug initiatives, including the identification and tracking of emerging drugs of abuse.

National annual estimates for selected benzodiazepines, regional alprazolam, clonazepam, and diazepam trends, and selected benzodiazepines reported by federal laboratories are presented. This presentation will also highlight selected benzodiazepines of interest that are not approved for therapeutic use in the United States, counts of alprazolam reported with other drugs in the same item, and reports of clonazepam, phenazepam, and etizolam by state in 2009 and 2015.

Based on previously published NFLIS 2009-2014 data, a total of 369,738 benzodiazepine reports were identified by state and local laboratories. Alprazolam, clonazepam, and diazepam were the most commonly reported benzodiazepines during this period, with alprazolam accounting for 66% of all selected benzodiazepines. Phenazepam was first reported to the NFLIS in 2005 and had a total count of 302 reports between January 2009 and December 2014, and etizolam was first reported in 2012 and had a total count of 254 reports during that same period. Diclazepam was first reported in 2014 and by that year's end had a total count of two reports.

The NFLIS publicly shares data that can benefit management decisions of crime laboratories through various reports throughout the year, including special reports on such drug classes as presented in this presentation. The NFLIS provides a resource for the community to identify and respond to drug trends.

NFLIS, Benzodiazepines, Regional Trends

B14 Hand Odor Volatiles and Drug Abuse: A Pilot Study Using a Chemical-Dependent Target Group

Silas Kibet Kemboi, BA, Texas Tech University, 4434 S Loop 289, Lubbock, TX 79414; Megan Thoen, PhD, Texas Tech University, Institute for Forensic Science, 4434 S Loop 289, Lubbock, TX 79414; and Paola A. Prada, PhD, Texas Tech University, Institute for Forensic Science, 4434 S Loop 289, Lubbock, TX 79414*

After attending this presentation, attendees will better understand the usefulness of employing hand odor volatiles as an alternate bio-specimen for monitoring drug use using a criminal justice population.

This presentation will impact the forensic science community by providing a proof-of-concept study that uses a novel bio-specimen, such as hand odor, which has proven to be a valuable forensic tool with human scent canines, by extracting further traits (i.e., drug use bio-markers) from a single odor sample. Odor sampling could become another favorable sampling technique for use in forensic laboratories due to its non-invasive character as well as its low adulteration possibility during routine treatment programs mandated by court systems.

Different types of drugs are commonly sampled and detected in urine, sweat, blood, hair, and other biological materials of the human body; however, little or no information has ever been available on the physiognomies of drug excretion and detection in human hand odor under any controlled or designed drug admission.

The main purpose of odor sampling in this study was to obtain a chemical representative of the odor source in order to monitor drug use by the subjects. This pilot study was designed to "chemically fingerprint" different hand odor samples, their concentration, variability of the drug metabolite excreted, and dose dependency by human subjects undergoing court-ordered drug treatment programs at the Lubbock County Community Corrections Facility/ Court Residential Treatment Center (CRTC). Human odor was collected using Solid Phase Micro-Extraction (SPME) -gas chromatography and kept for 24 hours to allow maximum headspace volatilization before analysis. Due to the organic origin by nature, human odor contains Volatile Organic Compounds (VOCs) that are generated by the body and excreted through superficial pathways, such as skin. The collection method was a passive, contact-surface source (i.e., the mass flow from the cotton gauze into the headspace through volatilization of odor to achieve equilibrium distribution.) Gas Chromatography/Mass Spectrometry (GC/MS) was the main technique used to analyze the odor as carrier gas aids in the transfer of odor from the headspace into the analyzer. There were various types of drugs excreted in odor depending on the individual cases observed for each subject in this study.

A total of five male individuals receiving drug abuse treatment at the CRTC were monitored on a bi-weekly basis to obtain the chemical odor profile as a function of rehabilitation time. Detailed histories and subjective reports of chemical dependency of the individuals' substance use patterns were gathered for comparison with collected samples. To further obtain a baseline as to the types and amounts of volatiles observed, the same number of non-drug users were sampled to evaluate a drug free hand odor profile. It was hypothesized that a small number of drugs or their metabolites would be detected from odor samples following drug administration and would constantly increase upon repeated administration or lengthy abuse periods. Hence, due to the cessation of drug administration and use by the subjects at the facility, this resulted in decreased excretion and detection of drug-related volatiles and/ or their metabolites in the excreted hand odor over time.

Odor excretion can become an important mechanism that can be used to monitor drug use in forensic settings, other than its extensive detection by canine use. The data from this pilot study could be implemented to shift the already established drug testing sampling methods. Thus, hand odor can serve as an important non-invasive, low-adulteration method to monitor drugs of abuse among individuals in criminal justice settings.

Hand Odor, Drug Abuse, SPME-GC/MS

B15 Forensic Drug Analysis by Thermal Desorption and Pyrolysis Combined With Direct Analysis in Real Time-Mass Spectrometry (TDP/DART®-MS)

Hiroko Abe, MA, University of Chiba, Inohana, 1 8 1, Chuo-ku, Chiba-shi 260-0856, JAPAN; Chikako Takei, BioChromato Inc., 1 12 19, Honcho, Fujisawa-shi, Kanagawa-ken 251-0053, JAPAN; Yasuo Shida, PhD, BioChromato, Inc., 1 12 19, Honcho, Fujisawa-shi 251-0053, JAPAN; Motoshi Sakakura, PhD, AMR, Inc., 2 13 18, Nakane, Meguro-ku 152-0031, JAPAN; Teruhisa Shiota, AMR, Inc., 2 13 18, Nakane, Meguro-ku 152-0031, JAPAN; Kayako Suga, AB Sciex, 4 7 35, Kitashinagawa, Shinagawa-ku 140-0001, JAPAN; Daisuke Yajima, MD, University of Chiba, 1 8 1, Inohana, Chuo-ku, Chiba-shi 260-0856, JAPAN; and Hirotaro Iwase, PhD, Universty of Tokyo, 7 3 1 Hongo, Bunkyo-ku 113-0033, JAPAN*

After attending this presentation, attendees will understand the value of a TDP device combined with DART®-MS for the rapid identification and screening of forensic drugs in biological and autopsy specimens (e.g., urine and blood).

This presentation will impact the forensic science community by explaining how DART®-MS can be effectively applied as an identification and screening technique for the forensic drugs present in biological and autopsy specimens.

Drugs present in biological and autopsy specimens cannot be detected without first selecting the pretreatment and analytical conditions appropriate for the drugs. Thus, it is extremely important to investigate the analytical conditions suitable for specific compounds and samples; however, recently several new substances that threaten society have appeared one after another, including New Psychoactive Substances (NPS). It is very difficult to individually examine the analytical conditions that are appropriate for each new substance. Thus, a comprehensive analysis system for drugs that requires minimal investigation of pretreatment and analytical conditions is greatly desired. This study investigates an analytical technique for directly analyzing drugs in blood and urine that does not require any pretreatment.

The samples were standard drug mixture solutions and drug mixture-loaded blood and urine (i.e., blank blood and urine samples with several types of drug mixture added). Mass spectra were obtained by using a quadropole Time-Of-Flight (qTOF) mass spectrometry equipped with a DART® ion source and a TDP unit. The TDP unit was mounted between the DART® ion source and the mass spectrometry. This study assessed whether drugs could be detected by using this analytical system. Mass spectra were measured in positive-ion mode as the samples were heated from ambient temperature to 600°C at a rate of 100°C per minute.

Each drug was separated and detected through thermal gradient heating for all samples, and thermal desorption profiles were highly reproducible for individual drugs. The detected ions were correctly identified according to their measured accurate mass and product ion spectra. Moreover, this analysis system was deemed to have the potential of quantitative analysis for drugs, as the drug's ion intensity was increased with increasing drugs concentrations in the samples; however, the drug's ion intensity was decreasing in the order of standard drugs solution > urine-added drugs > blood-added drugs, even at the same drug concentration, with the drug's ion intensity being markedly reduced in blood in particular. Accordingly, the blood samples that were pretreated by using dispersive solid-phase extraction for removing phospholipid were analyzed, whereupon the drug's ion intensity was dramatically improved. Future research should continue to investigate pretreatment conditions and mass spectrometry conditions in order to further improve the detection sensitivity, with eventual application in real samples.

Forensic Drugs, DART®-MS, Thermal Desorption

B16 Semi-Quantitation of Trace Drug Residues on Fabric by Direct Analysis in Real-Time (DART®)

Samantha B. Josselyn, 908 Ashridge Court, Erlanger, KY 41018; and David Cunningham, PhD, Eastern Kentucky University, 5142 NSB, 521 Lancaster Avenue, Richmond, KY 40475*

After attending this presentation, attendees will better understand the sample introduction methods currently available for DART® systems and the recent progress toward obtaining semi-quantitative results for drug residues on fabrics. Fundamental aspects of the DART® source ionization and signal optimization will be reviewed along with options for extraction of drug residue from a variety of fabrics. Several examples of applications will be provided, including the analysis of trace amounts of methamphetamine and cocaine.

This presentation will impact the forensic science community by providing a sound fundamental description of currently available methods for sample introduction into DART® systems. While DIP-It™ glass tips and QuickStrip™ cards provide rapid analysis options for some types of samples, additional options based on membranes and paper disks will be presented. The potential advantages these options offer for several types of samples, including drug residue on clothing, floor coverings, and upholstery, will be described.

The general approach is to add an internal standard solution to cloth and re-absorb the solution using an absorbent material in the shape of a disk. The amount of internal standard solution added to the fabric is matched to the diameter of the absorbent disk to maximize recovery of traces of drug that dissolve in this applied internal standard solution. Initial screening studies were performed with ink-jet printer paper, cellulosic membrane material and glass fiber membranes. Conditions were developed that resulted in reasonable recovery with all types of absorbent disks. After re-absorption, the disks were allowed to dry and were placed between the DART® source and the mass spectrometer entrance. For rapid analysis in the DART® instrument, the disks must allow interaction of the energized gas from the DART® source with the extracted trace drug residue and internal standard. So, prior to use, a portion of the disk was removed using a hole punch or a craft cutter to allow gas to flow through the membrane. Removal of 20%-40% of the disk had a minimal effect on the amount of drug and internal standard recovered, but greatly enhanced the magnitude of the DART® signal. Also, the patterned membrane disks gave signal intensities that were much greater than found with the commercially available sample introduction systems, namely the DIP-It™ glass tips, which are dipped into liquid solutions, and QuickStrip™ cards, which consist of a metal wire mesh.[1] Presumably, the surface area of the patterned membrane is much larger than the surface area of either the glass tip or wire mesh, allowing ionization of much more drug and internal standard.

Comparison of the peak heights of protonated-parent ions associated with several drugs of interest (i.e., methamphetamine and cocaine) with the peak height of the internal standard allowed quantitation of the amount of drug traces in cotton fabric at the five-microgram level. Studies were performed using a Simplified Voltage and Pressure (SVP) ion source interfaced to an LTQ XL™ linear ion trap mass spectrometer with data analysis using the Thermo Xcalibur™ software. Custom holders were constructed and placed inline between the DART® source outlet and the ceramic tube leading to the Vapur™ flange before the inlet to the mass spectrometer. Key operating parameters, including the DART® source temperature, were characterized over the range of 200°C-500°C.

In summary, the extraction of drug residues from fabric with patterned absorbent disks in addition to the use of an internal standard in the extraction solution is a promising approach for semi-quantitation of small amounts of drug residue in a variety of fabrics.

DART®, Drug Analysis, Trace Analysis

B17 Microcrystalline Tests for Emerging Drugs of Abuse

Matthew Quinn, West Chester University of PA, 750 S Church Street, Schmucker Science, S, Dept of Chemistry, West Chester, PA 19383; and Monica Joshi, PhD, West Chester University, Dept of Chemistry, Schmucker Science, S, 750 S Church Street, West Chester, PA 19383*

After attending this presentation, attendees will be able to describe the steps used to develop and validate new microcrystalline tests. Attendees will be informed of the development of a database of microcrystalline tests for emerging drugs.

This presentation will impact the forensic science community by providing a detailed study of microcrystals observed for an array of emerging drugs of abuse. This presentation discusses performance characteristics of the tests, such as precision and selectivity. The forensic science community will be able to assess the tests for practical applicability.

Forensic laboratories have used microcrystalline tests both as preliminary and confirmatory tests when presented with unknown substances. A microcrystal representative of the substance being studied results from the formation of a temporary complex between the precipitating reagent and the substance. The crystal shape, habit, and optical activity are often used as parameters to identify the substance. Tests for cocaine, heroin, and amphetamines are very well documented. The tests are simple and rapid, requiring minimal sample manipulation. Creating an ideal environment for reproducible crystal growth has its challenges. Factors such as pH, concentration, humidity, and interfering compounds can all play a role in determining the quality of crystal growth. When these factors are studied and described, microcrystalline tests can be very valuable as screening tests and, with expertise, serve as confirmatory tests.

Recently, numerous substances with psychoactive properties have emerged as drugs of abuse. Despite the advantages discussed for microcrystalline tests, they have not been studied extensively for these substances. A recent compendium of microcrystals for various drugs and pharmaceutical substances describes tests for piperazines and crystal growth in mixtures.[1] More such studies are needed to understand the behavior of other emerging drugs with traditional microcrystalline test reagents.

This presentation describes a systematic evaluation of microcrystalline tests for 32 emerging drugs of abuse categorized into the following classes: cathinones, phenethylamines, opioids, piperazines, and others. A previous presentation discussed the feasibility of the study and demonstrated crystal formation for some compounds.[2] This follow-up presentation is an expanded study and discusses the performance characteristics of the individual tests. Each substance was studied with seven reagents to determine tests that provide reliable crystal formation. Effects of pH, concentration, temperature, and interferences on the crystal habit are presented. Mixtures of closely related substances affect the crystal formation in a concentration-dependent manner. Understanding crystal deformations in mixtures of two or more compounds is useful when heterogeneous samples are presented. All of this information is used to create a database of microcrystals for several emerging drugs of abuse.

Microcrystalline Tests, Psychoactive Substances, Emerging Drugs

B18 The Development of a Characterization Scheme for Emerging Synthetic Phenethylamines

Alexandria Anstett, BS, East Lansing, MI; David Alonso, PhD, LECO Corporation, 1850 Hilltop Road, St. Joseph, MI 49085; A. Daniel Jones, PhD, 219 Biochemistry, East Lansing, MI 48824; and Ruth Waddell Smith, PhD, Michigan State University, School of Criminal Justice, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will be familiar with the development of a characterization scheme that can be used to assign new synthetic phenethylamine analogs according to structural class. The scheme is based on mass spectral data and uses isotope patterns, neutral losses, and mass defects to define the structural class.

This presentation will impact the forensic science community by providing a tool that can be used to screen emerging analogs to determine the likely designer drug class. While this initial work focuses on synthetic phenethylamines, similar characterization schemes can be developed for other designer drug classes.

The identification of synthetic designer drugs by conventional Gas Chromatography/Mass Spectrometry (GC/MS) methods is challenging due to the high degree of structural similarity among members of a given class. For example, the 2C-phenethylamines consist of a core 2,5-dimethoxyamphetamine structure, but compounds within this series differ in the position and identity of substituents on the aromatic ring. Such modifications to the core structure create compounds that have similar psychoactive effects but may not be regulated under current legislation. As a result, new analogs rapidly appear on the market to circumvent current legislation and no reference standards are immediately available to aid in the identification.

The objective of this study was to develop a characterization scheme to assign emerging analogs to a designer drug class such that more resources can be focused on definitive identification, as necessary. This initial study uses synthetic phenethylamines as the model class to develop such a characterization scheme. A set of 2C-phenethylamines that included alkyl, halogen, and nitro substitutions on the aromatic ring was analyzed by Gas Chromatography/Time-Of-Flight/Mass Spectrometry (GC/TOF/MS). This high-resolution instrument uses electron ionization, insuring that the fragmentation patterns obtained are similar to those obtained by the more conventional GC/MS instruments currently used. Further, the exact mass of each molecular (when detected) and fragment ion is determined from which elemental formulas can be assigned with a high degree of confidence.

To begin developing a suitable characterization scheme, the mass spectral data for each 2C-phenethylamine were probed to identify common features. These features included isotope patterns, neutral losses, and mass defects of characteristic ions. Isotope patterns in the mass spectra were used to identify the presence of chlorine and bromine. Neutral losses from each molecular ion were determined and losses common to all 2C-phenethylamines in the training set were identified. These losses included CH_3N, C_2H_6N, and C_2H_6NO, which were measured as neutral losses of 29 Da, 44 Da, and 60 Da, respectively, from the molecular ion. Finally, the Kendrick mass defect of the fragment ion remaining after each neutral loss was calculated. For example, for the loss of $CH_3N\bullet$, the Kendrick mass defect filter based was defined as 85.96 mDa ± 0.7224 mDa, at the 95% confidence level.

The characterization scheme was then applied to a prediction set containing additional 2C-phenethylamines, other synthetic phenethylamines, and synthetic cathinones, which are structurally similar to the phenethylamines. Spectra for the test set were interrogated first for isotope patterns and, second, for the characteristic neutral losses previously identified. For those test set compounds that displayed the targeted neutral losses, the Kendrick mass defect of the remaining fragment ion was calculated and tested against the previously developed filter. Overall, the characterization scheme showed promise for initial screening of 2C-phenethylamines, despite some false positives and negatives.

This presentation will demonstrate the characterization scheme in the form of a flow-chart and further discuss the development and application of the scheme for the characterization of 2C-phenethylamines.

Synthetic Phenethylamine, High-Resolution MS, Mass Defect

B19 Portable Trace Vapor Sampling With Field-Capable Porous Layer Open Tubular (PLOT) -Cryoadsorption

Megan Harries, BS, NIST, 325 Broadway, Boulder, CO 80305; and Thomas J. Bruno, PhD, NIST, 325 Broadway, Boulder, CO 80305*

After attending this presentation, attendees will be able to apply a portable (briefcase-mounted) vapor sampling instrument based on PLOT-cryoadsorption to trace vapors of explosives, fuels, drugs, fuels, pollutants, and so forth.

This presentation will impact the forensic science community by enabling the use of a very rapid, yet very sensitive, dynamic trace vapor sampling method that facilitates comprehensive rapid vapor collection for qualitative identification and quantitative determinations of low uncertainty.

Building on the successful application in the laboratory of PLOT-cryoadsorption for collecting trace vapor samples, a robust portable instrument suitable for field conditions is presented.[1-4] The unit mounts in an aluminum briefcase, easily transported by vehicle or by air. The instrument functions entirely on compressed air, making it suitable for use in locations lacking electrical power, and for use in flammable and explosive environments. The three major functional aspects of the instrument will be discussed: (1) the field-capable PLOT-capillary platform; (2) the supporting equipment platform; and, (3) the interface with the necessary peripherals. The PLOT-capillary platform used in the portable unit differs from the lab unit in that it uses a high-flow multipath module that is highly robust. Vapor sampling can be conducted with either a wand-like hand piece (containing the PLOT module) for close sampling or with a special standoff module for more remote sampling. In both cases, the PLOT module can be heated and cooled to facilitate vapor collection and subsequent vapor sample removal. The interface (between the support platform and the sampling units) features a unique countercurrent approach to minimize thermal loss. Several types of PLOT-capillary elements and sampling probes are described, and applications to a variety of samples relevant to forensic analysis will be discussed.[5]

To demonstrate the capabilities of the portable unit, trace vapors were sampled from coumarin (a drug), the explosive 2,4,6-trinitrotoluene (solutes used in initial development of PLOT-cryo technology), naphthalene, aviation fuel, and diesel fuel on a variety of matrices and test beds. It was demonstrated that trace vapors from these analytes can be easily detected and reliably identified using the portable unit. By leveraging efficiency-boosting temperature control and the high-flow-rate multiple capillary wafer, very short collection times (three seconds) yielded accurate detection. For diesel fuel spiked on glass beads, a method detection limit below 1ppm was determined.

Current work in which vapor sampling inside of a large volume, closed chamber shows that quantitative performance is somewhat more uncertain than the lab version of PLOT-cryo (approximately 1%, mass/mass), but the portable unit nevertheless provides lower uncertainty than conventional purge and trap methods.

Headspace Analysis, PLOT-Cryoadsorption, Trace Vapor Sampling

B20 An Examination of Hypergolic Mixtures Involving Potassium Permanganate and Select Fuels

Stephanie R. Harrold, BS, 601 Vairo Boulevard, Apt 822, State College, PA 16803; and Wayne Moorehead, MS, 329 Whitmore Laboratory, University Park, PA 16802*

After attending this presentation, attendees will better understand what types of chemicals can be used to create hypergolic mixtures, the types of evidence that a hypergolic reaction may leave at a crime scene, and how changing a single variable, such as the type of fuel added to the mixture, can change both the reaction and the post-combustion material (residue).

This presentation will impact the forensic science community by providing a framework for the examination and analysis of specific hypergolic mixtures, the threat they present to the public, and possible avenues of analysis to obtain as much relevant information as possible from hypergolic residues.

Bombings due to criminal and terrorist activities are in the news on a weekly or daily basis. The heightened alertness of law enforcement and security personnel does not seem adequate to prevent the destructive actions of terrorists when explosive materials are so easily obtained. Hypergolic mixtures are chemicals useful for retail or commercial purposes but, when mixed, create a type of oxidation-reduction reaction that results in spontaneous combustion, without the need for external ignition. Hypergolic mixtures can be created with a number of different oxidant and fuel combinations. Based on a literature search, little research has been published exploring the time to reaction, temperature, and the variety of commercial products involved in initiating these reactions. These mixtures are very simple to construct and are made with materials that are readily available for purchase, such as pool chlorine, pool shock, water softening chemicals, and fuels, such as brake fluid or antifreeze.

Typically, a delay in the combustion reaction occurs after the reactants are mixed. This delay can allow a person to leave the area before the reaction occurs. After combustion, the post-burn products may include the remnants of the containment vessel and the post-burn hypergolic products. Original ingredients may also be present.

This study involves the creation and examination of the hypergolic mixture of potassium permanganate (a strong oxidizer) and selected fuels, including polyethylene glycol, ethylene glycol, and glycerin. Potassium permanganate can be found in select water softening chemicals. Polyethylene glycol has several uses in cosmetics, pharmaceuticals, commercial products, and industry. Ethylene glycol can be used as antifreeze and in the fiber industry in the manufacture of polyester fibers. Glycerin has uses in the food, pharmaceutical, and chemical industries.

Hypergolic mixtures were created and recovered on a small scale (approximately 0.5g of powdered potassium permanganate and approximately 0.25mL of a chosen fuel) in open Pyrex® glass petri dishes (100mm x 15mm) in a fume hood (with a flow of at least 100fpm) to explore the reactions and analyze the residues. After a brief period, typically less than one minute, a small flame with white smoke occurred that moved across the mixture. After the reaction, the resulting products were examined visually, with the aid of a stereo light microscope, with a diamond-attenuated total reflectance Fourier Transform Infrared (FTIR) spectrometer and by a Gas Chromatograph with a Mass Spectrometer (GC/MS) detector.

The small-scale reactions were varied to determine optimal ratios. The resultant ratio of 2:1 weight/volume (g/ml) of potassium permanganate to liquid fuel consistently produced combustion. Still images and video recordings captured the reactions. The video recordings showed differences in both the speed and duration of combustion.

Preliminarily, the results of hypergolic mixture residues analyzed by FTIR, which has been used as a discriminatory technique for explosive residues on other types of explosives, may not have the discriminating power necessary to identify post-combustion products to determine original reactants. The GC/MS data will also be presented.

Hypergolic, Potassium Permanganate, Alkyl Glycols

B21 A Comparison of Headspace Cannabinoid Profiles Detected From Different Structures of Dried Cannabis Inflorescences

Austin L. McDaniel, BS, Sam Houston State University, 851 Elkins Lake, Huntsville, TX 77340; Jorn Chi-Chung Yu, PhD, Sam Houston State University, Dept of Forensic Science, Box 2525, Huntsville, TX 77341; and James D. Sweet, PhD, US Customs and Border Protection, LSSD, 4150 Interwood S Parkway, Houston, TX 77032*

After attending this presentation, attendees will better understand the variations in cannabinoid profiles detected from different structures of dried cannabis inflorescences as well as the effect of homogenizing the plant matter on intra-sample variation.

This presentation will impact the forensic science community by providing evidence that homogenization of plant material samples for marijuana yields profile results with less variation when generating headspace cannabinoid profiles.

Marijuana is one of the most common drugs analyzed in a forensic laboratory. When analyzing marijuana, which may be composed of dried plant materials of *Cannabis sativa*, there are several structures of the plant that can be sampled for chemical analysis. The leaves, stems, and buds are the main structures present in the majority of both legal and illegal marijuana samples; however, not all of these dried cannabis plant materials have the same concentration of cannabinoids, such as Δ9-tetrahydrocannabinol (Δ9-THC), Cannabinol (CBN), and Cannabidiol (CBD). Marijuana in its natural state is not a homogenous sample. Sampling from different plant structures within the same marijuana sample may lead to various cannabinoid profiles for that sample. A solution to reduce intra-sample variation is to make the plant material more homogenous by grinding the sample.

In this research, reference marijuana samples (N=14) obtained from the National Institute of Drug Abuse (NIDA) with known concentrations of Δ9-THC and CBD were tested. Headspace cannabinoids of marijuana were extracted by Heated Headspace/Solid-Phase Microextraction (HHS-SPME) and headspace cannabinoid profiles were then obtained by using Gas Chromatography/Mass Spectrometry (GC/MS). Each reference marijuana sample was divided into two groups. Group A was analyzed by HHS/SPME-GC/MS without any sample preparation. Group B samples were homogenized using an herb grinder before HHS/SPME-GC/MS. Using a stereomicroscope, samples in group A were first divided into sub groups of stems and leaves. Each of these structures was documented and verified. Plant materials containing only one type of structure collected from different structures of cannabis inflorescences were weighted (10mg) and transferred to the headspace vials for HHS/SPME-GC/MS. The peak area of major cannabinoids, Δ9-THC, CBD, and CBN, were recorded for comparison. Finally, each sample in group A was also run as a mixture of structures (leaves, buds, and stems) and the cannabinoid profiles of each were compared to the profiles of group B.

The results of the experiment illustrate that samples collected from different plant structures in the same batch of dried cannabis inflorescences exhibited variations of headspace cannabinoid profiles. The whole sample containing both stems, leaves, and other structures presented a higher level of intra-sample variation in Δ9-THC peak areas compared to the samples containing only one type of plant structure. The ground sample registered the lowest level of intra-sample variation in Δ9-THC peak areas when compared to the single-structure samples and the multiple-structure samples. In order to obtain more consistent headspace cannabinoid profiles for marijuana by the HHS/SPME-GC/MS approach, the selection of single structures of cannabis inflorescences from marijuana samples will be discussed in this presentation.

Marijuana, Homogenization, Headspace SPME

B22 Validation of Various Fingerprint Processes in a Medium-Size Municipal Laboratory

Dave Castle, BS, 675 10th Street, Huntington, WV 25701; Catherine G. Rushton, MSFS, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; Ted Smith, MS, Marshall University Forensic Science Center, 1401 Forensics Drive, Huntington, WV 25701; Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701; and Amanda A. Wilberg, BS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand the processes for validating fingerprint methods for a medium-sized municipal laboratory while trying to complete the quality requirements necessary to achieve the International Organization for Standardization (ISO) accreditation.

This presentation will impact the forensic science community by providing a benefit for the Huntington Police Department Forensic Investigations Unit (HPD FIU) that will lay the foundation for the laboratory's workflow and the product it generates.

According to the 2009 National Academy of Sciences Report, Recommendation 7, laboratory accreditation should be mandatory and follow the standards published by the ISO. There are many different types of methods utilized to visualize latent prints, and they all need to be tested in order to see which is best suited for the HPD FIU.

This project includes non-porous, porous, adhesive, and blood processes, with many different methods for each process. Each process must be used in the proper sequence of a series of development techniques or risk the possibility of destroying certain matrix components that react with subsequent processes. If one method is performed out of order, the fingerprints could be underdeveloped or even destroyed. The HPD FIU has to be very careful in order to preserve a possible fingerprint and allow it to be detected. Validating these methods allows the HPD FIU to know if the method works for its intended use or if there is another that is better suited.

Validations of fingerprinting processes and methods will allow this medium-sized municipal laboratory to become accredited through ISO 17020 standards. Five data sets were generated for each method and results were evaluated based on the method's ability to be visualized. A result of a positive (able to see ridge detail) or a negative was noted for each to ascertain if any ridge detail was seen. To offer proof that these tests function accordingly or produce inadequate results, pictures or possible prints were kept in order to be accredited through the American Society of Crime Laboratory Directors/Laboratory Accreditation Board (ASCLD/LAB) by the ISO 17020 for crime scene response.

Three validations were to be produced for each method, but unforeseen circumstances developed. Unfortunately, the unit lost some employees, resulting in a problem getting tests validated twice more in a timely fashion, due to casework. Once the two other validations are completed, those results will create a new decision as to whether or not the methods are valid to use in this laboratory.

Additionally, new methods were tested and validated for implementation in the workflow of the medium municipal laboratory. Some of the new methods, such as 1,2-indanedione and acid fuchsin, are now validated for utilization in the laboratory. The saying, "You always get the good with the bad," came into play here, as there were four methods that were found to be no longer useful for this laboratory, which will save the laboratory money. These methods include Coomassie Blue, 5-MTN, ThermaNin, and Oil Red O. D.F.O did not work well either, but future use is being evaluated by the laboratory.

Nearly all of the fingerprint methods produced results that were expected. The few that did not meet expectations were D.F.O., 5-MTN, Oil Red O, and ThermaNin; however, 5-MTN, Oil Red O, and ThermaNin were new products to this laboratory and did not produce the results the products' manufacturers stated they would. The validation of these methods helped the HPD FIU in the accreditation process as well as discovering which methods produce better results.

These and other details of the study will be discussed.

Fingerprints, Validation, Accreditation

B23 An Appropriate and Practical Sample Preparation Procedure for Clean-Up and Analysis of Explosives Residues

Hui Si Lim, 11 Outram Road, Singapore, Singapore 169078, SINGAPORE*

After attending this presentation, attendees will better understand an appropriate and practical Solid-Phase Extraction (SPE) procedure for the analysis of explosives residues.

This presentation will impact the forensic science community by establishing streamlined clean-up procedures for the recovery of explosives residues.

The detection of trace explosive residues from post-blast scenes has always been challenging in the forensic field, due to possible high matrix interference from the background of the scene, trace amounts of explosive residues left after the blast, and the wide range of possible compounds used by the perpetrator. Thus, there is a compelling need to develop an efficient extraction procedure for clean-up and analysis of samples.

An optimized single-step SPE procedure was reported by Nopporn Song-im et. al. involving four target organic explosives and two inorganic anions.[1] In this study, an SPE method will be utilized for sample clean-up and analysis of a wide range of analytes. A suitable solvent system and SPE adsorbent will be determined to effectively retain the target organic explosive analytes while allowing inorganic explosive analytes to be eluted. The target organic explosive analytes will then be eluted in subsequent steps. Other parameters of the SPE method will also be optimized. Liquid Chromatography coupled to high-resolution accurate mass Orbitrap mass spectrometer (LC-Orbitrap) and Gas Chromatography coupled to a Mass Spectrometer (GC/MS) will be used for the analysis of organic explosive analytes while Ion Chromatography (IC) will be used for the analysis of inorganic analytes. This SPE sample preparation method will provide efficient clean-up of the samples. The resultant effluents are compatible with multiple types of instrumental analysis for a wide range of explosive analytes.

Explosives, Extraction, SPE

B24 Seeing Through Noise: Investigating Information Sampling and Weighting in Fingerprint Recognition

Silke Jensen, University of Leicester, Dept of Criminology, 154 Upper New Walk, Leicester, Leicestershire LE1 7QA, UNITED KINGDOM; Doug Barrett, PhD, University of Leicester, Henry Welcome Bldg, School of Psychology, Leicester, UNITED KINGDOM; and Lisa L. Smith, PhD, University of Leicester, Dept of Criminology, 154 Upper New Walk, Leicester, Leicestershire LE1 7QA, UNITED KINGDOM*

After attending this presentation, attendees will better understand the visual processes at the root of fingerprint examination and comparison. Understanding the perceptual processes that underlie pattern recognition in fingerprint examination can lead to improvements in recruitment, training, and examination guidelines, as well as error mitigation.

This presentation will impact the forensic science community by improving understanding of the perceptual processes that underlie pattern recognition in fingerprint examination.

The present research seeks to model and compare the manner in which fingerprint examiners and naïve observers sample and weight information across different fingerprint regions. This research also investigated whether any differences in information sampling and weighting are due to: (1) differences in the information available in the print; (3) learned differences in expertise; or, (3) general perceptual biases.

Artificially generated fingerprints were presented as experimental stimuli to control for low-level cues of identity (e.g., luminance, contrast, and/or size information). Fingerprint stimuli consisted of a central core and a peripheral region. Each region could be independently manipulated, meaning that the core could be drawn from a different fingerprint identity than the periphery. The boundary of the regions was masked to avoid completion cues. Additionally, Gaussian noise masks were used to simulate the loss of detail typically encountered in latent prints. In a 2-Alternative Forced-Choice (2AFC) recognition task, a target and probe display were presented serially, for one second each, with a one-second inter-stimulus interval. To examine information sampling across the core and periphery regions, the relationship between the target and distractor was manipulated using five conditions: (1) only the core region is visible (core-only); (2) only the peripheral region is visible (periphery-only); (3) only the core region changes (core-change); (4) only the peripheral region changes (periphery-change); and, (5) both regions change (both-change). Additionally, three core-to-periphery size ratios were used to assess information weighting across the fingerprint regions. Participants, consisting of naïve observers as well as fingerprint examiners at different levels of experience, indicated their recognition response (match/no match) and response confidence (six-point scale) after every trial.

Initial results were analyzed using Signal Detection Theory, and models describing the weighting and integration of information from the core and peripheral regions will be presented. Additionally, the potential impact of these findings on fingerprint training, recruitment, and examination guidelines will be discussed.

Fingerprint Examination, Visual Processing, Information Sampling

B25 Gold Nanoparticles (AuNPs)/Aptamer-Based Paper Microfluidic Devices Developed for the Detection of Cocaine

Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199; and Ling Wang, MS, Florida International University, CP-304 11200 SW 8th Street, Miami, FL 33199*

The goal of this presentation is to describe the development of AuNp/aptamer-based paper microfluidic devices for the presumptive determination of cocaine in acid and base form. Information provided will include the optimized design of the paper chip and the validation of this device.

This presentation will impact the forensic science community by demonstrating the application of this newly designed paper microfluidic device in the presumptive detection of cocaine. This new method is rapid, inexpensive, and specific toward the cocaine molecule.

Over the past ten years, a number of specifically targeted aptamers have been developed to identify illicit drugs. The most common detection methods involve Ultraviolet/Visible (UV/Vis) spectroscopy or gold nanoparticles. These tests were developed as rapid solution-based tests, similar to immunoassays; however, these tests are less convenient for field use. Many of these kits require infrastructure to keep and store the reagents because they can be sensitive to temperature, light, and age. An alternative platform for AuNPs/aptamer detection based on paper microfluidic devices has been investigated. A new chip design has been created that adapts the AuNPs and aptamers to a ready-to-use format. In the field, samples are dissolved in a carrier solvent in vials and then applied to the paper just before analysis. The devices can be used at crime scenes, in laboratories, and at any other locations where the suspected powders may occur. The paper chips are easy to prepare and inexpensive to operate. Furthermore, they can be conveniently stored for later uses.

The paper microfluidic devices are prepared using a wax-ink printer, thermal laminator, chromatography paper, aptamers, and gold nanoparticles. The wax-ink printer and a thermal laminator produce hydrophilic channels defined by melted wax on the paper. Next, gold nanoparticles and aptamers are prepared for the channel. Cocaine samples in acid/basic form are dissolved in solutions, then transferred to the chips. Cocaine next travels down the channel via capillary action, interacting with the aptimers and causing a color change to occur due to the aggregation of the nanoparticles. When cocaine is not present, the nanoparticles cannot aggregate and no color change occurs as aptimers are then free to bind gold. The entire process takes approximately five minutes. The applied aptamer is specific for cocaine. This presentation will also report a preliminary validation of this device, including tests for sensitivity, specificity, and stability against a variety of potential interferences.

The use of paper microfluidic devices permits the development of rapid, inexpensive, and easily operated tests for cocaine samples. These devices present a safe and convenient presumptive tool that can be used in the field.

AuNPs/Aptamer, Cocaine, Paper Microfluidic Device

B26 The Analysis of 2,5-Dimethoxy-N-(N-methoxybenzyl)phenethylamine (NBOMe) Isomers Using Traditional and Fast Gas Chromatography/Mass Spectrometry (GC/MS)

Jay T. Davidson, BS, West Virginia University, 21 Marion Street, Apt 101, Morgantown, WV 26505; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will better understand NBOMes and their analysis via traditional and fast GC/MS. The concepts of retention time, retention index, relative ion abundance, and characteristic ion ratios will be discussed, as well as an assessment of the relative contribution of various factors on the relative ion abundances of the different isomers.

This presentation will impact the forensic science community by providing attendees with characteristic ion ratios for the ortho, meta, and para isomers of 25C- and 25I-NBOMes. Additionally, the effect of tune file on each analysis as well as the assessment of the variability of relative ion abundances through repeated analyses will assist attendees through a more comprehensive understanding of their casework. Finally, the conserved nature of the characteristic ion ratios between traditional and fast GC will further validate the use of fast GC as a means of seized drug analysis.

It is hypothesized that each NBOMe isomer has a unique retention time (and therefore retention index) and Electron Ionization (EI) fragmentation pattern that can be used to successfully identify each isomer from a series of possibilities. Additionally, it is proposed that although the tune profile will have an impact on the data, it will not be statistically significant in practice. Finally, it is hypothesized that the developed characteristic ion ratios will be conserved between both traditional and fast GC/MS.

In this project, the analysis of NBOMe isomers was conducted using both traditional and fast GC/MS. NBOMes are synthetic phenethylamine derivatives that have become increasingly popular throughout the world. Due to their hallucinogenic potency being derived from their structure, the ability to differentiate NBOMe isomers is becoming increasingly important.

For the purpose of this research an Agilent GC/MS was used for both the traditional and fast analyses. The traditional analyses were performed with a 30m HP-5 column in less than 30 minutes, while the fast GC analyses were performed with a 10m VF-5MS column in less than seven minutes. Standards of the ortho, meta, and para isomers of both 25C- and 25I-NBOMe were obtained from the Drug Enforcement Administration (DEA). The retention times, retention indices, relative ion abundances, and characteristic ion ratios were determined using both traditional and fast GC/MS. Furthermore, the variability of the relative ion abundances was assessed through repeated analyses of each NBOMe isomer standard. Finally, an evaluation of the effect of the tune profile on each analysis was performed.

One-way Analysis of Variance (ANOVA) was performed to evaluate the significance of different factors on the within-factor to between-factor variance. The factors that were assessed include positional isomers, day of analysis, week of analysis, tune profile, and speed of GC. The variables that were used to assess these factors include the retention time, retention index, absolute peak areas, relative ion abundances, and characteristic ion ratios.

It was determined that each NBOMe isomer had a different statistically significant (α=0.05) retention time, retention index, and characteristic ion ratios. Additionally, the variability of relative abundances through repeated analyses of each NBOMe isomer standard was captured. Finally, it was determined that the tune profile does not have a statistically significant effect on the variables assessed

Seized Drugs, Fast GC, EI Fragmentation

B27 Profiling the Use of Explosives in Automated Teller Machine (ATM) Robberies in Brazil

Joao Carlos L. Ambrosio, MSc, Brazilian Federal Police, Edificio INC SPO Quadra 7 Lote 23, Setor Policial Sul, Brasilia, Distrito Federal 70610-200, BRAZIL; Lucio L. Lograd o, MS, Brazilian Federal Police, SPO Quadra 7 Lote 23, Setor Policial Sul, Brasilia 70610-200, BRAZIL; and Natália H. Puentes, BS, Brazilian Federal Police, SPO Quadra 7 Lote 23, Setor Policial Sul, Brasilia, Distrito Federal 70610-200, BRAZIL*

The goal of this presentation is to describe the first attempt to create a database of the use of explosives in ATM robberies in Brazil. This presentation endeavors to shed light on possible solutions to the epidemic use of explosives in ATM robberies.

This presentation will impact the forensic science community by presenting actual case evidence of the use of explosives in Brazil and by introducing the first relevant data on which types of explosives are commonly used, in addition to exploring regional tendencies of different explosives.

The Explosives and Post-Explosives Section of the Central Laboratory of the Brazilian Federal Police has routinely analyzed samples collected at post-blast scenes of ATM robberies in Brazil and has used the data available to try to create a more concrete picture of which explosives are more commonly used, where they are used, and the *modus operandi* of these criminals.

Since 2007, Brazil has experienced an exponential growth of the use of explosives to breach ATM cash machines. Although statistics are unreliable as there is no unified bomb data center, some states have reported an increase of more than 200% in the number of attacks since 2010. According to the Brazilian Bank Federation (FEBRABAN), in the three-year span from 2009 to 2012, approximately 2,500 Brazilian ATM's were targeted with explosives, an average of 833 per year. As a result of this increase, banks have adopted various measures to rectify this situation, such as stronger vaults, spray painting the bank notes in case of an explosion, and even an agreement with the army to provide a convoy to protect the transport of explosives (it is estimated that 1,000kg of explosives are stolen every year from mining companies). Unfortunately, none of the proposed solutions have generated positive results.

In the past three years, the Explosives and Post-Explosives Section of the Central Laboratory of the Brazilian Federal Police has analyzed 49 cases of post-blast events related to ATM robberies. In 2016 alone, 14 reports were written and another 11 cases are pending analysis. The first glaring problem is that such a number represents only about 0.5 percent of post-blast cases in Brazil during the same period, so it is clear that most cases either were not sent to a forensic laboratory for determination of the explosive or, even worse, were not processed at all.

The analyses were performed using a Dionex™ ICS-5000 ion chromatographer for inorganic residues, an AB Sciex API 3200™ system coupled with an APCI probe for organic explosives, and an energy-dispersive X-ray spectroscopy with an FEI Quanta 200 3D to detect metals, primarily aluminum, in the composition of the explosives.

In 61% of the cases (30 events), the thieves used chlorate/perchlorate-based explosives as the main charge, whereas emulsions, mainly Ammoniun Nitrate Fuel Oil (ANFO), was used in 25% of the cases (12 events). Only twice were organic explosives detected. In one case, a Triacetone Triperoxide (TATP) booster was recovered unexploded and, in another case, a small sample of a Pentaerythritol Tetranitrate (PETN) cord was recovered from the crime scene. These results are preliminary and do not represent an accurate portrayal of the problem, since nearly half of the cases (47%) were sent from only one state, Minas Gerais. Hopefully, in time there will be sufficient data from other states to be able to provide more accurate statistics.

The Explosives and Post-Blast Section has implemented technical training for forensic experts to increase the number of ATM explosions that are adequately processed in Brazil. Some patterns are beginning to emerge and, hopefully, with more information, a realistic database will be created to help investigators better understand the *modus operandi* of these criminals.

Explosives, ATM Robbery, Chemical Analysis

B28 The Development and Preliminary Validation of an App for Recording and Interpreting Colorimetric Drug Test Results

Kelly M. Elkins, PhD, Towson University, Chem Dept & Forensic Science Program, 8000 York Road, Towson, MD 21252; Thomas Boise*, 506 Cedarcroft Road, Baltimore, MD 21212; Alicia Quinn, BS; and Subrata Acharya, PhD, Towson University, 7800 York Road, Ste 425, Towson, MD 21252*

After attending this presentation, attendees will be aware of the availability and capabilities of a new smartphone application to aid in recording and interpreting colorimetric drug test results.

This presentation will impact the forensic science community by demonstrating the ability of an app for Apple® and Android™ devices and software that runs on a Personal Computer (PC) and a Raspberry Pi that aids in the interpretation of colorimetric drug test results and also standardizes and secures testing records.

Millions of suspected drug-related crimes are reported annually in the United States. Colorimetric drug tests are used to aid in the identification of the substances, based upon their reactivity and the colors rendered with the test reagents.

A database of Red, Green, and Blue (RGB) three-point numerical colors for over 3000 colorimetric test-drug combinations has been recorded and uploaded to the app. Assigning numerical RGB values to the colors standardizes the color record and enables the use of an algorithm to search for the color in the database. The application searches the database and matches the results using a Euclidian distance algorithm or another algorithm designated by the examiner. The display lists the results. The suggested matches based upon the closest set of RGB values in the database are listed in rank order with accuracy of prediction for evaluation by a technical expert. The crime laboratory or another examiner can be consulted about the results in real-time through the secure server.

This study investigated colorimetric drug test results for 800 unique drug/test combinations. Three versions of the software were on a PC and a Raspberry Pi. The software has been tested on Samsung Android™ and Apple® iPhone® devices, a Dell™ PC and a Raspberry Pi B+. The Raspberry Pi, purchased from the Raspberry Pi Foundation, runs a Linux-based operating system, "Raspbian." The RGB value is determined using the ColorAssist app with the device camera light or using a mini spectrometer connected via the USB port. ColorAssist was demonstrated to outperform other similar apps for this purpose in a recent study. The software is a technical solution to limitations of visualizing color at crime scenes and due to constraints of human vision differences, training, and experience of the examiner. The apps also allow the user to view previous test results by date and time and to add case notes. Interpretation of controlled substances and drug standards via tests performed on different replicates, different days, by different examiners, and with different devices will be discussed. The functionality of the apps and results of a preliminary validation of seized substances using the software will be presented.

Smartphone App, Apple® iOS®, Android™

B29 Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Detection of Cocaine in Packaging Residue

Jonas Widness, Saint Olaf College, 1520 Saint Olaf Avenue, Northfield, MN 55057; Jason Dickmeyer*, Saint Olaf College, 1520 Saint Olaf Avenue, Northfield, MN 55057; and Douglas Beussman, PhD, Saint Olaf College, Dept of Chemistry, 1520 Saint Olaf Avenue, Northfield, MN 55057*

After attending this presentation, attendees will understand the potential for LC/MS/MS to be used as a fast and accurate method to detect the presence of cocaine from very small amounts of adulterated powder residue.

This presentation will impact the forensic science community by illustrating the ability of LC/MS/MS to be used in forensic investigations as a fast and reliable method to analyze powder samples that may contain illicit drugs, such as cocaine.

In modern forensics investigations, common evidence of drug possession comes in the form of powder residue from packaging materials. Previous research has shown LC/MS/MS can be used to detect and quantify trace amounts of methamphetamine from packaging residue. This study proposes that Liquid Chromatography coupled with TOF Mass Spectrometry can also be used to detect minute amounts of cocaine within powder residue. Common drug packaging materials, such as zip-lock bags, may only have very small amounts of residue on them, and the drug itself may be impure. Powdered street drugs like cocaine are almost invariably mixed with adulterants, which reduce the amount of drug present in the powder residue and could make drug detection more difficult. The primary objective of this study was to determine lower Limits of Detection (LOD) and lower Limits of Quantitation (LOQ) for cocaine from bag residue when cut with different adulterants.

In order to test the efficacy of this method, cocaine hydrochloride powder was cut with nine commonly used adulterants, creating samples with cocaine amounts ranging from 0.1% to 4% by mass. One gram of each sample was loaded into a 1in-square zip-lock bag, then emptied, leaving behind approximately 10mg of residue. The bags were rinsed out with 1mL 18MΩ nanopure water, which was then diluted 100-fold and mixed with an internal standard of 10ppm D3-cocaine. Each sample was run using an Agilent® 1100 series binary pump liquid chromatograph coupled to a Bruker® Compact quadropole Time-Of-Flight (qTOF) mass spectrometer. Analysis was performed using Bruker® QuantAnalysis 2.2, and results were compiled in Microsoft® Excel®.

To unambiguously confirm the presence of cocaine, MS/MS was used to obtain fragmentation mass spectra of all ions with the *m/z* of cocaine and D3-cocaine, which were matched with literature fragmentation mass spectra of cocaine and D3-cocaine. LOD and LOQ were obtained for each of the nine adulterants tested. Calibration curves were created for each adulterant by correlating the cocaine: internal standard ratios with the percentage of cocaine in the samples. LOD ranged from 0.11% to 0.65% by mass, while LOQ ranged from 0.37% to 2.16% by mass.

This study explored the ability of LC/MS/MS to detect cocaine from packaging residue. Cocaine could be detected down to a purity as low as 0.11% by mass, from residue amounts averaging 10mg. Most real-world cocaine samples contain a far purer drug than the obtained LOD values, qualifying this method as a sufficiently sensitive cocaine detection tool. Adulterant properties such as water solubility and affinity for the inside of the bags appeared to influence the sensitivity of this method, but all LOD values were below 1%.

Trace Drug Detection, Cocaine, LC/MS/MS

B30 Direct Thermal Desorption Coupled to Gas Chromatography/Mass Spectrometry (GC/MS) for the Characterization of Organic Firearm Discharge Residues

William Feeney, BS, 801 Second Street, New Martinsville, WV 26155; Lindsay Cheeseman, 108 3rd Street, Apt B, Morgantown, WV 26505; and Suzanne Bell, PhD, West Virginia University, Oglebay Hall, Rm 208, 1600 University Avenue, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand how thermal desorption may be used to characterize organic Gunshot Residue (GSR).

This presentation will impact the forensic science community by providing an overview and method validation data for a new way of characterizing organic GSR using GC/MS instrumentation.

The development of powerful new hybrid mass spectrometry systems has led to renewed interest in targeting the organic constituents of Firearms Discharge Residue (FDR). Several methods have been published in the last decade reporting on the analysis of organics found in FDR using Liquid Chromatography/Mass Spectrometry (LC/MS). The mass spectrometers used include Time-Of-Flight (TOF), quadrupole Time-Of-Flight (qTOF), and Triple quadrupole (QqQ) designs. For LC/MS analysis, a substrate such as a hand swab is typically extracted, concentrated, and introduced into the chromatographic system and analytes such as Diphenylamine (DPA), ethyl and methyl centralites, and dinitrotoluenes and other diphenylamines are detected. Forensic laboratories are adopting advanced LC/MS instrumentation, but in most cases these instruments are devoted to toxicological assays, which presents real-world limitations for adaptation to routine casework. Conversely, forensic laboratories often have greater access to GC/MS, but the detection limits of even the best of these systems for extracted samples is often too high to be used with the same type of extracts often used for LC/MS. This problem is difficult to alleviate procedurally, even using multiple extractions, drying, and selected ion MS; however, thermal desorption has already been shown to be useful as an inlet for FDR types of analysis using ion mobility spectrometry and pre-concentration using Solid-Phase Microextraction (SPME) and similar techniques.

This study reports on the development of a direct thermal desorption method as an inlet for GC/MS analysis of hand swabs collected on clean room wipes. A commercial Thermal Separation Probe (TSP) was used to hold swabs as they were placed directly into the injection port of the GC. Desorption proceeded over ~30 seconds while the GC column was held at room temperature. Samples were then eluted using a temperature program and detected using Selected Ion Monitoring (SIM) of three to four ions per target compound. An internal standard and surrogate spikes were utilized for semi-quantitative analysis and recovery monitoring, respectively. Ethyl centralite and diphenylamine were the most frequently detected compounds, with swab recoveries estimated at >65% based on surrogate spike data. Limits of detection corresponded to µg quantities, which is comparable to what is expected to be deposited by realistic forensic shooting scenarios. The results for several shooting experiments using different weapons, ammunition, and number of shots will be presented, along with method development and validation, figures of merit, and instrumental parameters.

Organic Gunshot Residue, Thermal Desorprtion, GC/MS

B31 Fabric Phase Sorptive Extraction (FPSE) Media: A Novel Forensic Sample Collection and Storage Device

Abuzar Kabir, PhD, Florida International University, 11200 SW 8th Street, AHC4-215, Miami, FL 33199*

After attending this presentation, attendees will have a thorough understanding of the fabrication, working principle, and advantages of FPSE media as a forensic sample collection and storage device for accumulating fluidic samples from different crime scenes as the potential evidence of the crime, storing them for a prolonged period of time, if necessary, and analyzing them using chromatographic separation and mass spectrometric identification in order to obtain chemical profiles of the collected samples.

This presentation will impact the forensic science community by assisting those who are actively looking for a better alternative to conventional approaches of collecting fluidic samples from crime scenes. Future adaptation of the proposed forensic sample collection device as a standard practice will potentially minimize the majority of the sampling-related errors that often compromise the quality of the forensic evidence and consequently brings into question the admissibility of the evidence to a court of law.

Although recent decades have witnessed an exponential growth in modern analytical equipment possessing superior sensitivity, higher resolution, portability, and exceptional selectivity that synergistically help in solving forensic criminalistics cases faster with higher confidence, little progress has been conducted in standardizing a universal forensic sample collection protocol and tool thereof. Due to the lack of such a universal protocol and a sample collection media, crime scene sample collection teams often use a non-standard sample collection medium, such as cotton gauze, to collect fluidic samples from the crime scene as the potential chemical evidence. These non-standard sample collection tools often fail to collect pertinent chemical information from the collected sample in order to complement the criminal investigation and may be thrown out by the court of law due to inferior quality as forensic evidence.

FPSE media, developed by Kabir and Furton, have eloquently addressed a majority of the hurdles often experienced by the forensic sample collection team, such as variability between different collection media, the inability to retain chemical information for a prolonged period of time, and a lack of standard sample collection protocols, among others.[1] FPSE sample collection media are prepared using flexible fabric substrate (cellulose/polyester/fiber glass) coated with high-efficiency, sol-gel hybrid inorganic-organic sorbents. Due to the ultra-thin film of the robust sorbent system, the FPSE media retains its flexibility. The chemical bonding between the substrate and the sol-gel sorbent network offers unprecedented mechanical and chemical stability to the sample collection device. As such, the FPSE media can be used to wipe any fluidic forensic sample from the crime scene, even from uneven surfaces. The sponge-like porous architecture of the sol-gel coating on the FPSE media allows rapid permeation of the fluid through its body for effective analyte-sorbent interaction, leading to the successful accumulation of the chemical information of the suspect sample. Due to the strong interaction between the analytes and the FPSE sorbents, the FPSE media containing the chemical information can be stored at ambient conditions under proper chain of custody without risking any potential loss of the chemical information. A small volume of organic solvent can be used to desorb collected analytes for chromatographic profiling.

Analytical data obtained from a number of real-life applications of FPSE sample collection and storage media mimicking different crime scene samples, including blood and saliva, will be presented, showcasing the advantages of FPSE forensic sample collection and storage media.

Forensic Sampling, FPSE, Sample Collection

B32 The Identification and Quantification of Sexual Lubricant Degradation Pathways From Exposure to the Vaginal Bacterial Environment

Danielle Green, BS, 2761 Blowing Breeze Way, Orlando, FL 32820; and Candice Bridge, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand how the vaginal bacterial environment can degrade sexual lubricants and change their chemical composition prior to laboratory analysis. The goal of this presentation is to educate the forensic trace evidence community on how lubricants collected can differ from the known source over time based on bacteria and how to address that issue in casework.

This presentation will impact the forensic science community by bridging the gap in knowledge regarding the characterization of residual lubricant degradation and by describing how degradation from microbial exposure affects the identification and comparison of condoms and sexual lubricants for forensic and judicial purposes.

Due to the use of DNA analysis for identification in criminal acts, an increasing number of offenders are using condoms to mask their identity from law enforcement. During the act of coitus, lubricant found on the condom can be transferred to the victim. In forensic lubricant analysis, the major components of lubricants are used as indicators of the presence of sexual lubricants. The major components of lubricants can include Polydimethylsiloxane (PDMS), Polyethylene Glycol (PEG), and Nonoxynol-9 (N-9). These normal alkane and aromatic compounds can be degraded, into smaller components, by the bacteria that is natural to the vaginal cavity.[1,2]

In order to maintain a healthy environment, the female genital tract will maintain stable conditions using bacteria with the ability to produce lactic acid. This lactic acid-producing bacteria, which includes members of the *Lactobacillus, Pseudomonas*, or the *Megasphaera* species, keep the pH at the desired levels and keeps out any disease-causing microorganisms. The lactic acid production from these bacteria can use residual lubricants that remain in or near the vagina as a possible energy source, thus leading to sample degradation, which can change the original chemical composition. The degradation caused by microbial exposure makes it necessary to understand how the microbes degrade the condom lubricant components and how the degradation changes the overall chemical profile of the lubricant.

The degradation of a common lubricant, PEG, was studied using a common vaginal microbe, *Pseudomonas putida* (*P. putida*). PEG was inoculated with *P. putida* and the resulting samples were collected over a four-day period. Chemical degradation was determined with the use of a Direct Analysis in Real Time-Time-Of-Flight/Mass Spectrometer (DART®-TOF/MS). The DART®-TOF/MS was selected for this analysis primarily based on the direct MS analysis. This instrument can analyze individual components in the sample simultaneously with high resolution and accurate mass measurements, which provides a high degree of discrimination between samples. Coupled with the short run time and minimal sample preparation of the DART®-TOF/MS, the instrument is ideal for analysis of degraded and non-degraded lubricant samples.

Preliminary data suggest the *P. putida* bacteria will degrade the lubricant component over a period of three to four days before the lubricant chemical profile is no longer detectable. Based on this information it is necessary to determine how other common bacteria affect PEG, PDMS, or the condom lubricant as a whole. This information can provide the forensic science and sexual assault investigation communities with a new analytical timeline for vaginal samples collected after a sexual assault.

DART®, Microbial, Degradation

B33 Application of Gas Chromatography-Vacuum Ultraviolet (GC-VUV) Spectroscopy in the Analysis of Synthetic Cathinones

Angelica D. Szewczak, BS, 8105 Leon Street, Philadelphia, PA 19136; Cory A. Vaught, BSc, The George Washington University, 3905 Davis Place, NW, Apt 102, Washington, DC 20007; Jonathan P. Smuts, PhD, VUV Analytics Inc, 715 Discovery Boulevard, Ste 502, Cedar Park, TX 78613; Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand characteristics of synthetic cathinones, problems surrounding current methods of analysis for these compounds, principles of VUV spectroscopy, and the application of this instrumental analysis to synthetic cathinones.

This presentation will impact the forensic science community by providing an additional and complementary method of analysis for emerging drugs, such as synthetic cathinones. VUV methodology will be particularly valuable for previously problematic analysis of positional isomers of synthetic cathinones.

Gas Chromatography/Mass Spectrometry (GC/MS) is a standard method of analysis for synthetic cathinones; however, GC/MS, as well as alternative Liquid Chromatography/Mass Spectrometry (LC/MS), often show limitations in the differentiation between isomers with the same molecular weight (positional isomers and diastereomers) that may co-elute and/or have identical mass spectra.

In order to address this limitation, new detectors have begun to emerge, including the introduction of VUV. This instrument rapidly measures absorption in the range of 115nm to 240nm. One distinct advantage to VUV is the unique ability to probe the excitation energy associated with electrons forming most single bonds (σ à σ^*) as well as monitor some π à π^* bond transitions. VUV also has the ability to deconvolute multiple co-eluting compounds when the spectra are different and properly added to the working library. This is extremely valuable for screening and confirmation purposes and could lead to faster separations where resolution is sacrificed. GC-VUV, which combines the high resolving power of GC with a detector that can provide a unique spectrum for a given compound, appears well suited for the analysis of emerging drugs, such as synthetic cathinones.

Comparisons of 35 spectra taken from multiple classes of synthetic cathinones were examined, including spectra from ten sets of positional isomers. Synthetic cathinones provide a unique UV spectrum. This was particularly valuable for the identification of positional isomers. For solutes differentiated by MS, VUV provides useful complementary information. VUV also allows for unique overall VUV patterns for different classes of synthetic cathinones, proving to be very useful in the analysis and identification of unknown compounds. In some instances, VUV can also tell substitution in the aromatic position. The potential for quantitative analysis, the repeatability of VUV detection, and the effect of concentration on spectral identification will be described.

GC-VUV, which provides excellent peak shapes and high specificity of detection, is well suited for the analysis of synthetic cathinones. In order to accomplish good chromatographic performance, de-salting of the analytes is required, which is easily accomplished by the addition of sodium bicarbonate to the methanolic sample solution.

GC-VUV, Synthetic Cathinones, Positional Isomers

B34 Our Future Reflects Our Past: The Evolution of Criminalistics

Patrick Buzzini, PhD, Sam Houston State University, Chemistry/Forensic Science Bldg, 1003 Bowers Boulevard, Box 2525, Huntsville, TX 77314; Rebecca E. Bucht, PhD, Pietarinkatu 11 A 13, Helsinki 00140, FINLAND; Peter R. De Forest, DCrim, Forensic Consultants, PO Box 141, Ardsley, NY 10502; Douglas M. Lucas, DSc*, 5280 Lakeshore Road, #1111, Burlington, ON L7L 5R1, CANADA; Pierre A. J-L. Margot, PhD*, University of Lausanne, Ecole de Sciences Criminelles, Batochime, Lausanne 1015, SWITZERLAND; Claude Roux, PhD*, Univ of Technology Sydney, Centre for Forensic Science, PO Box 123, Broadway, NSW 2007, AUSTRALIA; and Sheila Willis, PhD*, Forensic Science Ireland, Garda HQ, Phoenix Park, Dublin , IRELAND*

After attending this presentation, attendees will gain deeper knowledge and insight on the evolution of the practice of criminalistics from the perspectives of experienced and knowledgeable forensic scientists. This presentation will engage attendees in discussions regarding the current state of criminalistics. Experienced forensic scientists on the panel will share their views of the past development of criminalistics, their views on current practices, and their visions for the future evolution of this field.

This presentation will impact the forensic science community by increasing awareness of present issues in the field that developed from the past and by offering insights into possible tracks that may lead to the future evolution of criminalistics.

Criminalistics has evolved on many fronts, resulting in an increase in the demand for its services, in the number and size of forensic laboratories, and also in the number of academic programs offering undergraduate and graduate degrees in forensic science. Efforts in the area of laboratory accreditation, expert certification, and proficiency testing have contributed to improving the quality of the analytical work being conducted. These, along with continuing technological advances, are obviously perceived as positive developments. The services delivered have progressed from microscopical comparisons of trace evidence items, through application of advancements in science, such as wet chemistry analytical and serological techniques, to sophisticated instrumental and digital analyses, which allow for greater and greater sensitivity and specificity. The result has been a massive increase in the reliability of the results presented to the criminal justice system. The introduction of DNA and the related developments has been the paradigm shift in this era. What is the future of criminalistics? Who does define the path of criminalistics — criminalists themselves or outsiders from the field? How can one learn from the past of criminalistics to define its future?

Criminalistics was seen as multifaceted by pioneers at the turn of the 20th century. The focus was on tiny details, trace materials that could provide clues to a hidden and uncertain past, otherwise inaccessible. As highlighted by the historian Carlo Ginzburg, who noticed the change of paradigm that occurred with Freud's psychoanalysis, Morelli's art studies … and Sherlock Holmes, a philosophical and historical movement was underpinning the views of pioneers who saw the perspectives offered and opened by the study of "signs." Whereas some, like the Austrian magistrate Hans Gross, saw the tactical aspects offered in the form of an investigative science (which he incidentally called "criminalistics") as well as the value of these signs in the form of evidence, others, such as Alphonse Bertillon, saw their value in classifying, identifying, and creating databases, leading to police files, or Edmond Locard and later Paul Kirk, as a form of clinical science with laboratory support. These categories were not rigid; even if they reflected each pioneer's background, knowledge, and vision. During the 20th century, this was taken up by practitioners with little vision or power to develop the astonishing potential of this new "science" and it is only now that science is reclaiming its ground over test providers and other administrative organizations to offer new perspectives in detecting crime phenomena through detection, intelligence, and databasing (strategic and tactical dimension), as well as support for evidential purposes. The future, in that perspective, may not be what law enforcement administrators want or what the legal profession perceives. Currently, isn't the forensic laboratory conceptualized as a mere testing facility focusing exclusively on associative evidence problems rather than more general scientific problem-solving with the total physical evidence record? Isn't there too much emphasis on the question of "who" being addressed? Wouldn't notions such as transfer, persistence, and alterations coupled with an appreciation of background, contamination, and preservation of the recovered trace materials be needed for the evaluation of the significance of findings?

This special session will engage attendees in discussions regarding the current state of criminalistics.

Foundations, History, Current Practice

B35 Implementing 3D Virtual Comparison Microscopy Into Forensic Firearm/ Tool Mark Examinations

Erich D. Smith, MS, Federal Bureau of Investigation, 2501 Investigation Parkway, Rm 4340, Quantico, VA 22135; and Heather J. Seubert, MS, FBI Laboratory, Firearms/Toolmarks Unit, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the validation method used to evaluate 3D instruments for virtual comparison microscopy, the method used to incorporate these technologies into traditional forensic firearms/tool marks examinations, and the capabilities of using 3D technology for training, examination verification, and blind verification/testing.

This presentation will impact the forensic science community by demonstrating the effectiveness of 3D technologies for integration into forensic firearms/tool marks examinations. The topics covered will include how the Federal Bureau of Investigation (FBI) Laboratory Firearms/Toolmarks Unit (FTU) has been tasked with evaluating 3D technologies for validation and incorporation into casework.

The FTU has been conducting a validation study for the incorporation of various 3D platforms into operational casework as another tool to assist in the examination of ammunition components. It is anticipated that having these technologies available will enable efficiency for cases with a high number of submitted components, provide additional training aids, and also provide larger-scale views of information captured for the examiner's examination and review. A portion of the validation study was to determine if a qualified firearms/tool mark examiner could successfully determine, using virtual comparison microscopy, the correct answers to previously distributed proficiency tests and consecutively manufactured test sets. The FBI Laboratory has a repository of Collaborative Testing Services® (CTS), Inc. firearms proficiency tests previously distributed to evaluate the FTU for quality assurance. Ten of these proficiency tests were selected, with test distributions spanning from 2003 to 2012. Some of the test participants had previously taken these proficiency tests using traditional optical comparison microscopy. All proficiency test samples, including the three knowns submitted for evaluation, were provided random identifiers for virtual microscopic comparison. Additionally, three test sets were assembled using consecutively manufactured slides from the FBI Laboratory Consecutively Manufactured Slides and Barrel Collection (CMSBC), which is used for training and research. Consecutively manufactured Ruger®, SR9 slides were selected using Winchester® ammunition to create test samples. Each consecutively manufactured test set consisted of ten cartridge cases with randomly assigned identifiers for virtual comparison. The participants contributing to this study ranged in years of experience and included qualified examiners and examiner trainees.

The Cadre® Forensic TopMatch-GelSight instrument uses the Bidirectional Reflectance Distribution Function (BRDF) to acquire 3D surface images and was acquired by the FBI Laboratory in 2014. The system's software allows for side-by-side evaluation of surface topographies and matching algorithm search capabilities for topography similarities. For this virtual comparison microscopy evaluation study, test participants did not have access to the matching algorithm to assist in reaching a conclusion. Test participants were given operating instructions on GelSight prior to conducting test examinations. Results were recorded by the individual test participant on an answer key and they were encouraged as well as the incorporation into the Firearms/Toolmarks Unit's standard operating procedures and implementation into casework as an alternative to traditional comparison microscopy.

3D Technology, Firearms, Virtual Comparison

B36 A Framework for Firearm Tool Mark Population Statistics

Xiaoyu A. Zheng, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Johannes A. Soons, PhD, NIST, 100 Bureau Drive, MS 8223, Gaithersburg, MD 20899; and Daniel Ott, PhD, NIST, 100 Bureau Drive, Mail Stop 8212, Gaithersburg, MD 20899*

After attending this presentation, attendees will better understand a potential pathway toward developing firearm tool mark population statistics.

This presentation will impact the forensic science community by providing a potential statistical framework for reporting error rates in firearms and tool mark identifications.

The population statistics describe the frequency distributions of a similarity score for, respectively, same-source comparisons and different-source comparisons of ballistic samples, such as cartridge cases and bullets. Similar to DNA analysis, these distributions are needed to establish a statistical foundation for the estimation of identification confidence limits and error rates. An important component of the proposed research is to systematically evaluate, for different firearm populations, the effects of key processing parameters on the comparison score distributions and associated error rate estimates. Conducting this research will play an important role in determining the extent to which the comparison protocol, population statistics, and error rate estimation need to be tailored to a particular firearm subpopulation.

Firearms from five manufacturers were chosen for this research. These include a minimum of 50 firearms each from Sig Sauer®, Ruger, Smith and Wesson®, Glock®, and Colt®. The breechface impression on 568 test-fired cartridge cases were measured from 284 firearms. Distributions for known match and known non-match comparison scores were generated for all the samples, for each firearm model, and for each breechface class characteristic. Furthermore, the effects of key processing parameters on these distributions were evaluated. The distributions were applied to estimate the respective cumulative false positive and false negative error rates. The proposed framework will enable evaluation of other similarity metrics and the dynamic update of distributions when new data becomes available.

Using the improved processing parameters, the National Institute of Standards and Technology (NIST) will be able to continue entering new batches of firearm comparison results into each of the established populations to create continually growing "living distributions." These can be used to estimate cumulative false positive and false negative error rates for each subpopulation and will play an important role in assessing the strength of the evidence for a particular comparison. Results provide guidance for the collection of new data and enable further research into whether or not groups of firearms or class characteristics converge to the same statistical model and processing parameters. The data and framework can be applied to generate distributions for other tool mark identification metrics and guide their development. The conclusions drawn from this research serve as a stepping stone to answering important questions regarding subpopulations and the role they play in firearm identification error rates and data processing parameters. While not covered in this research, the protocol used can be applied to other tool mark regions of interest, such as firing pin and land impressions. There is also a potential for this research to be applied in other pattern evidence disciplines, such as fingerprint and shoe print identification.

Firearms, Tool Marks, Populations

B37 Performance Evaluation and Calibration Artifacts for 3D Ballistic Imaging

Michael T. Stocker, National Institute of Standards and Technology, 100 Bureau Drive, #8212, Gaithersburg, MD 20899; Johannes A. Soons, PhD, NIST, 100 Bureau Drive, MS 8223, Gaithersburg, MD 20899; Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; Thomas B. Renegar, BS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; and Xiaoyu A. Zheng, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the fundamental metrological requirements for a smooth transition of 3D ballistic imaging from research to application in crime laboratories.

This presentation will impact the forensic science community by providing a roadmap to practitioners for obtaining accurate and traceable surface topography measurement results of ballistic samples in crime laboratories. A new effort at the National Institute of Standards and Technology (NIST) is working toward providing instrument performance evaluation specifications, performance evaluation procedures, and custom reference artifacts tailored to objective tool mark identification.

A promising approach to improving objective tool mark identification is the direct optical measurement of 3D sample surface topography; however, forensic laboratories seeking to implement this new approach are faced with several challenges. There is no guidance on instrument performance specifications that address the challenges and requirements of tool mark identification. Consequently, when a crime laboratory compares instrument specifications, it is difficult to determine which system is most appropriate for its measurement needs. Furthermore, there is no guidance on the type and frequency of tests that the laboratory needs to conduct to ensure that the instrument performs to specification and to establish traceability of measurement results. Finally, many physical reference artifacts for testing surface topography measurement devices are not compatible with the instruments and sample mounts designed for forensic applications and are time consuming to apply.

NIST is addressing these challenges by first developing a detailed performance-specification document, explicitly defining instrument performance parameters relevant to forensic tool mark metrology. This document will enable a laboratory to make informed decisions when specifying and comparing 3D optical instruments for ballistic imaging purposes. The specification will address relevant performance parameters, such as the instrument transfer function, lateral and vertical measurement accuracy, stitching performance, maximum measurable slope, and environmental conditions.

The main part of the project is focused on the design of a set of ballistics-oriented test procedures and physical reference standards that enable a forensic laboratory to validate the specified instrument performance. The standards are complementary to the NIST Standard Reference Manuals (SRMs) 2460 (standard bullet) and 2461 (standard cartridge case) and are envisioned as having the shape and dimension of a cartridge case to facilitate their application. The process control and calibration artifacts will be made available in one set, calibrated at NIST and International System of Units (SI) traceable. The set will likely include roughness standards, step height standards, 2D grids, and a reference flat. The specifications, test procedures, and reference artifacts addressed by this project are critical in establishing traceability of tool mark measurement results in forensic laboratories.

This presentation will outline the primary components of the performance evaluation specification detailed above and will present initial designs of the new ballistics-oriented physical reference standards.

Tool Mark, Topography, Standards

B38 Determining the Angle of Impact From the Analysis of Bullets Following Perforation of Glass

Roger Jefferys, BS, 27 Dafonzo Hill Road, Pursglove, WV 26546; and Keith B. Morris, PhD, 208 Oglebay Hall, 1600 University Avenue, PO Box 6121, Morgantown, WV 26506-6121*

After attending this presentation, attendees will better understand how applying different methodologies in analyzing a bullet can assist investigators in determining the position of a suspect in the reconstruction of a shooting incident, specifically in situations where that bullet has perforated a glass target.

This presentation will impact the forensic science community by providing a quantitative measure in analyzing and interpreting bullet evidence for future use in the courtroom.

When two objects come into contact with one another, there is a potential for the transfer of material between those objects. The goal of this research was to develop statistical models to aid investigators in the reconstruction of a shooting incident. Specifically, the determination of the direction of fire from the bullet's angle of impact was addressed by assessing the deformation of the bullet and the transfer of glass onto the bullet.

Transfer of material to bullets is an underexploited area of trace evidence. Current research has mainly been observational, and no attempt has been made to provide a quantitative measure to the results.

Four aspects of bullet deformation after perforation of a glass target were studied during this research: (1) the shape of the bullet holes; (2) the side view of bullet deformation; (3) the frontal view of bullet deformation; and, (4) the distribution of glass onto the bullets. A Ruger SR9 9mm pistol was used to fire 100 cartridges at individual glass targets at angles of 45º, 50º, 60º, 75º, and 90º using Winchester® 115 grain, 9mm, Luger® full metal jacket factory ammunition and reloaded lead round nose ammunition consisting of 115 grain Missouri Bullet Company bullets, 4.1 grains of Hodgdon® Titegroup powder, and Sellier & Bellot® 4,4 small pistol boxer primers.

The following methodologies were employed for image capture and analysis: (1) focus stacking using Zerene Stacker to generate high-quality images of the frontal view of the bullet; (2) analysis of the bullet holes in the glass targets using HemoSpat; and, (3) analysis of bullet deformation and distribution of glass onto bullets using ImageJ. Regression modeling and principal component analysis were performed on the data. The research found that examining bullet holes in glass is not a viable method for determining angle of impact. It also found that the side view deformation of full metal jacket bullets can be used to distinguish between some impact angles, for example, 90º and 65º, but cannot be used for lead round nose bullets. Furthermore, the front view deformation and distribution of glass on full metal jacket bullets can be used to distinguish between some impact angles, for example, 75º and 50º, but cannot be used for lead round nose bullets.

Bullets, Angle of Impact, Shooting Reconstruction

B39 The Determination of Critical Angle in Automobile Windshield Glass Using 9mm Luger® Ammunition

Peter J. Diaczuk, Penn State University, 329 Whitmore, State College, PA 16802; and Tara L. Goldfrank, MS, 930 5th Avenue, Apt 7E, New York, NY 10021*

After attending this presentation, attendees will better understand the characteristics of automobile windshield glass and how it reacts to bullet impacts. Attendees will also be aware of the type of ammunition used in these experiments and the factors influencing bullet perforation or bullet ricochet off a windshield.

This presentation will impact the forensic science community by exploring the angle necessary for a bullet to perforate or ricochet after impacting a windshield, which has implications in examining a shooting scene involving an automobile.

An understanding of bullet ricochet is a vital part of deconstructing shooting scenes; however, a bullet's ricochet depends on many factors, the totality of which may not be replicated from one scenario to the next. This presentation deals with bullet ricochet off windshield glass. All variables were held constant with the exception of incident angle, which is the angle at which a projectile impacts the target surface. The angle at which the projectile leaves the substrate is the ricochet angle. When a bullet strikes a target, it may perforate or penetrate the substance, fragment into pieces or ricochet off the surface. Ricochet is the change in direction of a bullet's trajectory after impact with a surface. Each surface has an angle called the critical angle, below which a projectile will ricochet. The critical angle is dependent upon each type of surface. The inability to generalize is due to the fact that there are many factors that affect the ricochet of a bullet, such as incident angle, impact velocity, bullet shape, bullet weight, bullet hardness, bullet center of gravity, the hardness of the impact surface, and the response of that surface to the bullet's impact. It is important to note that not only do the characteristics of the bullet have an effect on the ricochet, characteristics of the impact surface do as well. Both need to be analyzed in cases of ricochet.

Laminated glass, which is used on automobile windshields, is composed of a thin polyvinyl plastic layer sandwiched between two pieces of glass. The glass is bonded to the plastic by heat and pressure. The layers are then secured to the auto with a gasket material. This type of glass is the strongest available for its particular thickness of glass according to the National Glass Association.[1] It is also more resistant to shattering because the plastic middle layer will remain bound to glass pieces that have been broken. This prevents the glass from breaking up into large sharp pieces after impact. In the United States, laminated glass must be installed in the windshields of vehicles while tempered glass is required in the side and rear windows according to the United States Department of Transportation.[2]

Because there are many variables associated with bullet ricochet in general and specifically with windshield glass, the firearm, ammunition, and substrate were kept consistent throughout the course of the experiments. This study used 9mm Luger® ammunition with a Full Metal Jacket (FMJ) bullet. According to the manufacturer, the muzzle velocity is 1,150 feet per second, which was confirmed using a chronograph to determine the velocity of the specific lot of ammunition used.

Initial test shots at 5°, 10°, and 20° incident angles were performed to determine the effect the bullet had on the windshield. Five degrees yielded a clean ricochet with minimal damage to the windshield and a fairly intact bullet. This was not the case with 20°, where the bullet perforated the windshield. High-speed photography elucidated the mechanism of the bullet-glass interaction. Shots fired at 10° resulted in a ricocheted bullet that retained a substantial portion of its initial mass. Ten degrees was then bracketed by shots at 9° and 11° to compare the damage caused by the bullet and the associated damage caused to the bullet. A system was devised to capture and recover bullet fragments from both the surface of the windshield and from underneath the windshield, which was used to determine the percent of post-ricochet weight loss. Witness papers were used downrange to determine the ricochet angle using trigonometry. Incident angles of 5°, 10°, and 20° had ricochet angles of 3°, 8°, and 15°, respectively.

Ricochet, Windshield, Critical Angle

B40 Improved Total Nitrite Visualization (TNV) for Gunshot Distance Determination

Jason Berger, MS, 150-14 Jamaica Avenue, Jamaica, NY 11432-3725; Eliot Springer, MSc, NYPD Police Laboratory, 150-14 Jamaica Avenue, Queens, NY 11432; and Colin J. Upton, MS, 150-14 Jamaica Avenue, Queens, NY 11432*

After attending this presentation, attendees will better understand the improved TNV technique used to detect nitrites in gunshot distance determination casework. This technique has been shown to significantly increase the ability of analysts to detect nitrites on the clothing of shooting victims and has an increased potential for providing useful distance determination information.

This presentation will impact the forensic science community by illustrating that the TNV method is the best practice for Gunshot Residue (GSR) muzzle-to-target distance casework. This could potentially allow for the detection of residues at farther distances and the development of more accurate nitrite residue patterns, which can expand the value and reliability of cases in which gunshot distance determinations are conducted.

Visualization of residues is an essential part of gunshot distance determination. Typically, the current protocols include the Modified Griess Test (MGT) for nitrites and the Sodium Rhodizonate Test for lead. One problem with gunshot distance determination is that the nitrites that are tested for using the MGT are typically not stable in the environment. In addition, nitrites will only be deposited when partially burned gunpowder particles come into contact with the target, which is less likely at long distances. Unburned gunpowder particles may travel farther than vaporous residues or partially burned gunpowder, but they are not detectable using current MGT protocols. Glattstein et al. demonstrated the ability of alkaline hydrolysis to convert nitrates into nitrites to allow visualization of unburned gunpowder particles using the MGT.[1,2] This is referred to as TNV. This method involves using an adhesive lift of the residues, as well as a one-hour incubation time; however, in a laboratory setting, this method proved to be ineffective on soiled evidence items due to the inability of the adhesive to remove substantial residues. Also, the long incubation time proved to be inefficient in a casework environment.

A validation research study was conducted at the New York City Police Laboratory, which sought to improve upon and apply the TNV method to casework samples. Upon completing this study, it was found that effective results could be obtained using a five- to ten-minute incubation time. This is a significant improvement to the one-hour incubation from the original research. In addition, a direct application method of the hydrolysis reagent was found to be effective on soiled items, eliminating the need for an adhesive transfer. When the TNV method was compared to samples processed using the traditional MGT method, a significant increase in the abundance of nitrite residues was observed.

The TNV procedure was implemented in Gunshot Distance Determination casework at the New York Police Department (NYPD) Police Laboratory. To evaluate the effectiveness of the TNV procedure, reports released before and after the method's implementation were compared. This evaluation found that after the implementation of the TNV method, the percentage of analyzed holes in which nitrite residues were detected increased from 24.7% to 50.9%. In addition, the percentage of cases that contained residues that would allow for a muzzle-to-target distance determination increased from 9.9% to 18.6%.

The results of the validation study and the casework evaluation of the TNV method indicate that it is the best practice for GSR muzzle-to-target distance casework. This could potentially allow for the detection of residues at farther distances and development of more accurate nitrite residue patterns. Implementing this method can positively influence the criminal justice system by expanding the value and reliability of cases in which gunshot distance determinations are conducted.

Gunshot Distance Determination, Nitrite, Total Nitrite Visualization

B41 Using Clonal Massively Parallel Sequencing (MPS) to Characterize Heteroplasmy in the Mitochondrial DNA (mtDNA) of Human Head Hair, Pubic Hair, and Buccal Samples

Erin A. Laurie, MS; Janice Lin, BA, 860 NE Rimrock Drive, Bremerton, WA 98311; George Sensabaugh, DCrim, University of CA, Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720; and Cassandra Calloway, PhD, 5700 Martin Luther King Junior Way, Oakland, CA 94609*

After attending this presentation, attendees will better understand how MPS better characterizes heteroplasmy in the mtDNA profiles of head hair, pubic hair, and buccal samples.

This presentation will impact the forensic science community by contributing to an understanding of the heteroplasmy levels that are present in forensically relevant tissues, how heteroplasmy affects the interpretation of mtDNA profiles, and how MPS can be applied to forensic mtDNA analysis.

MtDNA is a useful target for analyzing forensic samples when nuclear DNA (nDNA) profiles are difficult to obtain (for example, when a hair sample does not have follicular tissue attached). Obtaining mtDNA does not often depend on the presence of follicular tissue because mtDNA is present in the hair shaft; however, mtDNA analysis presents challenges that nDNA analysis does not. One such challenge is interpreting heteroplasmy, which is an mtDNA mutation phenomenon that causes more than one mtDNA sequence to be present in an individual. Heteroplasmy has the potential to be useful in forensic mtDNA typing because the presence of heteroplasmy at identical sites in both a casework and a reference sample could not only help confirm a match but also increase the significance of the match.

MPS can overcome the challenges of forensic mtDNA typing. MPS methods are highly sensitive approaches for clonally amplifying and sequencing many samples at once. MPS methods can resolve complex mixtures (from ≥3 contributors) and can also quantify mtDNA mutations. The level of sensitivity achieved with MPS allows for better detection of low-level mutations unobtainable with Sanger sequencing, which is the current forensic mtDNA typing method. The goals of this study were to use an MPS method to better characterize low levels of heteroplasmy across tissues and to compare MPS to Sanger sequencing.

In this study, the Roche® 454 GS Junior MPS platform was used to sequence the mtDNA Hypervariable regions I and II (HVI/HVII) from human head hair, pubic hair, and buccal samples. The MPS sequencing results were compared to the Sanger sequencing results for different tissues from the same sample sets. Point heteroplasmy was detected in more samples when MPS was used than when Sanger sequencing was used. The frequency of heteroplasmy was highest in head hairs, followed by pubic hairs, then by buccal swabs. The 454 was able to quantify levels of heteroplasmy, which cannot be achieved with Sanger sequencing. The 454 detected low levels of heteroplasmy better than Sanger sequencing by reporting levels as low as 1.14% (with at least 500X coverage). With Sanger sequencing, only instances of heteroplasmy at approximately 10% or above could be confidently reported. The 454 also detected more somatic mutations and more heteroplasmy differences within and between different tissue types. Roughly equal numbers of somatic and germ-line heteroplasmy were observed, as well as four heteroplasmic "hot spots" at positions 150, 183, 185, and 189 in the HVII. Finally, there was no significant difference in the frequency of heteroplasmy with an increase in an individual's age.

In conclusion, this study improves understanding of forensic mtDNA sequencing by better characterizing the mutations inherently present in mtDNA. This study also further argues for the use of MPS platforms for forensic mtDNA sequencing.

Massively Parallel Sequencing, Mitochondrial DNA, Heteroplasmy

B42 The Forensic Value of Processed Human Hair Extensions

Caitlin E. Porterfield, MS, Forensic Science Insitute - UCO, 100 N University Drive, Edmond, OK 73034; and James P. Creecy, MS, Oklahoma City Police Dept, DNA Lab, 616 Colcord, Ste 217, Oklahoma City, OK 73102*

After attending this presentation, attendees will better understand the probative value of processed human hair extensions in forensic casework. Specifically, this presentation will address the inability to identify a hair as an extension using microscopic and genetic techniques and the associated forensic implications.

This presentation will impact the forensic science community by indicating the forensic value of processed human hair extensions and emphasizing the implications associated with not identifying a human hair as an extension in casework.

The human hair extension industry has grown immensely with revenues exceeding nine billion dollars each year. Statistics indicate that more than 60% of women have at some point invested in hair extensions and that they are even becoming popular with men.[1] In spite of the expansion of the extension consumer market, human hair extensions have never been evaluated for their evidentiary value in a forensic case. A human hair extension collected from a crime scene would be evaluated as a shed human telogen hair and analyzed using microscopic techniques and mitochondrial DNA (mtDNA).[2] Sequencing of mtDNA from the extension would place the hair donor, not the suspect, at the scene. Although it is not likely that the mtDNA sequence would be matched to the donor's maternal lineage, the evidence would be misleading. Hair extensions collected from a crime scene would misdirect an investigation and result in a misuse of time and resources. The ability to identify a human hair as an extension would be invaluable during an investigation and might exclude the hair as probative evidence.

In this study, three brands of processed human hair extensions were evaluated microscopically and genetically for their probative value in forensic casework. Microscopic analysis of hair morphology by transmitted light microscopy and Scanning Electron Microscopy (SEM) determined that the internal and surface characteristics of the human hair extensions were consistent with human head hair and failed to identify any distinguishing features (pitting, striations, indentations, or internal variations) that differentiated the extensions from natural human hair. Chemical analysis by an Energy Dispersive X-Ray (EDX) detector in conjunction with an SEM identified carbon, oxygen, sulfur, aluminum, and calcium as the main elemental components of the processed human hair extensions, which is consistent with human hair. No elements unique to the extensions were detected.

MtDNA extracted from the hair extensions was sequenced and compared to the revised Cambridge Sequence (rCRS) to identify Single Nucleotide Polymorphisms (SNPs).[3] SNPs were used to assign haplotypes and distinguish regional affiliations associated with the extensions in an attempt to establish the ethnicity of the hair donor's maternal lineage.[3] Haplotype assignments for the hair extensions were based on Hypervariable region 2 (HV2) genetic polymorphisms and represented multiple geographic regions and a large portion of the population. HV2 sequences were not restrictive enough to determine regional affiliations for particular extension brands or processed human hair extensions as a whole. More definitive haplotype assignments would be possible with Hypervariable region 1 (HV1) SNP discrimination. Also, sequence variation between hair extensions of the same brand indicated that the hair within a single package of extensions was from multiple donors. This has significant implications in forensic analysis.

Mitochondrial DNA, Haplotype, Hair Microscopy

B43 A Proteomic Analysis of Human Hair From Various Body Sites

Pei Wen Wu, MS, 400 Atrium Way, Unit 421, Davis, CA 95616; Zachary C. Goecker, BS, 14197 Ten Acres Court, Saratoga, CA 95070; Glendon Parker, PhD, Protein-Based Identification Technology, 4421 Ashwood CMN, Fremont, CA 94538; and Robert Rice, PhD, University of California, Davis, Dept of Environmental Toxicology, 4138 Meyer Hall, One Shields Avenue, Davis, CA 95616*

After attending this presentation, attendees will better understand that human hair is a biological link between its source and the forensic context in which it is found. This presentation will inform attendees regarding the proteomic information found within hair and how it can be exploited to render additional data regarding the anatomical location of human hair on the body.

This presentation will impact the forensic science community by informing attendees that forensic science is in critical need of new laboratory-based methods that provide a quantitative statistical association between an individual and a forensic context. If DNA is not available or is degraded, genetic information in protein may provide additional data.

Recent methodological advances in proteomic analysis offer the prospect of considerable improvement in the use of hair evidence for individual identification. An advantage is the supplementation of subjective findings from microscopic hair comparison with quantitative values amenable to probability estimates and experimentally determined error rates. Results to date are promising with respect to distinguishing among individuals by profiling protein expression levels in the hair shaft. Variations in expression level reflect variations in transcription factor levels, their affinities for response elements, and possibly epigenetic as well as genetic variation. Another form of variation is the presence of Genetically Variable Peptides (GVPs) that offer the prospect of even more discriminating analysis. GVPs are a consequence of non-synonymous single nucleotide polymorphisms that are translated as single amino acid polymorphisms. Increasingly well described by the database of single nucleotide polymorphisms in human DNA, the known non-synonymous mutations among them permit detection of GVPs in digests of hair proteins.

To maximize the usefulness of proteomic technology, two factors merit further exploration. First, optimization of hair processing, now very time consuming, is envisioned to increase the speed and sensitivity of the method so that eventually a single hair fragment will suffice for analysis. Progress in this optimization is occurring. Second, the relative value of hair from different anatomic sites remains to be assessed. The initial study indicated that the protein profiles of hair classes from four sites (axillary, beard, pubic, and scalp regions) are distinguishable. Current work addresses the relative discriminating ability of protein profiling of hair samples from these sites within and among individuals. Whether the profiles differ in a reproducible fashion according to site could be useful in assessing individual comparisons when a hair sample to be identified is of uncertain site origin. Complementing this direction, current work also addresses the yield of GVPs from hair from the different sites. Since GVPs from less abundant proteins are more likely to be observed with increased efficiency of hair digestion, optimization of the processing is envisioned to increase the number of GVP identifications and therefore increase the level of discrimination possible by this route.

Body Hair, Proteomics, Genetically Variant Peptides

B44 Validation of a Method to Sequence the Mitochondrial Genome of High-Quality Reference Samples Using the Illumina® MiSeq® FGx Platform

Michelle A. Peck, MFS, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Kimberly S. Andreaggi, MFS, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; Jacqueline T. Thomas, MS, 115 Purple Heart Avenue, Dover, DE 19902; Robert S. Oliver, MSc, 115 Purple Heart Drive, Dover AFB, DE 19902; Suzanne M. Barritt-Ross, MS, AFMEO / AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; and Charla Marshall, PhD, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will better understand the practical considerations in implementing next generation sequencing methods into a forensic laboratory.

This presentation will impact the forensic science community by presenting a method to sequence the entire mitochondrial genome of high-quality reference samples as well as detailing the validation studies performed in order to implement this method into a forensic laboratory.

The Armed Forces DNA Identification Laboratory (AFDIL) has recently validated a Next Generation Sequencing (NGS) method for degraded specimens using hybridization capture enrichment of the mitochondrial genome (mitoGenome) and multiplexed sequencing on the Illumina® MiSeq®. The capture procedure was shown to be robust and reliable for the generation of mitoGenome data from degraded DNA samples. The sequencing of the complete mitoGenome enables enhanced discriminatory power compared to Control Region (CR) sequence data obtained with traditional Sanger techniques. To take full advantage of the increased genetic information now generated from casework samples and to facilitate comparison with reference samples, it was necessary to validate a suitable NGS mitoGenome method for high-quality samples.

Recently, the AFDIL, in conjunction with the Federal Bureau of Investigation (FBI) Laboratory, performed an extensive evaluation of an NGS protocol for generating mitoGenome data from high quality samples.[1] The procedure begins with a target enrichment step that uses Long Range (LR) Polymerase Chain Reaction (PCR) to amplify the mitoGenome in two overlapping 8,500-bp amplicons. Libraries of the amplicons are prepared by the Nextera® XT DNA Library Preparation kit. This user-friendly kit involves enzymatic tagmentation to fragment the large amplicons followed by a limited cycle PCR step to incorporate indexed adapters necessary for massively parallel sequencing on the MiSeq® FGx. Single-end sequence reads are analyzed with the CLC Genomics Workbench using an optimized workflow that includes a custom mitochondrial DNA (mtDNA) analysis tool. The overall simplicity and rapid speed of this method make it ideal for high-quality sample processing.

For the present validation study, nearly 200 case-type samples and controls were processed following AFDIL's Nextera® XT mitoGenome sequencing and analysis protocol. The Scientific Working Group on DNA Analysis Methods (SWGDAM) validation guidelines were followed for a developmental validation of a novel mtDNA NGS procedure. The LR amplification, Nextera® XT library preparation, and Illumina® MiSeq® sequencing procedures were shown to generate robust sequence data at DNA inputs as low as 100pg. Stochastic artifacts due to amplification errors were observed when the input was less than 100pg, and in crude Bloodstain Card (BSC) extracts regardless of the DNA input (from 3.5ng to 19.5ng). The low template effects observed in these high quantity BSCs was likely attributable to the presence of inhibitors that reduced the amplification efficiency. Extracts that generated sufficient LR amplification product of approximately 4ng/μL produced concordant and reproducible mitoGenome profiles. Moreover, all control DNA samples generated high-quality sequence data consistent with the expected profiles. Only one of the 30+ negative controls was contaminated, which was likely introduced during library preparation due to the lack of detection of an amplicon peak and sequence data consistent with a neighboring sample. Based on quantitative metrics from the validation, interpretation guidelines using variant quality scores and percent of the mitoGenome covered were developed to ensure the reporting of reliable, single-source profiles. Validation testing of this NGS method demonstrated its sensitivity, reproducibility, specificity, stability, mixture detection capabilities, and reliability. As a result, the Nextera® XT mitoGenome sequencing method on the MiSeq® FGx platform was deemed suitable for implementation into casework at the AFDIL.

Mitochondrial DNA, Next Generation Sequencing, Validation

B45 Analyzing DNA Mixtures Using Polymerase Chain Reaction/Capillary Electrophoresis (PCR/CE) Compared to Next Generation Sequencing (NGS)

Katherine Welch, MSFS, Harris County IFS, 1885 Old Spanish Trail, Houston, TX 77054; Justin J. Foster, PhD, Harris County Institute of Forensic Sciences, 2450 Holcombe Boulevard, Ste 7, Houston, TX; Joseph Truppi, BS, Harris County Institute of Forensic Science, 2450 Holcombe Boulevard, Ste 7, Houston, TX 77021; Michael A. Donley, MS, 1885 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will better understand the contribution that NGS can make to the analysis of DNA mixtures when compared to typical PCR/CE methods.

This presentation will impact the forensic science community by providing a comparison of DNA mixture analyses from a study of two-, three-, and four-person mixtures using both standard PCR/CE methods and NGS to analyze Short Tandem Repeat (STR) profiles.

NGS or Mass Parallel Sequencing (MPS) is a newer technology that can simultaneously sequence multiple genomic regions. This technology has been widely used to study human genetics and testing has now begun on forensic samples. Current forensic DNA analysis methods use a combination of PCR and CE to produce informative results. Variable genomic regions known as Short Tandem Repeats (STRs) are amplified using PCR and the variable PCR fragment lengths are measured using CE. Alleles at multiple loci are used to produce highly informative DNA profiles.

NGS technology adds the ability to sequence the STR region to distinguish alleles of the same length but differing sequence, permitting some mixtures with shared alleles to be resolved. In addition, NGS technology can be more sensitive than CE, making it possible to detect alleles that CE misses.

This study examined some of the advantages of NGS. DNA mixtures were prepared using purified DNA extracted from saliva of known individuals. Two-, three-, and four-person mixtures were prepared at 1:1, 1:3, 1:10, 1:1:1, 1:1:3, 1:1:10, 1:1:1:1, 1:1:1:3, and 1:1:1:10. For CE DNA analysis, the mixtures were amplified using Identifiler® Plus or GlobalFiler™, run on a 3130xl Genetic Analyzer CE instrument, and analyzed with GeneMapper® ID-X software. In parallel, the mixtures were prepared for sequencing using the PowerSeq™ NGS library preparation kit, sequenced on a MiSeq®, and analyzed using ExactID® software.

The results show an increase in total alleles due to sequence variation of shared alleles and an overall increase in sensitivity by the NGS instrument compared to the traditional techniques. A comparison of corresponding loci from each kit showed that the Promega® PowerSeq™ had more total alleles called compared to Identifiler® Plus (418 to 496) and GlobalFiler™ (629 to 682). Of these additional alleles, 46 were due to sequence variation not seen in the PCR/CE based techniques. The increase in allele number enhanced the ability to determine the number of contributors at some loci. The additional sequence variant alleles led to 17 and 19 more loci with the correct number of contributors called, compared to Identifiler® Plus and GlobalFiler™, respectively. Overall, NGS technology improved the ability to interpret mixtures.

NGS, DNA Mixtures, Next Generation Sequencing

B46 Comparative Tolerance of Short Tandem Repeat (STR) and Massively Parallel Sequencing (MPS) Chemistries to Inhibited Samples

Kyleen Elizabeth Elwick, BA, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Charity M. Beherec, MS, Texas DPS, 1404 Lubbock Business Park Boulevard, Ste 200, Lubbock, TX 79403; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340*

After attending this presentation, attendees will better understand the difference in tolerance to common Polymerase Chain Reaction (PCR) inhibitors between the chemistries of a commercial DNA amplification kit for Capillary Electrophoresis (CE) -based STR typing and a Single Nucleotide Polymorphism (SNP) -based identity kit sequenced via MPS with the Ion Personal Genome Machine® (PGM™) platform.

This presentation will impact the forensic science community by demonstrating how common inhibitors found in challenging bone and tissue samples, such as those that may be recovered during a mass disaster or missing person's case, affect different genotyping successes employing conventional STR typing used in forensic laboratories and newer MPS methods.

Victim identification is one of the most important goals after a mass disaster event or in a missing person's case. Oftentimes, these human remains are very challenging samples to identify as they may be highly degraded and fragmented, burnt, decomposed, or containing inhibitory substances. CE-based STR markers and mitochondrial analyses are traditionally used for DNA identification, but MPS has more recently emerged as an alternative approach for identifying human remains. The purpose of this study is to compare the tolerance of a commercial STR kit and a MPS-based system to common inhibitors that are frequently encountered in skeletal and decomposed tissue samples requiring identification in forensic and missing persons' casework.

DNA (1ng and 0.1ng) was spiked with various concentrations of five inhibitors (humic acid, melanin, hematin, collagen, and calcium). Samples (*N*=150) were amplified with the GlobalFiler® PCR Amplification Kit and genotyped on the ABI 3500 Genetic Analyzer. A subset of samples (*N*=25) was also sequenced using the Human Identification (HID) -Ion AmpliSeq™ Identity Panel with the Ion PGM™.

In general, STR results showed a decrease in the number of alleles being amplified and detected as inhibitor concentrations increased. As expected, the average peak height and average heterozygote peak height ratios showed a decreasing trend as inhibitor concentration increased. Samples with 0.1ng DNA input resulted in considerably poorer STR profiles than 1ng DNA samples at all inhibitor concentrations, suggesting that samples amplified with less DNA template are more susceptible to the effect of PCR inhibition.

MPS sequencing results suggest that the HID-Ion AmpliSeq™ Identity chemistry may not be as tolerant to PCR inhibitors as STR amplification kits. Samples with the same inhibitor concentrations generated considerably worse results via MPS. The lowest inhibitor concentrations for humic acid, melanin, and hematin resulted in complete STR profiles but performed poorly when the samples were sequenced via MPS; however, the highest inhibitor concentrations for collagen and calcium resulted in poor STR profiles but performed well with MPS, resulting in complete SNP profiles.

Data also showed that when highly inhibited samples were pooled for library amplification and loading onto the same chip for sequencing, carry-over inhibition from highly inhibited samples affected the performance of samples with little or no inhibition. In fact, when samples with the highest amounts of inhibitor were processed, library amplification failed completely. Overall, the chemistry in commercial STR kits is more tolerant to most of the common inhibitors found in biological samples than the MPS sequencing chemistry tested in this study.

Massively Parallel Sequencing, STR Typing, PCR Inhibitor

B47 Fetal DNA Detection in Pregnancy Serum Using the Ion Personal Genome Machine® (PGM™) System With an Identity Single Nucleotide Polymorphism (SNP) Panel

Jihyun Lee, 28 Yongon-Dong, Chongno-Gu, Seoul, SOUTH KOREA; Hee Jin Seo, 103 Daehak-ro Chongno-Gu, Seoul 110-799, SOUTH KOREA; Moon Young Kim, MD, Institute of Forensic Science, Seoul National Univ, 103 Daehak-ro, Jongno-gu, Seoul 03080, SOUTH KOREA; Chong Jai Kim, MD, Department of Pathology, Asan Medical Center, University of Ulsan College of Medicine, Songpa-gu, Seoul, SOUTH KOREA; Kun Woo Kim, MD, Hamchoon Women's Clinic, Seoul, SOUTH KOREA; Doyeong Hwang, MD, Hamchoon Women's Clinic, Seoul, SOUTH KOREA; and Soong Deok Lee, PhD, 28 Yongon-dong, Chongno-gu, Seoul 110-799, SOUTH KOREA*

After attending this presentation, attendees will understand the operability of a Next Generation Sequencing (NGS) system in Low Template DNA (LT DNA) analysis, specifically in fetal DNA detection in maternal serum, and the basic principle of the Ion PGM™ platform with the Human Identification (HID) -Ion AmpliSeq™ Identity Panel and its utility in practical casework samples.

This presentation will impact the forensic science community by analyzing DNA obtained from challenging sources, such as degraded DNA and mixed DNA.

NGS systems offer new possibilities in genotype analysis using established forensic markers for identification. The results of the analysis of fetal DNA in maternal plasma or serum is often similar to LT DNA and mixed DNA.

Serum samples were taken from eight anonymous pregnant women. There was no detailed information about the fetus due to the fact that miscarried pregnancies were included and no gender information was available. DNA was isolated using the QIAamp® DNA Mini Kit. DNA quantification was performed using real-time Polymerase Chain Reaction (PCR) and the Quantifiler® Duo Kit. The levels of sequence coverage and mixed DNA patterns were evaluated through HID-Ion AmpliSeq™ Identity Panel with 124-markers designed for the Ion PGM™ system.

Partial Y-chromosome Single Nucleotide Polymorphisms (Y-SNP) markers were typed. Negative Y-STR profiles (no single STR locus) were obtained from serum samples taken from two pregnant women who were assumed to carry male fetuses. Using those particular two Y-SNP samples, partial fetal autosomal SNP profiles were implicitly inferred via retrospective mixture analyses in all of the eight samples.

If additional information, such as portion and degree of mixtures, were available, this platform could be used for non-invasive prenatal testing to detect the mixture samples. This study also suggests that if relevant template chromosomal data are provided, NGS can be readily used to analyze mixed DNA samples. The findings also indicate that NGS will be practical for processing LT DNAs and mixed DNA.

Next Generation Sequencing, Fetal DNA, Mixed DNA

B48 A Preliminary Sensitivity Assessment Comparing Two Next Generation Sequencing (NGS) Laboratory Workflows for Forensic Analysis

Adriana N. Swatzell, 1400 Lascassass Pike, Apt H45, Murfreesboro, TN 37132; Jocelyn M. Bush, MS, 727 N 4th Street, #206, Columbus, OH 43215; and Elizabeth Montano, MS, Battelle, 505 King Avenue, Columbus, OH 37332*

The goal of this presentation is to educate the forensic science community concerning the progress of NGS and the performance of two specific workflows in regard to use in forensic DNA analysis.

This presentation will impact the forensic science community by sharing information about the potential of these two specific workflows in forensic crime laboratories.

DNA evidence recovered from a crime scene is rarely ample in quality or quantity. Therefore, it is vital to know the limits of any assay used for forensic DNA analysis. NGS DNA sequencing technology is now being implemented and investigated in forensic laboratories. Integration of NGS into forensic DNA analysis workflows provides value by its ability to: (1) successfully process degraded samples; (2) reduce the cost of materials, labor, and time by multiplexing a large number of DNA markers into one sequencing run; (3) better distinguish individual profiles from mixtures; and, (4) use phenotypic markers to identify persons by physical characteristics. It is important to perform a sensitivity assessment to ultimately validate this new technology.

The Scientific Working Group on DNA Analysis Methods (SWGDAM) recommends various studies be conducted in order to evaluate the limits of an assay. With these evaluations having been performed for current technology (i.e. capillary electrophoresis) in the forensic setting, SWGDAM guidelines are serving as a guide for the assessment and validation of the NGS technology.

For this experiment, the Promega® PowerSeq™ Auto/Y System Prototype and Illumina® ForenSeq™ DNA Signature Prep kits were evaluated as both use the MiSeq® instrument platform. Initially, two high-quality DNA samples were assessed at different titrations, ranging in amplification input from 500pg to 15.6pg. The same samples were processed with both laboratory workflows being compared according to the manufacturer's instructions. Following this study, eight mock casework samples were tested with both workflows on separate sequencing runs. Data were analyzed using default analytical threshold settings using software platforms recommended in the manufacturer's instructions. Preliminary results indicated full DNA profiles were obtained for autosomal Short Tandem Repeats (STRs) at lower amplification input levels in samples processed with the PowerSeq™ workflow than samples processed with the ForenSeq™ DNA Signature Prep kit. Similar trends were observed with the mock casework samples. Genotypes for each marker were deemed concordant when the correct allele or alleles were the most abundant for homo- and heterozygous loci, respectively. Correct alleles were obtained from capillary electrophoresis data previously generated.

It is recommended that more sensitivity and forensic casework-like studies be performed within the community to further supplant these initial findings. This assessment will be valuable for the forensic casework and academic research communities in order to demonstrate the capability of NGS to assist in their selection of an appropriate methodology. This preliminary study can assist laboratories that are seeking to integrate this new technology to gain an initial idea of which kit and workflow are best suited for their needs.

Next Generation Sequencing, Sensitivity Assessment, Validation

B49 Optimization of a Droplet Digital™ Polymerase Chain Reaction (ddPCR™) Assay for the Quantitative and Qualitative Analysis of Illumina® MiSeq® Massively Parallel Sequencing (MPS) Libraries

Brittania J. Bintz, MSc, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand ddPCR™, a cutting-edge technique used to quantify nucleic acids. Focus will be placed on the use of ddPCR™ to accurately quantify prepared MPS libraries. Additionally, the use of ddPCR™ as a way to determine the average length of fragments in an MPS library will be discussed.

This presentation will impact the forensic science community by describing a newly optimized method that enables laboratories to fully assess prepared MPS libraries. This level of library assessment results in the generation of large amounts of high-quality data without sample or sequencing run failures. Furthermore, the assay described has been optimized to reduce the potential for contamination.

MPS methods are quickly being adopted by the forensic community for analysis of precious evidentiary samples. These methods are capable of generating an unprecedented amount of data, particularly when analysis is performed using commercially available highly multiplexed panels designed to target hundreds of loci per amplification. Accurate qualitative and quantitative assessment of prepared MPS libraries is of paramount importance for obtaining maximum yield of high-quality data from a sequencing run. Many vendor-recommended protocols suggest assessment of the final library using fluorometric methods, agarose gel or chip-based electrophoresis, or quantitative PCR (qPCR); however, these methods can be problematic because they often: (1) result in over- or underestimation of library DNA concentrations; (2) do not enable estimation of the size of DNA fragments in the library, which can lead to incompatible kit selection; and, (3) are not typically specific for those fragments that are MPS-ready.

A ddPCR™ is similar to qPCR in that target-specific primers and 5' nuclease probes are utilized for detection following an end-point PCR reaction; however, due to the nature of the method, no standard curve is needed for estimation of DNA concentration. With ddPCR™, a 20µL aqueous PCR reaction is emulsified into 1nL uniformly sized droplets. Each droplet is then counted as fluorescence positive or negative and a Poisson correction is applied to estimate the starting copy number of DNA fragments in the sample. In addition, previous literature has shown that droplet florescence intensity is dependent upon the average length of the fragments being assessed.[1] Longer fragments tend to result in lower droplet fluorescence intensities than shorter fragments due to the kinetics and stoichiometry of the PCR reaction. As a result of this observed fluorescence intensity:fragment-size correlation, Laurie et al. have developed a ddPCR™ assay that allows for simultaneous quantitative and qualitative assessment of MPS libraries.[1] The assay specifically targets MPS platform-specific library modifications (i.e., flow cell adapter sequences) to enable quantification of only those fragments that are sequenceable. The assay also includes the use of a series of size standards to facilitate estimation of average length of fragments in the prepared library; however, the standards are derived from a commercially available agarose gel electrophoresis ladder. The reported preparation is time-consuming, labor intensive, and may give rise to low-level contamination evident in MPS data.

This presentation reports an optimization of the aforementioned assay using synthetically prepared size standards. Initially, a series of oligonucleotides with known sizes ranging from 25bp to 700bp was designed to consist of PhiX DNA with Illumina® MiSeq® sequencing primer flanking regions. The oligonucleotides were designed using PhiX to reduce possible run contamination from exogenous sources. PhiX is supplied for use as an MPS control, and data generated from any part of the PhiX genome is easily identified and bioinformatically filtered from raw data. The sequencing primer region serves as a primer binding site to allow for additional incorporation of barcoding indices and flow cell adapters into the synthetic oligonucleotide during the limited-cycle PCR step. Final products are then normalized for reaction input of 10,000 copies to avoid fluorescence intensity variability due to copy number and not length. Average observed droplet fluorescence intensities range from 13,157RFU (+/- 203.3) for the 25bp standard to 3,860.4RFU (+/-352.3) for the 700bp standard. The standard series appears to be efficient at predicting the average size of Illumina® MiSeq® libraries while avoiding quantification of adapter dimers and other artifacts often generated during library preparation. This increases first-pass Illumina® MiSeq® run success.

Quantitative PCR, Droplet Digital™ PCR, Massively Parallel Sequencing

B50 Separating Complex DNA Mixtures Containing Related Individuals Using TrueAllele® Mixture Interpretation Software

Olivia D. Goodwin, 16 Alpine Drive, Mohnton, PA 19540; Lisa R. Ludvico, PhD, Duquesne University, Biology Dept, 238 Mellon Hall, Pittsburgh, PA 15282; and Lyndsie N. Ferrara, MS, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15219*

After attending this presentation, attendees will better understand an analysis method that reliably separates (deconvolutes) familial DNA mixtures of two to five individuals using TrueAllele® technology. Furthermore, this presentation demonstrates the difficulty of deconvolution of mixtures with high levels of allele sharing at both optimal and low levels of DNA.

This presentation will impact the forensic science community by demonstrating the effectiveness of a reliable tool that can be used for the interpretation of complex familial DNA mixtures, as well as the benefits of automated DNA analysis.

According to the preliminary 2015 report from the Federal Bureau of Investigation (FBI), violent crimes have increased 1.7% from the reported 1,165,383 violent crimes in 2014.[1,2] Major devastating events such as the Boston Marathon bombing and incest sexual assaults are only some of the recent occurrences that have bombarded laboratories with biological evidence. In the eyes of forensic scientists, many of these crimes have two matters in common: related individuals and complex DNA mixtures. DNA mixtures can pose multiple analysis issues; some of these issues stem from degraded DNA, small amounts of DNA (Low-Template (LT-DNA)), and the number of contributors in the mixture.[3,4] Using manual interpretation, the complexity of DNA mixtures often leads to inconclusive reports.[5]

The use of computer technology in the past ten years has successfully simplified DNA mixture interpretation. Innovative forensic Short Tandem Repeat (STR) commercial software available today is primarily used to separate contributors in a mixture. Recent studies are being conducted to validate these systems, especially for deconvoluting mixtures of more than two contributors; however, complex mixtures limit this new technology, especially when contributors share genetic material as a result of being from the same biological family.[3,4] There has been limited published research on how familial DNA mixtures affect automated interpretation.

This research focuses on the analysis of DNA mixtures containing related individuals and the prospects of using the continuous probabilistic STR analysis software TrueAllele® for statistical calculations in complex mixtures containing up to five individuals. It is proposed that TrueAllele® technology will resolve complex DNA mixtures containing three to five related individuals, generate Likelihood Ratio (LR) match statistics suitable for court, and reproduce those match results to show reliability in automated analysis.

Buccal swabs were collected from individuals in three separate families to create single-source DNA profiles. These samples were extracted using the DNA IQ™ System and quantified using Real-Time Polymerase Chain Reaction (RT-PCR) with Applied Biosystems® Quantifiler® assay. Based on the family pedigrees and the quantification results, 25 mixtures of two to five contributors were created using related individuals from those families. These mixtures were then replicated and diluted to provide mock LT-DNA samples. After amplification using the PowerPlex® Fusion STR kit and genotyping on Applied Biosystems® 3130 genetic analyzer, the mixtures were analyzed using TrueAllele®. The statistics produced across all mixtures were compared to determine if TrueAllele® could separate mixture contributors, regardless of family origin. Reproducibility among triplicate runs was assessed within each mixture set to ensure the software was correctly separating the contributors and producing similar match statistics. Finally, the degree of shared alleles in a mixture (in relation to the produced match statistics) was compared.

Analysis of familial DNA mixtures provides an insight to the complexity of interpretation in a situation in which allele sharing is at its highest. Obtaining accurate and unbiased results with the help of automated analysis could lead to further advancements in other methods, such as kinship analysis and paternity testing. Conclusions from this study may not only provide a reliable tool for forensic scientists to analyze complex familial mixtures, but may also standardize the analysis process and decrease the number of inconclusive reports.

DNA Mixtures, Familial DNA, TrueAllele®

B51 Microhaplotypes (MHs): A Possible Biogeographic Ancestry Predictor for Forensic DNA Evidence

Kelly E. Long, BSc, The George Washington University, 7308 Snowden Court, Springfield, VA 22150; and Katrina F. Maddela, BS*, 4888 MacArthur Boulevard, NW, Washington, DC 20007*

After attending this presentation, attendees will understand MHs and the potential that MH analysis has in predicting the biogeographic ancestry of an individual.

This presentation will impact the forensic science community by suggesting how MHs can enhance mixture interpretation and ancestry prediction capabilities, potentially providing investigators with an extra tool for identifying and/or eliminating suspects.

MHs are short regions (<250 base pairs long) that have two or more Single Nucleotide Polymorphisms (SNPs) with three or more allelic combinations. Given the short distance between SNPs in MHs, recombination is highly unlikely. Furthermore, the mutation rate is significantly less than that of Short Tandem Repeat (STR) markers, which makes them a better candidate for familial testing. Contrary to STRs, the amplification of MHs is not affected by polymerase slippage; given the absence of a short sequence repeated multiple times, this feature eliminates the presence of a common STR analysis artifact: stutter. With conventional SNP typing methods, such as Sanger sequencing, TaqMan®, and SNaPShot®, haplotypes cannot be determined. Using Massively Parallel Sequencing (MPS) methods, the *cis/trans* relationship between SNP alleles within the same amplicon (i.e., haplotype detection) can be accomplished. MPS-based MH analysis can be a valuable forensic tool for parentage testing and mixture deconvolution, particularly in mixtures where the minor contributor (or contributors) is in the stutter range of the major. The small amplicon size also makes MHs a good candidate for typing degraded DNA samples. Although initially selected based on the highest effective number of alleles across populations, MH allele frequencies vary significantly in different populations. The goal of this project was to evaluate if a selected panel of MHs, together with individualization, could also effectively predict biogeographic ancestry.

A panel of 33 MHs was used on 98 individuals who self-identified as European-Americans. Samples were sequenced on an Ion S5 MPS platform using a 530 chip. The initial library preparation was conducted manually but the templating step was carried out on an Ion Chef™. Allele frequencies from a database of 58 different populations were used to calculate the Random Match Probability (RMP) of each profile in each individual population. A biogeographic prediction was performed by evaluating the raw RMP values for each population and whether or not the highest RMP was in a European population. A second method to evaluate biogeographic inference was by calculating a Likelihood Ratio (LR) determined by dividing the probability of the highest (as in most common) RMP in question by the RMP of the population chosen for comparison.

Of the 98 individuals, only nine were found to have their highest RMP in a non-European population. All nine were within one order of magnitude or less. For these nine individuals, the highest RMP was calculated in a Middle Eastern population. European populations and Middle Eastern populations are generally considered admixed.

The LR was calculated for all 98 individuals by placing the European-American RMP in the numerator and RMPs of Yoruba, African-American, Cambodian, San Francisco Chinese, and Arizona Pima populations in the denominator as proxies for the major United States populations. The value of the LR obtained represents how much more likely it is to observe that profile if the individual is of European descent versus one of the other populations. The average LR was ~3 E^{18} for European-Yoruba or -Pima, only a magnitude greater for European-Cambodians, but three orders greater for the European-San Francisco Chinese at E^{21}. The European-African-American was the smallest range from 556 to 5.5 E^{14} while the European-San Francisco Chinese was the greatest from 208 to 6.3E^{23}. The European-Pima and European-Yoruba LRs were similar from the 10,000s to E^{20}. For the 98 samples, 94 LRs were above the arbitrary level of confidence of 1,000. The lowest value in the four remaining was 208 (European/-San Francisco Chinese), and the second lowest value was 556 (European-African-American). These four profiles also had high frequencies in other non-European populations, suggesting they may have originated from admixed individuals.

Further research is necessary to identify more effective ancestry informant MHs. Yet, these results support the hypothesis that MHs can be used for biogeographic ancestry prediction, which can provide investigators with

useful information in cases in which the STR profile from crime scene evidence does not match any suspects or database profiles.

Microhaplotypes, Forensic, Ancestry

B52 Rapid DNA Amplification of Forensic Samples

Silvia Zoppis, MD, Viale Regina Elena 336, Rome 00161, ITALY; Manuela Rosini, MSc, Viale Regina Elena 336, 00161, Rome, ITALY; Fabio Verginelli, PhD, Via dei Vestini 31, 66100, Chieti, ITALY; Carla Vecchiotti, Viale Regina Elena 336, 00161, Rome, ITALY; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand various principles of genetic analyses on forensic samples and the challenges related to this type of investigation, especially concerning bone remains.

This presentation will impact the forensic science community by highlighting the importance of reducing the forensic DNA-typing workflow time through the possibility of dramatically speeding up the Polymerase Chain Reaction (PCR) amplification procedure. In this regard, the rapid PCR protocol described was shown to be effective for single-source forensic samples, allowing the procurement of reliable Short Tandem Repeat (STR) profiles, not only from saliva and blood collected at the crime scene, but even from challenging bone samples recovered in extremely critical environmental conditions.

Forensic DNA typing typically involves a multi-step workflow, including DNA isolation, quantification, amplification of a set of STR markers, separation of PCR products by Capillary Electrophoresis (CE), and DNA profile analysis and interpretation. Considering all these steps, the process can take approximately ten hours. The PCR amplification portion of the workflow typically takes approximately 1.5 to 3 hours with standard thermal cycling protocols. For many peculiar and critical forensic caseworks, it would be extremely helpful to speed up this process and allow the generation of an interpretable, DNA profile-suitable DNA database search within a few hours.

Through the use of a faster DNA polymerase coupled with the use of a rapid thermal cycler, the amplification cycling times were reduced down to as few as 16 minutes using PCR primers from the commercially available multiplex STR typing kit AmpFℓSTR® Identifiler® Plus. This rapid protocol employs the commercially available TaKaRa Z-Taq™ DNA Polymerase and the Philisa® Streck Thermal Cycler. A previously described three-step thermal cycling protocol was evaluated on single-source DNA extracts from saliva, blood, and bone samples. In addition, a comparison among different DNA extraction methods (i.e., FTA™, Chelex®, Promega® DNA IQ™ System, and MP Biomedicals Geneclean® For Ancient DNA Kit) was conducted due to the constantly negative typing results obtained by samples extracted with the Chelex® method, then subjected to the rapid PCR protocol.

Capillary electrophoresis characterization of the PCR products indicated good peak balance between loci, strong signal intensity, and minor adenylation and PCR artifacts. Genotyping results were concordant with standard amplification conditions utilizing a standard thermal cycling procedure with a GeneAmp® 2720 PCR System. Assay conditions were robust enough to routinely amplify 250pg to 500pg of template DNA.

Forensic DNA Typing, Rapid PCR Amplification, Forensic Samples

B53 Using Rapid DNA Analysis to Obtain DNA Profiles From Improvised Explosive Devices (IEDs)

Alexis Parr, BS, 27 Mulberry Road, Woodbridge, CT 06525; Timothy M. Palmbach, MS, JD, University of New Haven, Dept of Forensic Science, 300 Boston Post Road, West Haven, CT 06516; and Michael S. Adamowicz, PhD, University of Nebraska-Lincoln, 103 Agriculture Hall, PO Box 830702, Lincoln, NE 68583-0702*

After attending this presentation, attendees will better understand the potential for using Rapid DNA analysis to obtain DNA profiles from low-level samples. This presentation compares the performance of traditional versus Rapid DNA analysis on low-level samples. This presentation presents data from both traditional and Rapid DNA methods regarding quantity and quality of DNA recovered from various components of IEDs pre- and post-deflagration.

This presentation will impact the forensic science community by determining whether Rapid DNA analysis can produce detectable DNA profiles from low-level samples and by determining the limitations of Rapid DNA analysis. Using Rapid DNA analysis, it is possible to produce a DNA profile in less than two hours. Therefore, this presentation will assist analysts in determining whether it is appropriate to use Rapid DNA analysis methods on low-level samples when time is of the essence, especially when generating investigative leads.

DNA recovery from IEDs was evaluated using traditional and Rapid DNA analysis to compare the performance of both methods. IEDs were chosen because the DNA recovered is low level by nature (touch), often degraded (heat and pressure), and time may be critical when obtaining a profile due to the potential danger of further detonations. In the first stage of the study, mock IEDs were assembled using previously cleaned materials to assess each method's potential for successfully generating a Short Tandem Repeat (STR) profile. The external surfaces and wire twists of the mock devices were swabbed using a double-swab technique (moistened and dry). In addition, DNA samples from tape were collected using a single swab moistened with QIAGEN® ATL tissue lysis buffer. Duplicate swabs were used and processed using traditional DNA analysis and Rapid DNA analysis methods. All samples were produced at least in triplicate. In the second stage of the study, the first stage was repeated using actual IEDs that were deflagrated by professionals in a controlled setting rather than using assembled mock IEDs.

For traditional DNA analysis, standard methods utilized in forensic laboratories including extraction (QIAamp® DNA Investigator), quantification (Investigator® QuantiPlex™), and amplification (PowerPlex® Fusion) were used. Samples were separated and detected using a 3130*xl* and analyzed using GeneMapper®ID 3.2.1 software. For Rapid DNA analysis, the NetBio DNAscan (BioChipSet™ Cassette) was used. Materials that were cleaned for mock IED assembly were checked for background DNA prior to assembly. Each component swabbed was assessed by the average recovered yield of DNA from the entire surface area of the component. Additionally, sample collection from tape was assessed by the average recovered yield of DNA per cm^2. DNA profiles produced by both methods were then generated and analyzed by comparing sample profiles to reference profiles obtained from the known device assemblers (mock and real) and by comparing sample profiles to each other. Profiles were assessed by examining the total number of alleles out of the possible 45 and the total number of complete loci out of 23. Upon analyzing the data for the samples collected from the mock devices, traditional methods yielded complete and concordant profiles from the tape and the external surfaces. Also, traditional methods yielded either no results or partial concordant profiles from the wires. Rapid DNA analysis yielded either no results or partial profiles from the components. Initial results with the DNAscan on mock IEDs indicated that samples collected from deflagrated devices may yield reduced information when processed with Rapid technology instruments.

The goal of this research was to determine whether Rapid DNA analysis can be used on time-sensitive evidence that most likely yields low-level DNA rather than using traditional DNA analysis in order to decrease the time it takes to produce a DNA profile and potential investigative lead. Overall, traditional DNA analysis performed better on the low-level samples; however, Rapid DNA analysis did produce partial profiles on some samples.

Rapid DNA, Improvised Explosive Device, Low-Level DNA

B54 The Characterization and Differentiation of 21 Fentanyl Analogues by Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Mass Spectrometry (LC/MS), and Nuclear Magnetic Resonance (NMR) Spectroscopy

Tatsuyuki Kanamori, 6-3-1, Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Yuko Togawa Iwata, PhD, 6-3-1, Kashiwanoha, Kashiwa, JAPAN; Hiroki Segawa, PhD, National Research Institute of Police Science, 6-3-1, Kashiwanoha, Kashiwa 277-0882, JAPAN; Tadashi Yamamuro, PhD, 6-3-1, Kashiwanoha, Kashiwa, JAPAN; Kenji Kuwayama, PhD, 6-3-1, Kashiwanoha, Kashiwa, JAPAN; Kenji Tsujikawa, PhD, 6-3-1, Kashiwanoha, Kashiwa, JAPAN; and Hiroyuki Inoue, PhD, 6-3-1, Kashiwanoha, Kashiwa, JAPAN*

After attending this presentation, attendees will gain a deeper knowledge regarding the analysis of fentanyl analogues. This analysis includes the separation and identification of the structural and geometric isomers of fentanyl analogues and the unusual behaviors exhibited by several fentanyl analogues evaluated by NMR spectroscopy.

This presentation will impact the forensic science community by providing the analytical data of 21 fentanyl analogues, including the structural and geometric isomers, by GC/MS, LC/MS, and NMR spectroscopy.

Fentanyl is a powerful synthetic analgesic developed in the 1960s. To date, a wide variety of fentanyl analogues, such as α-methylfentanyl and 3-methylfentanyl, have been abused all over the world. In the present study, 21 compounds of fentanyl analogues, including structural and geometric isomers, were analyzed by GC/MS, LC/MS, and NMR spectroscopy.

GC/MS conditions: column, capillary column coated with 5% phenyl methylpolysiloxane (30m × 0.25mm i.d.); oven temperature, 120°C (1min hold) and programmed up to 300°C at a rate of 15°C/min; injection port temperature, 250°C; carrier gas, helium; sample injection, splitless mode; ionization, Electron Ionization (EI); electron energy, 70 eV. LC/MS conditions: column, ODS column (2.1 × 150mm); mobile phase composition, 10mM ammonium acetate (A) and methanol (B); linear gradient mode, 80% A and 20% B to 10% A and 90% B over 18min, followed by a 2min hold at 10% A and 90% B, and returned to 80% A and 20% B in 0.1min; flow rate, 0.20ml/min; MS interface, positive Electrospray Ionization (ESI). NMR conditions: proton resonance frequency, 600MHz; solvent, $CDCl_3$ or CD_3OD; internal standard, tetramethylsilane.

In GC/MS, fentanyl analogues, except for fentanyl and acetyl-α-methylfentanyl, were separated on the Extracted Ion Chromatograms (EIC) of the characteristic fragment ions of each compound. Fentanyl and acetyl-α-methylfentanyl were separated by slowing the rate of the temperature increase of the column to 3°C/min. Geometric isomers (*cis-trans* isomers) of 3-methylfentanyl analogues were completely separated by GC. The thermal decomposition of β-hydroxyfentanyl should be closely monitored: a high-injection port temperature (>250°C) induced the cleavage of the C-N bond of β-hydroxyfentanyl to form norfentanyl. The thermal decomposition of β-hydroxyfentanyl was completely suppressed by Trimethylsilyl (TMS) derivatization of the hydroxyl group.

In LC/MS, most of the fentanyl analogues were separated on the EICs of the protonated molecule of each compound. It is notable that the two diastereomers of β-hydroxy-*cis*-3-methylfentanyl were separated by LC, but not by GC; however, it was difficult to separate the diastereomers of β-hydroxy-*trans*-3-methylfentanyl by GC and LC in this study.

Several 3-methylfentanyl analogues exhibited unusual behavior when analyzed by ^{1}H-NMR. Specifically, the proton signal of the 3-methyl group of acetyl-*cis*-3-methylfentanyl hydrochloride split at a ratio of 3:2, when this compound was dissolved in $CDCl_3$. The same phenomenon was observed in the cases of *cis*-3-methylfentanyl hydrochloride and *cis*-3-methylthiofentanyl hydrochloride. In contrast, when these compounds were dissolved in CD_3OD, the proton signal did not split. This phenomenon may be explained as follows: the proton of the hydrochloride coordinated to the nitrogen of the piperidine ring when the hydrochloride salts of the 3-methylfentanyl analogues were dissolved in a non-polar solvent, such as $CDCl_3$. A pair of stereoisomers were formed by the coordination, and the split of the proton signal of the 3-methyl group was observed.

Fentanyl, Isomer, Analysis

B55 An Investigation Into the Preservation and Storage Conditions for Extracts of Ignitable Liquid Residues

Clare M. Fried, BS, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Thomas A. Brettell, PhD, Cedar Crest College, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will understand how the storage conditions of activated charcoal strips can affect the preservation of sample extracts of ignitable liquid residues from fire debris samples. Attendees will be provided with a short review of past documented preservation techniques and ideas as to what practitioners can do to create a consensus in the field.

This presentation will impact the forensic science community by providing information on storage and reanalysis conditions of carbon disulfide extracts of residues preserved on activated charcoal strips.

Fire debris analysis presents a constant challenge to those who investigate the scene. Practitioners responsible for determining what ignitable liquid may have been used to intentionally set a fire have a difficult challenge. It is crucial for practitioners to not only correctly identify which ignitable liquid is present, if any, but to also preserve extracts for future analysis and peer review. Forensic scientists commonly use passive headspace to sample and concentrate ignitable liquid residues onto activated charcoal strips. There have been some studies conducted on this topic, but little work has been reported on the preservation and reanalysis of activated charcoal strips that have been previously extracted with carbon disulfide. Presently, there is no accepted standard practice for storing and preserving these extracts. The American Society for Testing and Materials (ASTM) E2451-13 states "… changes to a preserved sample extract and the length of time it remains viable under storage conditions are unknown".[1] Clear standards and validation of the conditions for preservation of the extracts should be documented and universally accepted within the field.

In this study, Gas Chromatography/Mass Spectrometry (GC/MS) was used to analyze passive headspace extracts to study the changes of a Standard Accelerant Mixture (SAM) adsorbed onto activated charcoal strips and preserved under different storage conditions. The SAM consisted of a mixture of 1:1:2 ratio of gasoline, kerosene, and diesel fuel. Two different types of chromatographic vials were compared, screw cap vials and snap cap vials. Four different storage conditions for the extracts were studied: (1) room temperature (25°C); (2) refrigeration (4°C); (3) freezer (-20°C); and, (4) freeze and thaw cycles. The study examined three different conditions in regard to the preservation of the sample in a chromatographic vial during analysis: (1) no change to the septum after each injection of multiple injections; (2) septum replaced after each injection; and, (3) cap removed and carbon disulfide evaporated in order to reconstitute with carbon disulfide once the strip is dried. Area normalization of peak abundances was used to calculate recovery and reproducibility of GC patterns. Chromatographic peaks used for the quantitative comparison were validated through mass spectral analysis and comparison to library standard reference spectra.

The results indicate ignitable liquid residue passive headspace-activated carbon strip samples extracted with carbon disulfide may be dried and reconstituted at least two times with no loss of sample integrity or diagnostic chromatographic peaks used for identification. After three evaporation/reconstitution cycles, lighter constituents began to evaporate and affect the chromatographic validity of the data. Sample vial, storage temperature, and conditions are crucial aspects of fire debris sample preservation. Further studies are necessary to understand how the sample extracts should best be stored and preserved in order to test them in the future.

B56 Optimizing a Sequence of Methods for the Development of Latent Fingerprints on Thermal Paper

Reyne Spychalski, BSc, 1319 Park Street, Huntington, WV 25701; Kimberly Gerhardt, MS, Rapid City Police Dept, 625 1st Street, Rapid City, SD 57701; Dave Castle, BS, 675 10th Street, Huntington, WV 25701; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will be more knowledgeable regarding the best techniques that are currently available to process fingerprints on thermal paper. Attendees will understand the difficulties of working with thermal paper, how well current methods work, and how methods compare to each other.

This presentation will impact the forensic science community by illustrating what current techniques work the best with thermal paper substrates. This presentation will provide information on how well current thermal paper processing techniques work, separately and in sequence, as well as whether any methods stand out in terms of accuracy, consistency, and ease of use.

Thermal paper has been known to be a tedious substrate in latent fingerprint laboratories. Although it is considered a porous substrate, techniques that are commonly used to develop fingerprints on porous items have shown to be unsuccessful on thermal paper. A major issue is that chemicals used in these processes, as well as the common application of heat, can interact with the components of the paper, activate it, and darken the entire surface. The darkening of the paper makes the visualization of existing latent fingerprints a difficult task. Recently, numerous procedures have been created to successfully develop fingerprints on thermal paper evidence without interacting with the thermal properties. For other porous substrates, a sequence of methods may be followed to ensure that all existing fingerprints have been found' however, since thermal paper requires special techniques, a known sequence does not currently exist and laboratories may only utilize one method. If a latent fingerprint examiner solely uses one method for thermal paper evidence, the examiner may be unaware of fingerprints that were present but failed to develop. The examiner may also be unaware that a combination of these methods may yield better results than one method alone.

The goal of this study was to determine if a sequence of current processing techniques (1,2-indanedione with zinc chloride, PDMAC® paper, muriatic acid fuming, application of heat, and ThermaNin®) could be optimized to allow an analyst to state with confidence that all existing fingerprints have been found.

Nine sequences were created from the combination of the five methods previously mentioned. Each sequence was performed on known fingerprints that were 4 weeks, 3 weeks, 2 weeks, 1 week and 24 hours old. It was found that three out of the five techniques (1,2-indanedione with zinc chloride, PDMAC® paper, and ThermaNin®) developed fingerprints on both the thermal and non-thermal sides of the paper. It was found that 1,2-indanedione with zinc chloride and PDMAC® paper developed the highest number of fingerprints consistently. In many cases, treatment with PDMAC® paper directly after 1,2-indanedione with zinc chloride seemed to allow visualization of additional prints and enhanced fluorescence. This modified method was then applied to real receipt samples that were treated as mock evidence. In most cases, the same results occurred after treatment with 1,2-indanedione with zinc chloride and PDMAC® paper, but there were some samples where an additional latent print was seen after PDMAC® paper treatment. Lastly, it was studied whether magnetic powder, a common starting point in latent print processing sequences, interferes with other techniques. Fingerprints were developed with either plain black magnetic powder or fluorescent magnetic powder, followed by additional processing by either 1,2-indanedione with zinc chloride, PDMAC® paper or ThermaNin®. The only method that showed additional fingerprint development was 1,2-indanedione with zinc chloride on non-thermal side fingerprints previously developed with plain magnetic black powder; however, the black magnetic powder hindered the fluorescence.

In conclusion, the use of 1,2-indanedione with zinc chloride and PDMAC® paper allowed the highest number of prints to be visualized. In some cases, combining these two methods allowed previously missed fingerprints to be visualized. These worked best when other techniques were not previously used. These techniques were simple, required little preparation, and could be left alone to develop while performing other tasks. The use of either of these two methods alone would be sufficient on thermal paper samples, but using them in sequence may increase the likelihood that all fingerprints present have been found.

B57 Shooting Distance Estimation Using Gunshot Residue (GSR) on Mammalian Pelts

Cory A. Weiss, BS, Pennsylvania State University, 329 Whitmore Labratory, University Park, PA 16802; Ralph R. Ristenbatt III, MS, Penn State University, Forensic Science Program, 107 Whitmore Laboratory, University Park, PA 16802; and Jason W. Brooks, VMD, PhD, The Pennsylvania State University, Animal Diagnostic Laboratory, Wiley Lane, University Park, PA 16802*

After attending this presentation, attendees will understand how GSR is used for shooting distance estimation and the complications presented by mammalian fur. The various methods that are used to overcome interferences created by fur will be explained. These methods include some of the traditionally used visual and chemical methods, a few of which have been adapted from their traditional form.

This presentation will impact the forensic science community by providing methods that are useful in the field of veterinary forensic science when animals are subject to crimes involving firearms. This presentation will also provide additional methods of enhancing GSR patterns on surfaces that interfere with the commonly performed GSR tests.

GSR is produced from the discharge of a firearm and, for the purpose of this research, GSR includes any residue originating from the propellant, primer, projectile, cartridge case, residues from previous shots, and cleaning agents or lubricants present in the barrel that travel with the bullet to create a pattern on the target. The patterns, both visible and enhanced, may permit an estimation of muzzle-to-target distance to aid in reconstruction of firearm-related events. In cases involving animals, visualization of GSR is complicated by fur color and length. This requires visual and chemical techniques to be adapted so enough contrast is created to assist with muzzle-to-target distance estimation.

Initial photography of the pattern permits visualization, but the periphery shows little contrast. The use of a high-intensity, tunable-wavelength light source may excite some GSR, resulting in fluorescence, thereby increasing contrast between the fur and GSR. Infrared (IR) light can also be used to enhance GSR patterns using a specialized IR camera or an IR viewer. Radiography can be employed to detect the presence of radiopaque metallic particles surrounding the entrance hole. Once all methods of visual enhancement are complete, the Modified Griess test (MGT) can be used to detect the presence of nitrites.

Cow and rabbit hides were shot from a range of distances from contact to three feet with jacketed and unjacketed ammunition using handguns of various calibers, including a .38 Special, a 9mm, and a .45 Automatic Colt® Pistol (ACP). Visualization with white light and IR light shows patterns increasing in size as muzzle-to-target distance increases. In some instances, the presence of a radiopaque ring, presumably metallic lead, around the entrance hole was detected with radiography. The ability to visualize this ring can be enhanced by adjusting characteristics of the image, allowing the radiopaque ring to be visualized at greater distances. As expected, both observable features begin to fade with increasing muzzle-to-target distance. The MGT was conducted using filter paper rather than photographic paper and applying the heat to cheesecloth on the backside of the filter paper. Results of the MGT are consistent with the visual methods, as the patterns increase in size and become more dispersed with increased firing distance.

Gunshot Residue, Mammalian Pelts, Shooting Reconstruction

B58 The Development of an Infrared Microspectroscopy Method for Microcrystals

Michael Cain, Jr., West Chester University of PA, 750 S Church Street, Schmucker Science S, West Chester, PA 19383; and Monica Joshi, PhD, West Chester University, Dept of Chemistry, Schmucker Science, S, 750 S Church Street, West Chester, PA 19383*

After attending this presentation, attendees will better understand the combined role of infrared microspectroscopy and microcrystalline tests for the analysis of drug evidence.

This presentation will impact the forensic science community by creating a deeper understanding of the reliability and validity of an infrared microspectroscopy method for the analysis of drug microcrystals. This presentation describes the challenges and solutions associated with growing microcrystals on substrates suitable for transmission and reflectance infrared analysis.

Microcrystalline tests have long been used by forensic chemists for the analysis of drugs, but there is continued debate regarding the extent of their discriminatory power. The debate lies in the fact that the chemistry of the microcrystals is not completely understood, although characteristic crystals are obtained for some substances. Lack of tangible instrumental data to confirm the microcrystal identity has steered analysis schemes away from these tests; however, microcrystalline tests are advantageous for several reasons. They are easy to perform, require virtually no sample preparation, use negligible amounts of solvents, require microgram quantities of test samples, are cost-effective, very sensitive, are non-destructive and, most importantly, very rapid. Analytical techniques that can combine the simplicity of the microcrystalline tests and molecular structure information would be very useful.

Infrared spectroscopy is widely used in forensic laboratories for the analysis of drug evidence and is classified as a category A technique in the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) analytical techniques, affording the highest discriminating ability. Infrared spectroscopy is a valuable tool for differentiating between isomers based on spectral differences. Combining infrared microspectroscopy with drug microcrystals will provide unambiguous confirmation of the crystal identity, thereby removing the subjectivity often seen as a weakness of microcrystalline tests.

Infrared microspectroscopy has been previously demonstrated for the analysis of drug microcrystals; however, there are challenges associated with obtaining quality spectra with this technique.[1,2] Three modes of Fourier Transform Infrared Spectroscopy (FTIR) are commonly used: transmission, reflectance, and Attenuated Total Reflectance (ATR). ATR is destructive to the crystals and spatial resolution is poor. The microcrystalline reagents are often acidic and are incompatible with the traditional infrared substrates used for transmission and reflectance studies. A detailed study to improve the understanding of this technique will help analysts adopt this technique in their analytical schemes for drug evidence.

This presentation describes the challenges associated with analyzing microcrystals in the different infrared spectroscopy modes. This presentation compares the quality of spectra obtained with gold-coated slides to the MirrIR low-e microscope slides in the reflectance mode. In the transmission mode, barium fluoride windows are compared to the novel Amorphous Material Transmitting Infrared Radiation (AMTIR) windows. Differences in the vibrational bands of the drug-reagent microcrystal are observed when compared to the drug-only spectra. These differences are documented and quantified. In addition, procedures to reduce interference from the reagent in solution around the microcrystal are presented. These steps improve the quality of spectra obtained for the drug-reagent microcrystals. This presentation discusses the validity and reliability of the infrared microspectroscopy method for microcrystals analyzed in different modes.

B59 Ion Trap Mobility Spectrometry Nuisance Alarm Threshold Analysis for Illicit Narcotics Based on Environmental Background and a Receiver Operating Characteristic (ROC) -Curve Approach

Thomas P. Forbes, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Gaitherburg, MD 21075; and Marcela Najarro, MFS, NIST, 100 Bureau Drive, MS 8371, Gaithersburg, MD*

After attending this presentation, attendees will understand the effect environmental background has on the sensitivity and specificity of Ion Mobility Spectrometry (IMS) narcotics trace detection.

This presentation will impact the forensic science community by demonstrating the discriminative potential of an IMS for trace detection of illicit narcotics relative to the environmental background.

The rapid and sensitive detection of illicit narcotics remains vital to a multitude of law enforcement, corrections/prisons, customs and border protection, and transportation agencies. Laboratory-based analytical techniques including Thin-Layer Chromatography (TLC), Gas Chromatography and Liquid Chromatography (GC and LC), Capillary Electrophoresis (CE), and Mass Spectrometry (MS) have been developed and utilized for the detection of a wide range of narcotic compounds; however, many of these techniques require additional laboratory infrastructure and are not conducive to field deployment or point-of-measurement screening. Colorimetric methods for the detection of narcotics have been developed and provide rapid detection in the field; however, these presumptive tests are subject to screener interpretation of the resulting color(s) and require onsite reagent mixing. In recent years, IMS has surged forward as a robust field-deployable analytical technique for the trace detection of a wide range of compounds, most notably explosives, Chemical Warfare Agents (CWAs), and illicit narcotics.

The discriminative potential of an ion mobility spectrometer for trace detection of illicit narcotics relative to environmental background was investigated with a Receiver Operating Characteristic (ROC) curve framework. The IMS response of cocaine, heroin, methamphetamine, 3,4-Methylenedioxymethamphetamine (MDMA), and Δ^9-Tetrahydro-Cannabinol (THC) was evaluated against environmental background levels derived from the screening of incoming delivery vehicles at a federal facility. More than 20,000 samples were collected over a multiyear period under two distinct sets of instrument operating conditions, a baseline mode and an increased desorption/drift tube temperature and sampling time mode. ROC curves provided a quantifiable representation of the interplay between sensitivity (True Positive Rate (TPR)) and specificity (1 – False Positive Rate (FPR)). A TPR of 90% and minimized FPR were targeted as the detection limits of IMS for the selected narcotics. MDMA, THC, and cocaine demonstrated single nanogram sensitivity at 90% TPR and <10% FPR, with improvements to both MDMA and cocaine in the elevated temperature/increased sampling mode. Detection limits in the tens of nanograms with poor specificity (FPR ≈ 20%) were observed for methamphetamine and heroin under baseline conditions; however, elevating the temperature reduced the background in the methamphetamine window, drastically improving its response (90% TPR and 3.8% FPR at 1ng). On the contrary, the altered mode conditions increased the level of background for THC and heroin, partially offsetting observed enhancements to desorption. The presented framework demonstrated the significant effect environmental background distributions have on sensitivity and specificity. The implementation of ROC curves demonstrated the significant effect environmental background has on the sensitivity and specificity of IMS trace detection. The particular distribution of environmental background for each screening arena must be considered when evaluating the detection and discriminative potential of a methodology.

IMS, ROC Curve, Narcotics

B60 Primary Ion Middle Ion Structure Analysis (PIMISA®) -Enabled Direct Analysis in Real-Time (DART®) QDa Mass Spectrometer (MS): The Latest Development in Forensic Analysis Efficiency

Rachel C. Beck, PhD, 504 Rolling Hills Drive, Chelsea, AL 35043; Frederick Li, MS, Ionsense Incorporated, 999 Broadway, Ste 404, Saugus, MA 01906; and Brian Musselman, PhD, IonSense, Inc., 999 Broadway, Ste 404, Saugus, MA 01906*

The goals of this presentation are to: (1) describe the reverse search data analysis software, PIMISA®; (2) understand the capabilities of the DART® source, Waters Acquity QDa mass detector, and PIMISA® software; and, (3) recommend workflow that allows scientists to produce high-quality, efficient, and economic drug screening analyses in minutes.

This presentation will impact the forensic science community by introducing an innovative and cost-effective drug screening approach, PIMISA®-enabled DART® Acquity QDa® mass detector, and by recommending a potential workflow for increased efficiency.

The new combination of the reverse search library program, PIMISA®, and DART® -equipped compact mass detector offers an efficient, highly selective, and cost-effective drug screening approach for compound identification in forensic laboratories.

PIMISA®-enabled DART® QDa MS is evaluated for implementation into forensic workflow. The instrument exploits Collision Induced Dissociation (CID) to collect four spectra with varied fragmentation. The PIMISA® program analyzes these spectra, identifying analytes through library matching. The library contained spectra for 170 certified reference materials. This approach was evaluated through accuracy, specificity, limit of detection, experienced versus inexperienced users, and correlation studies. In all studies, samples were analyzed in triplicate with an analysis time of two to five minutes per sample, including data analysis.

Accuracy studies were performed through analyses of 70 adjudicated case specimens (pills, powders, plant materials, etc.) over a 4-day period by an experienced user. Samples were previously analyzed by traditional methodologies (visual identification, microscopy, gas chromatography/mass spectrometry, etc.) and reported to contain up to four drugs. The specificity study was evaluated for six sets of analytes, two pairs in three categories, at concentration ratios ranging from 10:1 to 1:10. Categories were determined by molecular ion differences of 1, 2, and 10s of daltons. Analyte pairs included methadone/alprazolam, codeine/temazepam, methamphetamine/CMP, hydrocodone/oxymorphone, hydrocodone/acetaminophen, and cocaine/procaine. The Limit Of Detection (LOD) study was performed for six analytes representing the Alabama casework population with varying polarities. Two scientists, a novice user (<1 year experience) and an experienced user (5^{+} years experience), and two sample introduction methods (semi-automated versus manual) were compared for 20 randomly selected, adjudicated cases (not included in the previous 70) in the blind study. The semi-automated sample introduction method utilized wire mesh consumable (QuickStrip®) cards, while the manual method used fused capillaries. The correlation study was designed to compare a DART® Time Of Flight (TOF) /MS with the PIMISA®-enabled DART® QDa MS. An experienced user re-analyzed 20 of the 70 adjudicated case samples on the DART® TOF/MS and compared the data.

Results of the selectivity studies were calculated as percentages of "analyte detection" versus "negative" and ranged from 81% to 100%. In the specificity study, analyte identification of molecular ions within 1 and 2 daltons was not observed at certain concentration ratio differences and this ratio varied between analyte pairs. For the 1 dalton separation pairs, observed interference began at concentration ratios of 2:1 for methadone/alprazolam and 4:1 and 1:10 for codeine/temazepam. Concentration ratio interference for methamphetamine/CMP was observed at 2:1, while hydrocodone/oxycodone was observed at 5:1. No concentration ratio interference was observed for cocaine/procaine; however, hydrocodone/acetaminophen was observed at 4:1. The LOD study included analysis of methamphetamine, diphenhydramine, cocaine, alprazolam, methadone, and THC. The cutoff concentration results varied between 0.5µg/mL and 10µg/mL. The robustness of the approach was demonstrated by both sample introduction and user experience during the blind study. Results for the experienced user were consistent between both sample introduction methods with a screening acceptability (accuracy and false positive) of 90%. Results for the novice user ranged from 70% to 80% screening acceptability with manual sampling preferred. Data comparisons

of the PIMISA®-enabled DART® QDa MS to the DART® TOF/MS resulted in 89% accuracy.

The DART® Waters Acquity QDa mass detector enabled with PIMISA® demonstrated capabilities for detection of multicomponent mixtures in minutes. With screening acceptability exceeding 70% and selectivity results above 80%, the approach is determined to be robust and highly selective. Additionally, the platform is shown to be comparable to existing DART® TOF/MS workflows at half the capital investment. Therefore, the DART® QDa MS and PIMISA® approach is an efficient, highly selective, and economic platform for forensic drug screening.

DART® MS, PIMISA® Software, Forensic Drug Screening

B61 Latent Print Development on Duct Tape Using Rhodamine 6G/Tween® 20 Solution on Simulated Evidence Samples

Nicole Rapino, BA, 6727 Country Club Drive, Huntington, WV 25705; Stephen C. King, 725 Jefferson Road, South Charleston, WV 25309; Catherine G. Rushton, MSFS, Marshall University Forensic Science Program, 1401 Forensic Science Drive, Huntington, WV 25701; and Pamela J. Staton, PhD, Marshall University Forensic Science MSFS & Center, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will have an opportunity to investigate this process and, in the future, possibly bring to their laboratories a latent print developing process that will both reduce the processing time and the materials needed.

This presentation will impact the forensic science community by offering a possible alternative latent print developing process for adhesive tape with results of equal if not better quality to two currently used processing methods for gray duct tape.

Forensic examiners are able to obtain multiple forms of information from gray duct tape submitted as crime scene evidence. While this can include DNA and trace evidence, it is also possible to apply one of the oldest forensic disciplines: the examination and development of latent fingerprints. While there are multiple techniques used to process adhesive tape for latent prints, currently different procedures are employed for processing the adhesive side versus the non-adhesive side of the tape. A parent study to this research optimized a rhodamine 6G/Tween® 20 solution that was successful in allowing both sides of adhesive gray duct tape to be simultaneously developed for latent prints after cyanoacrylate fuming, therefore shortening the overall processing time and materials. The results obtained from the former study were dependent on the use of pristine tape samples not often received as evidence, whereas the focus of this research involves validating this optimized solution for use on tape samples representative of the conditions commonly found in real-life crime scenes.

The research presented summarizes the results obtained when samples of gray duct tape were prepared to simulate real-life evidence samples, separated, and subsequently processed for latent fingerprints. Tape sample preparation involved attaching sample adhesive side to adhesive side, adhesive side to non-adhesive side, and simulations meant to represent the binding of a victim. Tape separation techniques included the use of adhesive neutralizer un-du®, a freezing technique, and the application of liquid nitrogen. After separation, each tape sample was processed using one of three processing techniques. These included either the optimized rhodamine 6G/Tween® 20 solution, crystal violet, or P-Methoxybenzylamino-4-nitrobenz-zoxa-1,3-Diazole (MBD). Three troubleshooting studies compared how the rhodamine 6G/Tween® 20 solution interacted with seven different brands of gray duct tape, two different fuming techniques, and three different alternative light sources.

Results obtained supported the conclusion that the optimized rhodamine 6G/Tween® 20 solution is a successful method for developing latent fingerprints simultaneously on both sides of duct tape samples representing the condition often encountered as evidence to a crime.

Latent Prints, Duct Tape, Rhodamine 6G

B62 Do Hygiene Products Cause False Positives in Arson Investigations?

Sierra M. Stinson, 1214 Scenic Drive, Latrobe, PA 15650; Gabriel M. Walkup, 329 McLane Avenue, Morgantown, WV 26505; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will better understand the frequency with which male hygiene products contain compounds that can interfere with Ignitable Liquid Residue (ILR) analysis. Through this presentation, attendees will learn that although several classes of hygiene products are very unlikely to contain traces of ignitable liquids, other products do contain potential interference that can complicate the interpretation of ILRs found on a suspect's clothing.

This presentation will impact the forensic science community by presenting information that may lead to the ability to help arson investigators arrive at better conclusions about the presence of ILRs on a suspect's clothing.

Arson investigators often search for the presence of ILRs in fire debris samples that are collected from suspected arson scenes and suspects. Such residues most frequently involve gasoline but can include other petroleum distillates, such as the kerosene. As described in the American Society for Testing and Materials (ASTM) E1618, fire debris analysts typically use Gas Chromatography/Mass Spectrometry (GC/MS) data to analyze samples for compounds that are common in ignitable liquid residues. These compounds include aromatics, naphthalenes, straight chain alkanes, branched alkanes, and cyclic alkanes. During an investigation, a suspect's clothing is sometimes collected and analyzed for the presence of ILRs. Previous research has shown that certain matrices — including clothing, fabric and footwear — contain compounds similar to those found in ILRs. In these cases, it is therefore important to distinguish between "innocent" background residues of ILRs from possible transfer during the crime. Although examples of matrix interference have been quite well documented, there are fewer studies that assess the likelihood of interference from common products that suspects are exposed to on a daily basis.

This study surveys the frequency of occurrence of ILRs in more than 27 men's personal care products. After headspace analysis, GC/MS analysis enabled the different components of ILRs to be elucidated through the use of extracted ion chromatograms. The various samples were analyzed using common extracted profiles, such as m/z 43, 91, and 142. The data were analyzed for the presence of toluene, ethylbenzene, p/o-xylene, n-alkanes, cycloalkanes, and branched alkylnaphthalenes. The results revealed that of the hygiene products tested, all samples were negative for each of the compounds in question. The absence of these compounds indicates that men's hygiene products are very unlikely to result in false positives for ILRs. Therefore, it is very unlikely that in an arson investigation, a male hygiene product would lead to a false positive in the suspect's clothing. In contrast, several hand cleaners and wipes designed for mechanics and construction workers were found to be formulated with petroleum distillates. These products have the potential to interfere with the determination of ILRs.

The results of this study may lead to the ability to help arson investigators arrive at better conclusions about the presence of ILRs on a suspect's clothing.

Arson, Ignitable Liquid Residues, Interferences

B63 Rapid Analysis of Peptides and Proteins Utilizing Matrix-Assisted Inlet Ionization Mass Spectrometry

Kyle E. Vircks, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Jesse M. Zavala, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Yibin Wang, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; Robert B. Cody, PhD, JEOL USA, Inc, 11 Dearborn Road, Peabody, MA 01960; Warren C. Samms, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Roger Kahn, PhD, Harris County Institute of Forensic Science, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will be aware of a recently developed mass spectrometric technique capable of analyzing a vast array of peptides and large biomolecules with minimal-to-no sample preparation prior to analysis.

This presentation will impact the forensic science community by demonstrating a simple method for the analysis of peptides and large biomolecules that can be easily implemented in drug identification laboratories, often utilizing pre-existing equipment.

The number of internet vendors selling performance-enhancing peptides and cosmetic peptides to the public is staggering. These vendors allow customers the convenience of purchasing peptides online at minimal cost with no questions asked. Received as lyophilized powders, these products are reconstituted in bacteriostatic water with the intention of being injected into the body to promote muscle growth or cosmetic augmentation. Though the sale of peptides may not necessarily be illegal, it is a major concern. Counterfeit peptide sales are known to be fairly common, especially those reportedly containing recombinant Human Growth Hormone (rHGH). This leads to questions regarding the authenticity of the peptides being sold and, more importantly, concerns regarding health and safety.

Many drug identification laboratories do not have protocols in place for successful identification of peptides and large biomolecules. Forensic drug analysis typically relies on Gas Chromatography/Mass Spectrometry (GC/MS) for identification; however, this technique is limited to relatively small molecules that are readily vaporized at the inlet. Due to the increasing presence of high-resolution ambient ionization mass spectrometers in crime laboratory settings, protocols can be easily implemented that utilize the analytical method discussed in this presentation. More importantly, this technique requires no external ion source or additional equipment aside from the mass spectrometer.

Various peptide standards and case samples were successfully analyzed utilizing matrix-assisted inlet ionization MS. To determine the molecular mass of the peptides, samples were dissolved in 1:1 acetonitrile:water with 1% formic acid. The matrix compound, 3-Nitrobenzonitrile (3-NBN), was added to the sample solutions until a noticeable amount of solid accumulated at the bottom of each sample vial. Approximately 5µL of liquid sample, including some of the solid 3-NBN, was drawn up into a microliter pipette. The sample mixtures were introduced directly to the mass spectrometer inlet to initiate ionization. In a matter of seconds, Electrospray Ionization (ESI) -like spectra were obtained. Molecular masses were calculated using a mass spectral interpretation software package.

To further characterize the peptides, a simple enzymatic protein digestion procedure was utilized. Matrix-assisted inlet ionization was utilized to analyze the resulting peptide fragments. Possible identifications for each peptide were assigned by comparing each digested spectrum against an online peptide database. Combined with the molecular mass attained from analysis of the intact peptides, identification of each peptide was made at a reasonable level of certainty.

This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this exhibition are those of the authors and do not necessarily reflect those of the Department of Justice.

Peptides, Mass Spectrometry, Inlet Ionization

B64 The Effect of Environmental Conditions and Substrate Material on the Weathering of Gasoline and Light Petroleum Distillates

Matthew Ciano, 56 Lauren Avenue, Dix Hills, NY 11746; Robert H. Powers, PhD, University of New Haven, Dept of Forensic Sciences, 300 Boston Post Road, West Haven, CT 06516; Erika Chen, MS, 6254 97th Place, Apt 7E, Rego Park, NY 11374; Michael Valetutti, MS; and Brooke W. Kammrath, PhD, University of New Haven, Forensic Science Dept, 300 Boston Post Road, West Haven, CT 06516*

After attending this presentation, attendees will understand how different environmental conditions and substrate materials affect the chromatograms of weathered ignitable liquids and how this affects their class identification.

This presentation will impact the forensic science community by offering attendees a better understanding of the consequences various conditions have on the chromatograms of weathered ignitable liquids and the effects these conditions have on their classifications.

In fire investigations, it is often crucial for analysts to determine if an ignitable liquid was present at the scene, as these liquids are often used as accelerants. A wide variety of ignitable liquids exist that can be used to help start or maintain a fire. The most commonly used is gasoline, in part because it is widely available and cost effective. Light petroleum distillates, such as paint thinners, lighter fuels, and cleaning fluids, are also a commonly used class of ignitable liquids because they too are easily obtainable and highly flammable. Both of these classes of ignitable liquids contain many highly volatile compounds and are particularly susceptible to weathering. Weathering is the effect of evaporation on the chemical makeup of an ignitable liquid. Samples recovered from fire scenes rarely show the characteristics of unweathered materials, so criminalists must be capable of recognizing ignitable liquids in their weathered forms.

It has long been stated that a wide variety of conditions may have effects on the weathering process of ignitable liquids. These conditions can include extent, temperature, air composition, airflow, exposure to sunlight (specifically Ultraviolet (UV) light), the chemical makeup of substrates, and several others. Various studies have sought to use pattern recognition software to either classify the ignitable liquids and/or determine the original conditions under which a sample was weathered. Few published studies have investigated how these conditions affect the presence of the various different compounds detected in ignitable liquids.

In this research, samples of three different ignitable liquids were studied: gasoline, lighter fuel, and a simulated ignitable liquid mixture made up of ten compounds from classes commonly found in ignitable liquids (alkanes, aromatics, and condensed ring aromatics). The simulated ignitable liquid mixture serves as a simpler system in which the effects of the different conditions on specific homologous chemicals can be studied before looking at the more complex mixtures that make up actual ignitable liquid samples. All samples were weathered to 25%, 50%, 75%, and 90% extents by volume while varying the following conditions: container size, temperature (a greater range of temperatures than in prior studies), exposure to UV, and substrate identity. Samples of each were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS), and the resulting chromatograms compared to determine any notable differences. Results indicate that extent and temperature have the greatest impact on the pattern of the weathered chromatogram, while other conditions have limited effects. Although the differences in the chromatograms from samples of the same ignitable liquids weathered to the same point are not significant enough to result in one concluding that they come from different classes, the different conditions can cause them to appear as if weathered to different extents. Consequently, these conditions must be considered and included in calculations if mathematical modeling of weathered ignitable liquids is to have meaningful and successful real-world application.

Arson, Ignitable Liquids, Weathering

B65 The Potential of Geochemical Soil Surveys for the Discrimination of Soil Traces From Remote Bushland Sites

Michael Aberle, BA, National Centre Forensic Studies, University of Canberra, Bruce, ACT 2601, AUSTRALIA; Brenda Woods, PhD, Australian Federal Police, Majura Road, Canberra 2601, AUSTRALIA; Patrice De Caritat, PhD, Geoscience Australia, GPO Box 378, Canberra 2601, AUSTRALIA; James Robertson, PhD, National Centre Forensic Studies, University of Canberra, Bruce 2610, AUSTRALIA; and Jurian A. WITHDRAWN

B66 Thermochemical Characterization of Cannabinoids by Porous Layer Open Tubular-Cryoadsorption (PLOT-Cryo) and Nuclear Magnetic Resonance (NMR)

Tara Lovestead, PhD, NIST, 325 Broadway, Boulder, CO 80305; Jessica Burger, PhD, NIST, 325 Broadway, Boulder, CO 80305; and Thomas J. Bruno, PhD, NIST, 325 Broadway, Boulder, CO 80305*

After attending this presentation, attendees will understand the importance of characterizing thermophysical properties (both vapor pressure and enthalpy of association) of two important cannabinoids, Cannabidiol (CBD) and Δ^9-Tetrahydrocannabinol (Δ^9-THC), for the development of useful, in-the-field vapor phase detection devices to aid law enforcement personnel in determining recent illicit drug use.

This presentation will impact the forensic science community by providing insight into the complexities surrounding the two most important questions that need to be addressed to develop an in-the-field vapor phase detection device to determine cannabinoid intoxication: (1) what is the correct "catch" material and how is it made selective for the compounds that will indicate intoxication; and, (2) what is the correct way to "release" these compounds for accurate analysis. This presentation will provide the chemical foundation necessary to begin to answer these non-trivial questions.

Decreased criminalization of cannabis has led to a surge in both medical and recreational use. Different plant cannabinoids impart either a therapeutic or psychoactive effects (e.g., CBD and Δ^9-THC, respectively). The physical and chemical properties of cannabinoids are difficult to investigate because cannabinoids are unstable in the presence of oxygen and heat. It is also difficult to detect recent use/abuse of cannabis with a chemical or biological test. While methods do exist to detect Δ^9-THC in the blood, urine, saliva, breath, and hair, these tests cannot indicate either recent use or intoxication/impairment.

In this study, the vapor pressure and enthalpies of association of Δ^9-THC and CBD were characterized by use of the ultra-sensitive, quantitative, trace headspace analysis technique, PLOT-cryo, and a 600MHz NMR spectrometer.[1-3] In the first experiment, PLOT-cryo was used to make thermodynamic measurements of the enthalpy of vaporization of select cannabinoids. The mass collected in the vapor phase is presented in the form of a Van't Hoff equation plot, which plots the concentration collected as a function of headspace collection temperature. A linear relationship of the recovered mass as a function of inverse collection temperature reveals the predictive capability of the methodology employed here.

In addition to PLOT-cryo techniques, NMR has been used to examine minute structural changes of Δ^9-THC and CBD in the presence of selected modifiers (such as Gas Chromatography (GC) stationary phases) and solvents. The ability to monitor intermolecular interactions of specific protons in biologically active molecules provides a more in-depth understanding of the thermodynamic and kinetic data associated with intermolecular interactions than is usually possible and is important in evaluating physiochemical properties and reactivity parameters. These parameters, such as association constants and enthalpies of association, have successfully been used to model thermodynamic and kinetic data. The resulting data were used to develop solvation models, which are used to guide research in more effective and rapid separation and detection methods and for the development of future field-ready detection devices.

Measurements on the vapor pressure and enthalpy of sublimation for pure Δ^9-THC and pure CBD will be presented as well as the enthalpies of associations of these compounds with different GC stationary phases. In conclusion, these important thermochemical data will inform the most useful materials for catch and release of cannabinoids for in-the-field law enforcement detection device development.

B67 The Applicability of Vacuum Ultraviolet (VUV) Spectroscopy as a Gas Chromatography (GC) Detection Technique for Synthetic Cannabinoids

Cory A. Vaught, BSc, George Washington University, 2100 Foxhall Road, NW, Somers Hall, Washington, DC 20007; Angelica D. Szewczak, BS, 8105 Leon Street, Philadelphia, PA 19136; Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Jonathan P. Smuts, PhD, VUV Analytics Inc., 715 Discovery Boulevard, Ste 502, Cedar Park, TX 78613; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand some of the detection principles of Gas Chromatography-Vacuum Ultraviolet (GC-VUV) spectroscopy; in particular, the ability to differentiate synthetic cannabinoids by their absorption spectra. Attendees will gain insight into whether GC-VUV should be used by forensic chemists to identify and detect emerging drugs.

This presentation will impact the forensic science community by presenting a new instrumental technique that has the potential to enhance the ability to screen or confirm the presence of synthetic cannabinoids. This information would be beneficial in assisting the analyst in determining which controlled substance is present and in distinguishing between a controlled and a non-controlled emerging synthetic cannabinoid.

The recently introduced detection method of VUV spectroscopy provides for rapid and relatively low limits of detection via absorption in the wavelengths range of 115nm and 240nm, a region in which almost all chemicals absorb.[1] The detector is capable of both qualitative and quantitative analysis and requires minimal maintenance.[1] VUV spectroscopy can be particularly helpful in the identification of positional isomers through distinctive absorption spectra, which can be particularly difficult to distinguish by Mass Spectrometry (MS) techniques. The VUV detector can also de-convolute co-eluting compounds by matching the measured signals to distinctive library reference spectra.[1] The library spectra can be updated with standards of compounds, to have an expanding library for screening and confirmation purposes. This is particularly useful in aiding in the detection and differentiation of synthetic cannabinoids and their isomers, many of which have the same exact mass and similar retention times.

In this study, VUV spectroscopy was investigated for the detection and differentiation of synthetic cannabinoids. Separation was performed using GC with a VUV detector. The synthetic cannabinoids studied consisted of 22 synthetic controlled drugs and at least 8 non-controlled isomers of controlled JWH-018 were analyzed using GC-VUV. Although all 22 solutes could not be distinguished via retention time, unique UV spectra were obtained for the target solutes.

Although some co-elution was observed for the controlled synthetic cannabinoids and non-controlled isomers of controlled JWH-018, the co-eluting compounds could be differentiated from one another by their individual spectrum. For the most part, unique UV spectra was obtained for the individual isomers. It is possible to determine the basic structure of the controlled synthetic cannabinoids from the shape of the spectra. Furthermore, the work demonstrates that GC-VUV is particularly valuable for the detection of controlled and non-controlled isomers of synthetic cannabinoids and the spectra can be used in conjunction with the retention times and MS spectra from runs using GC/MS or other relevant technique to identify positional isomers and diastereomers.

Synthetic Cannabinoids, Isomers, VUV Spectroscopy

B68 Profiling Reaction Intermediates and By-Products in Illicit Synthetic Drug Samples Using Direct Analysis in Real Time (DART®) and an Ion Trap Mass Spectrometer

Ashley Windom, The University of Tampa, 2417 W Gray Street, Apt A, Tampa, FL 33609; and Kenyon M. Evans-Nguyen, PhD, 401 W Kennedy Boulevard, Tampa, FL 33606*

After attending this presentation, attendees will better understand the detection of impurities present in synthetic drugs for the purpose of sourcing the drug being analyzed. Attendees will be aware of a method being developed for this purpose based on DART® ionization coupled with an ion trap mass spectrometer.

This presentation will impact the forensic science community by demonstrating a new approach for sourcing synthetic drugs. DART®-ion trap Mass Spectrometry (MS) is a rapid technique and the Tandem Mass Spectrometry (MS/MS) capabilities can determine the presence of minority components in samples that are primarily synthetic drugs.

Profiling of excipients has been previously used to source "cut" drugs. Characterization of impurities in methamphetamine samples can be an effective tool to determine the synthetic pathway used to make the drug. Typically, these profiling approaches have been conducted with Gas Chromatography/Mass Spectrometry (GC/MS). The goal of this work is to explore rapid drug sample profiling using DART® MS and to focus on contaminants in newer synthetic drugs. Recently seen designer drugs, such as the synthetic cannabinoids, are produced through multi-step reactions that are significantly more involved than methamphetamine production. Clandestine facilities are unlikely to have rigorous quality control and may contain some amount of impurities due to insufficient sample clean-up. These containments (even when present at low levels) are likely to originate from intermediate products in the multi-step reaction and could potentially be used to source the synthetic batch from which the drug came.

Using DART® to profile the impurities in these samples imparts the advantage of a fast and simple analysis with little sample preparation. The use of an ion trap capable of MS/MS analysis will allow detection of impurities present at low concentrations in a sample with large amounts of the drug product. This type of analysis allows for isolation of a known impurity ion and further fragmentation of that ion to yield a selective signal with high sensitivity.

Initial validation experiments were performed using an IonSense® DART® source coupled with a Thermo™ LTQ XL™ ion trap mass spectrometer. Diphenhydramine was used as an uncontrolled analog drug. The synthesis reaction was conducted using a commonly employed pathway and fractions from various points in the reaction were analyzed. Several reaction intermediates were observed in the final product and identified using MS/MS. Current work is focused on the synthesis of alkyl indoles, which are intermediate products used to make the naphthylindole class of synthetic cannabinoids (i.e., JWH-018, AM-2201). Additionally, a flow system was constructed and coupled with the DART® source for real-time analysis of the reaction products during synthesis.

Near-future work will focus on several areas: (1) determining the relative dynamic range of the DART®-ion trap instrument; (2) comparing this parameter with GC/MS analysis; and, (3) analyzing actual illicit synthetic drugs. The purity of clandestine synthetic drugs is likely to be relatively high, such that any signal from minority contaminants may be masked by the signal from the drug itself. The initial goal is to determine at what level the minority components can be determined in the presence of overwhelming signal for the majority component. The signal-to-noise for low-level contaminants is significantly enhanced through the use of MS/MS. The levels of minority components determined using DART®-MS/MS will be compared with the signal achieved using GC/MS. Finally, actual synthesized cannabinoids will be tested to determine if the presence of reaction intermediates or byproducts can be determined in these samples.

DART®, Impurity Profiling, Synthetic Cannabinoids

B69 A New Method for Non-Contact Recovery of Footwear Mark Impressions Using a 3D Structured Light Scanner

Paul Norris, Teesside University, Borough Road, Tees Valley, Middlesbrough TS1 3BA, UNITED KINGDOM; Tim Thompson, PhD, Teesside University, School of Science & Engineering, Borough Road, Middlesbrough, Cleveland TS1 3BA, UNITED KINGDOM; and Mark Butler, PhD, Borough Road, Tees Valley, Middlesbrough TS13BA, UNITED KINGDOM*

After attending this presentation, attendees will be informed regarding a new method for the recovery of footwear mark impressions in a totally non-contact manner using a 3D structured light scanner.

This presentation will impact the forensic science community by providing attendees with the ability to recover footwear mark impressions from crime scenes in a non-contact manner, which is faster than the traditional methods. The evidence can then be analyzed and shared electronically.

Footwear marks are one of the most common forms of evidence to be found at a crime scene and can potentially offer the investigator a wealth of intelligence. It is vital that this evidence is collected and preserved. Currently the combined techniques of photography and casting the mark using a product such as dental stone are used. The casting of the mark is a destructive process and, in the event of improper casting, potentially the evidence is lost. The goal of this research is to highlight a new and improved technique for the recovery of footwear impressions using 3D structured light scanning. This new approach is a non-invasive, safer method and is fast, reliable, and extremely accurate. Further, it is capable of recovering more detail than traditional casting techniques and does not require any fixatives to be used. The system used is portable and, after initial training, is relatively easy to operate. The system needs to be calibrated before use — this is a key stage — as it determines the accuracy of the scanned data.

To date, it has been possible to collect evidence from a number of different substrates including fine and coarse sand, soil, compost, and is currently being trialed on snow. After the data have been processed, which can easily be conducted at the crime scene, it is easy to share electronically. This will undoubtedly speed up the investigation process. If the need were to arise, the scanned footwear mark can be 3D printed so that investigators would have a physical model. An important phase of this research will be the validation stage, in which experts will be asked to compare the 3D models against casts of the same impression. The purpose of this is to obtain expert opinions as to whether the 3D scanned images capture at least the same amount of information as the traditional method of casting the mark. The second stage of the research is to look at the potential of using computer software to produce automatic comparisons of shapes and patterns to enable class matches. Using the software, it is also possible to overlay scanned items of footwear with the scanned impressions to aid in the identification process. Another important area of this research is to determine how the new method could be introduced to the courtroom.

It is envisaged that this research will provide investigators with a complete package, which includes the recovery of impression evidence along with the tools to conduct the comparisons of the evidence.

Footwear Marks, 3D Scanning, Crime Scene

B70 Service Implementation for the Identification of Gunshot Residue (GSR) in Rio de Janeiro, Brazil

Denilson Siqueira, PCERJ, Rua da Relação, 42 Centro, Rio de Janeiro, BRAZIL; and Renata C. Silva, Inmetro, Av Nossa Senhora das Graças 50, Rio de Janeiro 25250-020, BRAZIL*

After attending this presentation, attendees will better understand how to validate their methodologies and consequently improve laboratory analysis.

This presentation will impact the forensic science community by providing reliable information in criminal investigations and in the analyses of evidence to be presented before a court.

Metrology has become an indispensable tool for improving products and services to today's world where competitiveness demands more quality. The trinomial, reliability, credibility, and quality primarily serves the needs of justice, which uses laboratory tests for these reasons. In Brazil, there is no culture of research and development of forensic sciences, which causes a serious disparity in relation to global scientific advances. The Institute of Metrology, Quality and Technology (Inmetro) of Brazil has responsibility for standard measurements and is therefore the executing agency of public policies in this area.

The primary objective of this work was to validate methodologies for GSR analysis by a Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) technique according to the American Society for Testing and Materials (ASTM) 1588/2010 to meet the demands generated by Brazilian forensic institutes and to provide metrological traceability of all analyses. The results and protocols are available for the forensic community through specific publications and personal training. To this end, Inmetro has established a cooperation with the civil police of the state of Rio de Janeiro (PCERJ).

The observation of inconsistencies in the results obtained in the analysis of the Reference Material (RM), the analysis of samples obtained using different media, as well as problems in detecting submicroscopic particles, showcased the need to validate different methodologies. The first validated analysis of GSR was by SEM microscope. A synthetic GSR RM was developed and used in accordance to the International Organization for Standardization (ISO) Guide 34. For quality control, a sample of LaCe (Fe) particles were used, which simulate GSR particles in morphology, size and atomic number contrast. This method is qualitative, but the microscope verification using reference material is also quantitative. The validation protocol included: (1) selectivity, to verify if the presence of interfering particles in the matrix/support intervenes at analytes identification; (2) sensitivity, to evaluate the response variation due to the variation of the analyte concentration; (3) Detection Limit (DL), the smaller amount of analyte present in the sample that can be detected by the method, regardless of the background (DL is related to particle size and not to its concentration); (4) accuracy, to evaluate the agreement between the result of a test and the accepted reference value; and, (5) precision, results repeatability and reproducibility.

The data revealed that a random laboratory has a 79% probability of detection and a 76% chance of identifying a particle of 1µm in diameter. On average, 90% of 1.5µm particles are detected and 90% of particles ≥ 1.6µm are identified. The acquisition of a Quanta FEG 450 microscope allowed precision tests to be performed, resulting in acceptable values of repeatability (<1.3). The equipment has resolution to identify particles smaller than 0.5µm, generating more consistent results in all areas, especially the GSR analysis.

The results presented suggest that it is possible to perform more precise forensic analyses, improving forensic services and thus emitting more reliable reports. The GSR identification service was implemented in mid- 2013 and in April 2014, the first official test report was produced. Since then, 194 samples have been analyzed, resulting in 82 test reports. The service offered by Inmetro to the PCERJ has a direct impact on public safety as it provides essential information in criminal investigations and the analysis of evidence to be taken before a court.

Forensics, Metrology, Validation

B71 Flow Injection Analysis-Triple Quadrupole (FIA-QQQ) Characterization of Organic and Inorganic Constituents of Firearms Discharge Residue (FDR) Using a Single Injection: The Potential for Rapid Screening of FDR

William Feeney, BS, 801 Second Street, New Martinsville, WV 26155; Sydney Brooks, BS, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899-8102; and Suzanne Bell, PhD, West Virginia University, Oglebay Hall, Rm 208, 1600 University Avenue, Morgantown, WV 26506-6121*

After attending this presentation, attendees will be familiar with a GSR screening method using FIA-QQQ.

This presentation will impact the forensic science community by demonstrating a novel and simple screening protocol for FDR that works on an instrument found in many, if not most, forensic laboratories.

One of the intrinsic limitations to the forensic characterization of Gunshot Residues (GSR) is the lack of a quick and reliable screening test. Color tests have been used in the past on skin swabs, but most focus on nitrites and nitrates, which are nearly ubiquitous in the environment and thus of limited value for screening. Other methods used in studies, such as distance determinations, are not amenable to skin sampling or skin swabs. An ideal method would be designed to work with skin samples collected in the same or similar manner as stubs currently collected for traditional Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) characterization using the American Society for Testing and Materials (ASTM) 1588 methodology. In addition, such a method would have to be non- or minimally destructive to insure that subsequent confirmation analysis could be conducted without limitations. This presentation will present one option that is based on stubs, skin sampling, flow injection analysis, and mass spectrometry. The methodology is capable of detecting elemental and organic constituents (diphenylamine, ethyl centralite, and 2,4-dinitrotoluene), as well as lead, barium, antimony, and copper from a single extraction and in the same injection. The method presented here utilized QQQ mass spectrometry and Electrospray Ionization (ESI), but the approach could be adapted to any ESI-MS system. With FIA, no chromatography is needed.

For this project, typical SEM collection stubs were covered with a tacky adhesive-free pad used to mount posters. In a forensic setting, this stub sample would be collected using the same dabbing method used for GSR. The GSR stub would be collected first to insure no compromise. The sticky surface of the second stub collects remaining traces of both organic and inorganic residues. The pad is transferred to a plastic tube for extraction in dilute (~ 0.4%) nitric acid/water/methanol with sonication and mild heating. An equal volume of a complexing agent (15-crown-5-ether) at 200ppm is added to complex metal cations, such as Pb^{2+} and Ba^{2+}. The solution is centrifuged before injection using FIA. The QQQ detection is based on transitions (Multiple Reaction Monitoring (MRMs)) focusing on precursor ions and collision by-products. For example, diphenylamine forms an MH+ ion with a mass of 169.9m/z; collisions result in the formation of ions with m/z values of 92.6 and 65.4. To detect metal ions, the precursor ion is a complex between the metal, the ligand (crown ether), and nitrate ion. The crown ether did not interfere with any of the organic constituents. Samples from two weapons (0.38 revolver and 9mm semiautomatic) were characterized using skin swabs collected from shooters discharging one to five rounds in controlled firing events; lead, copper, and ethyl centralite were the most common constituents detected.

This presentation will present method development and validation data in addition to the results from authentic shooting scenarios. This method shows promise for forensic applications as it uses instrumentation available in many forensic toxicology sections but avoids the need for chromatographic analysis, reducing the barriers to routine use, given that method validation is simplified.

Firearms Discharge Residue, Flow Injection Analysis, Rapid Screening

B72 A Single Extraction, Consecutive Detection of Organic and Inorganic Firearms Discharge Residue Using Thermal Desorption Gas Chromatography/ Mass Spectrometry (TD-GC/MS) and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS)

Kristin M. Kelly, BSc, West Virginia University, 1505 N Willey Street, Apt 109, Morgantown, WV 26506; Joseph A. Stein, West Virginia University, 251 Stewart Street, Apt 204B, Morgantown, WV 26505; and Suzanne Bell, PhD, West Virginia University, Oglebay Hall, Rm 208, 1600 University Avenue, Morgantown, WV 26506-6121*

After attending this presentation, attendees will be familiar with a method that allows for characterization of both organic and inorganic Gunshot Residue (GSR) using a single sample.

This presentation will impact the forensic science community by presenting an alternative method for the analysis of Firearms Discharge Residue (FDR) using one hand swab sample.

FDR consists of unburnt and partially burned particles and particulates arising from the primer, cartridge, propellant powder, grease, and lubricant. GSR (an inorganic fraction of FDR) is currently associated principally with the primer and consists of particulates with a characteristic size, morphology, and chemical composition. GSR is detected by Scanning Electron Microscope Energy coupled to Dispersion X-ray (SEM/EDX) analysis with a methodology described by the American Society for Testing and Materials (ASTM) method E-1588-16a. Samples for this type of analysis are collected using a small adhesive stub. Some of the known limitations of this methodology include secondary transfer and concerns arising from newer primer formulations that minimize heavy metals, such as lead. These concerns, coupled with the development of new methods for sample introduction and advanced MS, have led to increased interest in the organic constituents of FDR or Organic Gunshot Residue (OGSR). These residues arise from the propellant, grease, and lubricant and include compounds such as stabilizers (diphenylamines), dinitrotoluenes, and methyl and ethyl centralite. The energetics (nitrocellulose and nitroglycerin) are not routinely used as target analytes for post-firing characterization. While the ability to characterize OGSR could at some point become viable for forensic laboratories, an even better analytical approach would facilitate characterization of both GSR and OGSR from a single sample. Here, a method is described using Thermal Desorption-Gas Chromatography/Mass Spectrometry (TD-GC/MS) to characterize OGSR, followed by acid extraction of the same swab and elemental analysis using Inductively Coupled Plasma/Mass Spectrometry (ICP/MS). The advantage of this method is that a single swab is used for both analyses; this is countered by the loss of morphological information obtained from SEM.

For this project, hand swabs were collected under an approved Institutional Review Board (IRB) protocol using isopropanol and clean room wipes. The collection area was ~1cm x 1cm and all surfaces of both hands were sampled and concentrated into this small surface area. The swab was placed in a thermal desorption probe and inserted directly into the injection port of the GC/MS. A selected ion mode analysis was employed targeting 2, 4-di-tert-butylphenol, 2, 4-dinitrotoluene, diphenylamine, methyl centralite, ethyl centralite, and dibutylphthalates, all common OGSR target compounds. After desorption, the swab was removed and subjected to a single 2% nitric acid extraction, followed by ICP/MS analysis. The method was developed using standards and swabs collected after shooting 10-20 rounds of a variety of weapons and ammunition. Subsequently, samples were collected from known shooters and non-shooters for analysis. Overall, diphenylamine, ethyl centralite, lead, barium, and copper were detected in most cases with three or more shots discharged; the results from smaller caliber weapons were variable with ethyl centralite, lead, and copper predominating. This presentation will describe method development, validation, experimental conditions, and results across a range of authentic sampling situations.

Firearms Discharge Residue, OGSR, GSR

B73 An Evaluation of the Repeatability, Reproducibility, and Uncertainty of Retention Indices and Electron Impact Spectra of Selected Novel Psychoactive Substances (NPS)

Kristin M. Kelly, BSc, West Virginia University, 1505 N Willey Street, Apt 109, Morgantown, WV 26506; Jordan Sekinger, 20008 Silverbell Drive, Morgantown, WV 26508; Victoria Zeger*, 2911 Cavel Street, West Melbourne, FL 32904; and Suzanne Bell, PhD, West Virginia University, Oglebay Hall, Rm 208, 1600 University Avenue, Morgantown, WV 26506-6121*

After attending this presentation, attendees will be familiar with ongoing work related to the characterization and identification of NPS.

This presentation will impact the forensic science community by disseminating current results related to forensic identification of NPS and uncertainties associated with retention indices and Electron Ionization (EI) ion abundances.

The analytical challenges presented by synthetic cannabinoids and cathinones (NPS) include the lack of reference materials and the rapid appearance of new synthetic variants. Consequently, the traditional forensic identification tools cannot keep pace with the flow of new structures and compounds appearing in physical and toxicological evidence. The structural similarity among families of NPS may afford tentative identifications or classifications, but laboratories often must report inconclusive results and new variants may go unrecognized for some time. This can have implications in law enforcement as well as public health, given the range of toxic effects being associated with ingestion of many of these drugs.

A long-term goal of this project is to develop algorithms capable of classifying novel synthetics based on structure and to create similarity measurements that can characterize new NPS as compared to existing and known structures; however, before this goal can be achieved, verified and validated data and figures of merit must be established for the necessary measurands: retention time/retention index and mass spectra; specifically, relative ion abundances. There is no point in attempting to build a quantitative predictive model for mass spectral identification without knowing how much relative ion abundances vary across time and instruments. Reported here are results to date of a selected group of NPS compounds (JWHs, UR-144, and cathinones, as well as methamphetamine and amphetamine) analyzed using three different GC/MS systems over time. All instruments are models commonly used in forensic science laboratories. Variables recorded included tuning conditions, elapsed time since tuning, time since inlet change, time since column maintenance, and all relevant instrumental settings. Retention indices were calculated relative to a C7-C30 alkane ladder. Three levels of sample concentrations were examined: near the detection limit, mid-range, and near the upper end of the linear dynamic range of the instrument. DB-1 and DB-5 columns of different lengths were used. Sample concentrations were at low (close to the method detection limit), mid-range, and high concentrations. Ion repeatability and reproducibility were determined based on the ratios of the ten most abundant ions in the spectrum. In cases in which ions were critical for identification but not one of the top ten abundant, these ions were included and characterized. Figures of merit to date for all instruments will be presented and initial estimates of uncertainty will be presented.

Novel Psychoactive Substances, Uncertainty Estimation, GC/MS

B74 Comparing the Response of Portable Hydrocarbon Detectors to Laboratory Analysis of Household Substrates

Jamie M. Baerncopf, MS, 355 N Wiget Lane, Walnut Creek, CA 94598; and Carl Anuszczyk, MS, Bureau of ATF, 201 Third Street, NW, Ste 1550, Albuquerque, NM 87102*

After attending this presentation, attendees will better understand the effectiveness of electronic hydrocarbon detectors (often referred to as sniffers or electronic noses).

This presentation will impact the forensic science community by informing attendees of the appropriate use of hydrocarbon detectors, which should be used with great caution and as a presumptive tool only.

Electronic hydrocarbon detectors have been commonly used in the field of fire investigations to aid in the possible location of ignitable liquid residues. These devices alert to the presence of volatile hydrocarbons to indicate a potential sampling location. In this study, the selectivity and sensitivity of two different brands of hydrocarbon detectors were examined. Sixteen common household substrates and building materials were tested, including foams, wood, flooring, carpet, and roofing material. Each substrate was tested in triplicate, using both hydrocarbon detectors, and the results were compared to laboratory analysis. Each substrate was tested in unburned and burned conditions to evaluate the effect of the addition of pyrolysis and combustion products. No ignitable liquids were spiked on substrates in this study; however, several substrates known to inherently contain petroleum products were intentionally chosen to determine detector efficacy in detecting such ignitable liquids.

Inherent petroleum products were identified by Gas Chromatography/Mass Spectrometry (GC/MS) in 5 of 16 substrates chosen. For each of these unburned substrates, both hydrocarbon detectors gave negative or inconclusive responses. These were considered false negatives. A sharp increase in the number of positive responses by the hydrocarbon detectors was observed for the burned substrates; however, only pyrolysis or combustion products were identified by GC/MS. These were considered false positives.

Overall, both detectors showed numerous false positives, false negatives, and inconclusive results. For both unburned and burned substrates, the hydrocarbon detectors yielded wrong or inconclusive results ranging from 31% to 56% of the tested samples. Additionally, consistent use of the detectors proved to be difficult as the sensitivity varied greatly during use. On each detector, a knob or dial was used to set the sensitivity, which is expressed as an audible chirp. Instructions regarding these devices require that they emit an audible chirp every one to two seconds, with the chirp increasing in frequency when volatile components are detected. During the study, the frequency of the chirp increased and decreased without any apparent cause. As this study was conducted in a static, climate-controlled environment, the variable sensitivity and poor selectivity could be extremely problematic on a fire scene. As such, these on-scene instruments should be used with great caution and as a presumptive tool only for sample location and selection and should not replace an investigator's training and experience.

Fire Debris, Fire Investigation, Ignitable Liquids

B75 Identification of Potential Target Compounds in Fire Debris

Mary R. Williams, MS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367; Anuradha Akmeemana, MS, National Center for Forensic Science, P O Box 162367, Orlando, FL 32816; and Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will better understand the chemical composition of fire debris from the identification of compounds within ignitable liquid residues and pyrolysis/combustion products from substrate materials.

This presentation will impact the forensic science community by providing information that can be utilized in determining the presence and classification of ignitable liquid residues by identifying potential target compounds.

Fire debris analysis is conducted to determine whether an ignitable liquid residue is present in the fire debris collected from the scene. One challenge to making this determination is the presence of decomposition products from the pyrolysis and combustion of substrate materials at the scene. Some of these decomposition products are extracted along with ignitable liquid residues to form a complex mixture of compounds from both. In 1991, Keto and Wineman developed a method for the analysis and identification of selected target compounds.[1] They identified target compounds from the American Society for Testing and Materials (ASTM) E 1618 classifications of gasoline, medium petroleum distillates, and heavy petroleum distillates.[2] They obtained semi-quantitative Gas Chromatography/Mass Spectrometry (GC/MS) peak areas for these target compounds to construct Target Compound Chromatograms (TCCs). The study determined that TCC for gasoline, medium petroleum distillates, and heavy petroleum distillates were different from those of plywood and carpet with padding. TCCs enable the analyst to visualize low concentrations of ignitable liquid residues in high concentrations of decomposition products.

The study being presented is based on the identification of potential target compounds in all ASTM E 1618 classes and in decomposition products from substrate materials.[2] The data consists of 660 neat ignitable liquids and 106 burned substrate materials from the Ignitable Liquids Reference Collection (ILRC) and the Substrate Databases.[3,4] A library containing retention time and mass spectra of 255 standards has been developed for identification of major peaks within ignitable liquids and substrates in the databases.[3,4] Identification of these compounds within the 766 samples is performed by Target Factor Analysis (TFA), which calculates a correlation between the spectrum of the sample and the 255 test spectra. Logistic regression is performed to convert the correlations to probabilities. When a probability is larger than a specific threshold, that compound is identified as being present in the sample. A maximum likelihood frequency of occurrence in ignitable liquids and substrates is tabulated for each of the 255 compounds. Compounds with a high frequency of occurrence in ignitable liquids and a low frequency of occurrence in decomposition products from burned substrate materials are potential target compounds. This concept can also be applied for each ASTM E1618 class of ignitable liquid.[2]

Fire Debris, Target Compounds, Ignitable Liquids

B76 Probabilistic Assertions in Fire Debris Analysis Based on Chemical Compound Occurrence

Michael E. Sigman, PhD, University of Central Florida, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; Mary R. Williams, MS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816-2367; and Alysaa Allen, National Center for Forensic Science, 12354 Research Parkway, #225, Orlando, FL 32826*

After attending this presentation, attendees will better understand one way to arrive at a probabilistic assertion regarding the presence or absence of ignitable liquid residue in fire debris based on knowledge of the frequency of occurrence of chemical compounds.

This presentation will impact the forensic science community by providing information that can assist in the development of statistical methods in trace analysis.

Ignitable liquids are often complex mixtures of many different chemical compounds. Similarly, the pyrolysis and partial combustion of common household furnishings and building materials often produce many different chemical compounds. The frequency of occurrence of 255 compounds has been determined in the Ignitable Liquids Reference Collection (ILRC) and the Substrate Database.[1,2] An analysis of the compounds in both databases demonstrates that some of the compounds are only observed in ignitable liquids, some are only observed in substrate pyrolysis samples, and some are observed in both types of samples. Failure to see a compound in ignitable liquids or in substrate pyrolysis does not mean that it will never be observed in these sample types. It is possible to estimate the frequency of occurrence in a population for compounds that were not seen in a sample of the population.[3] The approach of Good and Turing uses the maximum likelihood approximation for compounds that occur frequently and an approximation for the frequency of occurrence of compounds that are observed rarely or unseen in a sample.[3] This approach has, for the first time, allowed the determination of the frequency of occurrence of 255 compounds in ignitable liquids and substrates.

The frequencies of occurrence can then be used to classify a sample as positive or negative for ignitable liquid residue. It is also possible to calculate a likelihood ratio for a fire debris sample being positive or negative for ignitable liquid residue. Both of these calculations rely on the identification of a subset of the 255 compounds in a fire debris sample, the frequencies of occurrence of those compounds, and the naïve Bayes approximation. The naïve Bayes approximation assumes independence of the frequencies of occurrence of the 255 compounds. The naïve Bayes assumption is often not true, as is the case here; however, models based on the assumption often work very well. Analysis of 129 fire debris samples from large-scale test burns were performed. The results allow the calculation of likelihood ratios and the subsequent formulation of probabilistic assertions regarding the presence of ignitable liquid residue in each sample. The results will be discussed and evaluated using conventional methods, such as Receiver Operator Curves (ROCs) and Tippett plots. This method will be compared to previously published methods based on the total ion spectrum.[4]

B77 A Quantitative Approach to Differentiating Mixtures of Gasoline and No. 2 Fuel Oil From No. 2 Fuel Oil Using Gas Chromatography/Mass Spectrometry (GC/MS) Target Compound Analysis Ratios

Christopher Guglielmo, MS, 99 Tenth Avenue, Ste 721, New York, NY 10011; Thomas Kubic, JD, PhD, 8 Pine Hill Court, Northport, NY 11768; Nicholas D. Petraco, PhD, John Jay College of Criminal Justice, Dept of Science, 524 W 59th Street, New York, NY 10019-1007; and Philip R. Antoci, MS, NY City Police Department Crime Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432*

After attending this presentation, attendees will better understand the significance and fundamental importance of a quantitative approach to the analysis of ignitable liquids and fire debris samples.

This presentation will impact the forensic science community by demonstrating the application of a quantitative approach and methodology to characterize ignitable liquids and mixtures of ignitable liquids that can be implemented to facilitate the interpretation of analytical data.

The investigation of a suspected arson intimately involves the forensic laboratory. Ignitable liquids, in particular gasoline, are commonly used as accelerants. It is critical to an arson investigation that the presence of a trace amount of an ignitable liquid be detected and correctly identified by the laboratory. The laboratory detection, identification, and proper classification of ignitable liquids recovered from fire debris can be critical to an investigation.

In the United States, many homes and establishments are heated with No. 2 fuel oil. Gasoline, a common fuel and a common accelerant, is detected in many arson cases. A complication can arise when the fire scene involves a home or establishment that is heated with No. 2 fuel. The No. 2 fuel oil product inherently contains the compounds common to gasoline. The task of determining if gasoline is absent or present as a mixture with a No. 2 fuel oil can be both challenging and problematic under certain conditions.

The American Society for Testing and Materials (ASTM) E1618-14, Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography/Mass Spectrometry, is a test method utilized in many forensic laboratories. E1618-14 does not address or provide guidance in the identification and classification of complex ignitable liquid mixtures.

The data presented here include samples of gasoline, home heating fuel oil, and diesel fuel oil collected twice from selected distributors over an eight-month period. The collected samples were analyzed as neat liquids, combinations of neat liquids, liquids at varying degrees of (percent) evaporation, combinations of these evaporated liquids, and mixtures of neat liquids with the liquids at the varying degrees of evaporation. Diesel fuel samples were also collected in light of the fact that the diesel fuel product is purported to be identical to the home heating product without consideration of additives and the dyes used for identification. The samples were prepared with a deuterated internal standard containing benzene-d6, ethylbenzene-d10, and naphthalene-d8 and analyzed by GC/MS.

The data presented will demonstrate the utility of a quantitative approach and target compound ratio analysis methodology in differentiating complex mixtures of gasoline and No. 2 fuel oil from No. 2 fuel oil alone. The analytical methodology presented can be applied to further develop the criteria for the identification, classification, and discrimination of petroleum products and ignitable liquids.

Fire Debris, Ignitable Liquids, GC/MS

B78 Source Inference of Gasoline: The Contributions of Gas Chromatography/Mass Spectrometry (GC/MS) and Gas Chromatography/Isotope Ratio Mass Spectroscopy (GC/IRMS) Analyses

Luc Besson, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; and Olivier Delémont, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne, Vaud CH-1015, SWITZERLAND*

After attending this presentation, attendees will understand the possibilities and limitations of GC/MS and GC/IRMS results, used separately or in combination, for the comparison of gasoline samples from a source inference perspective.

This presentation will impact the forensic science community by providing new knowledge regarding the contribution of fire debris analysis in the association between ignitable liquid traces and possible ignitable liquids.

When gasoline is used to start and/or propagate arson, source inference of gasoline can establish a link between the fire and a potential source. This source inference is an interesting alternative to provide evidence in the event where physical traces (DNA, fingerprints, shoe prints, etc.) left by the perpetrator are rare, or more often than not, disregarded.

The main goal of this research was to develop a GC/IRMS method for the analysis of gasoline samples and to assess its potential to infer the source of gasoline traces compared to the GC/MS performances. An instrument that simultaneously analyzes samples by MS and IRMS was used in this research. An analytical method was developed, optimized, and validated for this instrument. Next, a large sampling of gasoline was collected at several time intervals, representing a regional area market and gasoline of different octanes. After collection, the samples were analyzed, either at that time or after several degrees of evaporation, by GC, then by MS and IRMS. In this research, isotope ratios were confined to measurements of $\delta^{13}C$. Finally, obtained data were processed and interpreted using chemometric methods.

The analyses revealed that the methodology, both for MS and for IRMS, allowed differentiation of unweathered gasoline samples from different gas stations. It also demonstrated that each new filling of gas station tanks generates an almost unique blend of gasoline. GC/MS achieved a better discrimination of samples from different stations, while GC/IRMS was more effective in distinguishing samples collected after each tank filling. Thus, these results indicate that the two components of the analytical strategy can be complementary to the analysis of unweathered gasoline samples.

The results also illustrated that the evaporation of gasoline samples does not compromise the possibility of grouping samples derived from the same source by GC/MS; however, it is necessary to make a selection of variables in order to eliminate those which are influenced by evaporation. Conversely, results demonstrate that the evaporation of gasoline samples has such a strong influence on the isotopic composition of the samples that it is not possible, even by performing a selection of variables, to properly group evaporated samples by GC/IRMS.

Arson, Gasoline, Source Inference

B79 Morphology and Microanalysis of Aluminum (Al) Powders From Amateur Improvised Explosive Device (IED) Methods

JenaMarie Baldaino, MS, 14701 River Walk Way, Apt 389, Woodbridge, VA 22191; Jack Hietpas, PhD, Penn State University, 329 Whitmore Lab, University Park, PA 16802; and JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the forensic potential of combining elemental microanalysis and micromorphology to provide insight into the method of Al powder production.

This presentation will impact the forensic science community by discussing the differences in surface characteristics, elemental composition, and particle micromorphology of Al powders manufactured using various amateur methods and extracted from commercially available products. These results may provide valuable lead identification for forensic investigations.

Starting materials for an IED are readily obtainable from local commercial sources. Al powder, a common metallic fuel, has a wide variety of legitimate uses and is widely available without significant regulatory constraints.[1] Al powders can be obtained from industrial manufacturers or can be produced inexpensively using basic instructional manuals and videos. Due to the online sharing of instructional manuals and published books on how to construct IEDs, bomb-makers are now informed on the easily accessible household materials that can be used to make explosive chemical mixtures.[2]

For this project, Al powders from Al foil, spray paint, pyrotechnics, and Al cans were obtained and produced. Al powder was extracted from Al flake-containing spray paint and pyrotechnics, and was manufactured from Al foil and Al cans using ball-milling, grinding, and blending techniques. For Al flake-containing spray paints, acetone was added to solubilize the binders and additives, followed by centrifugation to form an Al powder pellet; the supernatant was removed to isolate the Al powder pellet, which was then dried by solvent evaporation. For the pyrotechnics, several separation techniques were used to remove the explosives and additives. Density separation techniques were used to separate the charcoal and elemental Silicon (Si) from the Al powder. A hand magnet was used to remove iron filings from "gold" sparklers. Lastly, a ball-milling technique, which used a small 6 lb. rotary dual drum ball mill and ball bearings, and a grinding technique (using a coffee grinder) were used to manufacture Al powder from Al foil and Al cans.

Preliminary results obtained from Scanning Electron Microscopy (SEM) micrographs demonstrate that Al powder manufactured by ball milling could be confidently differentiated from those extracted from an Al flake-containing spray paint. Furthermore, SEM with Energy-Dispersive X-ray Spectroscopy (EDS) analysis of the Al flake-containing spray paints provided additional information that could differentiate between brands and among products within brands. Four different manufacturers of Al flake-containing spray paints were studied: (1) Manufacture A's product contained Al and iron; (2) one of the products from Manufacturer B contained Al, potassium, copper, Si, sodium, and titanium (the other product contained only Al); (3) Manufacturer C's products contained Al and Si; and, (4) Manufacturer D's product contained only Al. All of these elements were present in the Al powder after an acetone wash, which is how amateur bomb-makers are extracting Al powder from spray paints, so these differences are also expected to be present in case samples.

Aluminum Powder, SEM/EDS, Microanalysis

B80 The Effect of Time on the Quantity of Triacetone Triperoxide (TATP) on Different Surfaces

Mohammad H. Alotaibi, PhD, King Abdulaziz City for Science and Technology, National Center for Petrochemical Technology, PO Box 6086, Riyadh 11442, SAUDI ARABIA; Mansour Dahish Ajarim, PhD, Forensic Laboratory, 2883 Al Jabriah Al Kozama, Riyadh 12582-8828, SAUDI ARABIA; Abdulghani Alshehri, PhD, Forensic Lab, PO Box 270603, Riyadh 11352, SAUDI ARABIA; and Ahmed A. Aljanobi, PhD, Forensic Dept KSA, 7687 Alrmayah, Unit 1, Riyadh 3384-14812, SAUDI ARABIA*

After attending this presentation, attendees will understand the best practices for identifying the type of solvent that can be used with TATP swabbing, how long the TATP can survive before decomposition, and how the fingernail of a suspected person can be used to identify the explosives.

This presentation will impact the forensic science community by clarifying the best solvent that can be used to identify the explosives and by explaining how important the use of the suspect's fingernails is in proving that he/she touched the explosives.

In forensic science, the contribution of explosives trace detection in samples from skin, vehicles, hands, and clothes of the suspects has been essential in several forensic cases involving terrorists. Knowing the types of explosives used by terrorists can prevent future attacks by prohibiting these chemicals and controlling their precursors. The forensic analytical report could be used as evidence in judicial proceedings. Recently, the use of peroxide explosives, such as TATP and Hexamethylene Triperoxide Diamine (HMTD), has gradually increased by the terrorists around the world in the production of Improvised Explosives Devices (IEDs) due to their readily available precursors. Many studies have been published on sampling procedures for the collection of residues of firearms and explosives from suspects and/or clothing. The residues generally left inside baggage, bags, vehicle interiors, and garments are collected by a vacuum-lifting procedure and filters. Samples are usually collected by cotton swabs from smooth surfaces, such as skin, work surfaces, floors, leather, plastic, and post-blast debris. Solid Phase Extraction (SPE) is used for swabs and filters of explosives. For the efficient recovery of explosives residues, various materials are used for the sampling media; however, most forensic laboratories are using cotton-based material due to availability, ease of use, and low cost. A wide range of solvents has been reported to assist in the recovery of explosives residues in the sample media which were used.

Knowing the interval of time in which explosives may be active can play an important role in the investigation. Therefore, in this study, TATP was prepared, purified, and analyzed. A known quantity of TATP was applied to different service areas (such as hands, nails, tables, and car seats), then swabbed after different time intervals. The swabs were extracted by an organic solvent and analyzed by gas chromatography. The results disclose that the quantity of TATP left was dependent on the type of surface at a specific time.

Several solvents with different polarities were used. A known amount of TATP was applied to a clean surface of a lab bench. Johnson & Johnson® cotton pads were pre-wet with the selected solvent and directly used to swab the TATP. The pad was left in the ultrasonic for 30 minutes, the mixture was filtered and transferred into a 10mL volumetric flask, and topped with solvent in the presence of hexadecane. The results demonstrate that methanol was the best solvent, while acetonitrile was the least efficient. The excellent results with methanol can be attributed to the hydrogen bond formation with TATP rather than polarity.

A known quantity of TATP was applied to different parts of a vehicle interior when the outside temperature was 34 ºC-38ºC. The vehicle had only been used by the driver. After six hours, the TATP was swabbed and analyzed. Most of the TATP was lost from the surface areas of the car. The foot area under the passenger seat showed the best recovery as it had not been touched and did not face the sun like the dashboard.

A specific quantity of TATP was inserted under a fingernail. After a certain period of time, the fingernail was cut and the top of the finger was washed with methanol. The nail and the methanol were placed in a container and left in the ultrasonic for 30 minutes. When the fingernail was cut directly and immediately washed, the recovery of TATP was very high (97%); however, after only two hours, the TATP was found to be in the range of ca. 10%. After 48 hours, the concentration of TATP may remain under the fingernail, but in low concentrations (5%).

It can be concluded that TATP is easily decomposed; however, it can be detected from the suspect areas.

B81 Characterization of Pre- and Post-Burn Smokeless Powders by Direct Analysis in Real-Time Time-of-Flight/Mass Spectrometry (DART®-TOF/MS) vs. Gas Chromatography/Mass Spectrometry (GC/MS)

Emily C. Lennert, BS, National Center for Forensic Science, PO Box 162367, Orlando, FL 32816; and Candice Bridge, PhD, National Center for Forensic Science (UCF), PO Box 162367, Orlando, FL 32816*

After attending this presentation, attendees will understand how smokeless powders may be analyzed and classified pre- and post-burning using DART®-TOF/MS and how these results compare to the more traditional GC/MS results.

This presentation will impact the forensic science community by providing a rapid means of smokeless powder identification and differentiation by DART®-TOF/MS, which may be applied to Gunshot Residue (GSR) and explosive analysis, such as debris analysis following a bombing event.

Smokeless powders were analyzed by DART®-TOF/MS for the presence of several organic compounds of interest, including diphenylamine, nitroglycerin, ethyl centralite, dinitrotoluene, phthalates, and others. Positive and negative mode analysis was performed for each sample, with helium carrier gas at 200˚C and grid voltages set at 150 V. Unburned samples were analyzed as neat samples, as the smokeless kernel itself, and as extracts. Extracts were prepared by following a simple GC/MS extraction, the National Center for Forensic Science's procedures using dichloromethane. Extraction is not necessary for DART®-TOF/MS analysis of solid smokeless powder kernels; however, extractions were performed to determine if extraction increased the number of organic compounds observed and to allow for GC/MS testing. Each smokeless powder was subsequently burned and analyzed. Unburned or partially burned smokeless powder particles and burned smokeless powder residues may be recovered following an explosive event, such as discharge of a firearm or an Improvised Explosive Device (IED). Therefore, unburned and burned samples were analyzed to simulate possible real-world evidence. Burned and unburned samples were then compared and differences in the identifiable organic compounds were recorded to determine the effect of burning on the smokeless powder and residue composition. Sample extracts were later analyzed by GC/MS to confirm composition and compare results obtained by DART®-TOF/MS and GC/MS.

Compounds of interest were easily identified in smokeless powders analyzed via DART®-TOF/MS, and within seconds. Following characterization of the organic components of each smokeless powder, a classification scheme may be developed to further characterize smokeless powders. Classification of smokeless powders based on the organic components may aid investigators in determining the brand or origin of a suspect smokeless powder, burned or partially burned, recovered at a crime scene.

Sample preparation for DART®-TOF/MS is simple and requires minimal effort, because smokeless powder kernels can be analyzed directly by DART®-TOF/MS. Additionally, DART®-TOF/MS is a more rapid technique than GC-MS. DART®-TOF/MS samples may be analyzed in seconds, and mass spectra may be observed and evaluated almost instantly; GC-MS may take more than ten minutes to run one sample after sample analysis, and mass spectra may not be observed or evaluated until the sample run has been completed. DART®-TOF/MS is a viable method for rapid analysis of smokeless powders, which may be applied to explosive and GSR analysis.

Smokeless Powders, Explosives, Gunshot Residue

B82 Assessing the Quality and Reliability of Drug Identifications

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081; and Ramona S. Montreuil, MS, Drug Enforcement Administration, Office of Forensic Sciences, Quality Assurance Section, Arlington, VA 22202*

After attending this presentation, attendees will better understand how to evaluate laboratory data to obtain information on the quality of drug identifications.

This presentation will impact the forensic science community by providing an approach for estimating the quality and uncertainty of drug identifications in the forensic chemistry laboratory.

The Drug Enforcement Administration (DEA) laboratory system processes thousands of suspected drug exhibits every year, seized by federal, state, and local law enforcement officials during undercover operations and via interceptions of drug smuggling operations, among others. After laboratory analysis, results are summarized in official laboratory reports that are forwarded to the submitting investigative agency. Many of these laboratory reports are then used by government officials during court trials and sentencing procedures and, as such, should present accurate and scientifically supported results and conclusions, as incorrect decisions based on inaccurate reports could have significant legal and personal consequences. Laboratory reports and case documentation should also fulfill laboratory accreditation requirements and provide users in the judicial system, such as attorneys and jurors, with information regarding the quality of laboratory processes and resulting drug identifications.

The DEA laboratory drug identification process is separated in to three phases. Phase I includes evidence submission and Chain-Of-Custody (COC) procedures such as barcoding, secure vault storage, and safety protocols. Phase II forms the core of the laboratory identification process, as it incorporates the analytical scheme — the combination of sampling protocols and tests performed by expert analysts in order to achieve an unambiguous and scientifically supported identification. Phase III includes preparation of the final laboratory report by the analyst, and the technical and administrative reviews performed by laboratory managers. These peer-review steps ensure that analytical scheme requirements have been met, that identification results are accurately reported, and that the analytical case file contains all the documentation required to support the identification.

Even when best laboratory practices are in place and the appropriate analytical scheme is followed, the extensive series of laboratory procedures required to report a final identification may be susceptible to errors. Many of these errors are unforeseen or unanticipated and may occur during instrument operation, sample handling, and during the report-writing stages, among others. Consequently, the possibility of reporting a misidentification is always present. It is therefore crucial to assess the performance of a laboratory's identification procedure so that the quality of reported identifications can be described and communicated to the report recipients. This will undeniably result in a better understanding of the frequency of procedural errors and will help to evaluate and improve quality assurance measures throughout laboratories.

This presentation will include results from the evaluation of historical DEA laboratory system-wide Proficiency Testing Program (PTP) data obtained during the years 2005-2016. Analysis of this data provides estimates of the sensitivity (true positive rate) and specificity (true negative rate) of the DEA drug identification process, as well as estimates of the probabilities associated with Type I and Type II errors (false positive and false negative rates, respectively). This presentation will also demonstrate how Bayesian analysis can be used, in combination with the response rates, to evaluate the confidence and uncertainty associated with identification results. The PTP data and its evaluation and discussion will demonstrate that the DEA identification process is highly sensitive and specific, with rates of type I and type II errors below 1%.

Criminalistics, Seized Drugs, Identification

B83 2017 Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) Update — A Discussion on Drug Analysis Techniques and A-B-C Categorization

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will better understand the principles behind the categorization of analytical techniques used for drug analysis.

This presentation will impact the forensic science community by providing up-to-date information on the resources offered by SWGDRUG, in addition to other recent activities.

SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will comprise a discussion on SWGDRUG categories of analytical techniques and will also provide attendees with information on past and current SWGDRUG activities.

The development of new instrumental technologies and their introduction and use in seized-drug laboratories have brought up the need to clarify the classification of techniques into A, B, or C categories. In this presentation, the basis behind the three separate categories will be defined and discussed, from the point of view of structural characterization, discrimination ability, and the theoretically predictive value of each technique. Via example illustrations, this presentation will also discuss and emphasize the important factors to consider when establishing an appropriate laboratory analytical scheme, when the choice of techniques may depend on the particular analytical and judicial requirements of a laboratory.

During the summer of 2016, version 7.1 of the SWGDRUG Recommendations was approved and published (www.swgdrug.org). Also, Supplemental Document 6 (SD-6), titled "Examples of Measurement Uncertainty for Net Weight and Count Extrapolations," was finalized and posted. This document provides step-by-step examples for estimating uncertainty for scenarios in which the net weight of an exhibit is obtained via extrapolation or when the total count of a dosage unit exhibit needs to be extrapolated.

Core committee members are also working on revising Part IVB of the SWGDRUG Recommendations, pertaining to the validation of analytical methods. Revisions include clarifications on the performance characteristics to be evaluated during the validation of both qualitative and quantitative methods. Examples of method validation schemes for routinely used techniques, such as color test, Gas Chromatography/Mass Spectrometry (GC/MS) and Infrared (IR) spectroscopy, will also be provided in a separate supplemental document. This presentation will also summarize recent updates on SWGDRUG resources, such as the MS library, the IR library, and the Drug Monographs.

The SWGDRUG core committee includes representatives from federal, state, and local law enforcement agencies in the United States, Canada, Brazil, Great Britain, Germany, Austria, Switzerland, Australia, and Singapore. The following forensic organizations are represented: the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalistica y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC). Core committee members also include forensic science educators and representatives from forensic science organizations across the United States, the American Society of Crime Laboratory Directors (ASCLD), the American Society for Testing and Materials (ASTM), and the National Institute of Standards and Technology (NIST).

Criminalistics, SWGDRUG, Drug Analysis

B84 No Lab, No Plea … Eliminating a Controlled Substances Backlog

James T. Miller, BS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002*

After attending this presentation, attendees will better understand the testing guidelines implemented and the tools used to clear a backlog and maintain a turnaround time of 30 days or less. Attendees will also comprehend how to apply these tools in their own jurisdictions.

This presentation will impact the forensic science community by providing guidance on implementing managed processes, as well as testing guidelines that aid in the reduction of controlled substance backlogs. The Houston Forensic Science Center (HFSC) will share the lessons learned from its successful process in an effort to assist other jurisdictions in creatively managing their resources so they too can clear backlogs and maintain incoming caseloads.

Much attention has been paid to new legislation spreading across the United States regarding mandatory testing of sexual assault kits; however, it is often overlooked that in the controlled substance community, it has long been common practice for all seized drugs to undergo forensic testing, which creates a caseload of tens of thousands of cases. Due to limited resources, this often leads to large backlogs. Not only does this create strain within the lab, it also impacts the legal system. Also, drug convictions often move rapidly through the legal system as many defendants plead guilty rather than go through a lengthy trial. Recently, it has been discovered that some defendants have pleaded guilty to a drug charge prior to the seized substance being tested in the laboratory, only to find that subsequent testing showed no illegal substances were identified. This has led to approximately 200 drug case exonerations in Harris County, TX. The Houston-area legal system responded by instituting a "No Lab, No Plea" policy. While all involved agreed the policy was necessary, it did add pressure to clear the drug testing backlog and maintain a reduced turnaround time. Even though Federal funds are available for such upticks in work in the DNA area, the Controlled Substances Section had to find creative ways to increase capacity while reducing backlogs and turnaround times. By communicating with all stakeholders, HFSC's Controlled Substances Section established guidelines that reduced the amount of testing being requested, simultaneously prioritizing cases moving rapidly though the legal system. The section also developed managed processing plans through a mini Lean Six Sigma assessment that increased efficiency and reduced turnaround times to fewer than 30 days.

In this presentation, the Controlled Substances Section will share some of its process development results to illustrate how to communicate with stakeholders and use available resources to clear backlogs and maintain a 30-day turnaround time.

Backlog, Controlled Substances, Process Management

B85 The Implementation of Blind Proficiency Testing in Drug Analysis

Paula Evans, BS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002; Aimee R. Grimaldi, MS, Houston, TX; Callan Hundl, BS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002; Jackeline Moral, MS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002; and Lori Wilson, BS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002*

After attending this presentation, attendees will better understand the advantages and challenges of implementing a blind proficiency program in drug analysis.

This presentation will impact the forensic science community by providing a model for implementing a blind proficiency program in controlled substance testing. Laboratories, saddled with backlogs and high-priority cases, often do not have the time or resources needed to implement a blind proficiency program. After attending this presentation, attendees will recognize the benefits of blind testing despite the challenges and costs associated with the program.

Accrediting bodies require laboratories to participate in a minimum of one proficiency test annually in each area listed on the scope of accreditation. To fulfill this requirement, laboratories have used open proficiency testing provided by a commercial vendor as a tool to evaluate the performance and competency of staff, as well as to gauge the system's overall quality. The successful completion of these open proficiency tests demonstrates the quality of the test results and the staffs' competency. These commercially created tests attempt to mimic real casework, but often do not encompass the entire scope of testing. While the external commercial proficiency exams meet accreditation requirements and demonstrate competence, the laboratory is often limited to administering tests provided by the vendors. This means the tests may not always be representative of the majority of a laboratory's real casework. Blind proficiency testing has shown to be an advantageous quality control tool that can objectively test an entire system; however, implementing such a program can be challenging.

The Houston Forensic Science Center (HFSC) created its blind proficiency testing program in September 2015. The goal was to create and submit blind samples equal to 5% of the Center's average monthly caseload. Initially, tests had been created using old proficiency samples and non-controlled substances created in-house by the Quality Division staff. HFSC quickly learned of the challenges associated with obtaining samples of controlled substances that could mimic actual current casework. Another challenge involved packaging and describing evidence in a manner reflective of the laboratory's primary client. To further complicate matters, HFSC's Laboratory Information Management System (LIMS) is connected to the client's management systems. This allows for information exchange that could potentially expose the blind sample as a test.

As a result, HFSC had to work with the client to ensure tests remained disguised from receipt to reporting. To master evidence packaging, HFSC's quality team met with narcotic sergeants to learn their packaging and submission process. In addition, HFSC had to make a formal request to the Houston Police Department to receive approval for the use of narcotics' evidence submission forms and envelopes.

Obtaining controlled substances proved to be the greatest challenge due to state laws surrounding the forfeiture and destruction of seized drugs. Alternatively, negative samples that can be equally challenging to the system can be submitted, but it has proven to be difficult to create samples similar in appearance to true controlled substances. The key to overcoming these challenges has been a collaboration between the laboratory, the client, and the legal system.

Despite these challenges, the value gained from the program has been immeasurable. One researched benefit of blind testing programs is behavior change described as the "observer effect." Research has shown that when individuals believe they are being watched, their behavior changes. For this reason, a blind proficiency program can be a tool to combat perceived bias in forensic science. In addition, the clients and the analysts unanimously agree the program instills added confidence in testing results. The blind proficiency program is just one tool that HFSC uses to provide its clients with better service.

Blind Proficiency Test, Quality Control, Drug Analysis

B86 Quantifying Uncertainty in Estimations of the Total Weight of Drugs in Groups of Complex Matrices Using the Welch-Satterthwaite Equation

Ivo Alberink, PhD, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague, Zuid-Holland 2497 GB, NETHERLANDS; Annette Sprong, BSc, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague, NETHERLANDS; Annabel Bolck, PhD, Laan van Ypenburg 6, Den Haag 2497 GB, NETHERLANDS; and Peter Vergeer, PhD, Netherlands Forensic Institute, Laan Van Ypenburg 6, The Hague, NETHERLANDS*

After attending this presentation, attendees will better understand the use and robustness of a new statistical method to quantify estimations of total drug weight in groups of items, based on the Welch-Satterthwaite equation.

This presentation will impact the forensic science community by introducing a new method to quantify estimations of total drug weight in groups of complex matrices.

In a recent case at the drugs department of the Netherlands Forensic Institute (NFI), materials were received from the Schiphol national airport consisting of 43 T-shirts, boxer shorts, shorts and blouses; 12 socks; 8 vests and short trousers; 5 pieces of denim clothing; and 2 towels. Based on a color test, and verified by Gas Chromatography/Mass Spectrometry (GC/MS) analysis, the items were impregnated with cocaine. This type of casework is encountered often and the crucial question is: what is the total drug weight in the combined items? In order to answer this question, standard laboratory procedures have been developed. First, the total weight of each item is determined, then repeated concentration measurements are performed on some or all of the items (in this particular case, for example, not all items from groups 1 and 2 were sampled). The concentrations are measured using Gas Chromatography/Flame Ionization Detector (GC/FID) on samples taken from different locations on the items.

In the literature, guidelines exist on the expression of uncertainty in analytical measurements; additionally, the International Organization for Standardization (ISO) 17025 requires that forensic laboratories determine uncertainty on their measurements. The issue of how to sample from consignments of drugs, and how large samples should be in order to obtain required results, has been widely discussed. Frequentist and Bayesian methods have been described in cases in which no measurement uncertainty is attached; however, these studies do not address the question of how to deal with a situation in which considerable uncertainty is attached, which may differ for each item.

The question as to the total amount of drug weight, and the precision of its estimation, in the combined items may get complicated, and statistical methodology to handle this has been described.[1] The methodology is based on the following assumptions: (1) within each of the groups, the relative standard deviation on repeated measurements is the same; (2) the measurements are unbiased estimators of the real concentrations of drugs in the items, and repeated measurements on the same item (at different locations) are normally distributed; and, (3) when sampling takes place in one or more of the groups, the real concentrations of drugs in the items of the group are normally distributed.

It may happen that, for example, the assumption of a constant relative standard deviation is violated, or that normality of the measurements is untenable (e.g., for data with point masses at zero or if certain items in a group have a very high standard deviation). In cases such as these, it makes sense to use a model in which the relative standard deviation may be different for each item. A method is described for dealing with this type of situation based on the Welch-Satterthwaite equation, both for cases in which all items are sampled and cases in which this is not so. In this set-up, the assumption of constant relative standard deviations is not necessary.

In this presentation, case examples will be presented in which the method is applied, both for the situation in which all items are sampled and the situation in which this is not the case. Furthermore, results of simulation studies will be shown that study the effect if the data are not normally distributed but uniformly or if a substantial amount of them contain zeros (measurements are on locations containing no drugs at all). The simulation studies suggest that both the method described in this presentation and the methods described by Alberink et. al yield reliable results, including if data have point masses at zero or a large standard deviation.[1] Coverage of 95% intervals is always close to 95%. If the assumption of common relative standard deviations clearly does not apply, it is nonetheless advised that the method based on the Welch-Satterthwaite equation be used.

B87 Estimations of Measurement Uncertainty for Weights of Controlled Substance Evidence and the Effect of Environmental Conditions

Craig L. Huemmer, MS, NYPD Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432; and Kristine M. Scicchitano, MS, NYPD Police Laboratory, 150-14 Jamaica Avenue, NY 11432*

WITHDRAWN

B88 An Analysis of Illicit Drugs in Wastewater: A Forensic Perspective

Frederic Been, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Lisa Benaglia, MSc, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Robin Udrisard, MSc, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Pierre Esseiva, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; and Olivier Delémont, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne, Vaud CH-1015, SWITZERLAND*

After attending this presentation, attendees will understand the principles of wastewater analysis. Attendees will also be informed of the contribution this tool can bring in a forensic perspective, in particular deciphering the dynamic structure of illicit drug consumption in several types of environments.

This presentation will impact the forensic science community by emphasizing the value of the information that wastewater analysis can deliver and the added value of triangulating this data with other complementary sources of information.

In 1920, Edmond Locard formulated one of the core principles of forensic science, stating (in its epitomized form) that "every contact leaves a trace." By extension, this principle can also be applied to the consumption of a drug or, in particular, to an illicit drug. Actually, when one consumes such a substance, in order to assimilate and eliminate it, the product is transformed into its related metabolites. In other words, cocaine will be excreted via urine and feces in the form of its metabolite, benzoylecgonine, as well as the parent compound, cocaine itself.

These traces are then relics conveying objective information about the type, the relative quantity, and the pattern of consumption of a specific population. To obtain this information, the sampling strategy is essential. It is necessary to choose a place where these residues of consumption of the target population are combined; in this case, the entrance of the wastewater treatment plant of the area under investigation. Another application of this wastewater-based approach focuses on (semi-) closed environments, such as a prison or music festival. These configurations influence the sampling setting as well as the interpretation of the obtained data.

This study presents the application and limitations of this approach of wastewater analysis using results gathered over a three-year period, both for longitudinal and comparative studies. The main application of these results focuses on the determination of the consumption of illicit drugs in a population based on the amounts of the drug residue present in the target wastewater treatment plant, known as back-calculation. From these loads, it is also possible to infer the quantity of related illicit drugs or even the number of doses. While such findings are the most commented aspects of wastewater analysis, especially by the media, this study advises that there is more potential in these results, mainly by performing cross-analysis. A discussion on this interdisciplinary approach will be illustrated by presenting the added value of combining wastewater results with existing data related to illicit drugs, such as epidemiological or police data, as well as public health information.

Illicit Drugs, Wastewater, Triangulation

B89 Forensic Body Fluid Identification and Differentiation by Raman Spectroscopy

Claire Muro, BS, University at Albany, Life Sciences Research, Bldg 01113, 1400 Washington Avenue, Albany, NY 12222; Kyle C. Doty, BS, 2165 Robinwood Avenue, Schenectady, NY 12306; Luciana de Souza Fernandes, BS, University at Albany, 1400 Washington Avenue, Albany, NY 12222; and Igor K. Lednev, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222*

The goal of this presentation is to educate attendees regarding how multivariate data analysis can be leveraged to extract information from Raman spectra and build predictive models.

This presentation will impact the forensic science community by offering a new approach for body fluid analysis, which, in many respects, is an improvement over the current methods.

The ability to identify body fluid traces at crime scenes and preserve any DNA present is critically important in forensic science. Identification can be difficult because many of the current techniques are specific to one body fluid, and typical biochemical methods are destructive, which prevents any further analysis. To develop a universal, confirmatory, non-destructive approach that can be used to differentiate and identify body fluids, the specificity of Raman spectroscopy was combined with the analytical power of statistical modeling.

Raman spectra were collected from 75 body fluid samples, including peripheral blood, saliva, semen, sweat, and vaginal fluid. After preprocessing the experimental spectra, the samples were split into calibration and validation datasets. Several chemometric analysis techniques were trained and tested to find the best model. These included Partial Least Squares Discriminant Analysis (PLSDA), Support Vector Machine Discriminant Analysis (SVMDA) modeling, and variable selection by interval PLSDA (iPLSDA) and Genetic Algorithm (GA). By exploring so many different combinations of classification algorithms and variable selection methods, this research was able to study patterns in the data, the effects of various modeling parameters, and to ultimately determine the most robust method for differentiation. All of the models were internally cross-validated during calibration and externally validated with a test dataset.

The first PLSDA model, which used the entire spectral range, misclassified 2.3% and 2.1% of the calibration and validation spectra, respectively. When an SVMDA model was trained by the same dataset, it misclassified 0.9% and 0.5% of the calibration and validation spectra, respectively. When iPLSDA was employed for variable selection, the rate of error in calibration predictions decreased; however, the error rate of validation predictions increased. Lastly, the dataset produced through variable selection by GA was used to train a final PLSDA and SVMDA model. The rate of misclassifications in the calibration dataset by the PLSDA model decreased to 2.2%, while the misclassifications in the validation dataset dropped to 1.7%, both slightly lower than the first PLSDA model. The final SVMDA model built on a dataset produced by GA performed the best. This model accurately predicted the identity of 99.9% of the spectra from the calibration dataset. More importantly, it correctly predicted the identity of 100% of the spectra in the external validation dataset.

All five body fluids were successfully discriminated by coupling Raman spectroscopy and chemometrics. This technique is reliable, non-destructive, and is not specific to one body fluid, offering substantial advantages over the current techniques used to identify body fluids.

Forensics, Body Fluids, Chemometrics

B90 Accurately Estimating the Time Since Deposition (TSD) of Bloodstains Aged for More Than Two Years

Kyle C. Doty, BS, 2165 Robinwood Avenue, Schenectady, NY 12306; and Igor K. Lednev, PhD, University at Albany, State University of New York, 1400 Washington Avenue, Albany, NY 12222*

After attending this presentation, attendees will better understand how Raman spectroscopy, coupled with multivariate statistical analysis, can be used to analyze bloodstains aged for more than two years and subsequently: (1) confirm that the stains are blood and not another body fluid; as well as, (2) accurately predict the TSD.

This presentation will impact the forensic science community by demonstrating the ability to expand upon a unique non-destructive approach for the confirmatory identification of blood over time and the accurate estimation of bloodstain age, or TSD. Additionally, this presentation can significantly help with crime scene reconstruction by providing more clues about the time of a crime, or order of events, particularly when a body is not available for physical examination.

The identification of a body fluid stain is an important and necessary aspect of many forensic investigations. For blood in particular, knowing the TSD is highly desired in forensics, but it can be extremely complicated to accurately determine in practice. Although there have been numerous attempts to solve this problem using a variety of different techniques, currently no established well-accepted method exists. Since the amount of suspected blood evidence may be miniscule, it needs to be preserved and analyzed efficiently. Therefore, a non-destructive method to competently identify human blood and predict the TSD would be highly valuable. Raman spectroscopy is a technique that has the potential for both non-destructive confirmatory identification of blood and for detecting (bio) molecular changes over time that can be associated with the age of a bloodstain.

Raman spectroscopy has proven to be a versatile and effective analytical technique for numerous forensic applications, including the identification of drugs, explosives, gunshot residue, inks, and paints. Raman analysis often requires no sample preparation, is considered non-destructive, and has the ability to analyze microscopic amounts of sample. This technique is based on the detection of light that is inelastically scattered by a sample upon irradiation from a monochromatic light source. A Raman spectrum contains numerous distinctive bands that correspond to specific molecular vibrational modes. For blood in particular, Raman spectra provide rich detail and it has already been the subject of analysis in many forensic studies.

For this work, a previously developed Raman spectroscopic methodology for determining the TSD of bloodstains was tested.[1] Raman spectroscopy and chemometric modeling were used to analyze fresh bloodstains stored under ambient conditions for more than two years. A recently developed Support Vector Machines Discriminant Analysis (SVMDA) model was used for blood identification.[2] This model allowed for confirming a fluid's identity as blood through differentiation of blood from four other body fluids (i.e., saliva, semen, sweat, and vaginal fluid).

To provide quantitative predictions of the TSD, Partial Least Squares Regression (PLSR) and Principal Component Regression (PCR) models were built on spectra collected at 14 time points. Both models were internally Cross-Validated (CV) and externally validated. The PLSR and PCR models had a CV Root Mean Squared Error (RMSE) of 0.17 and 0.18, respectively. They both showed a high degree of linearity with an R^2 of 0.98. Also, both models demonstrated similar external TSD prediction abilities with an RMSE of prediction of 0.29 and 0.31 for PLSR and PCR, respectively.

These results demonstrate that Raman spectroscopy can be used as a non-destructive analytical tool for confirming the identity of blood over time and discriminating between bloodstains on the scale of hours to days to years. This is very important for forensic science in helping to reconstruct a crime scene, as well as in establishing the relevant association of multiple bloodstains. This approach shows potential for practical use in the field to predict the TSD with a high degree of accuracy, especially since portable Raman spectrometers are now available. In the future, more work will be conducted regarding analyzing bloodstains left to age under different environmental conditions as well as on different substrates.

This project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the authors and do not necessarily reflect those of the Department of Justice.

Bloodstains, Raman Spectroscopy, Chemometrics

B91 Toward Surface-Enhanced Raman Spectroscopy (SERS) -Active Forensic Evidence Swabs for Human Bodily Fluids

Matt Burleson, BS, 323 Natural Sciences Building, 111 Memorial Drive, Cullowhee, NC 28723; Katarina G. Ruehl, WCU, 90 Merlite Court, Cullowhee, NC 28723; Vinay G. Bhardwaj, PhD, Western Carolina University, 111 Memorial Drive, Cullowhee, NC 28723; Brittania J. Bintz, MSc, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; and David D. Evanoff, Jr., PhD, Western Carolina University, 231 Natural Sciences Building, 111 Memorial Drive, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand how SERS could be used in the forensics workflow for the confirmatory analysis of human bodily fluids.

This presentation will impact the forensic science community by providing results of the fabrication of SERS-active evidence swabs, identification of human bodily fluids by spectroscopic analysis, and the further extraction, quantification, and Short Tandem Repeat (STR) typing of the samples collected on the swabs. SERS-active evidence swabs are not currently available to the forensic science community.

The collection and identification of human body fluids at a crime scene can be a crucial aspect of an investigation. In the crime laboratory, evidentiary swabs that may potentially contain human body fluids are screened, using both presumptive and confirmatory tests. These tests, such as the Acid Phosphatase (AP) test and the Christmas tree stain for semen and the Kastle-Meyer and Takayama tests for blood, are quite time consuming, expensive, only test for one body fluid, and are prone to both false positives and false negatives; however, recent literature reports have indicated that Raman spectroscopy may have a far lower limit of detection than traditional methods and may allow investigators to perform one type of measurement for all body fluids, potentially leading to higher efficiency, more definitive results, and higher accuracy. Another recent report utilized SERS as a means to decrease the limit of detection of certain forensic samples. SERS, in which an analyte is placed on or near a nanostructured metal surface, has the potential to increase the Raman cross-section of the analyte by many orders of magnitude.

This presentation reports on the development of SERS-active forensic evidence swabs by attaching silver nanoparticles grown via the hydrogen reduction method to the fibers of commercially available swabs. For this study, SERS-active swabs were used to collect and measure the Raman spectrum of semen. Different swab fabrication parameters, such as reaction time (30 minutes-360 minutes), reaction temperature (40°C-100°C), and swab pretreatment protocols were varied in an effort to maximize the Raman signal of the semen. Integrated SERS intensity of semen-specific Raman bands were compared to silver particle size, silver concentration and spacing between particles on the swab fibers. Minimum volumes of semen that could be detected using the SERS-active swabs were also found. DNA extraction and quantitation was performed on semen samples collected on pristine swabs and SERS-active swabs, both those that had been exposed to laser radiation for Raman analysis and those that had not. Although extraction yields were higher for pristine swabs due to some dissolution of silver on the SERS-active swabs, STR typing was found to be possible.

Raman, SERS, Evidence Swab

B92 A New Approach Combining *In Silico* and High-Resolution Melt (HRM) Analysis to Quickly Identify New Loci for Body Fluid Identification Using DNA Methylation Melt Analysis

Joana Antunes, MS, Florida International University, 11200 SW 8th Street, Lab OE294A, Miami, FL 33714; Vanessa Aguiar-Pulido, PhD, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Kuppareddi Balamurugan, PhD, University of Southern Mississippi, School of Criminal Justice, 118 College Drive, PO Box 5127, Hattiesburg, MS 39406; George T. Duncan, PhD, Broward County Crime Lab, 201 SE 6th Street, Rm 1799, Fort Lauderdale, FL 33301; Giri Narasimhan, PhD, Florida International University, 11200 SW 8th Street, Miami, FL 33199; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will be informed of a new combined approach using bioinformatic tools and HRM analysis to quickly and inexpensively identify genome locations from an array dataset for DNA methylation analysis.

This presentation will impact the forensic science community by demonstrating that HRM is an excellent tool to identify epigenetic loci for body fluid identification at a research level and to be used as a body fluid discrimination method easily incorporated into the daily routine of forensic laboratories.

DNA methylation is a natural process in the mammalian genome involving the addition of a methyl group to the 5'carbon of cytosines in a dinucleotide Cytosine-Guanine (CpG) pair.[1] Tissue-specific Differentially Methylated Regions (tDMRs) present different methylation patterns depending on the cell type analyzed, making them interesting targets for body fluid discrimination.[2-7] To fully take advantage of this approach, it is necessary to identify new tDMRs that consistently show methylation differences in body fluids. Whole genome analysis of CpGs using a commercially available array followed by a confirmatory Polymerase Chain Reaction (PCR) -based assay can be costly and time consuming. Alternatively, a computer-based, *in silico* approach can save much effort through the use of bioinformatics analysis.

Bisulfite-modified PCR is a useful method to determine relative levels of DNA methylation. In this procedure, unmethylated cytosines are chemically converted to uracils, which then are converted to adenines during real-time PCR. The methylated cytosines are protected from bisulfite conversion; therefore, methylated DNA will have higher melt temperature (T_M) than unmethylated DNA.[8-10] Since HRM is cost- and time-effective, it constitutes an excellent experimental tool to perform screening for multiple tDMRs quickly. Due to its fast turnaround, HRM also has considerable potential to be used as a standard method to discriminate body fluids in forensic laboratories.

Blood, buccal swabs, vaginal, and semen samples were collected from volunteers according to the approved Institutional Review Board (IRB) 13-0555 from Florida International University. DNA was extracted using the EZ1® DNA Investigator kit and the BioRobot® EZ1 automated purification workstation according to the manufacturer's specifications. Fifty nanograms of DNA were bisulfite modified using the EpiTect® Fast DNA Bisulfite Kit according to manufacturer's instructions. Primers specific for the CpG of interest were designed using either the Methprimer or the BiSearch online tools.[11,12] Bioinformatic analysis was performed using R software to determine relevant CpGs to discriminate blood, saliva, and vaginal epithelia. Array data from the report by Park and colleagues was analyzed and the M-value calculated to perform statistical analysis.[13] CpGs identified as statistically significant were further filtered for relevance using the ratio of methylated versus unmethylated probes and comparing such ratio between body fluids. Real-time PCR reactions were performed using the Epitect® HRM kit on a Rotor Gene 6000 real-time machine.

Results illustrate that using bioinformatics tools to perform array data analysis reduces the cost to identify new genome locations for body fluid identification using DNA methylation. The most successful approach was to use the calculated M-values to statistically identify significant differences between blood, saliva, and vaginal epithelia from the array study.[13] The CpGs were further sorted by analyzing the relative light emission from the probes pertaining to one body fluid in comparison to the other two. To date, this approach provided 71% success in identifying new CpGs *in silico.* For example, from seven CpGs identified as potential blood markers, five proved to show a difference in their T_M for blood when compared to saliva, semen, and vaginal epithelia, using HRM.

Using the information gained from these studies, a protocol for a multiplex qPCR with melt analysis that includes semen-, blood-, and vaginal epithelia-specific primers capable of providing results in approximately two hours was successfully tested. In conclusion, the combination of new bioinformatics and HRM analysis provides a cost- and time-effective approach to identify epigenetic loci for body fluid discrimination using DNA methylation. Moreover, due to a high throughput of HRM, this method will allow forensic laboratories to determine differences in DNA methylation for body fluids without the need to invest in expensive DNA sequencers, reagents, or personnel training and time.[2,6,9]

High-Resolution Melt, DNA Methylation, Body Fluid Identification

B93 The Development and Validation of a Dual-Genus Quantitative Polymerase Chain Reaction (qPCR) Assay for African and Asian Elephants for Forensic Purposes

Merideth J. Fayman, BS, PA 19095; Caitlin Hoey, 5720 Walnut Avenue, Apt 1A, Downers Grove, IL 60516; Meredith Rohrbaugh, MS, 20232 Heather Drive, Princeton Junction, NJ 08550; and Jillian C. Fesolovich, MSFS, Keystone College, One College Green, La Plume, PA 18440*

After attending this presentation, attendees will understand how a qPCR assay has been developed that will detect and quantitate African and Asian elephant DNA simultaneously. Attendees will also learn how to efficiently create qPCR assays for wildlife identification and quantitation.

This presentation will impact the forensic science community by providing a standardized qPCR assay that detects and quantitates elephant DNA for use in wildlife investigations. The development of this assay fills a research gap in wildlife forensic science.

Real-time PCR is most commonly used in the forensic community to quantify small amounts of human DNA in evidentiary samples. In the growing field of wildlife forensic genetics, real-time PCR is utilized primarily for identifying the species of origin from illegally traded animal byproducts. Although DNA sequencing of mitochondrial DNA is the most common approach for species identification, it can be costly. Utilization of a multiplex real-time PCR assay can be a fast, inexpensive, and robust approach to species identification that can aid law enforcement in prosecuting crimes against animals.

African (*Loxodonta africana)* and Asian (*Elephas maximus*) elephant populations are categorized under Appendix I and II of the Convention on the International Trade of Endangered Species (CITES), respectively. CITES is an agreement that regulates plant and animal species throughout the world to ensure that international trade of their products does not impact their survival. An Appendix I listing includes species that are threatened with extinction; thus, trade of these plants and animals is highly restricted. Species not facing extinction that require extra attention and regulations so they don't become exploited and over-utilized are listed in Appendix II. The primary reason for the decline of these two animals is the illegal trade of their ivory. Other reasons for the decline in the elephant population are deforestation and human conflict.

In wildlife crime laboratories, species of origin can often be determined by morphology. This method is limited by the expertise of the taxonomist and the condition of the animal product. Ivory is commonly carved into small figurines and trinkets. Elephant meat, hair, and hide are traded, which can make it difficult to identify the species. These limitations have led to the development of genetic tests to identify species of origin in wildlife investigations. The *cytochrome b* (*cyt b*) region of the mitochondrial genome is well established as a genetic marker for species identification. African and Asian elephants do have highly similar genomes; however, variation exists in portions of their *cyt b* gene.

In this study a dual-genus, real-time PCR assay to identify elephant DNA for forensic purposes was developed. By eliciting information from the variable areas of the *cyt b* gene in elephants, both genera of animals can be differentially identified and quantified in a robust and cost effective assay. Costs were decreased by scaling down reaction volumes and using one set of primers. Following the assay development, a rigorous developmental validation was conducted according to current community recommendations set forth by the Scientific Working Group for DNA Analysis and Methods (SWGDAM). The completion of this work provides an assay that can generate data of evidentiary quality for wildlife crime laboratories.

Elephant, qPCR, DNA

B94 The Individualization of Pubic Hair Bacterial Communities and the Effects of Storage Time and Temperature

Diana W. Williams, MSFS, USACIL, 4930 N 31st Street, Forest Park, GA 30297; and Greg Gibson, PhD, Georgia Institute of Technology, School of Biological Sciences, 950 Atlantic Drive, Atlanta, GA 30322*

After attending this presentation, attendees will better understand a novel forensic technique using the pubic hair microbiome that has the potential to link individuals who have come into contact with each other. Additionally, attendees will understand the impact of storage time and storage temperature on the pubic hair microbiome.

This presentation will impact the forensic science community by introducing a novel forensic method with the potential to associate two individuals in a sexual assault. Attendees will also be informed regarding how to best store these types of samples for future analysis.

A potential application of microbial genetics in forensic science is the detection of transfer of the pubic hair microbiome between individuals during sexual intercourse using high-throughput sequencing. In addition to the primary need to show whether the pubic hair microbiome is individualizing, another aspect that must be addressed before using the microbiome in criminal casework is the impact of storage on the microbiome of samples recovered for forensic testing.

To test the effects of short-term storage, pubic hair samples were collected from volunteers and stored at room temperature (~20°C), refrigerated (4°C), and frozen (-20°C) for one week, two weeks, four weeks, and six weeks in addition to a baseline sample, followed by amplification and sequencing of the V3/V4 region of the 16S rRNA gene. Individual microbial profiles ($R^2 = 0.69$) and gender ($R^2 = 0.17$) were the greatest sources of variation between samples. Because of this variation, individual and gender could be predicted using Random Forests supervised classification in this sample set with an overall error rate of 2.7% $\pm$ 5.8% and 1.7% $\pm$ 5.2%, respectively. There was no statistically significant difference attributable to time of sampling or temperature of storage within individuals. Further work on larger sample sets will quantify the temporal consistency of individual profiles and define whether transfer between sexual partners can be detected. For short-term storage ($\leq$ six weeks), the microbiome recovered was not significantly affected by the storage time or temperature, suggesting that investigators and crime laboratories can use existing evidence storage methods.

B95 The Development and Validation of a New 13-Loci Short Tandem Repeat (STR) Multiplex for *Cannabis sativa* Genetic Identification

Rachel M. Houston, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340; and David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069*

After attending this presentation, attendees will understand the basic principles behind using an STR multiplex method for individualizing marijuana samples.

This presentation will impact the forensic science community by providing an STR panel that could not only assist law enforcement agencies in verifying legal marijuana products, but also aid in the linkage of illegal cases. This method could also serve as an additional tool to previously established marijuana profiling programs used in federal agencies such as the United States Customs and Border Protection (CBP) and the Drug Enforcement Administration (DEA).

Forensic DNA typing is typically performed on human DNA samples; however, the molecular analysis of plant DNA is increasingly being studied and considered for use in criminal justice systems around the world. Plant DNA can be used to link a suspect/victim to an area or, in the case of marijuana, can be used to aid in the investigation of drug cases. Marijuana (*Cannabis sativa* L.) is a plant cultivated and trafficked worldwide as a source of fiber (hemp), medicine, and intoxicant. The development and validation of a method using molecular techniques such as Short Tandem Repeats (STRs) could serve as an intelligence tool to link multiple cases by means of genetic individualization/association of *Cannabis* samples. In 2003, the first polymorphic STR markers were published for *Cannabis sativa*. Previous research has shown the utility of these markers in individualizing marijuana samples; however, the technique has been scarcely used in crime laboratories due to lack of standardization and validation.

For this purpose, a new 13-loci STR multiplex method was developed, optimized, and validated according to the International Society of Forensic Genetics (ISFG) and Scientific Working Group on DNA Analysis Methods (SWGDAM) guidelines. The 13-loci multiplex mainly consisted of previously described tri- and tetra-nucleotides *Cannabis* STRs: ANUCS501, 9269, 4910, 5159, ANUCS305, 9043, B05, 1528, 3735, CS1, D02, C11, and H06. Validation studies were comprised of: (1) species specificity; (2) sensitivity; (3) Hardy-Weinberg and linkage equilibrium in a reference population; (4) heterozygous Peak Height Ratios (PHR); (5) inter-loci balance; (6) stutter ratios; and, (7) precision and accuracy. In addition, a sequenced allelic ladder consisting of 55 alleles was designed to accurately genotype 101 *C. sativa* samples from three seizures provided by a federal agency.

Using an optimal range of input DNA (0.125ng-0.5ng), validation studies revealed minimal artifacts and stutter (average stutter ratio of 0.021 across all loci), relatively balanced heterozygous peaks (average PHR of 0.83 across all loci), and a well-balanced electropherogram (inter-loci balance range: 0.500-1.296). The combined power of discrimination of this multi-locus system was 1 in 55 million with a sensitivity of 125pg of template DNA. The 13-STR panel was found to be specific for *C. sativa*; however, non-specific peaks were produced with *Humulus lupulus*.

In conclusion, the results of this research demonstrate the robustness and applicability of this 13-locus STR system in identification of *Cannabis* samples for intelligence purposes.

Forensic Botany, Cannabis Sativa, Short Tandem Repeats

B96 The Development and Testing of a Top-Down Proteomic Method for the Confirmatory Identification of Saliva

Kevin M. Legg, 2300 Stratford Avenue, Willow Grove, PA 19090; Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038; Phillip Danielson, PhD, Department of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210; and Brianna L. Robbins, BA, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will understand some of the issues with current techniques for the identification of saliva, how protein mass spectrometry can be used to identify a panel of salivary protein biomarkers that are specific to saliva, and why protein mass spectrometry is a more sensitive and reliable method for confirmatory identification of saliva than methods currently in use.

This presentation will impact the forensic science community by providing a confirmatory method for identifying saliva in forensic casework, thereby potentially aiding in sexual assault investigations.

While DNA analysis is often considered the "gold standard" of forensic biology, being able to determine the source fluid(s) in addition to a DNA profile can provide critical context to a case. Immunochromatographic and enzyme-based tests are commonly employed for screening evidentiary material for saliva; however, neither of these assays provide true confirmatory results as false positive results with non-target fluids and false negative results with dilute and/or degraded samples are well known. Several emerging techniques for confirmatory body fluid identification seek to remedy this gap by developing more reliable analytical techniques based on protein mass spectrometry, messenger RNA (mRNA), micro RNA (miRNA), and epigenetic profiling of body fluids.

Several studies employing protein mass spectrometry have been successful in identifying saliva; however, serious throughput limitations exist, which can prohibit the adoption of these techniques for routine serological screening. For example, multi-day sample preparation workflows coupled with 60+ minute analytical runs are not uncommon.

The goal of the current research is to create a faster, laboratory-compatible workflow for saliva identification. This was achieved by direct enrichment for low molecular weight salivary proteins and analysis on an AB SCIEX™ TripleTOF® 5600 platform. Using this approach, sample preparation can be completed in less than two hours from collection to injection, therefore allowing same-day analysis of evidentiary samples. Initial studies have identified several saliva-specific candidates, such as basic salivary proline-rich protein 1/2, salivary acidic proline-rich proteins 1, 2, 3, and 4, and submaxillary gland androgen-regulated protein 3B. Further studies are underway to identify additional biomarkers and to identify the most reliable biomarkers for identifying saliva by characterizing the fluid in the population by analyzing 50 unique saliva samples.

In conclusion, this study illustrates that protein mass spectrometry is a sensitive and specific method for the confirmatory identification of saliva, providing a truly confirmatory method for the detection of saliva in sexual assault evidence.

Saliva, Confirmatory Identifiation, Proteomics

B97 A Rotationally Driven Microdevice (RDM) and Its Associated Low Footprint Instrument With the Potential of Fully Automated Integrated DNA Extraction, Polymerase Chain Reaction (PCR) Amplification, and Separation for Forensic DNA Analysis

Delphine Le Roux, PhD, University of Virginia, Dept of Chemistry at UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22901; Daniel A. Nelson, PhD, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; Brandon L. Thompson, MSc, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; Jacquelyn A. DuVall, BSc, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; An-Chi Tsuei, MS, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; Christopher Birch, PhD, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; Jingyi Li, PhD, University of Virginia, Dept of Chemistry at UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; Daniel Lee Mills, BS, TeGrex Technologies, LLC, 455 Old Hollow Road, Sperryville, VA 22740; Brian E. Root, PhD, University of Virginia, Applied Research Institute, 102 Cresap Road, Charlottesville, VA 22903; and James P. Landers, PhD, University of Virginia, Dept of Chemistry, McCormick Road, Charlottesville, VA 22904*

After attending this presentation, attendees will better understand the forensic application of RDMs and the recent advances toward a novel microfluidic device platform for forensic DNA analysis.

This presentation will impact the forensic science community by describing the development and proof-of-principle for an integrated "sample-to-answer" RDM platform for DNA analysis with the potential for fully automated genotyping.

Microdevices offer numerous advantages over the conventional methods used in forensic laboratories for rapid STR profiling, including: (1) smaller reagent and sample consumption; (2) the ability to integrate processes limiting the operator steps (hands free); (3) expediting sample-to-answer response; and, (4) portability. While several companies have successfully demonstrated the capability of Rapid DNA instrumentation, and while some are portable, they are still large and prohibitively expensive.[1-3] There is a need for the development of an inexpensive, rapid, and portable device for DNA extraction, Short-Tandem Repeat-Polymerase Chain Reaction (STR-PCR), and DNA fragment separation in forensic analysis. To meet these needs, this presentation reports the development of a unique, multi-layer, RDM and the associated centrifugal platform that can perform DNA extraction, amplification, and separation. This device is fabricated using a print-cut-laminate process that has been recently described using common office equipment, a laser cutter, and inexpensive substrates.[4] Unlike previously described systems, this does not require bulky instrumentation (external pumps, air compressor, and large actuators) as the integration of the processes and all fluid movement within the microchip rely on centrifugal force to drive fluidic movement. Therefore, this platform has the potential to be fully automated, compact, portable, and cost-effective human Identification (ID) system.

Initially, three separate rotationally driven microfluidic chips were designed (extraction, PCR, and electrophoresis), and their functionality demonstrated independently. The fabrication of RDMs from Polyester film (Pe), Pressure-Sensitive Adhesive (PSA), and other proprietary materials not typically used in microfluidics allowed for rapid, cost-effective, in-house prototyping. Non-solid phase extraction from buccal swabs using an enzyme-based reaction (ZyGEM® prepGeM) was successfully demonstrated on no fewer than 20 microdevices with different DNA donors and showed an average yield of 5.9ng/μL ± 2.4ng/μL, with all extractions leading to full STR profiles using a platform with spin-based capabilities. The same platform was used for microdevice PCR with rotation-driven fluid flow and reagent mixing. Successful PCR of ten STR markers in fewer than 20min was demonstrated with different substrates that were compatible with integration with the other steps. In this study, 100% of the profiles obtained were concordant with conventional typing methods, and presented satisfactory intra- and interlocus balance. Finally, electrophoresis on an RDM comprised of common materials, a Cyclic Olefin Copolymer (COC), and integrated gold electrodes was successfully demonstrated. The sieving matrix and sample were loaded centrifugally, and electrophoresis was complete in <8min with an unprecedented effective separation

length of only 4cm. This process was performed on a different platform with heating, spin control, and a high-voltage power supply for electrophoretic separation with optical detection capabilities.

Once the individual sub-assays were demonstrated, the architectural features needed for the integration of the three processes into a single hybrid RDM was designed and tested. A unified, integrated platform possessing all of the necessary hardware needed to perform sample-to-answer STR profiling was designed and manufactured in-house with off-the-shelf components, laser-cut materials, and 3D printed parts. While the forensic data quality of the integrated assay requires further optimization, proof-of-principle for integrated "liquid" extraction, STR amplification, and microchip electrophoresis is demonstrated on a cost-effective microdevice instrument whose small footprint is unprecedented. This system is a potential game changer for the criminal justice system where adoption of the Rapid DNA systems is limited by the cost of the instrument and the price of cartridges. In summary, this study presents the first rotationally driven, integrated, sample-to-result RDM for forensic DNA analysis operated by a device that is truly portable and can significantly reduce the price of Rapid DNA analysis.

B98 A Novel, Extraction-Polymerase Chain Reaction (PCR) Microdevice on a Rotation-Driven Platform: Buccal Swab to Short Tandem Repeat (STR) Product in Less Than Two Hours

Jordan Cox, MS, 1823 Floyd Avenue, Richmond, VA 23220; Teresa Sikes DeCarmen, MS, TeresaKatherine Designs, 14052 Cannondale Way, Gainesville, VA 20155; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Harris Hall, S, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Kemper Gibson, BS, 2230 E Teemont Court, Richmond, VA 23225; Kimberly Jackson, 409 McCormick Road, Chemistry Dept, Charlottesville, VA 22903; James P. Landers, PhD, University of Virginia, Dept of Chemistry, McCormick Road, Charlottesville, VA 22904; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will better understand the applications and capabilities of forensic microdevices, as well as the challenges of transitioning conventional DNA workflow onto the microscale.

This presentation will impact the forensic science community by describing an integrated plastic microdevice for DNA extraction and STR amplification that is capable of producing Capillary Electrophoresis (CE) -ready STR product from a buccal swab in less than two hours.

Microdevices have numerous advantages over conventional methods, including smaller reagent volumes, smaller equipment footprints, reduced contamination risk, and faster sample-to-answer time. Three unique aspects of the device presented in this work allow for successful integration. First, microfluidic flow control is achieved by exploiting centrifugal force on a simple rotational platform. This is coupled with the use of simple "passive" valves specifically positioned to physically isolate the different pre-electrophoresis chemistries. Second, enzyme-mediated DNA liberation (non-solid phase extraction) is fast (<10 minutes total) and effective as it circumvents the need for wash steps, hazardous chemicals, and solid beads, thus simplifying its incorporation into the overall microdevice architecture. Third, non-contact heating is integral to both DNA liberation and PCR amplification of STR loci. An Infrared (IR) -mediated heating system consisting of a platform, lamp, and fan is used to directly heat and cool the device, avoiding the need to transfer liquid into microtubes as required by conventional thermocyclers. During DNA liberation, the enzyme (a thermostable protease) is heated by the infrared lamp, lysing cells and exposing the nuclear DNA. During Infrared-mediated PCR (IR-PCR), thermal cycling of the sample is facilitated by the lamp and fan. Direct heating of the sample (instead of indirect heating on a heat block), small sample volume, and the effect of IR radiation on water (exciting the stretch mode) combine to dramatically reduce ramp and hold times, allowing IR-PCR with 28 cycles and a 10-minute final extension to occur in 45 minutes.

All microdevices were fabricated using laser ablation and thermal bonding of Poly(Methyl-Methacrylate) (PMMA) layers. Using this microdevice, the enzyme-mediated DNA liberation module produced DNA yields similar to or higher than those produced using the traditional (tube-based) protocol. Initial microdevice IR-PCR experiments to test the amplification module and reaction (using Phusion® Flash/SpeedSTAR™) generated near-full profiles that suffered from inter-locus peak imbalance and poor adenylation (significant –A); however, subsequent attempts using KAPA2G and *Pfu* Ultra polymerases generated full STR profiles with improved inter-locus balance and the expected adenylated product. An integrated run designed to test microfluidic control successfully generated CE-ready STR amplicons in less than two hours (<1 hour of hands-on time). Using this approach, high-quality STR profiles were developed that were consistent with those produced using conventional DNA purification and STR amplification methods. This method is a smaller, more elegant solution than current microdevice methods and offers a cheaper, hands-free, closed-system alternative to traditional forensic methods.

Forensic Microdevice, Microfluidics, IR-PCR

B99 Ultrahigh-Speed Polymerase Chain Reaction (PCR): A Method for Obtaining Short Tandem Repeat (STR) -Based Genotypes in Eight Minutes or Less

Georgiana C. Gibson-Daw, MS, 8920 NW 8th Street, Apt 518, Miami, FL 33172; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better appreciate new methods to accelerate the PCR reaction using a specially designed seven-loci STR multiplex that permits complete amplifications in eight minutes or less, thus aiding in the analysis of time-sensitive forensic casework.

This presentation will impact the forensic science community by demonstrating an approach toward optimizing rapid, multiplex PCR amplifications, which can be easily implemented in their own laboratories. This procedure uses small, high-speed thermal cyclers and fast polymerases with high processivity and inhibition resistance. The loci used in this multiplex are a small subset of the standard Combined DNA Index System (CODIS) set, making them readily compatible with current statistical approaches. This new procedure should be particularly useful for situations in which screening of suspects and crime scene samples is necessary.

It is often extremely important to rapidly screen suspect samples at border controls and police stations where the individuals in question can only be detained for short periods of time. Current DNA typing methods provide the best biometric information yielding identity, kinship, and geographical origin, but they are not sufficiently fast to permit identity of a suspect DNA in real time. Current rapid DNA systems take approximately 90 minutes, and full laboratory DNA analysis is even slower.[1,2]

Ultra-high speed PCR coupled with rapid polymerases can greatly reduce the processing time from sample to STR genotype.[3] Coupling these advances with new thermal cycler designs can make the analysis even faster. Using Peltier and flow-based thermal cyclers, PCR reactions have been optimized, resulting in the completion of singleplex reactions in four minutes and complete multiplex reactions in eight minutes. When coupled with microfluidic electrophoresis, complete genotypes can be produced in 15 minutes or less.[3]

To accomplish this, specially engineered enzymes and buffer systems have been tested to rapidly amplify autosomal and Y-chromosomal Short Tandem Repeat (Y-STR) multiplexes.[3,4] The designed multiplex includes D5S181, D13S317, D7S820, CSF1PO, D16S539, Penta D, and Amelogenin, which have sizes between 106bp and 454bp. A complementary rapid Y-STR multiplex has also been developed. By using off-the-shelf components and commercially available enzymes, it is possible to create a procedure that acts as a quick, highly informative sample screening process that also retains sufficient DNA for later manual processing using standard STR or Y-STR kits.

The first phase of this study further accelerated a previously reported amplification by increasing DNA concentration and reducing cycle number in order to produce a 7-locus multiplex amplification in eight minutes. Two different non-hotstart polymerases were compared in these studies. Additional work was performed on a novel flow-based thermal cycler in which the sample moves fluidically between two thermally isolated regions. This system was able to produce singleplex PCR reactions in four minutes. This work is currently being expanded to permit multiplex amplifications. In the current research, control DNA standards 9948 M DNA and K562 F DNA were used, as well as donated saliva samples from five adults. Samples were analyzed using gel, capillary, and microfluidic electrophoresis separation approaches.

The results of this study demonstrate the application of ultra-high speed PCR for the successful amplification of two different PCR multiplexes. With such a procedure in place, any crime laboratory can produce a nearly instantaneous genotype from buccal samples.

B100 Rapid DNA Analysis for Disaster Victim Identification

Selden Richard, MD, NetBio, 266 Second Avenue, Waltham, MA 02451; Rosemary S. Turingan, PhD, NetBio, 266 Second Avenue, Waltham, MA 02451; and Eugene Tan, PhD, NetBio, 266 Second Avenue, Waltham, MA 02451*

After attending this presentation, attendees will understand the applicability of Rapid DNA analysis technology to Disaster Victim Identification (DVI) and family reunification. Attendees will also learn: (1) the impact of tissue degradation on the selection of samples for generations of Short Tandem Repeat (STR) profiles in mass casualty events; and, (2) the use of field-based kinship analysis software to assist in both victim identification and family reunification.

This presentation will impact the forensic science community by presenting processes that enable rapid identification of human remains and kinship identification in field-forward settings. The ability of first responders, primarily individuals without backgrounds in laboratory-based forensic DNA analysis and genetics, to perform STR analysis as well as sophisticated genetic analysis offers the potential to change the current paradigm in DVI. In particular, eliminating the interval between the disaster and receipt and analysis of samples at a laboratory will minimize deterioration of sample quality and time-to-profile generation and, most importantly, will accelerate familial reunification and bring closure to grieving family members.

The fully integrated Rapid DNA Analysis™ and kinship determination system is based on 27-locus FlexPlex™ chemistry. This six-color assay is modeled after Promega's® Fusion 6C chemistry with two additional Y-chromosomal Short Tandem Repeat (Y-STR) loci (DYS570 and DYS576) and the substitution of Penta D with D6S1043. The assay contains all expanded Combined DNA Index System (CODIS), United Kingdom, INTERPOL, European Standard, German and Australian core loci, and D6S1043, an important STR marker broadly used in China. Accuracy, concordance, precision, resolution, Personal Health Record (PHR), sensitivity, species specificity, and all other relevant measures meet or exceed required metrics. Developmental validation of the system is in progress.

Data demonstrating the functionality of the Accelerated Nuclear DNA Equipment (ANDE) Rapid DNA system for fully integrated, fully automated processing of a number of DVI sample types will be presented, with a focus on bone, muscle, and liver. Data on Rapid DNA processing of degraded tissues will also be presented based on mock samples exposed to excessive heat, explosive materials, microorganisms, and other conditions associated with mass casualty events. Data supporting the use of automated kinship analysis software and database creation will also be presented.

In conclusion, this study demonstrates the broad applicability of Rapid DNA analysis in mass disasters with an easy-to-use mobile system that can generate STR profiles from a broad range of sample types and perform kinship analysis.

Rapid DNA Analysis, Disaster Victim Identification, Kinship Analysis

B101 The Recovery of Mitochondrial and Nuclear Touch DNA From Spent Cartridge Casings

Emily R. Heinz, BS, Forensic Science Program, Michigan State University, 560 Baker Hall, East Lansing, MI 48824; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand the advantages and disadvantages of Short Tandem Repeat (STR) analysis and mitochondrial DNA (mtDNA) sequencing of touch DNA from spent cartridge casings for the identification of the loader of a firearm.

This presentation will impact the forensic science community by detailing how the recovery of touch DNA from spent cartridge casings is influenced by casing caliber and how the type of testing employed, either mitochondrial or nuclear, influences DNA typing success and the potential identification of the loader of a firearm.

Crimes involving firearms are common, yet the weapon itself is seldom recovered at a crime scene. In contrast, cartridge cases that are ejected during a shooting are regularly left behind by the shooter and are commonly submitted as forensic evidence in an attempt to identify the loader or shooter of the gun. Fingerprints may be deposited on cartridge cases by the loader; however, they are seldom recovered following a shooting. Due to the lack of fingerprints, DNA profiling may be attempted. This has had limited success from spent cartridge cases, most likely because the DNA is in trace amounts or highly degraded, possibly due to the intense heat generated or other aspects of the shooting process. Thus, mtDNA, which is present in hundreds of copies per cell encased inside the mitochondria, may be more advantageous for DNA testing from spent cases.

In the research presented, all testing had Michigan State University (MSU) Institutional Review Board (IRB) approval. Volunteers loaded magazines of firearms with 0.22 and 0.45 caliber cartridges. The volunteers also provided a buccal swab for reference. Firearm examiners at the Michigan State Police Lansing Forensic Laboratory subsequently fired the weapons. The ejected cartridge cases were collected and taken to the MSU Forensic Biology Laboratory for DNA analysis. DNA was isolated using an optimized double swabbing technique and organically extracted, followed by purification using pre-treated Amicon® filters. DNA was quantified via an Alu-assay using real-time Polymerase Chain Reaction (PCR). STR analysis was then performed using a PowerPlex® Fusion kit, and results were assessed based on the number of alleles consistent and inconsistent with the loader. MtDNA sequencing was also performed, and results were categorized as consistent or inconsistent with the loader or the presence of a mixture. The two analysis methods were then compared.

MtDNA haplotypes and STR profiles were typically in agreement with regard to the mtDNA classification and number of alleles consistent with the loader. Mitochondrial haplotypes consistent with the loader had a median of 11 loader alleles in STR profiles, while haplotypes inconsistent with the loader had a median of 7.5 loader alleles. Haplotypes displaying a mixture had a median of nine; however, the methods differed in terms of amplification success and identification of the loader. MtDNA sequencing proved to be more robust than STR analysis, as mtDNA was successfully amplified from all extracts, whereas complete STR profiles were rare. Alternatively, STR profiles that had numerous loci amplifications were more individualizing than mtDNA in that some volunteers shared haplotypes, while STR results were unique. Cartridge caliber also played a substantial role in DNA results. Significantly more DNA was recovered from 0.45 caliber cases than 0.22 caliber cases ($p = 0.0023$), with 0.45 caliber cases also producing a significantly higher median number of loader alleles ($p = 0.0062$) even though both calibers were loaded into magazines in the same manner. On the other hand, classification of mtDNA haplotypes did not differ significantly between case caliber ($p = 0.321$). Given these results, it is important to recognize that STR analysis and mtDNA sequencing generate different outcomes, each having distinct advantages and disadvantages. The results also demonstrate the value of the optimized DNA isolation methods, which were successful in obtaining DNA from spent cases, which is vital if DNA profiling of cases is to widely undertaken.

Cartridge Casings, Touch DNA, Mitochondrial and Nuclear DNA

B102 Deliberations on Y-Chromosomal Short Tandem Repeat (Y-STR) Interpretation, Present and Future

Michael D. Coble, PhD, NIST, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8314; Kristy Kadash, PhD*, Jefferson County Regional Crime Lab, 200 Jefferson County Parkway, Golden, CO 80401; Tamyra Moretti, PhD*, Nuclear DNA Unit, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Bruce S. Weir, PhD*, University of Washington, Dept of Biostatistics, Box 359461, Seattle, WA 98195*

After attending this presentation, attendees will better understand the proper analysis of Y-STR profiles, with particular consideration paid to rapidly mutating loci and mixed haplotypes, and the current and future approaches for statistical analysis of Y-STR matches.

This presentation will impact the forensic science community by informing attendees of issues related to the application and interpretation of male-specific STR testing.

Y-STR typing methods were developed shortly after autosomal STR typing became adopted in forensic laboratories. It was quickly recognized that a male-specific typing test could be valuable in cases in which male DNA would otherwise be swamped by the amount of female DNA in certain samples. This opened up investigative opportunities for sexual assault cases that may have previously been passed over, particularly cases in which no spermatozoa were detected, either because the incident was not immediately reported or no ejaculation occurred.

Despite its advantage over autosomal STR typing in these cases, Y-STR typing was not implemented by forensic laboratories as readily. While the methodology required to obtain Y-STR profiles is nearly identical to that used in obtaining traditional STR profiles, a completely new approach to interpretation and statistical analysis had to be developed. What does the Y-STR profile mean? First, it is a true haplotype rather than a DNA profile of independent loci. All of the loci are linked and theoretically inherited as a group. Second, a match to an individual male is also likely to be a match to any patrilineal relative and to an unknown number of unrelated males. Third, the strength of the match is limited by the size of the database used for comparison and by the number of loci tested. Fourth, samples containing haplotypes from more than one male proved very difficult to reliably interpret.

New kits that include more Y-STR loci are now commercially available; however, only a small percentage of the samples in the commonly used Y-STR population databases contain haplotypes with these additional loci. Some of the new kits also have rapidly mutating loci that can assist in differentiating close male relatives. What impacts do the additional loci and the rapidly mutating loci have on conclusions and statistics, particularly for mixed haplotypes?

A two-hour block of time has been scheduled for deliberations on the present and future approaches to Y-STR interpretation. The panel convened for this session consists of analysts, researchers, and statisticians with extensive experience in the development of Y-STR interpretation approaches and in the application of Y-STR analysis to forensic casework. The discussion will include topics such as the cost-benefit of searching more haplotypes or more loci, comparing the counting method with the likelihood ratio methods, familial/pedigree studies, and the impact of future typing technologies.

Y-STR, Interpretation, Statistics

B103 Evaluating the Efficiency of the Use of the Qiagen® QIAsymphony® With High-Throughput Y-Screening Utilizing Phosphate-Buffered Saline as an Alternative to Conventional Serology

Season E. Seferyn, MSFS, Marshall University Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701; and Jason Chute, MSFS, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will better understand research that is taking a new approach to screening sexual assault evidence — a male DNA (Y) -screen using a phosphate-buffered saline cell extraction on substrates.

This presentation will impact the forensic science community by providing a conventional serological alternative for screening sexual assault kits that is scalable in such a way that it is affordable to all laboratories, regardless of laboratory size or throughput.

Sexual assault kit backlogs have been a common topic in news stories in recent years throughout the United States. According to the Rape, Abuse and Incest National Network (RAINN), there are 237,868 victims of rape/sexual assault per year. This project developed a high throughput screening method for the presence of male DNA. The goal of this project was to increase laboratory efficiency by performing a Y-screen utilizing the Qiagen® QIAsymphony® on a Phosphate-Buffered Saline (PBS) extract instead of completing conventional serology.

Historically, serology screening has been the method for processing sexual assault kits. Drawbacks of this method include: false positives and negatives, difficulty in automation, subjective interpretation, and lengthy time commitments to a microscope. Y-screening enables the process to be automated, using a 96-well format allowing simultaneous screening on a Polymerase Chain Reaction (PCR) -based method. This method brings objectivity to the screening process and provides a downstream correlation similar to the current DNA analysis techniques. Y-screening has been employed for a number of years.

This proposed process is unique in that this approach took a uniform cutting from the evidence and cells were removed from the substrate with PBS. The PBS extract was screened during the Y-screen. The extraction was performed on the Qiagen® QIAsymphony®, which lysed all cells in the PBS extract. Quantitative PCR with simultaneous male and human DNA quantitation setup was then conducted on the Qiagen® QIAgility® robotic liquid handler with the use of the Quantifiler® Trio DNA quantification kit by ThermoFisher Scientific or Qiagen® Investigator® Quantiplex HYres kit. Quantitation was performed on an Applied Biosystems® 7500 Real-Time® PCR system. The screening of the samples was based on the presence or absence of male DNA. During the Y-screen, the samples with the presence of male DNA proceeded to full DNA analysis. In order to do so, the remaining portion of the PBS extract was taken through the traditional DNA analysis procedures. Unlike conventional serology, this resulted in a quantitation that will directly correlate to downstream DNA analysis. In addition, it minimized the number of times that an analyst needed to go back to the evidence.

This project compared and evaluated laboratory efficiency of the Y-screen model versus conventional serology through various studies. Variables such as temperature, incubation time, PBS volume, and agitation method were optimized for the Y-screen. In addition, the amount of sample extract added to the quantitation reaction for the Y-screen was also studied and optimized. During the sensitivity study, the Y-screen had increased sensitivity when compared to semen serology. Although the supplies needed for the Y-screen procedure are costlier than conventional serology, the Y-screen approach is a more cost-effective method when analyst time is factored. It was concluded that the Y-screen is a valuable method for use on sexual assault kits for the Marshall University Forensic Science Center DNA Laboratory. It is not only cost-effective but also an objective method with thoroughness and specificity.

DNA, Y-Screen, Serology

B104 Why Perform Y-Screening? Validation of a Novel Sperm Lysis Protocol to Improve Sexual Assault Triaging

Victoria Hsieh, 140 W 69th Street, Apt 85B, New York, NY 10023; David R. Fisher, MS, NYC OCME, Dept of Forensic Biology, 421 E 26th Street, #11-50, New York, NY 10016; Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118; Jeffrey A. Hickey, MS, 1505 Rutledge Avenue, Charlottesville, VA 22903-1417; Kirsty Mayall, MS, Microlab Inc., 705 Dale Avenue, Charlottesville, VA 22903; Orion Scott, PhD, 705D Dale Avenue, Charlottesville, VA 22903; David J. Saul, PhD, ZyGEM NZ Ltd, Innovation Park, Ruakura Road, Hamilton, Waikato 3216, NEW ZEALAND; Delphine Le Roux, PhD, University of Virginia, Dept of Chemistry at UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22901; Jacquelyn A. DuVall, BSc, University of Virginia, Dept of Chemistry, UVA, McCormick Road, PO Box 400319, Charlottesville, VA 22904; and James P. Landers, PhD, University of Virginia, Dept of Chemistry, McCormick Road, Charlottesville, VA 22904*

After attending this presentation, attendees will better understand the process of screening sexual assault evidence using a novel sperm lysis protocol and commercially available quantitative Polymerase Chain Reaction (qPCR) kits.

This presentation will impact the forensic science community by demonstrating a method for triaging sexual assault kits by rapidly lysing sperm cells, allowing for the detection of male DNA with Y-specific qPCR.

Many laboratories in the United States are making efforts to reduce backlogged sexual assault cases and/or reduce the processing time for incoming cases. These laboratories often screen large amounts of evidence, looking for the best samples to test in order to get a perpetrator's DNA profile. This often involves presumptive tests for semen, amylase, or blood. Some laboratories have begun to use qPCR as a screening tool for male DNA since most sexual assault cases have a male suspect. Consequently, there is demand for a quick sperm lysis protocol, which would allow for rapid high-throughput screening of potential sexual assault evidence.

Typically, DNA is released from sperm using a combination of detergents and reducing agents, which can be inhibitory to downstream assays, such as PCR and real-time PCR. Most sperm lysis procedures require additional steps to remove these potentially inhibitory reagents from the DNA extract. These clean-up procedures add more transfer steps, which lengthen the process and can add cost. In addition to the time and cost considerations, extra transfer steps can lead to sample switching, contamination, or loss of DNA.

This presentation will describe the validation of the ZyGEM® PDQeX for DNA extraction, including sperm lysis. This instrument uses a novel protocol and reagents for sperm lysis. The end result is DNA ready for qPCR or for Short Tandem Repeat (STR) profiling without additional clean-up steps. Data from the developmental validation of the manufacturer, as well as data from the internal validation of this system by the New York City Office of Chief Medical Examiner, will be presented.

The validation data includes sensitivity, precision and accuracy, mixture, contamination, and known and non-probative studies. This data has shown that the system can lyse sperm mixed with overwhelming quantities of female epithelial cells. Sensitivity studies have illustrated that male/female mixtures containing as few as one sperm per microliter can be lysed and then detected and quantified using qPCR. Mock casework and stability studies have shown that the system can extract DNA from realistic and challenging mock casework samples, such as mock vaginal swabs and sperm deposited on denim and other fabrics. The qPCR data was also used to accurately estimate the amount of template DNA for STR amplification with commercially available kits. The quantification data was found to be a good estimate for the purposes of STR amplification, indicating that the DNA extracts were not inhibiting qPCR or STR amplification.

This data will demonstrate that this system can extract DNA from typical sexual assault evidence that is ready for commercially available qPCR and STR kits. This process enables laboratories to use Y-specific qPCR to rapidly screen sexual assault kits for useful evidence. The screening method is an efficient way for laboratories to triage samples with sufficient male DNA to pursue STR analysis.

Y-Specific qPCR, Sperm Lysis, Male Screening

B105 Proximity Ligation Real-Time Polymerase Chain Reaction (PLiRT-PCR): A Protein-Based Confirmatory Method for Processing Sexual Assault Kit Samples for Semen and Sperm Cells

Sarah Riman, PhD, The George Washington University, 5500 Friendship Boulevard, Apt 2429N, Chevy Chase, MD 20815; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will possess valuable insight on the research efforts performed to integrate a potential confirmatory detection method of semen and spermatozoa to sexual assault casework workflow.

This presentation will impact the forensic science community by demonstrating that PLiRT-PCR can be easily integrated into forensic laboratories, as it requires only a thermocycler and a real-time PCR system as well as utilizing a small fraction of the total reaction.

Sexual violence affects millions of Americans. According to the United States Department of Justice's National Crime Victimization Survey (NCVS), each year there is an average of 288,820 victims of rape and sexual assault ages 12 or older. Every two minutes, a victim is being sexually assaulted. Therefore, processing sexual assault evidence is time sensitive. Rapidly confirming semen, and generating the assailant's DNA profile, is crucial for solving crimes and bringing closure to the victims and their families.

A large number of sexual assault kits submitted to forensic laboratories have yet to be analyzed. The current procedures of sexual assault workflow are presumptive serological testing, which include microscopic sperm slide searches, followed by differential extraction methods. This workflow is labor intensive, time consuming, and significantly affects case backlog.

This study has developed an alternative detection method with the potential for replacing microscopic sperm confirmation and enabling the processing of multiple samples at a time on a 96-well plate. In as few as three hours, the assay confirms whether a sample contains semen or sperm cells simultaneously and assists analysts in deciding whether to proceed to differential extraction, therefore helping to reduce backlogged cases.

The PLiRT-PCR assay begins with a small cutting from the evidence (e.g., a fifth of a swab) that is placed in lysis buffer to break open the sperm cells, thus saving the rest of the evidence for the downstream analysis pipeline: differential extraction, quantification, and Short Tandem Repeat (STR) analysis. The lysis step is followed by a binding reaction of specific antibodies against proteins of interest. The antibodies are coupled to short DNA strands, forming so-called pairs of proximity probes. Upon simultaneous detection and proximal binding of the probes to their respective target proteins, the two attached DNA strands are brought in close proximity and are hybridized to a connector oligonucleotide complementary to the oligonucleotide ends of the assay probe pair. Then, the DNA strands undergo an enzymatic ligation reaction, forming a new amplifiable DNA product that can be amplified and measured in a highly quantitative manner by quantitative Polymerase Chain Reaction (qPCR).

This presentation discusses the application of PLiRT-PCR for the identification of semen and sperm proteins from blind samples provided from Bode Cellmark by using only 2µL of the sample. The assay supports both swab samples and other substrates that have different dilution amounts of body fluids spotted on them. Once semen and/or sperm was determined, differential extraction, quantification, and STR typing using Applied Biosystems® Quantifiler® Trio, GlobalFiler™, and Yfiler® Plus kits were performed. Samples that tested positive with the PLiRT-PCR assays displayed a positive male quantification result with the Y-screen assay, Quantifiler® Trio, further validating the sensitivity of this assay.

This study demonstrates that PLiRT-PCR can be a powerful, robust, and quantitative confirmatory technique the DNA analyst can use to assess whether evidence from sexual assault kits contain semen or sperm cells. Without adding additional resources, the assay utilizes common instruments in the laboratory. This method is more sensitive than the currently used protein-based detection techniques and assists in deciding which sample to process with the differential extraction methods.

PLiRT-PCR, Sexual Assault, Spermatozoa

B106 Improving Seminal Fluid Detection Sensitivity in Extended Postcoital Intervals by Triple Quadrupole (QQQ) Mass Spectrometry

Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Catherine O. Brown, MSFS, Center for Forensic Science Research & Education, 2300 Startford Avenue, Willow Grove, PA 19090; Cameron Logan, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; and Phillip Danielson, PhD, Department of Biology, 2101 E Wesley Avenue, Lab 223, Denver, CO 80210*

After attending this presentation, attendees will better understand the use of protein mass spectrometry for the detection and quantitation of human seminal fluid during an extended postcoital interval.

This presentation will impact the forensic science community by illustrating how protein mass spectrometry can be used to enhance the potential for the successful detection and confirmatory identification of seminal fluid in an extended postcoital interval. The results of this study can provide the forensic science community with a powerful tool to aid in obtaining potentially probative evidence in sexual assault investigations.

This work adapted a fully validated multiplex QQQ Multiple Reaction Monitoring (MRM) method for multiple body fluid identification for the focused identification of seminal fluid protein biomarkers. The modified assay provides enhanced sensitivity for seminal constituents that surpasses the sensitivity currently achievable with commonplace serological screening techniques. This makes it possible to confidently detect the presence of seminal fluid in extended postcoital intervals.

Previous research has resulted in the development of a qualitative mass spectrometry-based assay for the confirmatory identification of human seminal fluid. The current study has demonstrated that Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS) can be utilized to both detect and quantitate seminal fluid four days postcoitus in authentic samples. Initial limits of detection and quantitation were determined using heavy isotope-labeled peptide standards complimentary to the targeted peptide fragments of interest. By comparison, paired analysis using the ABAcard® p30 and RSID™-Semen immunochromatographic assays failed to produce a positive test result one and three days postcoitus, respectively.

The goal of the current research was to facilitate the analysis of challenging sexual assault evidence by optimizing the quantitative tandem mass spectrometry method to increase the detection and quantitation of seminal fluid protein biomarkers. Using an Agilent® 6495 QQQ mass spectrometer coupled with a 1290 UPLC system, seminal fluid-specific proteins (selected based on previously acquired time-of-flight data) were analyzed. The specificity of the protein biomarkers as well as the potential for matrix interference was evaluated through analyses of two-, three-, and four-component mixtures of seminal fluid in combination with commonly analyzed body fluids (i.e., peripheral blood, vaginal and menstrual fluids, saliva, and urine). The sensitivity achieved by the MRM seminal fluid assay was established using a serial dilution of semen spotted onto vaginal swabs. It was found that a 1:131,072 dilution of seminal fluid in a vaginal fluid matrix could be reliably detected by the assay. This translates into a doubling of the detection interval for authentic postcoital samples — enabling detection up to more than eight days postcoitus.

Additionally, intact synthetic proteins (prostate-specific antigen and semenogelin-1) were used to create a "standard detection curve." These data provide insight into the lower limits of detection and quantitation of natural seminal fluid proteins. The ability to quantify seminal fluid protein biomarkers can be used to establish background interferences (semenogelin-1) and baseline levels (prostate-specific antigen) of the targeted proteins.

In conclusion, this study provides comprehensive data detailing the sensitivity and specificity of a novel serological assay approach utilizing protein mass spectrometry for the detection and quantitation of human seminal fluid.

Proteomics, Postcoital Interval, Sexual Assault

B107 Evaluating the Utility of Highly Sensitive Male Quantitative Polymerase Chain Reaction (qPCR) Targets for Simple, Low-Cost, and Rapid Screening of Sexual Assault Samples

Andrew Loftus, PhD, Innogenomics Technologies, LLC, 1441 Canal Street, Ste 307, New Orleans, LA 70112; Gina Murphy, MS, Innogenomics, 1441 Canal Street, Ste 307, New Orleans, LA 70112; Jonathan S. Tabak, InnoGenomics Technologies, 1441 Canal Street, Ste 307, New Orleans, LA 70112; Anne H. Montgomery, MS, InnoGenomics Technologies, LLC, 1441 Canal Street, Ste 307, New Orleans, LA 70112; and Sudhir K. Sinha, PhD, InnoGenomics Technologies, LLC, 1441 Canal Street, Ste 307, New Orleans, LA 70112*

After attending this presentation, attendees will understand the determination of the optimal genomic targets for the detection of male DNA in sexual assault cases.

This presentation will impact the forensic science community by evaluating the comparative utility of several male qPCR targets as a potentially valuable tool to improve a forensic laboratory's capacity to screen a high volume of sexual assault case samples.

The reduction of Sexual Assault Kit (SAK) backlogs has become of top concern and priority for many jurisdictions across the country. In 2011, the National Institute of Justice (NIJ) published a special report in response to recent discoveries of thousands of untested SAKs in police evidence rooms nationwide. In this report, one of the priorities identified for crime laboratories is to "create a plan to handle work if large numbers of previously untested SAKs are suddenly sent to the crime lab." This plan must include a more streamlined process for triaging SAKs to identify the presence of testable male DNA in these samples. Historically, serological screening using color immunological tests, chemical tests, or microscopic analyses have been the laboratory method of choice for initial processing of SAKs; however, these conventional methods have several drawbacks, including false positives and negatives, difficulty implementing automation, subjective interpretation, and the length of time the tests take in the laboratory. In the past decade, advancements in forensic quantitation systems based on real-time PCR have greatly improved the sensitivity and reliability of sample detection, allowing for higher throughput screening of sexual assault samples. Screening for male DNA (Y-screen) enables an objective, quantitative analysis of the presence of male DNA in a sexual assault sample. The process is easily automatable, using a 96-well format allowing for the screening of a high number of samples simultaneously using a real-time PCR-based method. These methods provide a downstream correlation with the profiling results obtained with commonly employed Short Tandem Repeat (STR) and Y-chromosomal Short Tandem Repeat (Y-STR) genotyping systems.

This study evaluates the utility of two different qPCR targets for detection and screening of male DNA in sexual assault and other casework samples. The methods studied include the use of a quick and simple lysis step to non-differentially lyse the cells in conjunction with two high-copy targets located on the Y chromosome. Studies performed include sensitivity, precision/reproducibility, male:female mixtures, and correlation with downstream STR and Y-STR results of mock sexual assault samples.

Results indicate that both tested targets are adequate for use in the accurate detection of male DNA, with the high copy target enabling the most sensitive detection of male DNA in sexual assault samples. Sensitivity studies using a dilution series conducted in triplicate with the National Institute of Standards and Technology (NIST) Standard Reference Material (SRM) 2372 Component A indicated the ability to consistently detect male DNA at quantities below one picogram. Mixture studies demonstrated the ability to consistently detect low quantities of male DNA (10pg) in all male:female mixtures tested, including 1:8000 male:female mixtures. Additionally, a quantitation threshold value that may reliably be used as a stopping point was determined for STR and Y-STR analysis, although this value may require adjustment based upon the sensitivity of the genotyping systems and interpretation criteria employed in each forensic laboratory. This study demonstrates the utility of real-time PCR male-specific targets in high throughput and fast screening of sexual assault cases. These methods will undoubtedly improve a laboratory's capacity to screen a high volume of sexual assault samples.

SAKs, Male DNA, QPCR

B108 Microchip-Based Antibody-Mediated Differential Lysis of Sperm Cells

Molly E. Woodson, BA, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; Kemper Gibson, BS, 2230 E Teemont Court, Richmond, VA 23225; Jordan Cox, MS, 1823 Floyd Avenue, Richmond, VA 23220; Kimberly Jackson, 409 McCormick Road, Chemistry Dept, Charlottesville, VA 22903; James P. Landers, PhD, University of Virginia, Dept of Chemistry, McCormick Road, Charlottesville, VA 22904; and Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284*

After attending this presentation, attendees will better understand the forensic applications of modular microfluidics, as well as the benefits of a separation module for the differential extraction of sperm-containing evidence samples from sexual assaults.

This presentation will impact the forensic science community by describing a separation module for the cell sorting and differential extraction of forensically relevant sexual assault samples on a rotationally driven microdevice.

These modular systems allow for the incorporation of advanced microfluidics technologies in forensic laboratories without the wait for development of Micro Total Analysis (μTAS) systems for casework samples. Modular devices would require a small footprint, would replace only limited steps of the workflow, and could potentially decrease the amount of time needed for sample processing, particularly in regard to the differential extraction and amplification steps.

Due to the increasing sexual assault kit backlog and the increased legislation proposed to reduce this backlog, there is a significant driving force to develop methods that decrease the sample processing time for these samples. Manual differential lysis separates only non-sperm from sperm cells and includes many analytical steps and significant user intervention, leading to an increased potential for contamination, increased processing time, and imperfect separation of male/female fractions. The proposed microchip has the potential to decrease the manual intervention currently required for differential extraction while minimizing the need for difficult mixture interpretations. This sexual assault microdevice incorporates an antibody-binding chamber, which utilizes polystyrene beads coated with an antibody specific to an antigen on the acrosomal cap of sperm cells. Previous studies identified a sperm-specific antibody (SPAG-8) and showed that, when coated onto the bead surface, it was capable of improving sperm cell DNA yield when processed in microcentrifuge tubes. Furthermore, studies using a modified ZyGEM® prepGEM™ differential method confirmed that this DNA liberation method was able to improve efficiency of sperm cell lysis when compared to traditional differential lysis/extraction methods. In these studies, the SPAG-8-coated bead mechanism was tested again, but testing was in the plastic microchip environment. Semen dilutions were processed on a simple chip that included an inlet reservoir, an antibody-bead binding chamber, and an outlet reservoir; following binding, samples were removed from the chip for modified ZyGEM® prepGEM™ differential extraction and quantitation of human DNA. Runs that included the SPAG-8-coated beads had 39% more sperm cell DNA captured versus on-chip incubation of the same samples *without* beads or antibody. In addition, these data demonstrated a 20% and 38% increase in the amount of sperm cell DNA captured on the microchip using SPAG-8-coated beads versus what was obtained using manual differential methods (modified ZyGEM® prepGEM™, and differential using the QIAamp® DNA Blood Mini Kit), respectively.

In broadening the search for a sperm-specific antibody, Male-Enhanced Antigen 1 (MEA-1) was also evaluated for its ability to separate cells associated with sexual assault samples. MEA-1 is encoded by the male-histocompatibility gene (HY) and is purported to be present on the cell membrane of *all* male epithelial cells; however, the literature data is contradictory. If expression is truly male-cell specific, the addition of MEA-1 to SPAG-8 in the microchip antibody-binding chamber may lead to male and female fractions with enhanced purity. Thus, similar to previous work, the binding performance of MEA-1 was evaluated via flow cytometry. Initially, MEA-1 displayed an average binding affinity of 10.7% to male buccal epithelial cells versus 9.8% to sperm cells, indicating that the antigen is indeed expressed evenly on all male cells, regardless of tissue origin. A follow-on study was performed to determine the difference in expression between male cells (buccal and sperm) and female cells (buccal and vaginal). MEA-1 antibody binding was ~6.5-fold higher in male buccal cells and sperm cells than female buccal and vaginal epithelial cells, respectively. Although flow optimization using these antibodies (and their respective fluorophores and isotype controls) is needed to combat the overall low average binding affinity

in male cells, these data clearly indicate a much higher MEA-1 expression rate in males; thus, these results are promising. Optimization is critical for future work. Adding a male-specific antibody could bring an added value to this microdevice upon commercialization. Future work on this project will include integration and testing of this module into a microdevice that also includes downstream DNA liberation and Infrared-mediated Polymerase Chain Reaction (IR-PCR) -based Short Tandem Repeat (STR) amplification.

Microdevice, Sexual Assault, Antibody

B109 We Did It! Houston's Sexual Assault Kit Backlog Elimination Story

Jessica L. Powers, MA, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002*

After attending this presentation, attendees will have a better grasp of the gravity of the nationwide Sexual Assault Kit (SAK) backlog. This presentation will share the challenges and successes associated with eliminating a backlog of SAKs in Houston, TX, the fourth-largest city in the United States, and the achievement of a sustainable, 30-day turnaround time on sexual assault cases.

This presentation will impact the forensic science community by introducing workflow and personnel management strategies that helped Houston eliminate its SAK backlog and achieve a sustainable, 30-day turnaround time.

In 2013, the Houston Police Department (HPD) had 6,663 untested SAKs on property room shelves, the oldest dating back to the 1980s. At the time, the HPD Crime Laboratory was tasked with outsourcing the untested kits. Each case would have to be internally reviewed following the outsource testing in order to upload relevant information into the Combined DNA Index System (CODIS), the national DNA database. To complete this task, the laboratory had to quickly develop a plan to locate the evidence, prepare the documentation, and ship the items for testing. Internal training began as the laboratory prepared for the large amount of case reviews that would occur when the completed cases returned. Meanwhile, in April 2014, HPD's Crime Laboratory ceased to exist. The Houston Forensic Science Center, an independent local government organization, took over management and oversight of Houston's forensic operations, including DNA testing. By February 2015, the outsourcing project had been completed and analysts had successfully reviewed close to 10,000 cases. More than 4,200 profiles were uploaded into CODIS, resulting in more than 1,800 hits. The project also helped with the identification of a serial rapist and confirmed that no one had been wrongfully accused.

With efforts focused on reviewing the outsourced cases and their accompanying reports, the laboratory was cognizant that it could end up with a backlog of current cases. It developed a plan to maintain a workflow for SAK processing in order to prevent a backlog from reoccurring. Unfortunately, the outsourcing project ended before the laboratory had a fully functioning workflow for SAK processing. Each month, the number of backlogged SAKs grew. By October 2015, the backlog had risen to 716 kits. The laboratory began operating under the new workflow with the help of 14 people whose job it was to whittle away at the backlog. On April 6, 2016, Sylvester Turner, Houston's newly elected mayor, instructed the laboratory to eliminate the backlog and reach a sustainable 30-day turnaround time by July 1, 2016. On that day, the backlog (counting both those that were untested and those already in progress) was 575 SAKs. The laboratory succeeded by utilizing different resources to achieve the goal. The laboratory's staff had to be reorganized to focus on SAK processing, additional instruments had to be quickly purchased, and 99 kits had to be outsourced. By combining into one report male quantification for screening and the DNA results, the SAK workflow was streamlined to nine days from extraction to report completion. The laboratory completed 702 SAK cases, reviewed data from the 99 outsourced kits, and achieved a 30-day turnaround time in only 90 days.

Sexual Assault Kit, Backlog, Workflow

B110 The Development of a Dissolvable Swab for Increased Biospecimen Recovery

Blaine Butler, BS, Luna Innovations Inc, 706 Forest Street, Ste A, Charlottesville, VA 22903; Nikolai A. Braun, PhD*, Luna Innovations Inc, 706 Forest Street, Ste A, Charlottesville, VA 22903; Lauren Costella, MS, Luna Innovations Inc, 706 Forest Street, Ste A, Charlottesville, VA 22903; Robert I. O'Brien, BS, 8285 Bryan Dairy Road, Ste 125, Largo, FL 33777; and Christopher Tison, PhD, Luna Innovations Inc, 706 Forest Street, Ste A, Charlottesville, VA 22903*

After attending this presentation, attendees will understand existing forensic swab techniques and processes and the potential of a high-surface-area dissolvable swab to enhance biospecimen acquisition and subsequent recovery for forensic analysis.

This presentation will impact the forensic science community by discussing the increases in forensic competence as advances in material technologies are applied to biospecimen acquisition and processing for improving forensic analyses. Swab fiber technology with increased acquisition properties and complete specimen release through total swab dissolution allows for the collection of small amounts of cellular evidence while still producing robust Short Tandem Repeat (STR) profiling using standard methods.

Swabs are routinely used by crime scene investigators and forensic scientists for the collection of a wide range of evidence types for analysis. The most commonly used swab device for collection of biological specimens is the sterile cotton swab due to its ease of use, low cost, and ability to collect on multiple substrates such as wood, fabric, and metal. Although cotton swabs readily adsorb biological material, they exhibit low efficiency of DNA sample release. While material and manufacturing advances have resulted in a diversity of new forensic swab types and materials, sampling and extraction efficiency from these swabs varies significantly by substrate and sample type. The loss of biological material for downstream processing can be 40%-80% from merely the swab extraction process.

The primary objective of this study was to evaluate the effectiveness of high-surface-area, dissolvable, electrospun nanofibers on biospecimen capture and DNA recovery. Using prototype swabs made from sheets of electrospun biopolymeric material, experiments were conducted that evaluated adsorption of high and low volumes of biological material (wet and dried cells) from glass slides, and subsequent DNA extraction using commercially available forensic analysis kits. Both manual and automated DNA recovery was investigated. DNA extraction was conducted using the QIAGEN® QIAamp® DNA Mini Kit or the QIAGEN® EZ1 Robot. The Quantifiler® Human DNA Quantification Kit, in conjunction with an Applied Biosystems® 7500 Real-Time Polymerase Chain Reaction (PCR) instrument, was used to estimate the quantity of human DNA present in each sample. Following DNA quantification, STR typing was performed on all samples of DNA recovered from the dissolvable swabs using the GlobalFiler™ PCR Amplification Kit and analyzed using the GeneMapper™ ID-X software.

Dissolvable nanofiber swabs were shown to have excellent performance in cellular adsorption (99%) and in DNA extractions (82%). All DNA samples recovered from dissolvable electrospun swabs were also capable of producing full, high-quality STR profiles. The results of these experiments demonstrate the potential usefulness of high-surface-area, dissolvable, nanofiber swabs for both enhanced biospecimen capture and increased DNA recovery of biological evidence.

Any opinions, findings and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the United States Army Small Business Innovation Research (SBIR) Program Office or the Army Research Office.

B111 A Comparison of Methods of Analysis for the Extraction and Identification of Drugs Using Microfluidic Mass Spectrometry (MS) From Different Substrates

Emily Lichtenberger, BS, 1806 D Gorman Street, Raleigh, NC 27606; Michael Roberts, BS, Shimadzu Scientific Instruments, 4022 Stirrup Creek Drive, Durham, NC 27703; and Nelson R. Vinueza, PhD, North Carolina Sate University, 2401 Research Drive, Campus Box 8301, Raleigh, NC 27695*

After attending this presentation, attendees will better understand the utilization of a microfluidic extraction device and how, in conjunction with High Performance Liquid Chromatography (HPLC) and high- and low-resolution MS, it allows for accelerated analysis of multiple drugs of abuse in a single sample run.

This presentation will impact the forensic science community by introducing multiple methods for accelerated analysis of numerous drugs (up to 70) at the same time, which can aid in determining the efficiency of the system depending on the Microfluidic Device (MFD) MS instrumental set up.

This specific MFD was originally developed for the extraction of dyes from fibers; however, it is now being fully tested for other areas of forensic science that use extraction, such as inks on questioned documents or analgesic tablet analysis. Benefits of this device include: (1) smaller amounts of sample needed, allowing for less damage to the evidence; (2) less contact between the examiner and the evidence, allowing the integrity of the evidence to be kept intact; and, (3) speed of extraction, which is generally less than five minutes per sample run.[1]

The primary focus of this presentation is to compare the different methods of MFD-MS to illustrate the versatility of the device and to describe how high-resolution MS can be utilized for facilitated identification of the extracted drugs. Increasing the efficiency of drug analysis is essential in the forensic community simply because it allows for faster analysis of data, meaning rapid identification of the drugs used by perpetrators. Also important is ensuring that the majority of the evidence is kept accessible if later testing is needed, which this extraction device enables.

In these experiments, the MFD was used to extract a standard solution containing 70+ drugs from multiple substrates including Quantisal™ saliva collection devices, cotton swabs, paper, and more. Multiple instrumental set ups of the MFD-MS were tested: (1) directly connecting the MFD to the Shimadzu® LCMS-8060 series Triple quadrupole (QqQ) MS and directly injecting the sample into the MS; (2) extracting the sample using the MFD and introducing the extraction to HPLC for separation, then analysis via the QqQ MS; (3) extracting the sample using the MFD, adding 2mL of Methanol (MeOH) to enhance solubility and ion signal, and analysis through HPLC/MS; and, (4) connecting the MFD to the HPLC system using a T-valve for direct connection into the HPLC/MS system. These methods were also compared using the MFD attached to a different MS instrument, specifically, an Agilent Technologies® 6520 series quadrupole Time-Of-Flight (qTOF) MS. Comparison of analysis via these MS instruments demonstrates the diversity of compatibility this MFD possesses. The efficiency of each set up was compared by determining the number of drugs identified from a known standard solution of 70+ drugs. Sample preparation for all substrate types can be generalized in the following steps. First, a sample of the standard drug solution containing the 70+ drugs was administered onto the substrate (~2mL-3mL). Second, using either scissors or a Harris® micro-punch tool, a small portion (~0.5mm-2mm) of the substrate was removed. Third, the removed sample was placed in the sample cavity of the MFD sample chip and inserted directly into the MFD. From there, a computer program determining the number of flushes of solvent into the cavity for extraction was selected, and the process began.

In conclusion, the experiments conducted reveal the versatility and diversity of this MFD for extraction of multiple drugs on multiple different substrates, and also exhibits its compatibility with different MS instruments, which is beneficial as many crime laboratories have different instruments available. This MFD-MS and MFD-HPLC/MS set up will allow accelerated analysis of multiple drugs, increased integrity of evidence, and less contact between the evidence and the examiner, which are all essential for forensic analysis today.

Drug Analysis, Mass Spectrometry, Microfluidics

B112 Ionization Efficiency of Drugs Using Direct Analysis in Real-Time Mass Spectrometry (DART®-MS)

Yuriy Uvaydov, MS, 99 Tenth Avenue, Ste 721, New York, NY 10011*

After attending this presentation, attendees will better understand the ionization efficiencies of controlled substances utilizing DART®-MS. Specifically, this presentation will demonstrate that chemical properties of controlled drugs play a critical role in ionization and directly relate to DART®-MS sensitivity.

This presentation will impact the forensic science community by explaining the ionization efficiencies of drugs using DART®-MS and how this can be an effective technique for the identification of seized drugs.

DART®-MS is a fast ionization technique for mass spectral analysis of compounds. DART®-MS allows for ambient ionization of small molecules without sample preparation. The samples are directly introduced into the ion-source using capillary glass tubes and are desorbed from the sample surface by a flow of heated nitrogen gas while being ionized. DART®-MS, in combination with a High-Resolution Accurate Mass (HRAM) spectrometer, can deliver quick results with accurate mass determinations and highly specific mass-to-charge spectral data.

Ionization efficiency can be affected by a number of factors, such as MS interface design, inlet temperature, matrix composition, nitrogen or helium gas, or an analyte's chemical properties. Much of the research conducted to ionization efficiencies to date has been performed using Liquid Chromatography/Electrospray Ionization/Mass Spectrometry (LC/ESI/MS). Ionization efficiency studies using DART®-MS have been limited to instrument conditions, such as inlet temperature, capillary temperature, type of ionizing gas, and grid voltages. Presently, there is little information concerning ionization efficiencies for seized drugs of abuse.

The purpose of this work was to study ionization efficiencies for cocaine, heroin, oxycodone, fentanyl, acetylfentanyl, caffeine, and levamisole utilizing a previously developed 24-second DART®-MS screening method. Equimolar concentrations (400nM) of each analyte were prepared in methanol using an internal reference standard, Diethyltoluamide (DEET, 10ppm). Mass spectral acquisition of data was performed in positive mode utilizing a DART®-Simplified Voltage and Pressure (SVP) ion source with an Exactive™ Plus Mass Spectrometer. Five microliters of each sample solution were directly introduced into the ion source via glass capillary tubes, utilizing the Dip-It linear rail system connected to the DART®-SVP ion source. Data acquisition included fragmentation patterns utilizing Source-Induced Dissociation (SID), generated at 30eV, 60eV, and 100eV.

Preliminary results revealed cocaine had the greatest ionization efficiency, followed by levamisole and acetylfentanyl. These results explain why trace submissions of cocaine exhibits naturally demonstrated greater signal response on DART®-MS. The results also indicated that ionization efficiencies for other basic drugs are different and are significantly dependent upon the chemical property of each analyte. It was disclosed that for compounds that ionized more efficiently, the sensitivity response on DART®-MS was much greater. Likewise, compounds with weak ionization efficiencies revealed diminished sensitivity. In either case, confirmation of drugs was always obtained by an orthogonal technique, such as an LC/ESI/MS or GC/MS. Overall, this approach appeared to be an effective way to study ionization efficiencies of commonly encountered drugs in the laboratory.

DART®-MS, Drugs, Ionization

B113 Rapid Screening of Emerging Novel Psychoactive Substances (NPS) Using a Portable, Ambient Sampling Mass Spectrometer (MS)

Sabra R. Botch-Jones, MS, MA, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Boston, MA 02118; Zachary E. Lawton, BS, Illinois State University, Campus Box 4160, Normal, IL 61790-4160; Alessandra Bruno, BS, lllinois State University, Dept of Chemistry, Campus Box 4160, Normal, IL 61790-4160; David A. Barajas, BA, Boston University School of Medicine, 72 E Concord Street, R 806, Boston, MA 02118; Jamie R. Wieland, PhD, Illinois State University, Dept of Management and Quantitative Methods, Normal, IL 61790; Michael C. Gizzi, PhD, Illinois State University, Dept of Criminal Justice Sciences, Normal, IL 61790; and Christopher Mulligan, Illinois State University, Dept of Chemistry, Campus Box 4160, Normal, IL 61790-4160*

After attending this presentation, attendees will better understand how the merging of ambient ionization techniques and portable mass spectrometric technologies can be utilized to rapidly characterize new psychoactive substances onsite and offer high throughput detection via automated library searching methods of evidence ranging from trace residues surfaces to paraphernalia types, such as blotter paper.

This presentation will impact the forensic science community by introducing attendees to recent advances in portable, ambient sampling MS technology and the application of such a system for the analysis of new psychoactive substances.

The creation and use of NPS continues to increase throughout the world. In Europe alone, it has been reported that from the period of 2005-2014, over 400 NPS were reported to the European Union Early Warning System. In 2014, it was estimated that two NPS appeared on the market every week.[1] NPS are unregulated recreational drugs that have been synthetically modified to mimic traditional drugs of abuse while avoiding scheduling as an illicit substance. NPS pose a serious challenge for forensic identification in comparison to traditional drugs of abuse as structural characteristics can be variable and unknown.[2] The frequency and complexity of NPS evidence point to the need for robust screening methods, particularly portable technologies that could expedite legal investigations and reduce the burden on the crime laboratory system. In this study, a portable MS coupled with conventional and ambient ionization methods, such as Desorption Electrospray Ionization (DESI) and Paper Spray Ionization (PSI), was investigated as a flexible asset to combat the emerging threat of NPS.[3,4]

Substituted phenethylamines, particularly the 2C-series and prominent analogues featuring the addition of *N*-benzylmethoxy derivatives (i.e., NBOMes or "N-bombs") were the focus of this study. Analytical standards and mock forensic evidence were investigated via ESI, DESI, and PSI on a FLIR® Systems AI-MS 1.2 portable Cylindrical Ion Trap (CIT) MS.[5,6] The FLIR® Systems AI-MS 1.2, ruggedized for fieldwork, features an atmospheric capillary inlet with on-board high voltage and syringe pumping for coupling to conventional and ambient ionization methods. Both MS and Tandem Mass Spectrometry (MS/MS) data were collected for all analytes of interest in this study, incorporated into a simplified user interface that allows automated identification of threats via data dependent scanning and spectral database matching.[7] Automated spectral interpretation and simplified ionization methods, in turn, allow the collection of reliable and accurate data by non-technical users and first response personnel.

Data collected in this study suggest the use of interchangeable ionization sources outfitted on the AI-MS 1.2 system can provide a high throughput fieldable solution for NPS identification. Trace analysis, in the form of surface residues, was demonstrated by determining Limits of Detection (LODs) via surface swabbing PSI/MS from a variety of surfaces of forensic relevance. LODs ranged from low to high nanograms of deposited analyte from the relatively smooth surfaces (i.e., glass, aluminum, plastic identification and electronic entry cards, and plastic storage bags) and textured and geometrically complex substrates (i.e., brass key, ceramic floor tile, and textured laminate countertop). Furthermore, application to realistic paraphernalia types, such as blotter paper, was shown, allowing accurate identification of illicit species even when present in complex mixtures.

Field Analysis, Ambient Mass Spectrometry, NPS Detection

B114 Optimal Headspace Extraction for the Detection of Volatile Organic Compounds (VOCs) Released From Synthetic Cathinones Using Solid-Phase Microextraction (SPME) for Field Application

Vanquilla L. Shellman, BS, 2071 Renaissance Boulevard, Apt 207, Miami, FL 33025; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand the headspace analysis of synthetic cathinones. This presentation will provide detailed information regarding the volatile organic compounds associated with these drugs.

This presentation will impact the forensic science community by presenting a detailed method to sample synthetic cathinones in a non-destructive manner and by introducing a precise, safe, volatile compound in the form of a Controlled Odor Mimic Permeation System (COMPS), which will equip canine teams with the ability to detect synthetic cathinones (bath salts) currently being smuggled across United States borders. Because of an inadequate knowledge of the volatiles of these bath salts, narcotic detection canines have been unable to detect these illicit substances.

Methylone, ethylone, Methylenedioxypyrovalerone (MDPV), and α-Pyrrolidinopentiophenone (α-PVP, also known as Flakka), collectively referred to as bath salts, are a new trend of illicit substances known as synthetic cathinones. Designed by chemically modifying the core structure of the compound cathinone (the natural amphetamine of the khat plant), synthetic cathinones became prevalent within the United States in the mid-2000s. As an inexpensive and less-controlled alternative to the traditional Methylenedioxymethamphetamine (MDMA, Ecstasy), it has become heavily abused, prompting emergency scheduling by federal regulators. As a result of the drastic increase in popularity and abuse of synthetic cathinones, research studies have been conducted to gain a deeper understanding of its toxicological effects; however, the analytical components (sampling and analysis) required to understand and characterize bath salts are still vastly underrepresented.

This study will present results for an optimal extraction method that has been developed, which can be applied to the indirect analysis of synthetic cathinones. Method development was conducted using a headspace SPME technique on an actual confiscated bath salt sample known as Methylone (Molly). After performing extraction optimization, it was determined that a Polydimethylsiloxane Divinylbenzene (PDMS/DVB) -coated fiber, in addition to complimentary ionization techniques, resulted in the most beneficial set for the extraction and analysis of synthetic cathinone volatile components. This method allows for cathinone derivative samples to be rapidly sampled by non-invasive means, followed by analysis utilizing traditional gas chromatography/mass spectrometry. Determination of the VOCs comprised in these drugs can be beneficial in the creation of an effective canine training aid utilizing the Controlled Odor Mimic Permeation System (COMPS). COMPS involves a deployable source housing a target odor in a permeable polymer, which releases the odor at a known and controlled rate. This controlled system will aid canine teams throughout the country in the detection of synthetic cathinones, a task that a large number of canine teams are currently unable to achieve.

Synthetic Cathinone, SPME, COMPS

B115 Improving Qualitative Synthetic Cathinone Identification by Gas Chromatography/ Mass Spectrometry (GC/MS) Using Cold Electron Ionization (Cold-EI)

Matthew P. Levitas, BS, 208 Forest Drive, LaVale, MD 21502; Emily Andrews, MFS, 2300 Foxhall Road, Washington, DC ; Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007; and Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007*

After attending this presentation, attendees will understand the merits of Cold-EI in comparison to those of classical Electron Ionization (EI) in the analysis of synthetic cathinones. Attendees will be shown that better identification of synthetic cathinones is possible with Cold EI due to the presence of molecular ion in the mass spectra compared to no molecular ion in the EI spectra.

This presentation will impact the forensic science community by suggesting an alternative avenue for improved identification of forensic drugs using MS. Examples include analyses of emerging drugs, such as synthetic cathinones that yield inconclusive mass spectra due to the lack of molecular ions under classical EI.

Synthetic cathinones are emerging drugs with molecular structures similar to that of cathinone, the active ingredient in the khat plant. They are specifically designed to avoid legal prosecution of the manufacturers and dealers. Synthetic cathinones, which are beta keto-amphetamines, produce amphetamine-like effects when abused. Many synthetic cathinones are scheduled in the United States to protect the public interest. They became known as bath salts, mainly because they are typically misbranded when sold.

Synthetic cathinones are notoriously labile compounds that undergo extensive fragmentation when analyzed using classical EI. As a result, the resulting mass spectra contain little to no molecular ion peak, making the identification uncertain. The interpretation of the spectra is further complicated because synthetic cathinones produce relatively few fragments. Cold-EI relies on vibrational cooling of the analytes prior to ionization, thus reducing thermally induced fragmentation. This technique has been shown to increase the relative abundance of the molecular ion for thermally labile compounds and maintain the integrity of the fragments obtained by classical EI, thus improving the confidence in their identification. The confidence can be further improved by performing Tandem Mass Spectrometry (MS/MS) analyses.

This study subjected a total of 35 controlled synthetic cathinones and positional isomers to analyses by two GC/MS instruments; one equipped with a classical EI ion source and a quadrupole analyzer and another equipped with a cold-EI ion source and a quadropole Time-Of-Flight (qTOF) analyzer. Both instruments used 30m x 0.25mm, 0.25µm Elite-5MS columns for the GC separation.

As expected, all the classical EI mass spectra of synthetic cathinones contained molecular ion with relative intensity of less than 1%. In most cases, more of the molecular ions survived when the analysis was conducted by cold-EI ionization, with some analytes reaching molecular ion relative intensities of more than 25%. MS/MS analyses were performed on analytes that provided molecular ion with more than 5% relative intensity.

To reveal the additional discrimination that the presence of the molecular ion in the mass spectra brings to the spectra, the MS data obtained by the two methods was subjected to Principal Component Analysis (PCA).

Cold Electron Ionization, Synthetic Cathinones, Molecular Ion

B116 Using Coupled Columns With Ultra High-Performance Supercritical Fluid Chromatography (UHPSFC) for the Analysis of Synthetic Cathinones

Lauriane Tremeau-Cayel, 83 Weymouth Lane, Palm Coast, FL 32164; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand the uses and principles of UHPSFC with coupled columns for the separation of synthetic cathinones.

This presentation will impact the forensic science community by demonstrating the benefits of coupled column UHPSFC in drug analysis. Screening or confirmation of bath salts, including their positional isomers, using coupled columns is accomplished with significantly greater reliability compared to the use of a single column. Identification can be accomplished by retention time, Ultraviolet (UV) spectrum, and molecular ion and major fragment ions.

UHPSFC has been used to separate bath salts, including their positional isomers. The current method uses a Torus™ DIOL column with a 10mM ammonium formate in methanol, run isocratically with 3% methanol and 97% carbon dioxide as the mobile phase. This method separates 10 out of 15 controlled bath salts and 28 out of 34 isomers with a resolution of 1 or greater. In order to achieve better separation, coupled columns using different stationary phases were investigated. The two coupled columns were connected through a short length of narrow bore tubing and isocratic conditions were employed to the combined columns. The retention times from each column were approximately additive, so an estimation of the retention times of the coupled columns could be achieved prior to testing.[1] In order to investigate if greater separation of bath salts and their positional isomers could be achieved by using a coupled column approach, eight columns were tested. The columns include seven 1.7µm 3.0x100mm achiral columns (Torus™ DIOL, CSH Fluoro-Phenyl, HSS C18 SB 1.8 µm, BEH 2EP, 1-AA, Torus™ DEA, Torus™ 2PIC) and one 2.5µm 3.0x150mm chiral column (Trefoil CEL 1).

A combination of Torus™ DIOL and Torus™ 2PIC run with 3% 10mM ammonium formate in methanol has demonstrated significantly better resolution, in which 11 out of 15 controlled bath salts and, more importantly, 32 out of 34 positional isomers were separated in less than 15 minutes. In contrast to the use of a single column, six positional isomers of pentedrone and 4-methylethcathinone are now fully resolved. Percent methanol, temperature, pressure, and flow rate can also be adjusted in order to increase the resolution.

The effects of using coupled columns compared to single columns on the retention factor, selectivity factor, and efficiency were also investigated. During coupling, both the connecting tubing and temperature gradients caused by the increased pressure can contribute to band broadening.

Synthetic Cathinone, Supercritical Fluid, Coupled Column

B117 The Stability of Select Synthetic Cathinones in Non-Alcoholic Beverages

Stephanie L. Oddi, BSc, Arcadia University, 450 S Easton Road, Glenside, PA 19038; and Karen S. Scott, PhD, Arcadia University, 450 S Easton Road, Glenside, PA 19038*

After attending this presentation, attendees will better understand the role of synthetic cathinones in today's drug-facilitated sexual assaults and how various matrices and storage temperatures can affect the stability of specific synthetic cathinones.

This presentation will impact the forensic science community by offering information on the stability of select synthetic cathinones in beverages, an area of cathinones that has been investigated insufficiently. Through presenting this stability research, samples from suspected spiked drinks can be accurately analyzed and properly stored to aid in the investigation of drug-facilitated sexual assault cases.

Cathinone is a beta-ketone amphetamine found in the leaves of the khat plant (*Catha edulis*). While cathinone is a Schedule I drug, many of its derivatives continue to be unscheduled and referred to as new psychoactive substances. These cathinones can cause euphoria, tachycardia, paranoia, increased sex drive, and lowered inhibitions. It is for these reasons that synthetic cathinones can be used as aids in Drug-Facilitated Sexual Assault (DFSA). When combined with alcohol, synthetic cathinones can lead to an ideal situation for someone to be taken advantage of. These drugs have been seen in recent studies of sexual assault, and their prevalence in the United States has increased over the past ten years. Since synthetic cathinones are becoming a more regular part of forensic casework, exploring the stability of these drugs in different matrices is crucial. Knowing the stability of synthetic cathinones can assist in choosing appropriate storage after seizure to ensure accuracy at the time of testing. This research investigates the stability of naphyrone, alpha-Pyrrolidinopentiophenone (a-PVP), and Methylenedioxypyrovalerone (MDPV) in tap water and Coca-Cola® under different storage conditions throughout a one-month period.

The stability of these three drugs was evaluated based on the matrix, the storage temperature, and the extraction day. Each beverage was spiked at 1mg/L and stored in 1mL individual aliquots at room temperature, 4°C (refrigerator), and -20°C (freezer), all in the absence of light. Aliquots from each storage temperature and matrix were extracted using Clean Screen® DAU cartridges on days 0, 3, 7, 14, and 30 to evaluate how stable each drug was in the matrices at each temperature. Analysis of these extractions was conducted via Gas Chromatography/Mass Spectrometry (GC/MS) in full scan mode.

Naphyrone appears to be stable in both matrices at all temperatures, with no significant drug loss during the 30 days; however, a-PVP was not stable in water at room temperature. By day 14, most of the drug had degraded; however, in the refrigerator and freezer, a-PVP remained mostly stable. Coca-Cola® spiked with a-PVP and MDPV in both water and Coca-Cola® all followed the same trend of room temperature being the least-stable storage condition.

A study comparing the efficiency and recovery of synthetic cathinone extractions using solid phase extraction, Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS), and Filter And Shoot (FASt) extractions was also completed, but by using Liquid Chromatography/Mass Spectrometry/Mass Spectrometry (LC/MS/MS). Comparable results were observed for all drugs.

Synthetic Cathinones, Stability, DFSA

B118 Ultraviolet (UV) Spectra of Synthetic Cathinones: Resurrecting an Old Technique

Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; Stephanie R. Carnes, BS, 34 Woodcross Drive, Apt 214, Columbia, SC 29212; Ioan Marginean, PhD, George Washington University, 2100 Foxhall Road, NW, Somers Hall L14C, Washington, DC 20007; and Ira S. Lurie, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Somers Hall, Lower Level, Washington, DC 20007*

After attending this presentation, attendees will understand the value of UV spectroscopy for distinguishing positional isomers of the synthetic cathinones. Attendees will also better understand how ortho, meta, and para alkyl substitution on the aromatic moiety in the synthetic cathinones produces predicable shifts in the major UV absorption bands. Observation of differences in the near UV spectra of positional isomers of synthetic cathinones can permit the differentiation of these isomers when the electron impact mass spectra of the isomers are uninformative, as is often the case.

This presentation will impact the forensic science community by demonstrating the utility of UV spectroscopy as a detection mode for liquid and supercritical fluid chromatography. A scheme for the prediction of the position of major UV absorption bands for synthetic cathinones having multiple substituted aromatic moieties will be presented.

UV spectroscopy was at one time a widely used instrumental method for the analysis of controlled substances. Analysts would record the near UV spectra of the suspected controlled substance in an appropriate solvent and then consult tables of λ_{max} values to make an identification; however, the latest Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) guidelines now relegate UV spectroscopy to Category C, the lowest category of analytical technique for the analysis of controlled substances. Nevertheless, for certain types of analytical problems confronting forensic drug chemists, UV spectroscopy may be very useful, if not indispensable. The synthetic cathinones are a case in point: their electron impact mass spectra (a Category A technique) typically show weak molecular ion peaks and uninformative fragmentation patterns. Their UV spectra often provide information about the substitution of the aromatic moiety in these compounds. The basic UV chromophore of the synthetic cathinones can be viewed as acetophenone. Acetophenone has four electronic transitions in the near UV: in n-hexane these bands are found at 238.7nm (ε = 12,500), 276.5nm (ε = 900), 285.2nm (ε = 880), and 321.0nm (ε = 44). The very weak 321.0nm transition is the n$\rightarrow\pi^*$ transition of the carbonyl; the remaining bands are $\pi\rightarrow\pi^*$ transitions involving the benzene ring. The strongest band is designated $^1B_{1u}\leftarrow{}^1A_{1g}$. The synthetic cathinones α-PVP, α-PBP, pentedrone, buphedrone, ethcathinone N,N'-dimethylmethcathinone, and methcathinone have an acetophenone-type structure with substitution on the acetophenone methyl group. When these compounds are analyzed by Ultra High-Performance Supercritical Fluid Chromatography (UHPSFC) with a near UV detector, spectra of these compounds were dominated by a strong peak at 238nm-239nm. Analysis of other synthetic cathinones under the same conditions demonstrated that ortho alkyl substitution increases the wavelength of the $^1B_{1u}\leftarrow{}^1A_{1g}$ transition by 0.9nm, meta alkyl substitution increases the wavelength of the band by 4.4nm, and para alkyl substitution increases the wavelength of the band by 10.9nm. For multiple substituted benzene rings, the effects of alkyl substitution are generally additive. Using the increment values for ortho, meta, and para alkyl substitution of 0.9nm, 4.4nm, and 10.9nm, respectively, yields the following predicted λ_{max} values for the $^1B_{1u}\leftarrow{}^1A_{1g}$ transitions of di-alkyl substituted cathinones: 2,3-dimethylmethcathinone 243.9nm (observed 243nm), 2,4-dimethylmethcathinone 250.4nm (observed 250nm), and 3,4-dimethylmethcathinone 253.9 nm (observed 254 nm). These results illustrate that near UV spectra can differentiate alkyl-substituted synthetic cathinones and that rules can be formulated for the prediction of the locations of UV transitions of new alkyl-substituted synthetic cathinones.

Cathinones, Ultraviolet Spectroscopy, Aromatic Substitution

B119 The Evolution of Forensic Household Dust Analysis Over the Past Century

Nicholas Petraco, MS, Petraco Forensic Consulting, 73 Ireland Place, Ste 128, Amityville, NY 11701; Jack Ballantyne, PhD, University of Central Florida Dept of Chemistry, 4000 Central Florida Boulevard, Orlando, FL 32816-2366; Erin K. Hanson, PhD, University of Central Florida, PO Box 162367, Orlando, FL 32816; Nicholas D. Petraco, PhD, John Jay College of Criminal Justice, Dept of Science, 524 W 59th Street, New York, NY 10019-1007; and Mary Eng, BS, New York City Police Laboratory, 150-14 Jamaica Avenue, Jamaica, NY 11432*

After attending this presentation, attendees will recognize how forensic household dust specimens are formed and how the fibrous components form a cage-like structure that acts as a snare, which in turn entraps an array of human and animal hairs, natural and synthetic fibers, and an assortment of particulate materials. Attendees will learn about the development of techniques used to study household dust specimens in the forensic laboratory over the past century and the probative value of household dust specimens.

This presentation will impact the forensic science community by demonstrating the probative value of an underused form of physical evidence — forensic household dust specimens.

In the late 19th century, Hans Gross, a German magistrate, speculated in his writing that dust is a representation of a person's environment in miniature. Gross further proposed that by recognizing the constituents composing a particular dust sample, one could estimate the surroundings from which the dust originated, and that this information could be used to help solve crimes. At approximately the same time, the importance of trace evidential material in solving crimes was being popularized by Sir Arthur Conan Doyle through his fictional character, Sherlock Holmes, who solved many mysteries by reconstructing the events of the crime from dust traces left at or taken away from the crime scene. Gross's and Conan Doyle's writings are believed to have inspired many European and American scientific detectives to look for valuable dust clues while investigating crimes.

In the early 20th century, Edmond Locard established a police laboratory in Lyon, France, and soon his ability to solve crimes by analyzing the dust found on a suspect became known throughout the world. Locard's successful implementation of scientific methodology in criminal investigations and his belief that dust analysis could link every criminal to his or her crime are probably responsible for the use of trace evidence in contemporary times. Moreover, his work served to spur the development of forensic laboratories throughout the world.

Between 1910 and 1970, forensic laboratories were developed in France, England, Sweden, Germany, Switzerland, and Austria as well as the United States. In the early 1930s, a national crime laboratory was maintained by the Federal Bureau of Investigation (FBI) in Washington, DC.

During this era, forward-thinking scientists and scientific investigators such as Edmond Locard and many others throughout the world advanced the use of microscopic trace evidence and the analysis of dust traces to solve crimes and reconstruct events.

As postulated by Edmond Locard, the ultimate goal of trace forensic evidence in a criminal investigation is to identify the people, places, and things involved in the commission of the crime. A commonly encountered but often ignored form of physical evidence, traces of household dust, has the potential to achieve these goals. Dust bunnies, as they are often called, should be a unique entangled conglomeration of fibers containing a variety of inorganic and organic particulates from the immediate environment that are formed over time. Thus, in principle, if one or more dust bunnies are found associated with a crime, it should be possible to positively identify the location from which it originated and maybe the people involved in the event.

In the past few years, several papers have been presented which demonstrate that household dust specimens may in fact be unique to a given location. These preliminary studies have focused on developing a rapid microscopic method for tabulating the materials, such as animal and human hair, natural and synthetic fibers, and the particulates commonly found in household dust specimens.

The data collected in prior studies and for newly acquired specimens was tabulated on a revised dust tabulation data sheet specifically designed for this study. The newly acquired and previously acquired data study was combined and subjected to rigorous statistical analysis. A number of interesting trends were found, extensively studied, and reported.

A subsequent study postulated that the probative value of household dust specimens would be enhanced not only if the room could be identified by its material makeup but also by the habitual occupier(s) of the room. Thus, the latest study focused on both the common materials present in the dust and the materials from the occupant(s), which is trapped inside the dust bunny (likely originating from the habitual occupier of the room). Promising results were statistically evaluated and reported.

It is believed that the combination of these different approaches will greatly enhance the discriminating power, as well as the probative value, of household dust by enabling one to not only identify a location, but also to identify its habitual occupant(s).

Edmond Locard, Household Dust, Trace Evidence

B120 The Probative Value of Very Small Particles (VSPs) Adhering to Common Items of Physical Evidence

David A. Stoney, PhD, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20151; and Paul L. Stoney, MBA, 14101-G Willard Road, Chantilly, VA 20124*

After attending this presentation, attendees will appreciate the potential probative value of VPSs, present as dust on or within common items of physical evidence.

This presentation will impact the forensic science community by increasing awareness of the potential value of such particle combinations on common items of physical evidence, as well increasing the awareness of the computational methods that can be applied to recognize associations and measure the strength of associations based on these combinations.

Particle combination analysis uses co-occurring particles to test alternative attribution hypotheses. One application of particle combination analysis is the exploitation of the thousands of VSPs that are found in and on items of evidence, using these particles to test associations and enhance probative value. The combinations of VSPs are so complex that, until recently, there was no practical method to identify and interpret these combinations.

This presentation will cover the application of statistical methods of particle combination analysis to Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) analytical results for very small particles recovered from the surface of common items of physical evidence, such as handguns, cell phones, ski masks, and drug packaging.

VSPs were collected from actual items of evidence from cases in one jurisdiction where detectives had determined that the items were no longer of value and had approved them for disposal. Particles were harvested from plastic drug packaging by directly applying commercially prepared SEM stubs analogous to those commonly used in protocols for the recovery of possible Gunshot Residue (GSR) from a subject's hands. Clean room swabs, slightly moistened with pre-filtered distilled water, were used to recover VSPs from handguns, cell phones, and ski masks. Two separate specimens were recovered from each evidence item.

The SEM stub specimens from drug packaging were suitable for SEM/EDS processing without further preparation. The swab specimens were prepared for SEM by extraction of particles into an aqueous suspension, followed by low-vacuum filtration onto 0.4 micrometer pore size 13mm polycarbonate filters and mounting on SEM/EDS stubs.

For each specimen, up to 10,000 VSPs were individually characterized by semi-automated SEM/EDS analysis, binning the analytical response for each particle into 18 X-ray energy bins corresponding to a set of 18 elements. The data sets were filtered to reduce noise represented by: (1) particles having no dominant elemental composition detected under the analysis conditions; and, (2) elements present in low quantities for any given particle.

Sets of Target Particle Types (TPTs) were defined based on normal mixture modeling using a training set composed of random sampling from all sources. Multinomial distributions were defined for each source based on the numbers of particles corresponding to each of the TPTs. For comparison of TPT profiles, the probability density of the observed count in a test specimen was assigned in each of the N multinomial densities (corresponding to each of potential sources). This probability was used as the measure of correspondence to each of the reference sources. The probabilities can be used for classification or for ranking of candidate sources as in a library search.

Measurements of probative value were defined using a Bayesian classifier applied to the multinomial probability densities, assuming an equal prior among all N classes. This results in posterior probabilities obtained using the classifier for all N sources. A corresponding likelihood ratio was calculated as a measure of evidential weight, based on assumptions of the representativeness of the N sources.

This project was supported in part by awards from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this presentation are those of the author and do not necessarily reflect those of the Department of Justice.

Particle Combination Analysis, Trace Evidence, Evidential Value

B121 Using Kernel-Based Methods for Inferring the Source of Very Small Particles (VSPs) From Recovered Forensic Materials

Douglas E. Armstrong, MSc, 104 Medary Avenue, Brookings, SD 57006; Cedric Neumann, PhD, South Dakota State University, Mathematics & Statistics Dept, Brookings, SD 57007; Christopher P. Saunders, PhD, 272 Indian Hills Road, Brookings, SD 57006; Donald T. Gantz, PhD, George Mason University, Dept of Applied IT, MS 1G8, 4400 University Drive, Fairfax, VA 22030; John J. Miller, PhD, Dept of Statistics, MSN 4A7, 4400 University Drive, Fairfax, VA 22030; and David A. Stoney, PhD, Stoney Forensic, Inc, 14101-G Willard Road, Chantilly, VA 20151*

After attending this presentation, attendees will better understand a method that objectively models pairwise scores that are often obtained in the analysis of complex and high-dimensional forensic data. This method can be used to estimate the weight of evidence for a particular object of forensic interest.

This presentation will impact the forensic science community by: (1) providing a method to infer the source of forensic material by using the VSPs found on the surface of the material; and, (2) providing a method that models the dependency structure of pairwise scores and provides a numerical weight of evidence.

The objective comparison of complex signals in chemistry and, more particularly in forensic chemistry, with the view of inferring the source of a particular "trace" object is an ongoing issue. These issues show up either in how measurements are taken (dimensionality and/or compositional data) or the production/mass manufacturing of the trace material (e.g., paint, metals), leading to difficulty in the identification of identical materials.

Instead of looking at the trace material itself, the VSPs found in contact with the trace material are considered. VSPs are picked up in the environment(s) in which the trace material has been. These VSPs offer information regarding the geographic origins of the material despite non-uniqueness of the trace material due to manufacturing processes and allow a measure of relation between VSPs on trace material and known material, assisting in source identification of trace material.

Initial efforts classified sets of VSPs using a multinomial classifier. In order to reduce the complexity of the parameter space for this model, the types of the VSPs were categorized as determined by their dominant compounds.[1] Each source was characterized by a vector of relative proportions of these Target-Particle Types (TPTs), which could be used as parameter estimates in a multinomial model. The definition of TPTs involved the use of unsupervised clustering techniques with their inherent drawbacks (e.g., arbitrary choice of a limited number of TPTs to keep the dimension of the parameter space reasonable).

In this project, a method is proposed that circumvents these problems and enables the assignment of a probability distribution to control material from any given source based on its chemical signal. Instead of estimating parameters for TPTs, the raw data is directly worked with by leveraging the dimension reduction and discriminative powers of kernels, then extending the work of Gantz and Saunders for pairwise-score parametric models.[2] The subsequent model only requires the estimation of three parameters (once a kernel is chosen) and is subsequently used to infer the source of a trace object using a simple Bayes classifier.

The application of this method to the inference of the source of trace objects based on VSPs is illustrated. A dataset of VSPs recovered from carpet fibers throughout the United States is used and this method is applied method to: (1) reduce the complexity of compositional data obtained by SEM/EDS; and, (2) infer the source of the trace material. Initial results of the method have a slightly improved classification rate of the trace fibers than that of the multinomial classifier, while significantly reducing the complexity of the parameter space.

This method can be extended to VSPs found on other types of recovered forensic materials such as weapons, drugs, or Improvised Explosive Devices (IEDs), and to other types of complex chemical signals.

High-Dimensional, Weight of Evidence, Forensic Material

B122 Forensic Analysis of Trash Bags: Part I — Microscopical Discrimination of Trash Bags

Deanna-Kaye D. Daley, Xavier University of Louisiana, 1 Drexal Drive, New Orleans, LA 70125; Morgan M. Clothier, BS, George Washington University, 2121 I Street, NW, Washington, DC 20052; and Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand that trash bags have differing physical features: color, type of closure, surface textures, and heat seals. The bags may also contain different crystalline additives with varying concentrations. Attendees will also understand the role of light microscopy (both reflected light and Polarized Light Microscopy (PLM)) in the forensic analysis of trash bags.

This presentation will impact the forensic science community by informing attendees of a database that was created and includes different brands of trash bags with their descriptions, dimensions, thicknesses, and distinguishing features. This database includes more than 80 different brands of trash bags. Such a database will be useful to forensic examiners as it includes trash bags sold in the United States.

Trash bags can appear as evidence at crime scenes as they can be used to package everything from controlled substances to dead bodies. A frequently asked question is whether a trash bag found at the crime scene can be associated with a roll or box of trash bags found in a suspect's possession. The physical measurements (such as length, width and thickness), optical properties and the additives of each trash bag would be compared. Physical matches of tears, perforations or manufacturing imperfections have proven useful for identifying sequentially manufactured bags.

Eighty-eight trash bag samples were collected, most from the Washington, DC, area and a few were purchased in the Midwest. Boxes or rolls of trash bags were purchased at supermarkets, department stores, and dollar stores. Special emphasis was placed on "store brands." Roughly equal numbers of white "kitchen" trash bags and the large, dark trash and lawn and leaf bags were collected for examination. A majority of trash bag samples were found to have been manufactured in the United States, while a very few were manufactured in China and Canada.

Photomicrographs of the side-edge and bottom-edge heat seals and surface textures were obtained for each bag using a low magnification reflected light stereomicroscope equipped with a 14-megapixel eyepiece digital camera. For transmitted light microscopy, pieces of each trash bag were cut from the side edge. The side seal was retained so that the extrusion direction of the sample could be determined. The pieces of trash bags were cleaned with methanol, left to dry overnight, then permanently mounted on a standard microscope slide with a cover slip for further microscopic examination (brightfield and Polarized Light Microscopy (PLM)). Photomicrographs of the trash bags were obtained under each of the viewing conditions.

The thicknesses of the trash bags varied from 10.1µm to 1,100µm, with majority of the trash bags having a thickness of 22.9µm. The dimensions of the trash bags varied from 55.8cm x 60.9cm to 98.4cm x 114cm, with majority of the trash bags having dimensions of 60.9cm x 68.5cm. The dimensions and thicknesses differentiated the trash bags into 31 and 23 different groups, respectively. PLM provided little differentiation of the trash bags. While crystalline additives in the bags were visible due to their birefringence, the particles were too small to be identified *in situ* by optical crystallography. At most, bags with significant concentrations of additives could be distinguished from those with low concentrations of additives. It was found that the side and bottom heat seals were very useful for distinguishing different brands of trash bags. The side-edge and bottom-edge heat seals differentiated the trash bags into 37 and 31 different groups, respectively. Such differences presumably reflect differences in the processing of the side and bottom heat seals (e.g., the width of the heated metal strips used to create the seals). The side and bottom heat seals provide better brand discrimination than Fourier transform infrared spectroscopy or X-ray diffractometry.

Trash Bags, Reflected Light Microscopy, Polarized Light Micrscopy

B123 Forensic Analysis of Trash Bags: Part II — Fourier Transform Infrared (FTIR) Spectroscopy and X-Ray Diffraction (XRD)

Morgan M. Clothier, BS, George Washington University, 2121 I Street, NW, Washington, DC 20052; Deanna-Kaye D. Daley, Xavier University of Louisiana, 1 Drexal Drive, New Orleans, LA 70125; and Walter F. Rowe, PhD, George Washington University, Dept of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand the use of FTIR and XRD to discriminate between various brands of trash bags. Trash bags are common in forensic investigations because they can be used to conceal victims, dispose of evidence, or transport controlled substances. Attendees will understand the potential for using FTIR and XRD to discriminate trash bags of different brands by identifying and quantifying crystalline additives.

This presentation will impact the forensic science community by providing forensic examiners with instrumental methods of analysis for the discrimination of trash bags from different sources. Additionally, this study provides data on trash bags used in the United States and Canada, while other publications on the forensic examination of plastic bags have examined samples used in other countries.

Trash bags are typically manufactured from virgin polyethylene pellets, pigments, and other particulate additives melted together to form a molten plastic. The melted plastic is extruded through a ring-shaped die and mandrel, which impresses tool marks into the bag surface, creating identifiable patterns. Such patterns can be useful in identifying sequentially manufactured bags, but would have less utility for the identification of the brand of trash bag. On the other hand, FTIR and XRD can provide information on the brand of trash bag and permit the comparison of trash bags when the questioned and known trash bags were not sequentially manufactured. These instrumental methods would also be of value when only fragments of bags are recovered at a crime scene.

This research investigated the discriminatory power of FTIR and XRD for the forensic examination of trash bags. Eighty-eight different samples representing 28 different brands were examined. Most of the samples were purchased in the Washington, DC, area; a few bags were purchased in the Midwest. While samples of national brands were collected, special emphasis was placed on "store brands." Features of the bags, such as color, odor, type of closure, dimension, thickness, and place of manufacture were recorded for each sample to create a database.

Square pieces of each trash bag were cut from the side-edge, approximately 5cm x 5cm in size. These pieces were cleaned with methanol, in order to eliminate possible interference of coatings on the surfaces of the bags. Two strips were then cut from each square, one for FTIR analysis and the other for XRD. The samples analyzed by FTIR were scanned in transmission mode from 525cm^{-1} to 4,500cm^{-1}, 128 scans per sample. The samples used for XRD analysis were glued to a standard microscope slide. The samples were flattened on the slide using a rubber roller and left to dry before testing. The diffraction angle (2q) was scanned from 3° to 40° at 2° per minute.

The FTIR and XRD analyses of the trash bags provided basic information on their compositions. Most samples were composed of Low-Density Polyethylene (LDPE); a small number of samples were comprised of Linear Low-Density Polyethylene (LLDPE). Some bags had no additives; some contained either calcite or talc but not both; and some contained both calcite and talc. XRD revealed the presence of a low concentration of an additional additive, montmorillonite, which was not detected by FTIR. Based on their FTIR spectra, the bags could be placed into 14 groups based on the presence or absence of additive peaks and their relative intensities. Based on their XRD patterns, the bags could be placed into 18 groups based on reflections present in the diffraction patterns. The discrimination of the trash bag samples in this research demonstrates the value of XRD for polymeric material containing a number of additives. Based on the results of this project, XRD should be preferred to FTIR for the analysis of trash bags.

Trash Bags, FTIR, X-Ray Diffraction

B124 An Assessment of the F-108 Polymer and Capillary Electrophoresis Single-Strand Conformational Polymorphism (CE-SSCP) to Screen Human DNA Mixtures

Deidra Jordan, BS, Florida International University, 11200 SW 8th Street, International Forensic Research Institute, Miami, FL 33199; and DeEtta Mills, PhD, Florida International University, OE 167, Biological Sciences, 11200 SW 8th Street, Miami, FL 33199*

After attending this presentation, attendees will understand the principles of CE-SSCP analysis, why the F-108 polymer is used in contrast to the Performance Optimized Polymers (POP), and how the two are utilized to identify Single Nucleotide Polymorphisms (SNPs) in forensic samples that have previously been identified as human DNA mixtures.

This presentation will impact the forensic science community by demonstrating the application of CE-SSCP to quickly identify SNPs in or around regions within the commonly used Short Tandem Repeat (STR) loci. This will allow scientists to compare a mixture sample with overlapping alleles to a reference sample, thus allowing scientists to screen and determine which samples may need to be further analyzed via next generation sequencing.

Current technology in forensic science uses instrumentation such as a thermal cycler to amplify the DNA by the Polymerase Chain Reaction (PCR) and a CE instrument to produce DNA profiles. These profiles are a series of peaks of varying heights that represent alleles from loci that were amplified in the PCR. At each locus in a single source sample, there should be a maximum of two visible alleles. But often there are more, indicating the presence of multiple contributors to the sample, commonly referred to as a mixture. Due to technological advances, the process of DNA typing is becoming extremely sensitive, allowing for the testing of DNA collected from touched objects. As a result, the amount of forensic mixtures obtained for analysis has increased; however, the actual interpretation of these types of samples remains an issue. Current methodologies only address allelic variation by fragment length and not the actual nucleotide sequence within the amplican. As a result, there may be alleles of the same size yet different sequence among the contributors in a forensic mixture sample, which further hinders the interpretation of useful results.

In traditional forensic CE, DNA is separated by a denaturing polymer (e.g., POP-7) that serves as an entanglement matrix that allows smaller fragments of DNA to move faster than larger fragments. A linear relationship is observed between fragment size and migration time. The denaturant keeps the single-stranded DNA from changing its conformation as it migrates through in the capillary. Another matrix, Pluronic F-108, is unlike the POP matrix because it is non-denaturing. F-108 is a Poly(Ethyleneoxide)-Poly(Propyleneoxide)-Poly(Ethyleneoxide) (PEO-PPO-PEO) triblock copolymer. The non-denaturing aspect of this polymer makes it ideal for the detection of SNPs in the DNA sequence using a phenomenon known as SSCP. The principle of SSCP is based on the fact that single-stranded DNA has a defined conformation (secondary structure). A change in this conformation in a non-denaturing matrix because of the presence of a SNP causes the single-stranded DNA to partially reanneal and migrate differently through the matrix even if only one nucleotide has changed out of several hundred bases.

DNA was extracted from three different Fast Technology for Analysis (FTA) cards containing blood samples from different contributors, and the extracted DNA was processed for downstream analysis. The locus D16S539 was amplified. The resulting PCR products were quantified and prepared for Sanger sequencing. The sequences were separated using the POP-7 polymer to identify SNPs within the amplicons. Several SNPs were subsequently identified in each sample. Additional DNA was extracted from those FTA cards and amplified for STR analysis where each sample produced a single peak for each allele on POP-7. That same PCR product was analyzed using the CE-SSCP method with the F-108 polymer. This approach was able to distinguish the presence of polymorphisms in sequence, even when the length of the amplicon was the same.

In conclusion, results from this study determine that the CE-SSCP technique can aid in resolving forensic mixtures. This method uses the same STR product and the same CE instrument but with the non-denaturing F-108 polymer to identify areas of SSCP, which suggests the presence of SNPs. Thus, incorporating this polymer could make the process of screening samples quicker and more efficient for subsequent next generation sequencing analyses.

Mixtures, CE-SSCP, SNPs

B125 An Improved Capillary Electrophoresis (CE) System for Human Identification

Andrea Chow, MS, Promega Corporation, 2800 Woo, Madison, WI 53711; Poncho Meisenheimer, PhD, Promega Biosciences, 277 Granada Drive, San Luis Obispo, CA 93401; Ann MacPhetridge, MS, 2800 Woods Hollow Road, Madison, WI 53711; Benjamin Krenke, MS, 2800 Woods Hollow Road, Madison, WI 53711; and Douglas R. Storts, PhD, Promega Corporation, 2800 Woods Hollow Road, Madison, WI 53711*

After attending this presentation, attendees will better understand the challenges to implementing new forensic technologies such as Next Generation Sequencing (NGS) and rapid DNA, will understand why CE will remain the method of choice for forensic DNA laboratories, and will learn about the advantages of using eight-color Short Tandem Repeat (STR) multiplexes and a CE system in the forensics workflow, such as the use of more mini-STRs to provide improved results with degraded samples, more usable data from inhibited samples, and improved overall efficiencies.

This presentation will impact the forensic science community by suggesting improvements that eight-color STR multiplexes will offer to the forensic DNA workflow, including more usable data from inhibited samples, enhanced results when degradation is present, and improved overall efficiencies.

Rapid DNA and NGS hold great promise for the forensic community to extend the reach and depth of DNA typing. While both of these approaches are powerful complements to traditional CE STR typing, neither approach is likely to replace CE analysis for the majority of forensic samples in the near future. CE will very likely remain the "workhorse" of forensic DNA typing. As such, improving upon CE technology is critical for the advancement of forensic DNA typing.

The Spectrum CE System offers increased spectral capacity by allowing the continued analysis of existing four-, five- and six-color multiplexes, as well as a new family of eight-color multiplex STR systems. With the inclusion of additional colors, more loci can be designed in the smaller size ranges. This will increase a laboratory's chance of success with degraded samples, a situation that forensic laboratories often encounter with their casework samples. Additionally, improved multiplex configurations will provide more complete and informative results with inhibited casework samples, which are quite commonly processed in forensic casework laboratories. The narrower range of product amplicon sizes will enable more consistent results with variable "direct amplification" samples. This CE system also offers increased workflow flexibility with four continuously accessible plate positions, and allows laboratories to process more samples at one time than is currently possible with existing CE instrumentation. This design improves laboratory efficiency by reducing scheduling conflicts, increasing overnight/weekend throughput, and reducing the number of instruments needed in the laboratory. Lastly, the system's analysis software, which has been specifically intended for human identification and forensics applications, offers several benefits, including time savings, ease of use**,** accuracy, and additional integrated post-genotyping applications.

Capillary Electrophoresis, DNA Typing, Eight-Color STR Multiplex

B126 A Comparison of Differex™ and Organic Differential DNA Extractions for the Acquisition of a Male Profile From Samples That Exhibit Mold Growth

Beatriz A. Pujols, 1420 Centre Avenue, Apt 414, Pittsburgh, PA 15219; Lyndsie N. Ferrara, MS, Duquesne University, 600 Forbes Avenue, Pittsburgh, PA 15219; and Lisa R. Ludvico, PhD, Duquesne University, Biology Dept, 238 Mellon Hall, Pittsburgh, PA 15282*

The goal of this presentation is to provide attendees with knowledge on which, if either, of the two DNA extractions explored is most suitable for mixed male and female DNA samples contaminated with mold growth.

This presentation will impact the forensic science community by potentially aiding forensic scientists in making a decision regarding how to process a DNA sample contaminated with mold growth. Finding an optimal method to process mold-contaminated vaginal swabs in sexual assault cases could allow for the analysis of samples previously deemed untestable.

Backlogged cases in crime laboratories have increased dramatically since 2005 due to lack of funding and personnel. The statute of limitations has also been extended in some states, allowing more sexual assault evidence kits to qualify for testing. These backlogs can range from months to years since collected and stored. Recently, there has been a push to allot funds for the processing of sexual assault evidence kits in an attempt to reduce these backlogs. The most commonly tested piece of evidence in sexual assault evidence kits is a vaginal swab. If not collected and stored properly, vaginal swabs can develop mold over time. This can be a result of varying environmental conditions or exposure to humidity; however, it has become common practice to dispose of samples with excess mold growth because it is believed that no accurate human DNA profile can be obtained. Some agencies choose not to process these samples due to the expense involved and the limited chance of obtaining successful results. While this practice may seem rash, it has been determined that the mold slowly degrades the DNA, causing it to become more fragmented. Additionally, mold acts as an inhibitor for Polymerase Chain Reaction (PCR), a crucial step in current forensic DNA analysis. PCR inhibition can cause loss of signal, peak imbalance, and/or allelic dropout.

This research attempts to compare the effectiveness of the standard organic differential extraction protocol to the Differex™ System on vaginal swab samples that exhibit varying degrees of mold growth. Optimal packaging procedures currently exist for sexual assault evidence to prevent the development of mold. These procedures reduce the incidence of mold growth, but they are not as effective if the sample has not been dried properly prior to packaging or if the sample is exposed to moisture during storage. There is little research and information on what to do with samples previously collected that may contain mold growth. Traditionally, a differential DNA extraction procedure is performed on these samples. This extraction involves wash steps, which theoretically get rid of any contaminants. While the organic differential extraction technique is regarded as the gold standard, the Differex™ System uses the same principle and is less time consuming. The Differex™ System employs the use of DNA IQ™ magnetic resin to bind the DNA, effectively reducing the sperm loss that is common to other differential techniques. This could allow for a partial or complete male profile to be obtained from samples contaminated by mold growth.

Mock sexual assault samples were prepared by obtaining sterile cotton swabs containing female epithelial cells and vaginal fluids. Four swabs were submerged in each of the following seminal dilutions: 1:2; 1:8; 1:32; and 1:128. The swabs were then stored in improper conditions to promote mold growth for 0, 1, 2, 3, 6, and 14 months. Photographs were taken of each swab to record mold growth. One-half of each swab was subjected to a standard organic differential extraction, while the other half was processed using Differex™. DNA quantitation values and profile quality were compared between the two extraction methods.

Examining alternative means of dealing with mold-contaminated samples is essential not only to further advance testing of backlogged cases, but also to avoid disposing of essential incriminating evidence that could potentially lead to the incarceration of a rapist. Comparing current DNA extraction methods could result in the discovery of an optimal technique for samples of this nature. An optimal method could limit the severity of inhibition and allow more accurate results in data analysis.

Differex™, Organic Differential, Mold

B127 Effects of Swab Collection and Storage Methods on DNA and Messenger RNA (mRNA) Profiling of Forensic Stains

Daniela Lacerenza, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, c.so Galileo Galilei #22, Torino 10126, ITALY; Giorgio Caudullo, MA, University of Torino, Dept Public Health Sciences, C So Galileo Galilei 22, Turin 10126, ITALY; Samuele Voyron, PhD, University of Turin, Viale Mattioli 25, Torino 10125, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; and Carlo Robino, University of Torino, Dept Public Health Sciences, C So Galileo Galilei 22, Torino 10126, ITALY*

The goal of this presentation is to evaluate the effects of different swabbing methods and the subsequent storage conditions of collection swabs on combined DNA and mRNA profiling of trace evidence.

This presentation will impact the forensic science community by providing crime scene investigators with directions on optimal procedures for the collection and storage of biological stains that are expected to undergo DNA/RNA co-analysis.

The increasing sensitivity of multiplex Polymerase Chain Reaction (PCR) assays for the simultaneous amplification of Short Tandem Repeat (STR) loci now "trace DNA"). Determination of tissue origin of trace DNA is often crucial for the reconstruction of crime dynamics. Recently, several robust protocols for DNA/RNA co-extraction from stains have been described and validated for forensic purposes, thus enabling the single pipeline analysis of both STRs and mRNA profiles to identify body fluids.[1] So far, limited research has been dedicated toward identifying an optimal solution for the retrieval and preservation of RNA from forensic stains. Trace samples are usually collected by means of wet swabs moistened with water; however, it has been suggested that this may not be the most suitable method for RNA because of its high susceptibility to hydrolytic breakdown.[2] Storage conditions of swabs after collection may also affect the quantity and quality of retrievable nucleic acids. It has been shown, for example, that freezing rather than drying swabs prior to extraction results in an improvement of DNA recovery.[3]

The goal of this study was to evaluate the impact on DNA/RNA retrieval rates and integrity for downstream applications of: (1) different moistening agents applied to collection swabs; and, (2) different storage conditions prior to DNA/RNA extraction of the swabs used for stain collection.

Mock stains were created by applying the following to glass slides: whole blood; 1:10 diluted blood treated with luminol; saliva; semen; and skin (by rubbing one thumb/index fingertip over the designated area for approximately 10s). Moistening agents applied to collection swabs were: water; ethanol; and RNAlater™. Swabs were either air-dried or frozen for one to seven days prior to DNA/RNA extraction. DNA and RNA were co-isolated and quantified with the Plexor® HY System and 2100 Bioanalyzer, respectively.[2] DNA was genotyped using the AmpF*l*STR® Identifiler® Plus PCR amplification kit and 3500 Genetic analyzer and mRNA profiling was performed.[4]

Concentration of total RNA isolated from mock stains was significantly higher for swabs treated with RNAlater™ compared with water and ethanol, with consequent effects on mRNA profiling. Interestingly, the impact of moistening media on DNA recovery rates varied among tissues. In skin samples, both ethanol and RNAlater™ significantly outperformed water, also generating more complete STR profiles. On the contrary, DNA retrieval from whole blood and semen stains was significantly lower with ethanol; however, because of the higher DNA yields obtained, on average, from whole blood and semen when compared to skin, moistening agents had no effective impact on STR typing in this case. Finally, no significant differences in DNA/RNA recovery were observed depending on storage conditions and storage time of collection swabs.

Trace Collection, Swab Storage, MRNA Profiling

B128 A Method for Optimizing Pressure-Based Extraction and Direct Polymerase Chain Reaction (PCR) of Simulated Sexual Assault Samples

Meghan Roig, BS, 10369 NW 8th Street, Unit 204, Pembroke Pines, FL 33026; Vanessa Martinez, BS, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Deepthi V. Nori, PhD, 7401 Eastmoreland Road, Apt 929, Annandale, VA 22003; and Bruce R. McCord, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will better understand a novel method for differentiating, extracting, and amplifying epithelial and sperm mixture samples.

This presentation will impact the forensic science community by providing results for a method that can decrease the analysis time for sexual assault samples. Attendees will see results of a new method to aid in direct PCR for amplification of simulated sexual assault samples. These results will add to previous work performed using pressure cycling by demonstrating a method to eliminate the long cell lysis and purification process as well as coupling these methods with direct PCR.

In this study, pressure cycling is used to prepare differentiated lysates of epithelial and sperm mixtures for rapid analysis. It is widely known that many Sexual Assault Kits (SAKs) currently await processing. For example, in January of 2016, more than 13,400 SAKs had been reported as not being analyzed in the state of Florida.[1] This study presents a method for faster analysis of these types of samples. Epithelial and sperm mixtures often require large amounts of time and effort to differentiate the fractions. The goal is to develop a rapid STR-based screening that eliminates the cell lysis, purification, and quantitation steps for a faster analysis.

This study involved the use of alkaline lysis and direct PCR to extract and amplify epithelial and sperm DNA from simulated SAK samples, with various concentrations of epithelial and sperm cells. The mixtures that were tested ranged from 1:1 to 20:1, epithelial: sperm. The first part of the project consisted of the optimization of pressure cycling and alkaline lysis for simulated sexual assault samples. Concentrations of Sodium Hydroxide (NaOH) and temperature were tested, as well as pre-pressure steps. Concentrations of 0.4N, 0.3N, 0.2N, and 0.1N NaOH were used to determine an increase in epithelial recovery. Immunomagnetic cell capture prior to the Pressure Cycling Technology (PCT) step was used to increase the differential recovery of epithelial and sperm fractions. This technique utilizes the EasySep™ Human EpCam Positive Selection Kit to capture epithelial cells with antibodies that target epithelial cell receptors. These are then attached to dextran-coated magnetic particles added to the sample. Once the sample tube was inserted into a magnet, excess epithelial cells were trapped on the sides of the tube. In the second part of the project, the simulated sexual assault samples were processed with pressure cycling and a direct PCR protocol was developed. Cotton swabs with epithelial and sperm cells were treated at room temperature with 0.2N NaOH in a PULSE™ tube. In the same tube, pressure cycling was performed with the optimized protocol using the Barocycler® NEP 2320; this step was repeated and the epithelial lysate was neutralized. Then the swab was treated again with alkali and heated to 95°C to lyse the sperm cells. These were also neutralized and the cotton swab removed. Both lysates were amplified with direct PCR using a 7-locus primer set on the Applied Biosystems GeneAmp® PCR System 9700 and/or amplified with rapid/direct PCR on a Streck Philisa® Thermal Cycler. Amplification conditions and speed were optimized by examining the effect of primer, polymerase, buffer, and dNTPs. The STR multiplex was then analyzed on an Applied Biosystems® ABI PRISM® 310 Genetic Analyzer to assess the quality of the mixture separation.

The results demonstrate the potential of alkaline lysis and pressure cycling to greatly expedite the analysis of differential extraction. In regard to optimization of the pressure cycling, the use of 0.2N NaOH resulted in improved recovery and removal of epithelial cell DNA from the substrate, 115% compared to the unmodified protocol, according to data obtained from quantification with Plexor® HY. Genetic profiles from the ABI PRISM® 310 Genetic Analyzer revealed a slight majority male profile for the sperm fraction at a 20:1 female epithelial cell to sperm cell ratio. The addition of the immunomagnetic cell capture treatment prior to the PCT step produced a clear majority male profile with female allelic dropout. The addition of faster amplification to this protocol can greatly increase the speed of the results obtained.

Direct PCR, Pressure Cycling Technology, Simulated SAK Samples

B129 The Use of Direct Polymerase Chain Reaction (PCR) on Semen and Spermatozoa and the Development of a Differential Isolation Protocol

Shanan S. Tobe, PhD, Arcadia University, Dept of Chemistry and Physics, Forensic Science, 450 S Easton Road, Glenside, PA 19038; Yuvaneswari Chandramoulee Swaran, PhD, No 16 Lorong Jambu Susu, Taman Sri Delima,, Kuala Lumpur, MALAYSIA; Lynn Dennany, PhD, University of Strathclyde, Dept of Pure & Applied Chemistry, 204 George Street, Glasgow G1 1XW, UNITED KINGDOM; Ursula Sibbing, PhD, University of Münster, Schlossplatz 2, Münster 48149, GERMANY; Kristina Schulze Johann, MSc, University of Münster, Schlossplatz 2, Münster 48149, GERMANY; Lindsey Welch, PhD, University of Strathclyde, Dept of Pure and Applied Chemistry, 204 George Street, Glasgow G1 1XW, UNITED KINGDOM; and Marielle Vennemann, PhD, University of Strathclyde, Dept of Pure and Applied Chemistry, 204 George Street, Glasgow G1 1XW, UNITED KINGDOM*

After attending this presentation, attendees will recognize the potential of direct PCR use in cases of alleged sexual assault to provide a higher level of sensitivity. Attendees will also learn a novel differential isolation protocol for use with direct PCR to obtain both female and male profiles.

This presentation will impact the forensic science community by demonstrating a more rapid method to determine the DNA profiles within sexual assault samples that also provides greater sensitivity. A differential isolation protocol for use with direct PCR will be presented to separate the male and female fractions of a simulated sexual assault mixture.

Sexual assault samples can be some of the most common samples encountered in forensic analysis. These samples can require a significant time investment due in part to differential extraction processes. This presentation reports on the first recorded use of direct PCR to successfully amplify semen for STR analysis. Amplification without prior DNA extraction, known as direct PCR, has gained increased interest in forensic science due to the reduced time to DNA profile and increased sensitivity of the technique. Benefits of direct PCR include reduced time and expense compared to standard DNA extraction prior to amplification. In this study, the potential for direct amplification of spermatozoa and seminal fluid is investigated in order to determine the donor. Stains containing seminal fluid (pure and mixtures) were subjected to the technique of direct PCR and a differential isolation method was investigated prior to direct amplification.

Neat seminal fluid, dilutions ranging from 1:5 to 1:160, and German DNA Profiling (GEDNAP) samples were successfully amplified using a direct method. All samples amplified full profiles to the 1:160 dilution in which approximately 50% of a full profile were obtained. All GEDNAP stains produced low-level but complete and reproducible profiles containing the same alleles as when analyzed using a traditional differential extraction technique. GEDNAP samples represent simulated case samples that are used for proficiency testing relating to presumptive testing and Short Tandem Repeat (STR) analysis. A mild differential isolation technique to enrich spermatozoa was developed and successfully implemented to separate and directly amplify a mixture of semen and female epithelial cells. Profiles resulting from the differentially isolated samples show high levels of amplification with good balance across all loci. Global balance ranged from 0.78 to 0.87 for liquid mixtures and 0.78 to 0.9 for dried mixtures. Aliquots of samples subjected to the differential isolation protocol were stained with hematoxylin and eosin for sperm scoring. To verify that the spermatozoa were being lysed during the direct PCR, samples stained after PCR showed a complete lack of intact spermatozoa. While the differential isolation protocol adds a small amount of time to the direct PCR process, it resulted in strongly enhanced male profiles. Even in samples with an excess of female epithelial cells, direct PCR can produce male profiles with surprisingly strong peak heights if combined with the differential isolation protocol. Direct PCR can offer increased sensitivity with reduced time and cost for sexual assault samples compared with traditional differential extraction methods.

Direct PCR, Differential Isolation, Spermatozoa

B130 Botanical DNA Evidence in a Case of Illegal Drug Trafficking: The Use of High-Resolution Melting (HRM) With the Internal Transcribed Spacer (ITS) Approach in the Identification of Psychedelic Fungus (*Psilocybe sp.*)

Alejandra Figueroa, BSc, Policia de Investigaciones de Chile, Aldunate 620, Temuco, CHILE; David A. Gangitano, PhD, Sam Houston State University, 13906 Paradise Valley Drive, Houston, TX 77069; Jaime H. Solano, PhD, Universidad Católica De Temuco, Avenida Rudecindo Ortega 02950, Temuco 4813302, CHILE; and Leonardo I. Anabalon, Universidad Católica De Temuco, Avenida Rudecindo Ortega 02950, Temuco 4813302, CHILE*

After attending this presentation, attendees will better understand how molecular biology techniques such as real-time Polymerase Chain Reaction (PCR) strategies, analysis of HRM curves, and DNA barcoding can help identify psychedelic fungus in illegal crops.

This presentation will impact the forensic science community by demonstrating how the results of coupling real-time PCR analysis with a DNA barcoding approach provided elements that were used in a drug trafficking court case in Chile.

Currently, as supporting evidence, DNA analysis is practically the only element that can be used as a reliable identification tool, due to the high variability of DNA nature across all species. One way to identify a distinctive DNA fragment for a species is the study of PCR products analyzed via real-time PCR. One of the most popular sequences of forensic interest at the generic and intra-generic levels in plants is the ITS. ITS refers to the spacer DNA situated between the small-subunit ribosomal RNA (rRNA) and the large-subunit rRNA genes in the chromosome or to the corresponding transcribed region in the polycistronic rRNA precursor transcript. ITS1 is located between the 18S and 5.8S rRNA genes, while ITS2 is between the 5.8S and 25S rRNA genes in plants.

Real-time PCR has many advantages over other molecular techniques since it does not require electrophoretic analysis. With real-time PCR, it is possible to distinguish PCR products using their melting Temperature (Tm) curves via differential analysis. In nature, there are more than 200 species of fungi with hallucinogenic properties. These fungi are classified as *Psilocybe*, *Gymnopilus*, and *Paneolus*. They contain active principles with hallucinogenic properties, such as ibotenic acid, psilocybin, psilocin, or baeocystin.

In Chile, fungi seizures are mainly composed of mature specimens or spores; however, it was found that clandestine laboratories processed fungus samples at the stage of mycelium. In this transient stage of growth (mycelium), traditional taxonomic identification is not feasible, making it necessary to develop a new method of study.

The case described in this presentation refers to the genetic analysis of mycelia of psychedelic fungi collected from a clandestine laboratory. The identity of fungus species was achieved using an ITS and HRM analysis approach. A genetic match was confirmed between the HRM curves obtained from the mycelia (evidence) and biological tissue extracted from the fungus' cap (the *Psilocybe sp.* mushroom, which served as a control). Therefore, mycelia recovered from the evidence and the fungus control were genetically indistinguishable. This HRM strategy enabled the molecular traceability of the psychedelic fungus and proved the usefulness of this approach for the identification of closely related species. The suspect was convicted of drug trafficking.

Forensic Botany, Psychedelic Fungus, High-Resolution Melting

B131 DNA Recovery From Waterlogged Bone: A Test of Three Methods

Claire M. Cartozzo, MSFS, 8207 J David Lane, Mechanicsville, VA 23111; Baneshwar Singh, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Rm 2015, Richmond, VA 23284; Edward Boone, PhD, 1020 W Main Street, Richmond, VA 23284; and Tal Simmons, PhD, Virginia Commonwealth University, Dept of Forensic Science, 1015 Floyd Avenue, Richmond, VA 23284*

After attending this presentation, attendees will better understand the effect of water on the quality and quantity of DNA retrievable from skeletal remains, as well as which extraction method, organic phenol-chloroform or solid-phase, and bone type is best for the isolation of DNA from skeletal remains found in water.

This presentation will impact the forensic science community by providing information concerning a neglected area of research: the quantity and quality of DNA retrievable from waterlogged skeletal remains, and the most successful type of bone (compact or spongy) for DNA extraction.

Following water-related accidents and mass disasters occurring over or in water (e.g. ferry disasters and commercial plane crashes), soft tissue on victims' remains could be entirely absent after a temperature-dependent period of time. Due to the physical and chemical components of bones that protect them from environmental deterioration and biological attack, the ability to identify the victims may rely on the examination of skeletal remains.[1,2] Ordinarily, DNA recovery from skeletal remains is difficult and results in a low yield of DNA due to degradation and Polymerase Chain Reaction (PCR) inhibitors.[3] Few case studies discuss remains found submerged in water. For example, a Short Tandem Repeat (STR) profile was successfully extracted from a 67-year-old bone found in a fresh water lake by creating and using a unique extraction protocol; however, a later study using the same protocol on remains found in seawater was unsuccessful.[4,5]

In this experiment, samples were derived from 12 pig (*Sus scrofa*) humeri and 12 pig ribs, divided into a total of 24 humerus and 24 rib samples. Cut bones and waterproof dataloggers were submersed in water and left outdoors. Water temperature was recorded hourly. Data from the loggers were monitored. Approximately every 500 Accumulated Degree Days (ADD), three rib and three humerus samples were collected and stored in a -20°C freezer. After collection, the DNA was extracted in triplicate using these different methods: organic phenol-chloroform, DNeasy Blood and Tissue Kit, and ChargeSwitch® gDNA Plant Kit. The quality and quantity of the DNA was determined using the NanoDrop™ Spectrophotometer, Qubit® 2.0 Fluorometer, and real-time quantitative PCR (qPCR), respectively.

In assessing the quality of DNA extracted from samples across 3,000 ADD, Analysis of Variance (ANOVA) and Tukey's Honest Significant Difference (HSD) analyses indicated a significant difference among methods (F=9.83, p=0.0004); the ChargeSwitch® gDNA Plant Kit had a decreased mean 260/280 ratio compared to DNeasy Blood and Tissue Kit. Qubit® quantitation values were highest using the ChargeSwitch® gDNA method and rib bone type. ANOVA analysis did not indicate a significant difference between bone type (F=200, p=0.1666) or among methods (F=0.87, p=0.4278). ANOVA analysis of Cycle threshold (C_t) from qPCR indicated a significant difference among the methods (F=5.36, p=0.0096). The ChargeSwitch® gDNA Plant Kit had the lowest mean C_t value (28.88) compared to DNeasy Blood and Tissue Kit (34.34) and organic phenol-chloroform (33.48). Analysis also indicated a significant difference between bone types with respect to DNA yield. The mean C_t value for humeri (33.81) was greater than the C_t value for ribs (30.83), indicating that the ChargeSwitch® gDNA Plant Kit method and rib bone type produced higher quantities of DNA.

Overall, this study suggests that magnetic bead technology is the most beneficial method for recovery of DNA from waterlogged bone, and ribs may be better suited for recovery of host DNA, contrary to common practice and belief.

After attending this presentation, attendees will better understand the proteomes from different segments of the pre-keratinized region in anagen hairs exhibiting and not exhibiting a Postmortem Root Band (PMRB). Manifestation of a PMRB is one form of decompositional change that is presented as an ellipsoidal-shaped banded area in anagen and early catagen-phase hairs derived from cadavers.[1-5] It has been demonstrated that these banded areas are gas pockets, as they appear dark in transmitted light microscopy and bright in reflected light microscopy.[4] Although the microscopic characteristics of PMRBs have previously been well investigated, the mechanism for their formation requires further research.[1-5]

This presentation will impact the forensic science community by contributing to the understanding of the possible biochemical mechanism(s) of the formation of a PMRB. The knowledge gained from this research will be useful to forensic science by providing support when determining whether the hair evidence was shed postmortem.

Anagen head hairs were collected at the Federal Bureau of Investigation Laboratory from human volunteers and at the University of Tennessee Knoxville Anthropology Research Facility from deceased donors of known postmortem interval. Hairs were trimmed to approximately 1cm from the proximal end to facilitate handling. A visual qualitative assessment of decomposition was performed for each hair using transmitted light microscopy. For each hair exhibiting a PMRB, three areas of the root were segmented for protein extraction: below (proximal), at (medial), and above (distal) the band. Hair segments (~300µm in length) of homologous locations were also obtained from postmortem and antemortem hairs that did not exhibit PMRBs. In total, at least 72 hair segments were processed for protein extraction and enzymatic digestion using trypsin.[6]

The peptide/protein composition of banded and non-banded hairs was characterized using nano-liquid chromatography/tandem mass spectrometry using labeled synthetic peptides and angiotensin added as internal standards. Chromatograms of the segments (i.e., proximal, medial, and distal) as well as the proteomes of these segments for both banded and non-banded hairs were compared. Preliminary qualitative and semi-quantitative analysis of protein profiles reveals subtle differences between the different hair segments. It was anticipated that the number, quantity, or modification of proteins in the non-PMRB hair segments may be different than in the PMRB hair segments because microscopic analysis of the banded segment showed significant decomposition. Results from this comparative proteomics analysis of the hair segments will be presented.

B133 The Effect of Using an Extra Polymerase Chain Reaction (PCR) Cycle With GlobalFiler® When Amplifying Skeletal Samples

LeAnn M. Harrel, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; and Sheree R. Hughes-Stamm, PhD, Sam Houston State University, Dept of Forensic Science, Huntsville, TX 77340*

After attending this presentation, attendees will understand the advantages and disadvantages of altering the suggested number of PCR cycles as a means to increase Short Tandem Repeat (STR) success for low template and/or degraded bone samples.

This presentation will impact the forensic science community by providing insight into the benefits and cautions when increasing the PCR cycle number using a common STR amplification kit in an attempt to improve the DNA typing results from low-template and/or degraded skeletal samples for human identification.

Using STRs to identify human remains has its challenges. By their nature, bone samples often contain low amounts of DNA template. Depending on the length of time and types of conditions they were exposed, bones are also often highly degraded and/or inhibited. When DNA degrades, it breaks into increasingly smaller fragments which may lead to amplification failure of the longer STR markers (>250bp). In addition, the low amount of DNA template (<100pg) available for amplification also often negatively affects STR results due to stochastic effects, such as allele and/or locus dropout or drop-in, allele imbalance, and increased stutter. A common approach to improving STR results from low-template samples (low copy number typing) is to increase the number of PCR cycles, but this method may also result in more complicated STR profiles.

In this study, various bone and tooth samples (N=24) were harvested from cremated, embalmed, buried, and decomposed human remains to compare the effects of increasing the number of PCR amplifications from 29 to 30 using the GlobalFiler® DNA Amplification Kit. Each bone was sanded, chipped, and cleaned with a wash series of 15% bleach, water, and ethanol before being powdered in a 6700 SPEX® freezer mill. DNA was extracted from 100mg of bone powder by following the recommended bone protocols using the QIAamp® DNA Investigator Kit or the PrepFiler® BTA Forensic DNA Extraction Kit (2x 50mg powder per sample – pooled elutes). The quantity and quality of each sample was determined using the Quantifiler® Trio DNA Quantification Kit, amplified using the GlobalFiler® PCR Amplification Kit (29 or 30 cycles), and detected using the 3500 genetic analyzer.

The results of this study demonstrated that when the number of PCR cycles was increased from 29 to 30, the number of alleles detected and the peak heights increased significantly (p <0.05). Although improvement in STR results was observed in almost all samples, the most notable improvement was observed in samples with the lesser DNA template (<0.05ng); however, no notable improvement in average heterozygote peak height balance was observed. While adding another PCR cycle increased the number of alleles detected and the average peak height, an increase in PCR artifacts was also observed in STR profiles generated using 30 cycles; however, this increase was minimal as only seven drop-in alleles, six off-ladder peaks, and one event of pull-up were observed in a total of 48 amplifications.

Overall, this research has shown that regardless of the DNA extraction method used in this project, consistently more alleles were recovered from bone and tooth samples with the addition of an extra PCR cycle using the GlobalFiler® PCR Amplification Kit with minimal adverse STR artifacts.

Skeletal Samples, Short Tandem Repeats, Low Copy Number

B134 Comparative Analysis of Quantity and Overall Quality of Trace DNA Evidence Collected From Substrates Found at Crime Scenes

Chad C. Hogan, BS, Florida Gulf Coast University, 10501 Florida Gulf Coast University Boulevard, S, Fort Myers, FL 33965; Lora Bailey Van Houten, MS, Department of Justice Crime Laboratory, Fresno, CA 93721; and Sulekha Coticone, PhD, Florida Gulf Coast University, Seidler Hall, #431, 10501 FGCU Boulevard, Fort Myers, FL 33965*

After attending this presentation, attendees will be able to compare various surfaces from which DNA is recovered based on the quantity and quality of the samples.

This presentation will impact the forensic science community by providing insight for crime scene analysts regarding information of the benefits and drawbacks of the substrates from which DNA samples are retrieved at a given crime scene.

The ability to recover high-quality trace DNA samples from a potential crime scene is an important aspect of forensic science and depends on a wide range of factors, such as the characteristics of the contributor, the different types of surfaces, the environment, and the time of recovery.[1] In this study, the number of variables was limited to the types of surfaces and the time of recovery. In the present investigation, samples were prepared by depositing a trace amount of saliva on various surfaces (21 locations), followed by periodic swabbing of the surfaces using the double-swab method at timed intervals for three months.[2] Insight into differences in recoverable DNA concentration due to surface characteristics (e.g., wood flooring, ceramic tile, plastic, granite, glass, and brick) was achieved through quantification of DNA. Data from a real-time quantitative PCR (qPCR) multiplex assay determined that the ratio of the shorter CSF locus (67bp) to the longer TH01 locus (170bp-190bp) target increased over time, indicating degradation of the samples.[3] The qPCR degradation ratio varied from 3.6 to 4.7 and correlated with the percent degradation determined by the relative DNA absorbance measured at 260nm. The percent degradation of DNA was 57% (±2.6%) from samples obtained from brick (most degraded) as compared to 20% (±2.4%) from samples obtained from the plastic surface (least degraded). To assess the quality of the recovered DNA, the extracted DNA was amplified using AmpFℓSTR® Identifiler® primers, followed by capillary electrophoresis. Among all the materials tested, only the DNA obtained from the glass sample provided a complete profile after three months. These results indicate that the quality and quantity of DNA obtained from deposited saliva samples depends on the type of surface from which the sample is obtained. Porous surfaces (e.g., brick) provide lower amounts and lower quality of DNA compared to smooth surfaces (e.g., plastic, glass). The results of this study will aid crime scene analysts by providing information regarding the most desirable location to retrieve sufficient quality DNA samples at a given crime scene.

Forensic Science, DNA, Crime Scene Investigation

B135 An Analysis of the Complex Biological Components of Touch DNA

Jenny Waranauskas, BS, 4780 St. Joseph Creek Road, #203, Chicago, IL 60532; Levi L. Borrego, 1660 G Street, Apt 206, Lincoln, NE 68508; Ray Wickenheiser, MBA, New York State Police Crime Laboratory System, 1220 Washington Avenue, Bldg 30, Albany, NY 12226-3000; and Ashley Hall, PhD, University of Illinois at Chicago, 833 S Wood Street, 456A PHARM (MC 865), Chicago, IL 60612*

After attending this presentation, attendees will better understand the complex biological components of touch DNA and the ways in which this important forensic evidence can be collected and analyzed.

This presentation will impact the forensic science community by providing a description of the relationship between the basic and applied scientific aspects of touch DNA. A systematic evaluation of the components of fingerprints, as well as the optimization of their collection and analysis, could help advance touch DNA technology and ultimately provide the forensic scientist with expanded capabilities.

Touch DNA is a trace-level sample left by human physical contact with surfaces, such as countertops, weapons, or clothing, that results in the transfer of epithelial cells. With advances in knowledge and technology over the past decade, forensic scientists have been increasingly more successful in profiling the nuclear DNA found in these touch samples, providing valuable evidence in many cases. Fingerprints are a prime example of the touch sample, but they also contain other biological components, such as microbial signatures and cell-free DNA, that could play a role in individualization.

The experimental approach described here was two-pronged, as it is rooted in both the basic and applied sciences: (1) basic science — analysis of the biological components of a fingerprint using massively parallel sequencing technology and evaluation of the differences between individuals; and, (2) applied science — optimization of the collection and analysis techniques of DNA in fingerprints deposited on various substrates and development of a set of fingerprint-positive controls for co-analysis with questioned samples to increase confidence in both positive and negative results.

To attain the basic scientific goals of the project, massively parallel sequencing technology was used to analyze the cell-free DNA and the microbiome of fingerprints. Cell-free DNA was collected as the portion of nucleic acid contained in a sample supernatant. Various extraction techniques were evaluated, including protocols involving carrier DNA and sample concentration. Metagenomic analysis of the microorganisms in fingerprints was accomplished after careful optimization of DNA extraction techniques designed to minimize bias introduced in the sample by factors such as incomplete homogenization of the sample matrix or insufficient and incomplete cell lysis. Bioinformatic analysis of sequence data provided an estimate of variance between samples and identified sequences that may be common between individuals. Further work will confirm the results.

To meet the applied science objectives of the project, a "fingerprint solution" was developed by the proportional combination of the major chemical components of an eccrine fingerprint. Buccal epithelial cells were collected in suspension, treated to reduce clumping, and counted using a hemocytometer. This number was equated to the DNA content of a certain volume of the suspension; therefore, a known quantity of DNA could be added to the fingerprint solution. The mixture was deposited on a surface and collected in parallel with true fingerprints, thus acting as a known positive control with the chemical characteristics of the fingerprint. The procedure has been tested and optimized for a number of surfaces and collection devices. The results of both the basic and applied experiments will be presented and discussed in the context of operational forensic science.

Touch DNA, Microbiome, Cell-Free DNA

B136 The Evaluation of a Hand-Held Raman Spectrometer for Field Identification of Controlled Substances

Madison Veronica Roussel, BS, 601 W Bacon Street, Apt 6314, Richmond, VA 23222; Marilyn T. Miller, EdD, VA Commonwealth University, 1015 Floyd Avenue, Rm 3001A, Box 843079, Richmond, VA 23284-3079; Rebecca C. Nugent, MS, LA State Police Crime Lab, 376 E Airport Road, Baton Rouge, LA 70806; and Adam Becnel III, MNS, LA State Police Crime Lab, 376 E Airport Road, Baton Rouge, LA 70806*

After attending this presentation, attendees will understand the advantages of using a hand-held Raman spectrometer over colorimetric field tests for suspected controlled substances. Attendees will also be aware of the types of samples that are suitable for Raman spectroscopy identification.

This presentation will impact the forensic science community by presenting an evaluation of an alternative method of preliminary identification of unknown substances. This method offers a safe, non-contact method of field analysis for law enforcement officers.

The PGR-1064™ Raman Spectrometer was evaluated for its suitability as a field test for suspected controlled substances. Its suitability was determined using controlled substance identification data as well as user observations about the functionality of the spectrometer. There are many advantages of Raman spectroscopy over commonly used colorimetric field tests. With Raman, there are no harsh chemicals or solvents, there is no need to open the packaging, and the interpretation of the results is not subjective.

Two identical PGR-1064™ Raman Spectrometers were used in this study. Blind triplicate scans of 135 samples suspected to contain controlled substances were taken with each Raman spectrometer and searched against two of its library databases. Each sample was then analyzed using Fourier Transform Infrared (FTIR) with an Attenuated Total Reflectance (ATR) attachment; IR spectroscopy is complementary to Raman spectroscopy. Once each sample was preliminarily identified using both Raman and FTIR, the results were compared to the true identity of the substance from Gas Chromatography/Mass Spectrometry (GC/MS) analysis.

Twenty-one samples had at least one compound that was not in the current library of the Raman spectrometer. Analysis of the 14 samples of plant material was not successful; the material was too dark and charred when it came into contact with the laser. Excluding the new compounds and plant material, the Raman library correctly identified the sample or part of the mixture in at least one of the scans 79% of the time. Separating results by compound, cocaine was identified 74% of the time (203/274 scans) and methamphetamine was identified 83% of the time (121/146 scans).

The Raman spectrometers evaluated in this study are suitable for field use for preliminary identification of suspected controlled substances. This technology would be most effective at identifying suspected cocaine and methamphetamine.

Field Test, Hand-Held Raman Spectroscopy, Controlled Substances

B137 The Evaluation of Portable Hand-Held Raman Systems for the Presumptive Identification of Narcotics

Cristina S. Spicher, BSc, Marshall University, Forensic Science Center, 1401 Forensic Science Drive, Huntington, WV 25701; Ilene K. Alford, MS, Palm Beach County, Sheriff's Office, 3228 Gun Club Road, West Palm Beach, FL 33406; Lauren L. Richards-Waugh, PhD, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; and Dustin Tate Yeatman, MS, 3228 Gun Club Road, West Palm Beach, FL 33406*

After attending this presentation, attendees will understand the advantages and limitations of portable Raman spectroscopy and its potential as a supplemental approach for the field testing of narcotics.

This presentation will impact the forensic science community by demonstrating the potential applicability of using portable hand-held Raman spectroscopy systems to detect illegal substances quickly and accurately using a single test, either within a laboratory system or as a field test by law enforcement.

Historically, presumptive testing for narcotics has involved colorimetric tests, otherwise known as spot tests. These tests are fast, sensitive, and can categorize a suspected illegal substance to a particular class of drugs; however, the interpretation of the color change is subjective and false positives and negatives are possible. Hand-held Raman devices have been developed for forensic application to eliminate the need for colorimetric testing. These user-friendly systems offer a non-destructive means to detect potential controlled substances, precursors, and cutting agents quickly and accurately either within a laboratory system or as a field test by law enforcement.

The goal of this research was to evaluate two portable hand-held Raman systems to determine their ability to accurately analyze narcotic samples. The Thermo Scientific TruNarc® and Chemring Detection Systems PGR-1064® were used to test more than 100 case samples by colorimetric and Gas Chromatography/Mass Spectrometry (GC/MS) analysis in the Palm Beach County Sheriff's Office Chemistry Unit. Case samples, which included opiates, stimulants, hallucinogens, and pharmaceutical tablets, were scanned in triplicate on three consecutive days in order to determine reproducibility. Results of the Raman scans were compared to the laboratory results. The TruNarc® successfully detected the target drug in 77% of the case samples and generated reproducible results in 84% of the case samples when the results were compared to the rescans on days two and three. An added benefit to the TruNarc® system is the Type H kit, which utilizes Surface Enhanced Raman Spectroscopy (SERS) to increase Raman scattering and fluorescence quenching, allowing drugs in low concentration or those with high fluorescence to be detected successfully. The PGR-1064® successfully detected the target drug in 36% of the case samples and generated reproducible results in 60% of the case samples when the results were compared to the rescans on days two and three.

These Raman detection systems exhibited the potential to provide accurate and reproducible results for single-component samples through certified reference standards; however, there are intrinsic challenges to the technology of Raman spectroscopy when dealing with mixtures. Case sample's homogeneity was unpredictable when adulterants, diluents, and other components were found within the samples. As a result, the laser was likely not always focused on the target drug within a sample. Additionally, limited sample quantities resulted in inconclusive or unidentified results. The ability to detect forensic narcotic samples likely depends on sample purity, amount, and where on the sample the laser is focused.

The data presented suggest that hand-held Raman systems have the potential to detect substances of abuse depending on the specific sample, although further evaluation is necessary for implementation within a laboratory and as a field test.

The opinions, findings, conclusions, and recommendations stated in this presentation are those of the authors and do not necessarily reflect the vendors or the Palm Beach County Sheriff's Office.

Presumptive Testing, TruNarc®, PGR-1064

B138 Seized-Drug Mass Spectral Libraries: Data Quality Control Measures

William E. Wallace, PhD, National Institute of Standards and Technology, 100 Bureau Drive, #8362, Gaithersburg, MD 20899-8362; Weihua Ji, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; Karen W. Phinney, National Institute of Standards and Technology, 100 Bureau Drive, #8314, Gaithersburg, MD 20899; and Stephen Stein, National Institute of Standards and Technology, 100 Bureau Drive, Stp 8362, Gaithersburg, MD*

After attending this presentation, attendees will better understand spectrum self-consistency as well as consensus comparison among several spectral library entries as a means for mass spectral library quality control.

This presentation will impact the forensic science community by providing greater understanding, and thus greater confidence, as to how curated mass spectral libraries are created and maintained.

Spectrum quality control measures suitable for forensic drug analysis have been developed. The mass spectral library maintained by the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) currently includes close to 2,300 spectra (version 04-01-2015). The National Institute of Standards and Technology (NIST) Mass Spectrometry Data Center has reviewed each SWGDRUG spectrum and brought the level of curation up to the standards of the NIST library. Having high-quality, controlled-substance libraries is critical to the criminal justice system.

Each spectrum in the SWGDRUG library was compared via standard library search methods to spectra of the same compound found in any of five mass spectral libraries. These libraries were: the NIST/Environmental Protection Agency (EPA)/National Institutes of Health (NIH) library (240,000 compounds), the Wiley Designer Drug® library (16,343 compounds), the Wiley Mass Spectral Library of Drugs, Poisons, Pesticides, Pollutants and Their Metabolites® (8,650 compounds), the Cayman Chemical Company library (748 compounds), and the Adams Essential Oil Components library (2,200 compounds). Confirmation of a good-quality SWGDRUG spectrum was contingent primarily on matching with a match factor of 750 or better (out of 999) any and all spectra in the five reference libraries. Outlier spectra in any library were flagged for further scrutiny using NIST's Mass Spectral (MS) Interpreter program.

Although the number of SWGDRUG spectra that were found to contain errors is small (on the order of fewer than 1%), the variety of errors found was wide. In essence, each error found was unique to that entry. Systematic, library-wide errors were not found.

Spectral errors are generally of three types: (1) missing peaks; (2) spurious peaks not attributable to the compound structure; and, (3) incorrect mass assignments (often from incorrect rounding of mass values). In addition, there are a variety of compound identification errors. These include: (1) incorrect chemical structure; (2) incorrect chemical name; (3) incorrect Chemical Abstracts Service (CAS) number or other identifier; and, (4) incorrect isomer identification. In a few cases, a compound exists only in the SWGDRUG library, so comparison was not possible. These were flagged for measurement by NIST for addition to the NIST library.

The use of NIST's MS Interpreter program was instrumental for adjudicating cases in which only a few measurements were available. MS Interpreter assigns peaks to plausible molecular substructures based on a set of rules for estimation of fragmentation energetics using a chemical structure (connection table) type analysis. MS Interpreter is freely available at chemdata.nist.gov/mass-spc/interpreter/.

Of the 2283 SWGDRUG spectra examined, 605 were not in the NIST library, 89 had only one measurement on record in any library, 10 had only poor quality spectra available, and 12 had incompatible spectra in two or more libraries. Additionally, 173 NIST/EPA/NIH entries required CAS number updates, 14 had incorrect chemical structures, and 4 had incorrect compound names.

The compounds not in the NIST library or of poor quality will be measured and added, if certified samples can be found. This should be completed in time for next year's library release, NIST17, available Spring 2017.

Mass Spectral Database, Consensus Comparison, Quality Control

B139 Evaluation of a New Technology for the Collection and Analysis of Breath Components for Marijuana Detection Using Capillary Microextraction of Volatiles (CMV)

D'Nisha D. Hamblin, MSFS, National Institute of Standards and Technology, 100 Bureau Drive, Bld 227, MLStp 8392, Gaithersburg, MD 20899; Bruce A. Benner, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Chemical Sciences Division, Gaithersburg, MD 20899; William A. MacCrehan, PhD, Stop 8392, Gaithersburg, MD 20899; and Jose R. Almirall, PhD, Florida International University, Dept of Chemistry, University Park, Miami, FL 33199*

After attending this presentation, attendees will be more familiar with the new CMV technology.

This presentation will impact the forensic science community by providing insight into a hopeful new technology for the non-invasive collection and detection of drugs (i.e., marijuana) in the breath of potentially intoxicated motorists.

Increased legalization of medical and recreational marijuana usage in the United States has led to an urgent need for forensic field tests for the detection and confirmation of drugged driving. Marijuana use has been found to have a detrimental effect on an individual's driving abilities, causing an increase in public concerns for road safety. The non-invasive approach of breath collection has made exhaled breath an attractive sample to collect for field detection of drugs. Breath analysis for marijuana detection, although potentially advantageous, has been limited by the available breath collection devices and analysis techniques. The endogenous compounds of breath, which naturally form in the body, make up the complex background of normal breath, which may interfere with analyses developed for the determination of compounds in the breath associated with the smoking of marijuana. Previous studies characterizing the breath of individuals who have smoked marijuana used filters as sample collection devices resulting in low collection efficiencies.

This study proposes the evaluation of a new technology, CMV, for its suitability for the collection of breath aerosols and volatiles in exhaled breath analysis. The CMV preconcentrates breath components using a mini capillary tube filled with Polydimethylsiloxane (PDMS) -coated glass filter strips. The CMV offers dynamic sampling of Volatile Organic Compounds (VOCs) with a simple coupling to the inlet of a Gas Chromatograph (GC) for analysis, avoiding expensive thermal desorption instrumentation needed for bulk sorbent-type collection devices. CMV offers a 5,000-fold increase in surface area and an improved collection capacity over the static, single Solid-Phase Microextraction (SPME) fiber based on the same preconcentration fundamentals. The collection efficiency and analysis of commonly known volatiles associated with normal breath and marijuana smoking were studied using a simulation of synthetic breath composed of vapors generated by permeation into a flow of humidified nitrogen. After collection of the synthetic breath onto the CMV, two extraction methods were tested for efficacy in releasing analytes for analysis. The comparison of the direct thermal desorption and online supercritical Carbon dioxide (CO_2) extraction of a CMV into a GC/Mass Spectrometer (GC/MS) inlet was used to determine the recovery profiles of the two recovery approaches. The chemical characterization of these breath components would provide a foundation and better understanding of breath collection with CMV. This understanding permits the differentiation between normal breath constituents and the exogenous compounds resulting from the smoking of marijuana. Reliable demonstration of the CMV for breath collection would serve as a proof of concept for future applications of the CMV for detection of marijuana smokers' breath for drug-impaired driver management. The portability and sensitivity of the CMV could aid law enforcement agencies in the future during traffic patrols of drug-impaired drivers.

Breath Analysis, Breath Collection Device, Drug Detection

B140 High-Throughput Analysis of Controlled Substances: Combining Multiple Injections in a Single Experimental Run (MISER) and Liquid Chromatography/Mass Spectrometry (LC/MS)

Sandra E. Rodriguez-Cruz, PhD, Drug Enforcement Administration, Southwest Laboratory, 2815 Scott Street, Vista, CA 92081; and Trevor R. Equitz, MA, Drug Enforcement Administration, 2815 Scott Street, Vista, CA 92081*

After attending this presentation, attendees will understand how the application of MISER to LC/MS can provide an efficient, high-throughput method of analysis for seized drug submissions.

This presentation will impact the forensic science community by demonstrating the efficiency, simplicity, and versatility of MISER LC/MS analysis of controlled substances, especially when applied to multiple-unit and/or multiple-component submissions.

Forensic drug laboratory personnel are frequently faced with the challenge of efficiently managing cases and evidence backlogs while also performing high-quality analyses that will fulfill jurisdictional and other requirements. Conclusions of analysis must be scientifically supported by the use of reliable and robust analytical techniques. Furthermore, analytical results need to be generated in an efficient and timely manner. The ability to perform high-throughput analysis is therefore a crucial need in today's forensic laboratories. This is especially true for state, local, and federal laboratories that routinely receive multiple-unit exhibits, as jurisdictional requirements often involve the testing of a large number of individual units in order to make an inference on the entire seizure, or on a high proportion of it.

MISER is an ideal technique for the rapid analysis of multiple-unit drug exhibits. It is a variation of flow-injection analysis in which samples are analyzed by direct injection into an eluent flow provided by a liquid chromatograph. In combination with an autosampler, samples can be continuously injected, allowing the rapid evaluation of their contents. The collection of results from multiple samples within a single chromatogram (misergram) also allows simple evaluation of data. Contrary to routine Gas Chromatography (GC) or LC applications, the proportion of strong solvent employed during MISER analysis should be sufficiently high to ensure only minimal interaction with the stationary phase, thus accelerating the passing of the analyte(s) through the column. Although sample components are not separated on the basis of retention time, this apparent limitation in selectivity is easily remedied by the use of an MS detector.

Included in this presentation are the results of several experiments in which the MISER technique was utilized in combination with LC/MS in the analysis of controlled substances. In one experiment, the analysis of 28 randomly selected units from a large cocaine submission was completed in approximately 36 minutes, demonstrating the time-saving advantages MISER offers. Isocratic solvent flow conditions were optimized for both rapid elution and minimal separation of the primary constituents present in the samples, and the samples were able to be injected every (approximately) 1.2 minutes.

Another drug submission consisting of oxycodone tablets was analyzed using similar solvent flow conditions, but with the mass analyzer programmed to perform three types of experiments on each sample: (1) full mass analysis (m/z 50-500); (2) then Tandem Mass Spectrometry (MS/MS) on the most intense ion detected during the full mass analysis scan; and, (3) followed by Triple Mass Spectrometry (MS/MS/MS) analysis on the most intense fragment ion detected during the MS/MS. This experiment sequence provided additional fragmentation information for the oxycodone present in the tablets, since the MS/MS analysis resulted in too few ions for unambiguous characterization.

In addition to multi-unit drug submissions, MISER LC/MS is well-suited for multiple-component mixtures, as demonstrated by the analyses of opium samples. Solvent conditions in one example were shown to produce slight separation of the major constituents while maintaining rapid elution; however, a much simpler misergram was produced when the eluent flow contained a higher proportion of organic solvent such that all sample components co-eluted. Furthermore, co-elution of multiple components did not preclude the ability of the mass analyzer to provide structural information on each individual substance present in the samples.

This presentation will benefit the forensic science community by offering a versatile and highly efficient screening method for multiple-unit and multiple-component seized drug submissions.

Controlled Substances, MISER, LC/MS

B141 Using Solid Phase Extraction (SPE) to Reduce Interference in Gas Chromatography/ Mass Spectrometry (GC/MS) Analysis of Fire Debris Samples

Julia B. Maier, BSc, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Thomas H. Pritchett, MS, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will better understand how SPE with GC/MS increases the chances of determining whether a hydrocarbon accelerant is present, then correctly identifying the accelerant used, even in the presence of matrix interferences.

This presentation will impact the forensic science community by describing another way to improve the identification of fire debris samples that otherwise would have been unidentifiable due to matrix interferences.

Interferences can be broken down into three types: (1) substrate products; (2) pyrolysis products; and, (3) combustion products.[1] Their presence makes identification of the accelerant components challenging, thus hindering the interpretation of arson samples. To reduce the interference and make it easier for identification, a simple method of extraction with SPE cartridges can be used to purify the samples. Silica and amino propyl cartridges were evaluated as they remove compounds with which hydrogen bonds, but they do not have π bond interactions, such as aromatics. Accelerants containing hydrocarbons were used in this study.

There were two phases to the research. The first phase was to document the degree to which SPE affects the components of ten neat accelerants of different classes. The neat accelerant samples were collected using passive headspace with activated charcoal strips to adsorb the compounds.[2] The cans were heated overnight in an oven. Approximately 1mL of Carbon Disulfide (CS_2) was used to extract the compounds from the strips in amber vials. Three activated charcoal strips were used per sample during the heating stage of research. One strip went through a Silicon Dioxide (SiO_2) cartridge, another through an amino (NH_2) cartridge, and the third strip remained as is. Each accelerant was sampled in triplicate. All extracts were analyzed by GC/MS.

The chromatograms from the neat, silica cartridge and amino propyl cartridge were compared for each accelerant by first isolating the six most prominent peaks. The compounds were then identified using the reference library from the GC/MS and verified from the National Center for Forensic Science (NCFS).[3] The areas for these six prominent peaks were normalized for each sample, then the mean normalized area was calculated and standard deviation was calculated for the triplicate samples. Finally, the upper and lower confidence limits were calculated for the differences in the mean normalized areas of the neat versus the mean normalized areas for each of the sample sets run on the different SPE media. In all of the tested accelerants, there were no statistical differences in the normalized means of the six most prominent peaks.

Phase two of the research focused on testing the effectiveness against interferences. Various interfering matrices were placed in the cans, then burned until a smoldering smoke was observed. At this point, the cans were spiked with an accelerant mix consisting of a 1:1:2 volume/volume (v/v) gasoline, kerosene, and diesel and sealed with three charcoal strips inside. The strips were extracted as before and one strip was analyzed with no clean-up, while the other strips were cleaned via SPE, one strip using the silica cartridge and the other using the amino-propyl cartridge. After the extracts were analyzed by GC/MS, the prominent interference peaks in the samples were normalized against the largest accelerant peak and decrease in the normalized intensity was documented.

B142 Developing Quantitative Measurements and Test Materials for Fingerprint Development Reagents Using Inkjet Printing

Edward Sisco, MS, NIST, 100 Bureau Drive, MS 6431, Gaithersburg, MD 20899; and Marcela Najarro, MFS, NIST, 100 Bureau Drive, MS 8371, Gaithersburg, MD*

After attending this presentation, attendees will: (1) understand the motivation and potential benefits of using standardized and quantifiable test materials to evaluate the stability and efficacy of their fingerprint development reagents; (2) understand what has taken place to create these materials and evaluate their stability and lifetime; and, (3) possess insight into potential issues that can arise with long-term storage of their reagents.

This presentation will impact the forensic science community by presenting a method through which examiners can reliably and reproducibly monitor the efficacy of their fingerprint developers using standard test materials, thus minimizing issues arising from using one's own fingerprint.

While the use of fingerprint development reagents is universal throughout forensic science laboratories, the methods for ensuring the reagents are working properly are not. Numerous methods exist, though the most common is to develop one's own fingerprint to see if the reagents are working properly. Due to the inherent variability in fingerprint composition, this practice does not provide a means for reproducible evaluation of the reagents over a period of time. In order to truly understand the efficacy, quality, stability, and lifetime trends of the developing reagents, a quantitative method of evaluation needs to be developed.

The work presented here highlights the development of quantifiable fingerprint reagent test materials created using high precision inkjet printing. Using this technology, it is possible to create highly reproducible (~1% Relative Standard Deviation (RSD)) deposits of chemicals to test the reagents. The test materials contain an array of arrays with increasing surface concentrations of an analyte(s) of interest. By providing a range of surface concentrations, it is possible to obtain a better understanding of the efficacy of the reagent beyond a single-point red light/green light approach. The original work began with the creation of amino acid-containing test materials to quantifiably evaluate reagents such as ninhydrin and 1,2-indanedione on porous surfaces. With the high precision of inkjet printing, it is not only possible to evaluate the efficacy of these reagents but also to establish limits of detection for the reaction to be observed.

This presentation will focus on the development of these test materials, which includes establishing appropriate test levels, evaluating the lifetime of the materials under different environmental conditions, identifying necessary storage considerations, and obtaining feedback from forensic laboratories throughout the country. This presentation will also discuss methods that have been developed to quantitatively evaluate the initial amount of material deposited to create the materials, the reactions, and potential solvent bleed of various developer reagents. In addition to the creation of amino acid standards, standards for the reagents which react with sebaceous components, cyanoacrylate, and non-porous surfaces will also be discussed. Advantages of this type of test material and potential issues with the use of one's own fingerprint as a check method will also be presented.

Latent Fingerprints, Developer Reagents, Inkjet Printing

B143 Investigating the Utility of Automated Flash Chromatography in Forensic Drug Analysis

Kimberly Setien, BS, Sam Houston State University, Dept of Forensic Science, 1003 Bowers Boulevard, Huntsville, TX 77340; Kyle E. Vircks, MS, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054; and Warren C. Samms, PhD, Harris County Institute of Forensic Sciences, 1885 Old Spanish Trail, Houston, TX 77054*

After attending this presentation, attendees will understand how automated flash chromatography systems can be utilized in forensic drug analysis. Such systems are capable of isolating and purifying components of a liquid mixture, much like a modern High-Performance Liquid Chromatograph (HPLC); however, unlike HPLC, flash chromatography systems are capable of collecting the isolated components for further analysis.

This presentation will impact the forensic science community by demonstrating a means to isolate and collect components of a liquid mixture that require additional analysis in order to attain an identification. This becomes especially important when encountering emerging synthetic drugs before reference material is available.

Gas chromatography/mass spectrometry is the gold standard for analyte identification in most forensic drug analysis laboratories; however, when new synthetic drugs are detected, more information may be needed to make an identification. Ideally, Nuclear Magnetic Resonance (NMR) spectroscopy would be used to gain insight into the molecular structure of the unknown compound. Unfortunately, NMR analysis requires fairly pure samples to avoid complicating the spectra with signals from multiple compounds. Therefore, the compound of interest must be isolated and purified before it can be analyzed via NMR spectroscopy. Several isolation and purification techniques, such as liquid-liquid extraction, could be attempted to meet this requirement; however, automated flash chromatography was explored as it provides a means to isolate compounds of interest when little-to-no chemical information is known.

Because synthetic drug standards are expensive and are only sold in small quantities, known mixtures of common controlled and non-controlled substances were used for this study as a proof of concept. Various method parameters, including different columns and mobile phases, were tested. Polar silica columns and non-polar C18 columns were both tested. Water, methanol, acetonitrile, hexane, ethyl acetate, and isopropanol were tested to determine the optimal mobile phase for the separation. Utilizing automated flash chromatography equipped with an Ultraviolet (UV) detector, cocaine was successfully isolated and collected from a mixture containing equal parts lidocaine and benzocaine. For this specific mixture, a silica column with a methanol mobile phase was found to provide the best separation when the cocaine was in freebase form. To successfully isolate the cocaine, a liquid-liquid extraction containing a 1:1 ratio of sodium bicarbonate and chloroform was first performed to convert any salts to freebase. The sample mixture was then run on the automated flash chromatography system. Results showed clear separation of cocaine from lidocaine and benzocaine. Further analysis of the purified cocaine was successfully performed via NMR spectroscopy.

The same process used to develop the method used for this study could be employed for unknown compounds, such as synthetic cannabinoids. Because so many parameters can be altered which affect the separation, it is suggested that quick tests using Thin-Layer Chromatography (TLC) be used prior to attempting a full-scale separation on an automated system. Once optimal method parameters are determined, automated flash chromatography systems provide a simple technique for the successful isolation and collection of analytes requiring further analysis for identification, making it a useful tool in forensic drug analysis.

Drug Analysis, Flash Chromatography, Synthetic Drugs

B144 The Use of Near-Infrared Spectroscopy (NIRS) and Chemometrics in Evaluating Growth Periods of Cannabis Seeds Seized and Cultivated in a Greenhouse

Bruna Tassi Borille, MS, Avenida Ipiranga 2752, Porto Alegre 90610000, BRAZIL; Taís Regina Fiorentin, BS, 210 Krewson Terrace, Willow Grove, Philadelphia, PA 19090; Rafael Scorsatto Ortiz, PhD, Avenida Ipiranga 1365, Porto Alegre 90160093, BRAZIL; Kristiane de Cássia Mariotti, PhD, Avenida Ipiranga 1365, Porto Alegre 90160093, BRAZIL; Marcelo Caetano Alexandre Marcelo, MS, Avenida Bento Gonçalves 9500, Porto Alegre 90040060, BRAZIL; Marco Flores Ferrão, PhD, Avenida Bento Gonçalves 9500, Porto Alegre 91501970, BRAZIL; and Renata P. Limberger, PhD, Avenida Ipiranga 2752, Porto Alegre 90610000, BRAZIL*

After attending this presentation, attendees will be able to assess the classification of cannabis seeds seized and cultivated in controlled conditions during their different growth stages.

This presentation will impact the forensic science community by providing a new and effective classification of cannabis plants by age and, consequently, by providing a fast and reliable solution to gathering information about indoor cultivation time, establishing a connection between the cultivation site, the trafficked seeds, and the route of cannabis trafficking.

In recent years, cannabis drug trafficking has been changing in Brazil. An exponential increase in the seizure of cannabis seeds sent by mail has been observed by the Brazilian Federal Police (BFP). This change in the cannabis trafficking scenario may be the result of BFP efforts to eradicate the cultivation of the plant in large-scale farms and the change of the outdoor setting for indoor cultivation. This same tendency is also observed in Europe.

Even though a simple chemical analysis of the seized drug is sufficient to identify cannabis as a drug for legal purposes, classification by age may be an important tool in forensic intelligence (e.g., to gather information regarding indoor cultivation time, establish a connection between the cultivation site and the trafficked seeds and route trafficking); however, the high intrinsic variability present in cannabis samples (brands, varieties, chemotypes and gender) makes it difficult to obtain a classification standard. Therefore, this study sought to develop a method for classifying cannabis germinated in a homemade greenhouse according to the growth period, using Near-Infrared Spectroscopy (NIRS) and chemometrics.

Twenty-nine seeds seized by BFP were cultivated in a homemade greenhouse, in three different growth periods and controlled conditions. The harvest was performed by removing the entire plant from the soil; the loss on drying was estimated by gravimetry until the sixth day post-harvest. The leaves, stems and inflorescence were ground in an agate mortar and directly analyzed by NIRS. The influence of the sample homogeneity on the classification was evaluated using triplicates, and at random.

The NIR spectra were obtained using a PerkinElmer® 400 IR spectrometer equipped with integrating sphere and Indium Gallium-Arsenic (InGaAs) detector. The spectra were measured with resolution of 4cm^{-1} in the range between 10,000 and 4,000 cm^{-1}. A total of 32 scans were performed for each sample.

Principal Component Analysis by intervals (*i*PCA) was performed to assess the spectral region. This provided the best separation between the groups. The PCA, Hierarchical Cluster Analysis (HCA), Partial Least Squares Discriminant Analysis (PLSDA) and Support Vector Machines Discriminant Analysis (SVMDA) were performed and the samples (n=87) were classified by age (5.5 weeks, 7.5 weeks, and 10 weeks). The software MATLAB with PLS_toolbox and iToolbox (http://www.models.kvl.dk) were used.

An absorption band above 8,000 cm^{-1} was observed, with only the absorption band associated with the third overtone of CH_3, CH_2 and CH being approximately 8,500 cm^{-1}. The absorption bands associated with the second and first overtone of CH_3, CH_2, and CH were observed in the area of 6,900 and 5,800 cm^{-1}. In the spectral region between 5,000 and 4,000 cm^{-1}, there was information associated with the combinations of CH_3, CH_2, CH, C-C, and CHO, among others.

The *i*PCA in the raw spectra demonstrated the best separation between the samples by age, identified in the spectral region 4,000-4,375 cm^{-1}, associated with CH_3, CH_2, CH, C-C, and CHO combinations. Both discrimination analysis algorithms were carried out in this interval. The PCA and HCA exhibited good separation between the three groups of cannabis with different growth periods. The PLSDA and SVMDA classified the samples with good

results in terms of sensitivity and specificity. The sensitivity and specificity for SVMDA classification were equal to unity.

These results revealed that, in the early stages of the cultivation of indoor cannabis, the age of the plant can be predicted by NIRS and chemometric tools; however, a larger study may be needed to confirm this observation due to the low number of samples obtained.

Cannabis, Near-Infrared Spectroscopy, Chemometrics

B145 Forensic Intelligence in Illicit Markets: The Contribution of Chemical Analysis on Counterfeit Watches

Sarah Hochholdinger, MSc, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Emmanuelle Erne, MSc, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Michel Arnoux, MSc, Anticounterfeiting Department, Federation of the Swiss Watch Industry FH, Biel/Bienne, SWITZERLAND; Quentin Rossy, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; Pierre Esseiva, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne 1015, SWITZERLAND; and Olivier Delémont, PhD, School of Criminal Justice, University of Lausanne, UNIL-Batochime, Lausanne, Vaud CH-1015, SWITZERLAND*

After attending this presentation, attendees will understand the mechanism of intelligence gathering through the chemical analysis of counterfeit goods. The added value that such information has on understanding the functioning of illicit markets will also be demonstrated.

This presentation will impact the forensic science community by highlighting the scope of the contribution that forensic science can provide from a security perspective, beyond the general emphasis that is placed on forensic science's role in criminal courts.

The practice of forensic science relies fundamentally on the study of trace evidence as remnants of a criminal activity and on the extraction and contextualization of the information this conveys. Counterfeit watches, as products of an illicit activity, hold trace details of their production and/or distribution that can provide information about the structure of illegal trafficking. Fundamentally, by the ability to reveal links between specimens or cases, trace evidence provides pertinent information to investigative activities. When combined with other types of intelligence gathered through spatiotemporal analysis of seizures or monitoring of internet sites selling counterfeit goods, trace evidence offers a powerful tool to decipher the structure of illicit markets.

The contribution of forensic intelligence in gathering information regarding illicit markets through the example of chemical analysis performed on seized counterfeit watches will be illustrated. By considering three types of chemical analyses — the profiling of perfumed plastic straps, the composition of leather and plastic straps, and the metal composition of watchcases — the challenges that characterize the extraction of intelligence from counterfeit watches will be illustrated.

The first challenge, data production, pertains to establishing an analytical strategy that provides representative and informative data on the composition of the different watch parts. Headspace/Solid-Phase Microextraction followed by Gas Chromatography/Mass Spectrometry (HS/SPME-GC/MS) was used for the extraction of volatile compounds from the watch straps, while X-ray spectroscopy and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) after acid dissolution were used to obtain the elementary composition of watchcases.

The second challenge, data treatment and organization, consists of creating reliable and informative profiles from the analytical results. Subsequently, the profiles for each of the counterfeit watches were compared and grouped by means of similarity indexes, providing intelligence about possible links between specimens.

The integration of this information with other types of intelligence, known as contextualization, is the third challenge. Contextualization revealed forensic science's contribution to the information regarding the illicit counterfeit watches market. Information gained through chemical analysis corroborated existing information from other sources and also revealed new links between seizures and specimens.

This presentation exemplifies a more general approach of forensic intelligence for concealed markets. The extraction and exploitation of information from an illicitly produced item to gain information about its production is a generic mechanism that is already widely used. For instance, the chemical profiling of illicit drugs has already been extended by analogy to other types or counterfeit goods (medicines, cigarettes, etc.) or illegal activities (forged documents, doping agents, etc.).

Illicit Markets, Chemical Analysis, Counterfeit Watches

B146 An Analysis of Ignitable Liquids Using Portable Ion-Trap Gas Chromatography/ Mass Spectrometry (GC/MS) With Solid-Phase Microextraction (SPME) Sampling

David A. Matthew, MA, International Association of Fire Chiefs, USA, 10 Dickerson Lane, Napa, CA 94558; Pauline E. Leary, PhD, Smiths Detection, 1934 Bulls Head Road, Stanfordville, NY 12581; John D. De Haan, PhD, Fire-Ex Forensics, Inc, PMB 314, 3505 Sonoma Boulevard, #20, Vallejo, CA 94590; and Arlene M. Mc Grath, National University of Ireland Galway, Whitefield, Loughmore, Templemore, Tipperary, IRELAND*

After attending this presentation, attendees will better understand the impact samples, sampling time, and sampling conditions have on data that was collected at fire scenes and analyzed using portable GC/MS with SPME sample introduction.

This presentation will impact the forensic science community by informing attendees how portable GC/MS may be applied to fire investigations, as well as by demonstrating the advantages and limitations of performing this method.

The analysis of Ignitable Liquid Residues (ILRs) from a fire scene is performed to provide investigative leads, as well as to determine whether or not the crime of arson was committed. Typically, samples that potentially contain ILRs at a fire scene are identified, collected, packaged and transported to the laboratory for GC/MS analysis. Determination of the presence of an ILR is achieved by the evaluation of GC patterns and by the conclusive identification of individual components present in the sample using both GC and MS data. There are many challenges to the successful performance of this type of analysis. Proper sample identification, collection, packaging, and transport are critical. If these tasks are not performed correctly, results of analytical testing may be meaningless or even misleading. In addition, laboratory backlog may delay analytical turnaround time. As a result, data may not be representative of the sample collected. This is because the longer these volatile and semi-volatile samples are stored, the more likely they are to change their chemical composition and, therefore, their chromatographic profile. This can significantly complicate the interpretation of the analytical data from the collected sample.

For these reasons, it may be desirable to take the analytical laboratory to the field and perform GC/MS during the fire scene investigation as the quality of the sample is at its greatest at the scene. Results are characteristic of the sample collected before storage and time have had a chance to alter its chemical composition. In addition, when analysis is performed at the scene, investigative leads are available in near-real time. Also, the use of portable GC/MS will prevent the submission of poorly collected samples to the laboratory for analysis. Portable GC/MS can be used to establish the presence of an ILR at the scene, preventing the submission of negative samples to the laboratory.

There are a number of different portable GC/MS systems available to perform field analysis. These systems vary based on the type of GC column and mass analyzer used, as well as how the sample is collected and introduced to the system. These factors can play a critical role in the chromatogram collected and, therefore, impact data interpretation. It is important that factors such as sampling conditions, as well as degree of sample weathering, impact the chromatogram generated before a method is applied to this type of evidence.

For this research, a portable ion-trap GC/MS with an SPME sampling accessory was used to analyze ILs representative of a range of different classes of these compounds. The portable GC-MS system used weighs less than 15kg and is designed for use in the field. Sampling was performed using SPME. Ignitable liquids tested included lighter ILs such as gasoline and paint thinner, as well as heavier ILs such as diesel and kerosene. Testing was performed to determine the impact sampling time and degree of sampling weathering had upon the resulting chromatogram. This is critically important because an understanding of these effects is necessary if proper interpretation of GC/MS data is to be achieved.

Results revealed that the chromatograms recovered from an IL are dependent upon many factors, including degree of aging of the sample, the type of IL analyzed, and other sampling conditions. A summary of the data will be presented so an understanding of how these factors impact the data may be understood. A discussion of the analytical advantages and disadvantages to the method will also be included. Attendees will understand the variability they should expect to see in the data should this method be applied in the field to samples collected during a fire scene investigation.

B147 The Utilization of Controlled Odor Mimic Devices to Improve Law Enforcement Canine Training

Alice Breia Boone, BSc, Florida International University, 11200 SW 8th Street, Miami, FL 33199; Alison Simon, BS*, 11200 SW 8th Street, CP304, Miami, FL 33199; Vanquilla L. Shellman, BS*, 2071 Renaissance Boulevard, Apt 207, Miami, FL 33025; Lauryn Degreeff-Silk, PhD, Office of Naval Research, 875 N Randolph Street, Arlington, VA 2217; Kimberly Peranich, BS, Office of Naval Research, 875 N Randolph Street, Arlington, VA 2217; Howard Holness, MBA, 11200 SW 8th Street, CP330, Miami, FL 33199; and Kenneth G. Furton, PhD, Florida International University, International Forensic Research Institute, University Park, Miami, FL 33199*

After attending this presentation, attendees will understand the advantages and shortcomings of odor detection canine training, why the canine's generalization-discrimination balance must be enhanced, and how odor recognition validation tests are conducted during canine trials.

This presentation will impact the forensic science community by demonstrating the canine's ability to become proficient in discriminating between target odors vs. similar odors and detecting mixtures of odorants. This will minimize both false positives and false negatives.

Canines are well known for their ability to detect and distinguish between large varieties of odors. Despite their discriminating power, previous studies have revealed some canine's deficiencies in proficiently detecting mixtures and generalizing molecularly similar compounds with varying vapor pressures and volatilities. In collaboration with the Naval Research Laboratory (NRL) and Naval Surface Warfare Center (NSWC), Florida International University (FIU) explored the capability of improving canine performance in detecting these odors using an odor delivery device. Field trials were then designed in order to demonstrate that the canines are capable of being trained to effectively discriminate between similar compounds.

In order to accomplish these tasks, it was necessary to first be able to deliver the target odors to canines. Known odor concentrations were released by utilizing Controlled Odor Mimic Permeation Systems (COMPS), a patent-pending device developed by FIU scientists. Utilizing COMPS ensured consistent and measurable delivery of a wide variety of target odor compounds, allowing for reduction in detection bias that may otherwise result from differences in odor vapor pressure and volatility that are characteristic of various odor compounds. The concentrations of the target odors were measured using gravimetric and headspace analysis. A variety of polymer bag densities and pore sizes were used to control dissipation rates of these compounds in the COMPS devices. The effect of exposure to temperatures and humidity on COMPS was also examined and the data gathered was utilized to build a variety of COMPS devices that were then used during canine training.

By combining COMPS with traditional canine field trials such as double-blind Odor Recognition Tests (ORTs), canines were able to be graded on their ability to recognize and distinguish between molecularly similar compounds in a controlled setting. The positive and negative canine alerts were statistically compared using the Positive Predictive Value (PPV). The results of using these COMPS will be discussed, as well as their ability to provide in-depth training of law enforcement canines to an ever-wider variety of compounds.

Advances in the use of odor detection canines are necessary for the enhancement of this field's scientific validity. The versatility, reproducibility, and low cost of this technology have the potential to revolutionize canine training and minimize its deficiencies. In conclusion, results from this study validate that utilizing COMPS is a safe and effective training tool for law enforcement canines.

Canine Training, COMPS, PPV

B148 An Investigation of Factors Affecting the Formation of 3D Fabric Imprint Patterns in Automotive Finishes

Rachel E. Downey, Penn State University, 329 Whitmore Laboratory, University Park, PA 16802; Zoltan Rado, PhD, Penn State University, 201 Transportation Research Building, University Park, PA 16802; Ralph R. Ristenbatt III, MS, Penn State University, Forensic Science Program, 107 Whitmore Laboratory, University Park, PA 16802; Wayne Moorehead, MS, 329 Whitmore Laboratory, University Park, PA 16802; and Ted R. Schwartz, MS, Westchester County, Forensic Lab, 10 Dana Road, Valhalla, NY 10595*

After attending this presentation, attendees will better understand the variables involved in the formation and quality of fabric imprint patterns in automotive finishes during vehicle-pedestrian impacts.

This presentation will impact the forensic science community by providing the means to establish an alternate evidentiary link between a vehicle and pedestrian in the absence of or in conjunction with tissue or paint transfer. This evidence may also provide additional information for the purpose of reconstructing vehicle-pedestrian impacts.

In vehicle-pedestrian impacts with sufficient force, imprint patterns from clothing fabric may be formed on vehicle bumpers and in automotive finishes. Even at low speeds, hit-and-run vehicle-pedestrian impacts are far too common.[1-4] A crime laboratory's focus in the event of a hit-and-run is currently on the individualization of paint left behind by the vehicle, either on the pedestrian or in the surrounding area.[5-6] In the absence of paint evidence, or of hair and tissue on the vehicle, it is often difficult to prove an evidentiary link between the vehicle and the victim.

The goal of this study is the elucidation of pattern production mechanics — type of fabric, surface coating, angle of impact, and impact force of the vehicle—and the eventual individualization of imprint patterns to specific fabrics. Rather than crashing full-sized vehicles, this preliminary study currently utilizes a standard six-foot pendulum. A dome-shaped weld cap is mounted to the front of the pendulum arm and covered with a layer of foam, then the fabric of choice, simulating a human kneecap. The pendulum impacts a section of either a door or fender, cut to an approximate 23cm x 23cm square and mounted in a custom-built frame using C-clamps. To vary the impact force, the pendulum arm is raised or lowered by five-inch increments.

In keeping both surface coating and fabric type consistent, and performing impacts normal to the car surfaces, preliminary results do show the consistent, repeatable formation of fabric imprint patterns, provided a narrow range of pendulum heights is reached or exceeded. Precise impact force can be calculated through the analysis of high-speed video, which is currently being assembled and optimized and will be utilized in further tests repeating the above procedure. This will allow for the determination of impact force and the study of pattern variability with changing fabric type, surface coating, or angle of impact.

Initial examinations of imprint patterns have been performed with Digital Single-Lens Reflex (DSLR) photography and optical microscopy with oblique lighting. In the future, micro-level terrain mapping may be able to provide individualizing characteristics. As little research in this area has been published, this study will be supported by a survey of industry professionals. This survey is currently undergoing Institutional Review Board (IRB) evaluation prior to distribution.

Once these variables — impact force, fabric type, surface coating, and angle of impact — are fully examined on a small scale, a continuation of this study will seek to analyze a more true-to-life impact, using mannequins, an 80-foot pendulum, and full-sized vehicles.

Forensic Science, Fabric Impressions, Hit and Run

B149 The Characterization and Rapid Detection of Synthetic Cannabimimetic Materials Using Ion Mobility Spectrometry (IMS) for In-Field Forensic Investigations

Jasmine M. Drake, PhD, Texas Southern University, 3100 Cleburne Drive, Houston, TX 77004; CaSandra Cantue, Texas Southern University, 3100 Cleburne Drive, Houston, TX 77004; Dominique Giger, Texas Southern University, 3100 Cleburne Drive, Houston, TX 77004; Shastazia S. White, BS, 304 McNary Street, Pittsburg, TX 75686; Jessica L. Gutierrez, MS, 11660 Huebner Road, Apt 1608, San Antonio, TX 78230; and Jazmyne McKenzie, MS, 11502 Moonmist Drive, Houston, TX 77072*

After attending this presentation, attendees will be able to evaluate the efficiency of a rapid and portable technique, IMS, for the identification of individual compounds and mixtures of Synthetic Cannabinoids (SCBs) for use in forensic field investigations.

This presentation will impact the forensic science community by providing detection parameters necessary to create and program a spectral library of SCBs into a commercially available IMS. As a result, this research may facilitate law enforcement's efforts to analyze suspected SCBs in the field and reduce the backlog of screening examinations of drug submissions in the laboratory.

The abuse of synthetic cannabimimetic or SCBs, which mimic the psychoactive effects of Δ^9-Tetrahydrocannabinol (THC) found in marijuana, has increased since their initial discovery. The marijuana-like effects of these designer drugs and marketing as "legal highs" have influenced their rising popularity in recent years. Although legislation has been passed to outlaw the manufacture, distribution, and use of a large number of SCBs, law enforcement officials are constantly challenged with the daunting task of rapidly detecting new chemical modifications of SCBs used by manufacturers to circumnavigate local and federal legislation. Routinely used screening methods for SCBs, such as color tests and microcrystalline tests, have been shown to be subjective and possibly lead to false positives. Although confirmatory identification of these SCBs has been successful using laboratory confined instrumentation, such as Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Mass Spectrometry (LC/MS), to date, there are no reliable and rapid analytical techniques available for detection and characterization of SCBs to support law enforcement efforts in the field. The concerning lack of objective analyses for SCBs may be addressed by investigating the reliability of IMS, which is an analytical tool that is sensitive to trace amounts of compounds.

In this study, the detection parameters (i.e., drift times (ms) and reduced mobility (K_o) values) of 21 widely abused SCBs were determined using IMS, and sensitivity, reproducibility, and selectivity of the instrument were evaluated.

This study will increase knowledge of the structures and detection methods for an ever-evolving class of materials (SCBs), which have greatly challenged forensic practitioners and law enforcement officials in clandestine field operations. The development of new rapid and portable analytical methodologies will assist with the identification of suspected SCBs for criminal justice purposes.

Twenty-one target compounds, which are widely abused and represent a variety of SCBs from different sub-classes with varying structures, have been analyzed. Samples included 21 commercially available certified reference SCBs at various concentrations (0.1mg/mL-1.0mg/mL). A certified THC standard was used as a positive narcotic control. Positive and negative verification standards were also used as positive instrumental controls. Detection parameters of the test samples were obtained using a Smiths Detection IONSCAN 400B IMS with an atmospheric pressure chemical radioactive 63Ni ionization source in positive (narcotics) mode. Each sample was analyzed in triplicate using approximately 2µL-5µL of the chemical standard solutions. Confirmatory analysis of test samples was performed using GC/MS. To determine variation of instrument detection, time studies were also conducted. The IMS detection parameters (ms and K_o) for each SCB were recorded and evaluated for reproducibility using statistical software.

Presumptive testing using IMS, limit of detection studies, and mixture analysis was conducted on selected SCBs to determine the efficacy of IMS as a quick and reliable technique for in-field use for law enforcement. Using IMS, all 21 SCBs were detected, and selected SCBs could be observed in trace concentrations as small as 0.09µg/mL. Analysis of mixtures containing multiple SCBs revealed that at least one compound can accurately be

identified when compared to a standard. Limit of detection experiments were also performed on six selected SCBs.

In this study, 21 SCBs were analyzed using IMS and were shown to exhibit high reproducibility and stability over the course of three years with similar K_o values as provided by the United Nations Office on Drugs and Crime (UNODC). Due to the similarities in the detection parameters obtained in this study and those reported for the selected SCBs in the literature, IMS (positive mode) is a suggested tool for the presumptive identification of SCBs in forensic field investigations.

Synthetic Cannabimimetics, Ion Mobility Spectrometry, In-Field

B150 The Identification of Synthetic Cathinones Commonly Found in Designer Drugs Utilizing Liquid Chromatography/Electron Spray Ionization/Quadrupole Time-of-Flight/Mass Spectrometry (LC/ESI/q-TOF/MS) and Direct Analysis in Real-Time-Mass Spectrometry (DART®-MS)

Kiana F. Nurideen, BS, Drug Enforcement Administration, 99 Tenth Avenue, New York, NY 10011*

LC/ESI/q-TOF/MS and DART®-MS methods were developed for the identification and confirmation of several commonly encountered synthetic cathinones. The goal of this presentation is to demonstrate two fast, efficient techniques for the identification of these emerging compounds.

This presentation will impact the forensic science community by demonstrating how effective both the LC/ESI/q-TOF/MS and DART®-MS methods are when identifying and confirming the presence of synthetic cathinone derivatives.

Analytical techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), Gas Chromatography/Flame Ionization Detector (GC/FID), Fourier Transform Infrared (FTIR), and Liquid Chromatography/Mass Spectrometry (LC/MS) are routinely employed at crime laboratories to identify the components found in designer drugs. Due to the structural similarities, many synthetic cathinones have similar Electron Ionization (EI) fragmentation patterns and retention times. The use of additional analytical techniques will assist in the positive identification of these compounds. The purpose of this study was to develop two independent qualitative methods for the identification and confirmation for several synthetic cathinones utilizing LC/ESI/q-TOF/MS and DART®-MS techniques.

The use of LC/ESI/q-TOF/MS for the confirmation of synthetic drugs has gained popularity over the past few years. It has been widely used for the identification of unknowns and targeted searches for compounds in complex matrices. This analytical technique has an advantage over traditional methodologies as it can deliver accurate mass and provide highly specific mass-to-charge spectral data with accuracies in the milli-Dalton (mDa) range.

DART®-MS is a rapid and efficient analytical technique that requires no sample preparation. The sample is directly introduced into the ion source utilizing a capillary glass tube and is desorbed from the sample surface by the flow of heated nitrogen while being ionized. DART®-MS coupled with High Resolution Accurate Mass Spectrometer (HRAMS) can produce rapid results with accurate mass determinations and very specific mass-to-charge spectral data.

Methylone, ethylone, butylone, pentylone, dimethylone, and dibutylone were the cathinones chosen for this study. In addition, several 3,4-methylenedioxyphenethylamines, such as 3,4-MDMA, 3,4-MDEA, 3,4-MDDMA (3,4-methylenedioxydimethylamphetamine), and 3,4-MBDB (3,4-methylenedioxy-phenyl-2-methylbutanamine), were analyzed for comparison. All analytes were prepared at a concentration of 10ng/µl in LC/MS grade methanol for both methods.

An Ultra High-Performance Liquid Chromatography (UHPLC) equipped with a binary pump and degasser interfaced with Agilent's® 6520 Q-TOF MSD was used. A 6.5-minute method employed an ESI source operating in positive mode with fragmentor voltage 150V; skimmer voltage 65V; octopole 1RF voltage at 750V; and Collision-Induced Dissociation (CID) analysis performed at 15V.

A 24-second method was developed applying DART®-MS in positive mode using Source-Induced Dissociation (SID) generated at 1V, 30V, and 60V utilizing a Simplified Voltage and Pressure (SVP) ion source with Thermo Fisher's Exactive™ Plus Mass Spectrometer Data acquisition.

Both methods have demonstrated successful identification, ion separation, and excellent mass accuracy for the ten compounds studied.

LC/ESI/q-TOF showed peak separation and mass spectral data with distinguishable fragmentation patterns for all compounds analyzed. In addition, this study demonstrated that isobaric compounds can be identified using LC/ESI/q-TOF/MS by both retention time and CID experiments.

DART®-MS coupled with SID experiments demonstrated ion separation and mass spectral data with distinguishable fragmentation patterns for most of the compounds when analyzed independently. The analysis of the ten component mixture posed a challenge due to the structural similarities and the combination of a significant

number of fragment ions. Many other product ion peaks overlapped and could not be attributed to a single cathinone in the mixture.

Both methods are very beneficial to the forensic community and each analytical technique has the potential to dramatically streamline sample analysis, minimize the number of sample preparation steps, and enable rapid characterization of emerging structural analogs.

DART®-MS, LC/ESI/q-TOF/MS, Synthetic Cathinones

B151 The Development of a Unified Gas Chromatography/Mass Spectrometry/Flame Ionization Detector (GC/MS/FID) Method to Determine Various Classes of Synthetic Drugs Using Retention Indices

Sarah Howshall, BSc, 601 Vairo Boulevard, Apt 822, State College, PA 16803; William Campbell, PhD, 107 Whitmore Lab, State College, PA ; Jenifer Smith, PhD, Dept of Forensic Sciences, 401 E Street, Washington, DC 20024; and Frank Dorman, PhD, 107 Whitmore Labs, University Park, PA 16802*

After attending this presentation, attendees will understand the method used to separate, identify, and quantify different classes of synthetic drugs using GC/MS/FID. The benefits of identifying these drugs using a library of retention indices rather than simply relying on a mass spectral library will be demonstrated. This retention index library can then be used by the forensic science community to identify synthetic drugs in street samples.

This presentation will impact the forensic science community by providing a more systematic and efficient method for the identification and quantification of various classes of synthetic drugs, which will allow for faster scheduling of these drugs and will allow crime laboratories to stay up-to-date on this growing problem.

The purpose of this research was to develop a single method using GC/MS/FID that would allow various classes of synthetic drugs, including synthetic cannabinoids, synthetic cathinones, piperazines, 2Cs, synthetic opiates, and benzodiazepines to be identified and quantified. This is important due to the growing abuse of emerging synthetic drugs in this country as an alternative to more historic illegal forms. To prevent this abuse, many states have passed laws banning these drugs, and the Drug Enforcement Agency (DEA) has begun scheduling and/or temporarily scheduling these drugs; however, as soon as one synthetic drug is scheduled, its structure is modified so that the new compound does not fall under DEA regulations. Due to the growing number of synthetic drugs being produced and the lack of research being conducted, crime and clinical laboratories are having difficulty identifying and analyzing these drugs efficiently. Therefore, developing a single analytical method to identify and quantify different classes of synthetic drugs using common instrumentation is needed so crime laboratories can analyze these drugs quickly and increase their productivity.

GC/MS was used to identify the synthetic drugs and a library of retention indices was created from reference standards as a better form of identification rather than relying on mass spectral libraries alone. GC/FID was used to quantify the drugs due to the documented reactivity of some of the synthetic drugs when using MS.[1] To separate these drugs, an Rtx-5 Amine column along with a base-deactivated split inlet liner with base-deactivated wool was used as it demonstrated the best inertness for this wide range of compounds. The method successfully separated six classes of synthetic drugs and was used to identify and quantify synthetic drugs in street samples; however, it was determined that derivatization of the 2Cs was needed for optimal separation performance due to the reactivity of the compounds. To date, only two of the synthetic cathinones posed a problem of co-elution, and thus could only be semi-quantified. For determination of the retention indices of the drug compounds, the Massachusetts (MA) Extractable Petroleum Hydrocarbon (EPH) Aliphatic Hydrocarbon Standard mix was used. Method precision (as percent of Relative Standard Deviation (%RSD)) was relatively low for all the compounds, with the synthetic cannabinoids showing the best precision and the synthetic cathinone, methylone, showing the poorest. Retention indices were calculated for all compounds, but extracted ion chromatograms were needed to calculate 2C-N's retention index.

With this method, six classes of synthetic compounds and street samples were able to be separated, identified using retention indices, and quantified. Utilizing retention indices has been demonstrated to be a clearly better method for identification than reliance on mass spectral data alone, especially for compounds that are isomers and have similar mass spectra. This is because retention indices are more specific to the target compound than retention times and mass spectra. The retention index library can then be expanded to include more synthetic drugs, and additions will need to be made as new synthetic drugs are uncovered in recreational use. This will provide a more systematic and efficient method for the identification and quantification of synthetic drugs, allowing for faster scheduling of these drugs and allowing crime laboratories to keep up with this growing problem. Also, once these compounds are identified, more toxicological research can be conducted on the drug effects at certain doses.

Synthetic Drugs, Retention Indices, Gas Chromatography

B152 The Analysis of the Fatty Acid Content of Fingerprint Residues Using Gas Chromatography/Mass Spectrometry (GC/MS)

Ashley Cochran, BS, West Virginia University, 208 Oglebay Hall, Morgantown, WV 26505; and Glen P. Jackson, PhD, West Virginia University, Dept of Forensic and Investigative Science, 208 Oglebay Hall, Morgantown, WV 26506-6121*

After attending this presentation, attendees will understand the within-person chemical variability of fingerprint residues of individuals.

This presentation will impact the forensic science community by providing attendees with an additional means of latent print analysis through the determination of the chemical composition of fingerprint residues. Often, smudged fingerprints deposited at crime scenes are of little value to latent print examiners because smudged prints lack minutiae that are necessary for comparisons. In cases in which DNA or fingerprint minutiae in the fingerprints are not able to identify a suspect or victim, the chemical composition of fingerprint residues could provide a useful investigative lead, if the residues enable the classification of individuals into groups according to biometric traits. For this approach to be possible, one must first establish that the chemicals found on a person's fingers are endogenous and not exogenous, then determine that the within-person variance is smaller than the between-person variance.

One of the recurring issues in forensic science is human subjectivity, especially within the field of fingerprint examination. Smudged fingerprints at crime scenes that contain little to no detail often cause problems to examiners who, in turn, are unable to make an identification or exclusion. Touch DNA is one solution to this problem, but mixed DNA and stochastic dropout are major barriers to interpretation. In recent years, researchers have begun to explore the chemical composition of fingerprint residues to provide an alternative means for including or excluding potential donors.

Research into the chemical composition of fingerprints has shown that it may be possible to determine sex, age, and race from residues that are left behind when a fingerprint is deposited on a surface; however, some issues have been encountered. Lipids, one of the major components of these residues, are also found in personal care products, such as moisturizers and cosmetics. It has been difficult for researchers to distinguish fingerprint residues deposited by an individual from the residues left behind by these products. The purpose of this study is to determine the variability of fingerprint residues within an individual over the course of several months, and to assess the relative proportion of endogenous and exogenous sources of lipids.

This study involved the collection of fingerprint residues of six individuals (three males and three females) over the course of three months. Natural, eccrine, and sebaceous secretions were collected from each participant multiple times per week. Saponification and derivatization were performed on each sample to convert the various types of lipids/glycerides to Fatty Acid Methyl Esters (FAMES). Analysis was performed using a standard GC/MS system with an HP5 column. Data analysis consisted of the identification of peaks and extraction of peak areas. One-way Analysis of Variance (ANOVA) was used to assess within-group variance to between-group variance at a 95% confidence interval to determine the variability of fingerprint residues deposited by individuals over a period of time. Results showed that within-person variability is smaller than between-person variability.

Fingerprint, GC/MS, Fatty Acid

B153 An Elemental Characterization of Firearms Discharge Residue Using Complexing Agents and Triple Quadrupole Mass Spectrometry (QQQ MS)

William Feeney, BS, 801 Second Street, New Martinsville, WV 26155; Sydney Brooks, BS, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899-8102; Brittany Yeager, BS, 277 Carr Avenue, Clarksburg, WV 26301; and Suzanne Bell, PhD, West Virginia University, Oglebay Hall, Rm 208, 1600 University Avenue, Morgantown, WV 26506-6121*

After attending this presentation, attendees will better understand a new analytical approach to detecting metal cations from firearms discharge residue using an instrument found in many forensic toxicology laboratories

This presentation will impact the forensic science community by offering attendees a new method to screen for and identify elements associated with Gunshot Residue (GSR).

Several methods have been published reporting on the analysis of organics found in Firearms Discharge Residue (FDR) using Liquid Chromatography/Mass Spectrometry (LC/MS). The mass spectrometers used include Time-Of-Flight (TOF), quadrupole Time-Of-Flight (qTOF), and Triple quadrupole (QqQ) designs. For LC/MS analysis, a substrate such as a hand swab is typically extracted, concentrated, and introduced into the chromatographic system and analytes such as Diphenylamine (DPA), ethyl and methyl centralites, dinitrotoluenes, and other diphenylamines are detected. This capability has the potential to increase the utility of FDR analysis in that current methods using Scanning Electron Microscopy/Energy-Dispersive X-Ray Spectroscopy (SEM/EDS) target the inorganic particulate residues from the primer. Even better would be a procedure that allows for detection of the inorganic and organic constituents of FDR from a single sample. The goal of this project was to demonstrate a novel method of detecting the key elemental constituents of FDR using complexing agents and direct infusion sample introduction using a QqQ instrument. This successful demonstration opens the doors to further development of method in which the organic and inorganic constituents of FDR can be characterized from a single sample.

Crown ethers are macrocyclic complexing agents that bind with +1 and +2 cations. For this project, 15:5 crown ether was chosen because its cavity size is amenable for binding known GSR metals (Pb, Ba, Sb, Cu). These crown ether metal complexes were created independently in methanolic solution and were analyzed using Electrospray Ionization (ESI) -QqQ via direct infusion, positive mode. The parent ions in all cases were in the form of M-L-NO3 (cation-ligand (15-crown-5)) and nitrate ion. Detection limits were established (ppm range in solution corresponding to ~ µg total solid) and Multiple Reaction Monitoring (MRM) transitions optimized such that the parent ion yielded the corresponded element as the transition product. This allows for detection of isotopes of the elements that occur at a natural abundance of ~ 5% or more via M-L-NO3 à M. For example, the metal complexes in which ^{208}Pb, ^{207}Pb, ^{206}Pb, and ^{204}Pb were all observed with MRM analysis, detecting all but ^{204}Pb, which has a natural abundance of <5%. Semi-quantitative results were obtained using an internal cesium spike. This element is monoisotopic and not expected to be detected in typical GSR samples. Antimony (Sb) proved to be the most challenging to detect, either due to low concentrations in sampled residues, poor initial dissolution, poor binding efficiency, or some combination of factors. This presentation will detail experimental methods, figures of merit, and the results from authentic shooting sampling events in which lead, barium, and copper were easily and routinely detected.

Firearms Discharge Residue, Complexing Reagents, Mass Spectrometry

B154 The Analysis of Gunshot Residue and Plastic Deposits From 3D Printed Polymer Firearms

Carol Crowe, BS, Colorado Bureau of Investigation, 6000 W 54th Avenue, Arvada, CO 80002; Alex Rugh, MS*, Colorado Bureau of Investigation, 6000 W 54th Avenue, Arvada, CO 80002; and Lisa Casey Yoshida, BS, 690 Kipling Street, Ste 2400, Denver, CO 80215*

After attending this presentation, attendees will better understand the residues that result from the discharge of an Acrylonitrile Butadiene Styrene (ABS) polymer firearm.

This presentation will impact the forensic science community by providing information that may be applied to casework in determining indications of polymer firearm use in crimes.

In recent years, there has been a significant increase in the availability of 3D polymer printers for use by individuals. These personal 3D printers are relatively sophisticated, while their affordability and ease of use make them ideal for home hobbyists. At the same time, designs and instructions for producing firearms by 3D printer are readily accessible on the internet. The production of these types of guns raises many concerns to law enforcement and has an unknown impact on the forensic science laboratory analysis of evidence collected during the investigation of shooting events.

Samples were collected during the discharge of five different 3D printed polymer firearms including both .22 Long Rifle (LR) and .380 Automatic Colt® Pistol (ACP) calibers. Scanning electron microscope stubs with carbon impregnated adhesive tabs were secured near the guns during discharge. Samples were analyzed for primer Gunshot Residue (pGSR) using a Scanning Electron Microscope with Energy Dispersive Spectrometer (SEM/EDS) and automated GSR analysis software. The instrument was operated using parameters typically used in casework at the Colorado Bureau of Investigation Forensic Services Laboratory. Each sample analyzed was positive for the presence of particles characteristic of Gunshot Residue (particles with lead, barium, and antimony combined in discreet particles with distinctive morphologies of pGSR). The number of characteristic GSR particles detected varied among the guns. This study attempted to determine if residues originating from a polymer gun have distinctive features that differ from the typical pGSR particles that are recognizable by the SEM/EDS automated particle analysis technique. Some of the detected pGSR particles have unusual shapes. This indicates a fusion of residues containing both polymer and typical primer components.

ABS plastic residues were present in samples, both on the SEM stubs and in the residues collected from the muzzle discharges. The detection of ABS residues presents analytical challenges for routine forensic polymer analysis. Infrared (IR) microspectroscopy was employed to characterize the polymer residues.

This presentation will report the results of the analysis of samples collected from the discharge of 3D printed polymer guns.

Gunshot Residue, 3D Printed Firearm, Polymer

B155 A Study on the Persistence of Gunshot Primer Residue on Clothing Subjected to Handling

Christopher P. Chany, MS, Texas Department of Public Safety, Austin HQ Crime Laboratory, Trace Section, 5800 Guadalupe Street, Bldg U, Austin, TX 78752; Thomas R. White, BS, Texas Dept of Public Safety, Austin Crime Lab, 5800 Guadalupe Street, Austin, TX 78752; Sandy Parent, BS, PO Box 4143 - MSC 0460, Austin, TX 78765; Juan A. Rojas, BS, Texas Dept of Public Safety, Austin Crime Lab, 5800 Guadalupe Street, Austin, TX 78752; and Lyndsi DeLaRosa, MS, Texas Dept of Public Safety, Austin Crime Lab, 5800 Guadalupe Street, Austin, TX 78752*

After attending this presentation, attendees will better understand the persistence of gunshot primer residue on clothing.

This presentation will impact the forensic science community by providing attendees with an insight into the dynamics of gunshot primer residue particle transfer on clothing. This presentation describes the methods used to artificially create the transfer of gunshot primer residue from one item of clothing to another and provides the results of this study.

Gunshot primer residue is produced by a firearm when it is discharged. The primer for centerfire cartridges is composed of lead styphnate, barium nitrate, and antimony sulfide. The residue from the primer explosion escapes from openings in the gun and can be deposited on a person's hands and clothing. These particles can be collected and analyzed using automated scanning electron microscopy energy dispersive X-ray. Characteristic gunshot residue primer particles have a molten appearance and are composed of barium, antimony, and lead. During a crime scene investigation, evidence technicians may package an item of clothing that has gunshot primer residue on it in the same evidence container as other items of clothing from the crime scene. While studies have been conducted as to how long gunshot primer residue persists on a living person's hand, studies have not been conducted about how long it will persist on clothing that is subjected to handling, such as packaging as evidence. Additionally, it has also not been determined whether gunshot primer residue easily transfers from one item of clothing to another item of clothing with which it may come into contact.

This presentation will detail the results of a study using a controlled mechanism for the transfer of gunshot primer residue from one item of clothing to another.

Gunshot primer residue was placed on clean cloth swatches of different types of clothing materials to create positive gunshot primer residue samples. Clean cloth swatches were then packaged with the positive gunshot primer residue cloth swatches in the same manner that samples are received in the laboratory. The cloth swatches were then subjected to different types of handling to mimic real-life conditions. The surfaces of the clean cloth swatches were then sampled using standard gunshot primer residue collection stubs. Those stubs were analyzed using scanning electron microscopy energy dispersing X-ray spectroscopy instrumentation using standard laboratory procedures for the analysis of gunshot primer residue.

This research takes a novel approach by investigating the likelihood of gunshot primer residue transfer between articles of clothing.

Gunshot Residue, Evidence, Scanning Electron Microscopy

B156 Clearing a Firearms Backlog Using Process Management and Available Resources

WITHDRAWN

B157 Microscopical and Ultrastructural Investigation Into Possible Chemical and/or Mechanical Degradation Mechanisms of Hair Roots Containing Induced Postmortem Root Band (PMRB) -Like Features

Barbara L. Fallon, MS, FBI/ORISE, 2501 Investigation Parkway, Quantico, VA 22135; Jack Hietpas, PhD, Penn State University, 329 Whitmore Lab, University Park, PA 16802; Joseph Donfack, PhD, 2501 Investigation Parkway, Quantico, VA 22135; and JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand the ability of various ionic and pH-specific buffers to elicit PMRB-like ultrastructural features in antemortem hairs as observed by light and scanning electron microscopy.

This presentation will impact the forensic science community by presenting possible mechanisms of hair root degradation for the formation of PMRBs with the goal of ultimately better understanding the complex processes that result in true PMRB formation *in situ*.

A PMRB is a microscopic feature that results from degradation of the pre-keratinized region of the roots of anagen and early catagen hairs obtained from cadavers.[1,2] A PMRB is located *in situ* approximately 0.5mm from the root tip and is surrounded by root sheath issue. A PMRB forms due to degradation to the Intermacrofibrillar Matrix (IMM) (or cell membrane structures) in the cortex, resulting in elongated, gas-filled void spaces. Scanning Electron Microscope (SEM) analysis has shown that the degradation is confined to the cortex and does not extend to the hair cuticle.[3] The morphology of the IMM degradation is highly complex; in some instances, the elongated void spaces are lined with jagged "saw-teeth" that are interpreted to be remnant IMM.[3] These structures may be due to chemical degradation or perhaps represent "pull apart" structures resulting from the build-up of decomposition gas. Resolution of this premise may provide valuable insight into the mechanism of PMRB formation.

Prior work has shown that exposing human scalp hairs to slightly alkaline (pH 7-8) aqueous ammonium salt solutions results in degradation that is microscopically similar to that observed in known PMRBs.[4] In addition, similar PMRB-like decomposition could also be achieved by immersing antemortem anagen head hair in various pH-specific (pH 6-8) aqueous buffers. The mechanism and manner for this decomposition is not known.

One hypothesized mechanism for *in vitro* band formation is the presence of the ammonium ions or ammonia gas that may chemically attack the IMM. Another hypothesis is that the change in hair pH, due to immersion in various buffers, may lead to IMM degradation/ collapse. Alternatively, decomposition gases may build up and subsequently become trapped inside the cortex, thus mechanically disrupting the integrity of the pre-keratinized region of the root. This process is hypothesized to be possible due to the presence of the root sheath or cuticle trapping the gas, preventing it from escaping from the hair into the surrounding tissue.

This work investigates whether the damage to the IMM is of chemical or mechanical origin and if the presence of the root sheath plays a role in the formation of PMRBs. To address this question, antemortem anagen hairs were obtained from living human donors. Hairs with root sheaths were included to better mimic *in situ* hair follicle conditions; hairs without root sheaths were included to investigate whether the root sheath is necessary for the development of PMRB-type degradation. Hairs were either left intact (controls) or embedded and sectioned by ultramicrotome. Hairs were then incubated in the following test solutions: 100mM ammonium acetate (pH 7.8); a proportional mixture of sodium phosphate solutions (pH 7.8); or ultra-pure water. After three to ten days, the hairs were examined via light and electron microscopy.

Preliminary data suggest intact hairs with and without root sheaths exposed to the ammonium acetate and pH 7.8 solutions developed dark PMRB-like degradation similar in appearance to true PMRBs; these results agree with prior work.[4] The hair samples immersed in ultra-pure water did not produce PMRB-like degradation. Next, in an attempt to investigate the potential effects of containment on the occurrence of IMM degradation, thin-sections of hair were immersed in the same solutions. If gas were produced while immersed in the various buffers it would not be able to build up in the hair shaft. These sections were compared to similarly prepared healthy anagen head hairs. Preliminary data suggest that the untreated and water-exposed head hairs exhibit little degradation to the cortex of the pre-keratinized region; however, hair sections immersed in ammonium acetate solutions, both with and without root sheath, do exhibit significant ellipsoidal voids similar to features seen in known PMRBs in the

pre-keratinized region. Sectioned hairs exposed to the pH-matched buffer exhibit some voids, but these are less prominent than those observed in hairs exposed to ammonium acetate solutions. Taken together, these results suggest that ammonium may play a role in the chemical attack of the IMM and that mechanical damage due to gas buildup is a less likely mechanism for PMRB formation.

Postmortem Hair Root Banding, Hair Microscopy, Trace Evidence

B158 Multivariate Classification Model Transfer of Ultraviolet (UV) /Visible Spectral Data From Acrylic Fibers Without Standards

Stephen L. Morgan, PhD, University of South Carolina, Dept of Chemistry & Biochemistry, 631 Sumter Street, Columbia, SC 29208; Nathan Fuenffinger, PhD, 4431 Chouteau Avenue, Apt 1107, St. Louis, MO 63110; John V. Goodpaster, PhD, FIS Program, IUPUI, 402 N Blackford Street, LD 326, Indianapolis, IN 46202; Edward G. Bartick, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; and Eric Jonathan Reichard, MS, 8519 Walden Trace Drive, Indianapolis, IN 46278*

The goal of this presentation is to illustrate the value of transfer of multivariate classification models for spectra of trace evidence fibers between laboratories. Such efforts could save time and resources in forensic analyses and contribute to an understanding of differences in spectra from multiple laboratories due to variations in sample preparation, environmental conditions, and instrumental signal response.

This presentation will impact the forensic science community by exploring the ability to transfer multivariate classification models between laboratories, which could save time and resources in forensic analyses. Successful sharing of such information between forensic laboratories may be valuable for confirming fiber identification and assessing the reliability of comparisons.

UV/visible microspectrophotometry is commonly employed for discriminating metameric fibers in forensic casework. Recent studies have demonstrated that multivariate classification techniques are an effective tool for characterizing such fibers. The ability to transfer multivariate classification models between laboratories could save time and resources in forensic analyses; however, issues transferring models of this type from one laboratory to another can arise as a result of differences in sample preparation, environmental conditions, and instrumental signal response. Spectra of 12 blue acrylic fibers were examined at five separate locations, including three academic research laboratories and two forensic laboratories. The data received from these facilities were analytically assessed in three manners. Multivariate classification models were initially constructed on each individual laboratory's dataset to evaluate intra-laboratory variability between samples. In a subset of the study, discriminant analysis was performed after merging all data collected in the study. Lastly, the transferability of classification models was assessed by predicting class membership of samples analyzed at a single laboratory using models built from the spectra collected at the four remaining locations.

Principal Component Analysis (PCA) followed by Linear Discriminant Analysis (LDA), Quadratic Discriminant Analysis (QDA), or Support Vector Machine Discriminant Analysis (SVMDA) was used to evaluate the agreement of results among the laboratories. An average classification accuracy of 93.2% was found after training discriminant analysis models using data collected at the four laboratories and using the information collected at the fifth laboratory as an external test set. For comparison, intra-laboratory studies that were conducted produced an average classification accuracy of 96.3%. The reduction in the discriminative abilities of the transferred models was likely due to the differences in spectral noise and peak intensities experienced between laboratories. On the whole, the errors generated by QDA were lower than those resulting from LDA and SVMDA. In conclusion, this inter-laboratory study confirms the ability to preprocess spectra to explore the agreement of spectral comparisons among forensic laboratories.

Inter-Laboratory Comparison, Classification Model Transfer, Inter-Laboratory Reliability

B159 Photobleaching in Cotton Fibers Dyed Using Red, Yellow, and Blue Direct Dyes During Examination With Microspectrophotometry (MSP)

Amanda Forster, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899; Sydney Brooks, BS, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899-8102; and Julie L. Bitter, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8371, Gaithersburg, MD 20852*

After attending this presentation, attendees will understand the susceptibility of cotton fibers to loss of color, or photobleaching, when being analyzed using MSP. Attendees will also understand how spectra obtained by performing Ultraviolet/Visible (UV/Vis) spectroscopy measurements on dye solutions compare to the spectra obtained from MSP of fibers dyed with the same dye.

This presentation will impact the forensic science community by increasing forensic examiners' awareness of the tendency of dyed cotton samples to undergo photobleaching while performing MSP analysis, which may affect procedures for examining dyed cotton fibers, and will also demonstrate the usefulness of MSP on fibers by comparing spectra of the dye solutions with the dyed fibers.

MSP is a promising technique for the analysis of trace evidence such as fibers and paint. Color can be a powerful tool for comparison of many types of trace evidence, but previously large samples or elaborate procedures were required for analysis of color in paint or fiber. This rapid, non-destructive technique combining microscopy and UV/Vis spectroscopy can eliminate the need for time-consuming extraction and analysis of dyes from textile fibers when performing analysis of colored fibers and can directly analyze color from multiple layers of paint, all while performing microscopic analysis of these materials.

This study will present an experiment in which bleached cotton fabric was dyed with direct dyes in blue, yellow, and red colors at different concentrations. The dyed cotton fibers were then examined using MSP. Photobleaching was investigated by measuring a specific spot on the fiber periodically over the course of one-half hour, which was considered the longest time a forensic examiner might ever leave a sample in the MSP. Visible color loss and a reduction in absorbance was observed for all three colors, but was most pronounced for the fibers dyed with red dye. Since forensic examiners expect MSP to be a non-destructive method, it is important to be aware of situations in which their selected analysis might unexpectedly be destructive. While some MSP vendors are educating examiners during training about the possibility of photobleaching of dyed cotton fibers, an informal poll of forensic trace evidence examiners indicated that this was not common knowledge among the trace evidence community. It is recommended that fiber trace evidence examiners become aware of the possibility of photobleaching when analyzing cotton fibers using MSP and that they understand how spectra collected using MSP from a fiber compare with UV/Vis analysis of dye solutions in the liquid state. After attending this presentation, attendees should better understand both concepts.

Microspectrophotometry, Fiber, Photobleaching

B160 Probing the Effects of Inherent Variability in Forensic Fiber Analysis

Julie L. Bitter, PhD, National Institute of Standards and Technology, 100 Bureau Drive, Mail Stop 8371, Gaithersburg, MD 20852; Amanda Forster, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899; and Sydney Brooks, BS, NIST, 100 Bureau Drive, MLStp 8102, Gaithersburg, MD 20899-8102*

After attending this presentation, attendees will better understand the various sources of variability inherent in forensic fiber analysis, which stem from both the sample itself and the methodology used.

This presentation will impact the forensic science community by increasing awareness of this variability and providing some suggestions as to how analysts might reduce this variability in their measurements. An eventual impact of this study will be the creation of a reference database that can be used by fiber examiners to compare their results and techniques to a standard set of known data.

In this experiment, a reference collection of synthetic fibers was used to investigate the effects of polymer type, starting diameter, shape, and compression on the resulting Fourier Transform Infrared (FTIR) spectra. Using a randomized experimental design, reference fibers were embedded in polyethylene and hand-sectioned to determine cross-sectional shapes and diameters via Scanning Electron Microscopy (SEM). A separate randomized experimental design was created to test two different known torques (5N·m and 7 N·m) to flatten these fibers in a diamond compression cell. A torque wrench with a 3D printed adapter was used to help standardize compression, and the resulting thickness of the fiber films was measured for uniformity with an optical profilometer. The starting versus ending thickness information was compiled and compared with the polymer material and shape to define any trends, note inconsistencies, and identify places for improvement. A similar action plan was taken to measure FTIR spectra before and after compression, and the spectral features were compared to see if any optimization in the process could be obtained.

SEM analysis verified that even along a single fiber there existed measurable variation in starting diameter, and the profilometer measurements showed that cross-sectional shape and different torque strengths influenced the fiber film thickness. Large relative standard deviations in the measurements resulted from different areas of the film being measured; for example, trilobal fibers, such as nylon, produced widely different thicknesses after compression, depending on the orientation of the fiber when it was placed in the diamond cell.

This study takes the first steps in understanding how differences in fiber type, fiber shape, and methodology affect the outcome of fiber analysis, with concerted effort placed on characterizing that variability. Primarily, this research seeks to raise awareness of the variability that accompanies the analysis process by evaluating and refining analytical techniques commonly used by forensic examiners. The end goal is to establish a database based on the Microtrace fiber reference collection of chemical spectra that combines microscopic measurements of fiber cross-section and diameter with FTIR spectra, and eventually add Microspectrophotometry (MSP) and Raman, where appropriate.

Fibers, Reference Database, Trace Analysis

B161 Applications of Infrared (IR) Imaging and Chemometrics to Facilitate the Forensic Examination of Automotive Paint

Barry Lavine, PhD, Department of Chemistry, 107 Physical Sciences, Stillwater, OK 74078; Nuwan Perera, PhD, Oklahoma State University, Dept of Chemistry, Stillwater, OK 74078; and Matthew D. Allen, Oklahoma State University, Dept of Chemistry, Stillwater, OK 74078*

WITHDRAWN

B162 Evaluating the Application of Micro X-Ray Fluorescence (XRF) and Micro Raman Spectroscopy to the Analysis of Duct Tapes: Intra-Roll and Inter-Product Correlations

Sergey Mamedov, PhD, 3880 Park Avenue, Edison, NJ 08820*

After attending this presentation, attendees will better understand XRF and Raman microscopy in applications in the analysis of duct tapes; this analysis is an important element in forensic identification of these materials.

This presentation will impact the forensic science community by serving as key aspect of duct tapes analyses and as an example of a practical application of XRF and Raman spectroscopy in duct tape identifications.

XRF and Raman spectroscopies are useful tools for identification substances and confirming their identity with little or no sample preparation. XRF provides information about elemental composition of the material, whereas Raman spectroscopy supplies molecular information. Both techniques are able to record not only spectra of small particles, but also hyper-spectral images, as well as collect average spectra over certain areas. Multivariate Analysis (MVA) can produce chemical distributions of elements and/or material classification based on Principal Component Analysis (PCA), Partial Least Square Discriminative Analysis (PLSDA), in particular, with association between elements that can aid in the identification of bonded phases. The analysis of micro XRF and Raman data of duct tapes can be used to identify the source of a duct tape or the vendor of the product.

XRF and Raman analytical microscopes were used in this study. XRF spectra of the materials were collected using 30keV acceleration voltage and with an X-ray spot size of 1.2mm. Two excitation wavelengths (532nm and 785nm) were used to collect Raman spectra.

The spectra of duct tapes from different sources were collected and analyzed by micro XRF and Raman spectroscopy. XRF analysis was performed in the range of 1.00keV-40.96keV. There are no spectral features in the energy range above 15keV; spectra were truncated and analysis was performed in spectral range of 1.00keV-15keV. Some tapes contain elements Ti, Ca, S, and Al in a fiber substrate, which may be used for duct tapes differentiation. Classification of duct tapes-based PCA of the spectra will be shown. Small pieces of glue from the tapes were collected and Raman spectra of this material were measured in the range of $100cm^{-1}$-$3,500cm^{-1}$. MVA was applied to these spectra to extract differences in connection with different source of the tapes. The data demonstrates that MVA allows differentiation of the samples, for example, duct tapes #1020 and #1110 or #1230. PCA of duct tapes exhibits significant separation between duct tapes of different vendors and brands. Raman spectra of the materials note many common features with some differences, which may originate from the filler. Data fusion technology was applied to the set of XRF and Raman data to create PCA and PLSDA models. Misclassification in PLSDA models was studied using randomly selected samples from available data. Results of standard and data-fused analysis are compared and discussed. In conclusion, this study provides methods that allow one to differentiate duct tapes based on spectra analysis of micro XRF and micro Raman data.

Duct Tape, XRF, Raman Spectroscopy

B163 Discrimination of Soil Organic Matter Via Nuclear Magnetic Resonance (NMR) Spectroscopy Combined With Interval Extended Canonical Variate Analysis (iECVA)

Victoria Hsieh, 140 W 69th Street, Apt 85B, New York, NY 10023; Nicholas D. Petraco, PhD, John Jay College of Criminal Justice, Dept of Science, 524 W 59th Street, New York, NY 10019-1007; and Elise Champeil, PhD, 7855 E Boulevard, Apt I, North Bergen, NJ 10040*

After attending this presentation, attendees will be able to apply the techniques presented. Attendees will be able to extract the organic matter from soil samples, prepare samples for NMR analysis, and understand how iECVA can be combined with NMR to pinpoint the exact location of a soil sample.

This presentation will impact the forensic science community by disseminating new methods for soil analysis. The new methods developed will provide both guidance to practitioners for soil sample collection and arguments to establish convincing corroborative evidence in court between a suspect and a crime scene, between a victim and a crime scene, or between a victim and a suspect when soil evidence is found.

A new method for the analysis of Soil Organic Matter (SOM) is described. Modern detection and identification methods for soil evidence at crime scenes suffer from some drawbacks. In particular, most techniques of identification are destructive and rely primarily on the inorganic fraction of soil. Forensic scientists have not given much consideration to the analysis of SOM. Forensic geoscientists also face the following problem: if a soil sample is found on a potential suspect, what is the probability that this soil sample comes from one particular area versus another? (i.e., is there a way to assess how common the observed points of similarity or difference between soils are?). Another issue is the small amount of published guidance regarding the small-scale spatial variability of the soil considered. Assessing this variability is important in determining where samples should be collected in order to adequately represent an area of forensic interest. In view of these current shortcomings, the work presented here seeks to: (1) identify the SOM at nine different locations in New York City by Nuclear Magnetic Resonance (NMR) spectroscopy; (2) combine iECVA with NMR to pinpoint the exact location of a soil sample; and, (3) produce a method (i.e., empirical base match probability estimate) to determine the probability of finding similar soil samples from a particular park in the wider environment.

Soil samples from New York City Central Park were collected in nine different locations. The organic matter of the soil samples was analyzed by liquid state ^{1}H NMR and solid state ^{13}C NMR using spectrometers JEOL 300 MHz instrument for liquid NMR experiments and AVIII 400 MHz instrument for solid NMR experiments. The iECVA was combined with NMR results using computers to discriminate the nine different locations of interest. The ability to correctly assign the origin of the soils was assessed. It is expected that the method developed in this presentation (i.e., NMR spectroscopy combined with iECVA) will produce superior results (i.e., better ability to correctly assign the origin of the soil sample) than the traditional techniques. Finally, statistical analyses (iECVA and Wilks' lambda statistic) were used to assess the degree of small spatial variability in the soil properties observed by NMR.

Soil, NMR, Statistics

B164 Using Solid-Phase Microextraction-Gas Chromatography/Mass Spectrometry (SPME-GC/MS) to Detect Volatile Compounds Remaining From the Storage of Dead Mice

Angelica D. Wilz, BS, Cedar Crest College, 100 College Drive, Allentown, PA 18104; and Thomas H. Pritchett, MS, 100 College Drive, Allentown, PA 18104*

After attending this presentation, attendees will understand the principles of how Volatile Organic Compounds (VOCs) from decomposition can be used as evidence and how the volatile profile is affected once the decomposed body is removed.

This presentation will impact the forensic science community by demonstrating that the VOCs released by decomposition can be collected, analyzed, and differentiated, allowing for detection of a decomposing body, even after removal. This is important as it can aid investigators in the discovery of the body or in determining that a body was present, but moved to a secondary crime scene.

One of the main objectives in forensic science is to analyze evidence so a linkage can be made. The linkage can be between a number of different elements, such as the victim(s), suspect(s) and crime scene(s). These linkages help law enforcement officers reconstruct the events that took place during a crime, which aids their investigation. One possibility is linking a body to a certain area based on the VOCs detected in the surrounding area (soil, air, etc.). Body odors are emitted from both living and decaying bodies. Each occur due to different taphonomic processes; therefore, the VOCs released from the body could be different. There are five stages of decomposition: (1) fresh; (2) bloated; (3) active decay; (4) advanced decay; and, (5) dry remains. The two main processes that are involved in the stages of decomposition are autolysis and putrefaction. As these processes occur, different VOCs are released from the body.

In this study, four mice were placed into four separate quart-sized arson cans. Three of the cans were used for data collection, while the fourth can was utilized for photographing the decomposition process. The headspace above the decaying mice was analyzed by utilizing three different SPME) fibers (one fiber per can): (1) Polydimethylsiloxane (PDMS); (2) Polydimethylsiloxane/Divinylbenzene (PDMS/DVB); and, (3) Polydimethylsiloxane/Divinylbenzene/Carboxen (PDMS/DVB/CAR). The VOCs collected using these fibers were analyzed and compared using a splitless method for GC/MS. Cleaning and storage conditions in addition to instrument parameters were assessed to determine the optimal procedure. This allows for a fast and simple sample collection methodology without any sample preparation prior to analysis. The run time for each sample was 25.67 minutes. A diluted standard mixture, of similar compounds to those observed in previous literature, was prepared and run using a split method to confirm that the method was working properly.

VOCs associated with decomposition stages of the mice were collected once a week for each can using a different fiber. The most abundant VOCs present within the first week of decomposition consisted of dimethyldisulfide, dimethyl trisulfide, dimethyl tetrasulfide, phenol, and indole for all three cans and all fibers. These results support previous studies that indicate sulfide compounds are among the first to be released during decomposition. By day 13 of decomposition, the PDMS fiber only detected five compounds (abundances of $2x10^5$ or greater). By day 16 of decomposition, the PDMS/DVB fiber detected more than ten compounds and the PDMS/DVB/CAR fiber detected more than 13 compounds (both with abundances of $2x10^6$ or greater). I n addition to the compounds listed above, additional compounds included: hydrocarbons, esters, amines, alcohols, ketones, and furans. Based on these results, the PDMS/DVB/CAR fiber was chosen as the optimal fiber. This fiber was then utilized to determine the VOC signature that remained after the mice were removed from the three cans.

Decomposition, Volatile Organic Compounds, SPME-GC/MS

B165 Black Box and White Box Forensic Examiner Evaluations — Understanding the Details

R. Austin Hicklin, MS, 3150 Fairview Park, Falls Church, VA 22042; Bradford Ulery, BA, 3150 Fairview Park Drive, S, Falls Church, VA 22042-4519; Maria A. Roberts*, 2501 Investigation Parkway, Quantico, VA 22135; and JoAnn Buscaglia, PhD*, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

The goal of this presentation is to assist attendees in understanding the issues involved in using the black box approach to assess the accuracy and reliability of forensic examiners.

This presentation will impact the forensic science community by describing an approach for assessing potential areas of strength and weakness in forensic science, as well as by offering several objective measures to support admissibility requirements.

Recently, there has been a great deal of interest in using "black box and "white box" techniques to evaluate decisions made in a variety of forensic disciplines. This presentation will help dissect the details of conducting such evaluations, which are not as deceptively simple as they seem.

Black box evaluations are conducted by assessing the examiner's decision without regard to how those decisions are made. Black box evaluations can provide a useful overall understanding of the accuracy, reproducibility, and repeatability of the decisions made in response to a given task. Such evaluations do not attempt to assess how a specific examiner performs on specific data — but black box evaluations are a necessary first step toward such detailed tests. Black box evaluations provide a means of quantifying forensic examinations for which quantitative models do not (yet) exist and, therefore, provide both an interim solution while such models are under development, as well as a means of validating such models.

Conversely, white box evaluations are conducted to gain an understanding of how and why examiners make decisions. White box evaluations are detailed assessments of the bases of examiners' decisions, focused not just on the end decisions but on the features and attributes used by the examiners in rendering conclusions. While analyses of black box results deal with the inter-examiner variability of decisions, white box analyses also deal with inter-examiner variability of the detection of features and other attributes.

This presentation will discuss topics that should be considered in the design of black and white box evaluations, including: (1) representativeness of data (dealing with heteroscedastic data, avoiding biased data selection); (2) assessing accuracy vs. reproducibility and repeatability (methods of measurement, data selection implications); (3) test size (precision of measurement, measuring rare events); (4) the Hawthorne effect (dealing with the differences between behavior in tests vs. operations, minimizing differences between test and operational procedures); (5) measuring rates of errors and non-consensus decisions; and, (6) dimensions of examiner skill (accuracy and effectiveness).

Evaluation, Error Rates, Examiner Accuracy

B166 The Implications of Latent Print Quality, Black Box, and White Box Studies

R. Austin Hicklin, MS, 3150 Fairview Park, Falls Church, VA 22042; Bradford Ulery, BA, 3150 Fairview Park Drive, S, Falls Church, VA 22042-4519; Maria A. Roberts*, 2501 Investigation Parkway, Quantico, VA 22135; and JoAnn Buscaglia, PhD*, FBI Laboratory, CFSRU, 2501 Investigation Parkway, Quantico, VA 22135*

The goal of this presentation is to help attendees understand the implications of this series of studies on the latent print examination discipline.

This presentation will impact the forensic science community by describing a portfolio of research that was conducted to evaluate the latent print examination process.

In response to a fingerprint misidentification in the 2004 Madrid bombing case, a proactive, internal Federal Bureau of Investigation (FBI) Laboratory review committee evaluated the scientific basis of friction ridge examination and recommended a portfolio of research.[1] To address those recommendations, since 2007 the FBI Laboratory and Noblis® have engaged in a research program evaluating the latent print examination process, which has resulted in eight journal publications to date.[2-9] This portfolio of work has provided a systematic series of analyses of key aspects of the latent print examination process.

The Latent Quality Study involved: (1) conducting a detailed survey of how quality and clarity are assessed within the latent fingerprint community; (2) developing guidelines and metrics for describing the clarity of friction ridge impressions; and, (3) developing software tools to provide objective, reproducible methods for assessment of friction ridge impression clarity.

The Black Box Study was a large-scale study of the accuracy and reproducibility of latent print examiners' determinations. The follow-on Black Box Repeatability Study retested examiners to evaluate the repeatability of their determinations.

The Sufficiency for Value Study evaluated how image clarity and feature content are associated with the assessment of latent value by latent print examiners.

The White Box Study investigated the relationship between examiners' annotations and their determinations. This included: (1) analyses of how examiners assess the sufficiency of information for individualizations; (2) analyses of how examiners revise their analysis of a latent after comparison with an exemplar; (3) analyses of inter-examiner variation of minutia markup; and, (4) analyses of the factors associated with exclusion decisions.

These studies have been critically important with respect to fingerprint examiner testimony in the legal system and are frequently introduced in court in admissibility hearings; in response to these results, some agencies have changed their policies on how examiners testify in court. These studies have also had an impact on laboratory standard operating procedures, examiner training, certification and competency testing, and quality assurance.

This presentation will provide summaries and a synthesis of these studies to date and will discuss their implications and recommendations on how the results of these studies and their implications may be used to enhance the field of latent print examination.

This research has a variety of implications or recommendations on latent print business processes, including not only error rates, but consensus rates, standardized markup for detailed casework documentation, verification (and blind verification), proficiency testing, conflict resolution, and the effects of human factors.

Latent Prints, Error Rates, Examiner Accuracy

B167 Toward Reform: Implementing Quantitative Methods Into Practice for Latent Print Examination

Henry J. Swofford, MSFS, 4930 N 31st Street, Forest Park, GA 30297; Anthony Koertner, 4930 N 31st Street, Forest Park, GA 30297; and Michael J. Salyards, PhD, 45 High Street, Sharpsburg, GA 30277*

After attending this presentation, attendees will have a greater understanding of how friction ridge comparisons may be quantified, the policies and procedures guiding the use of such methods in practice, and the next steps currently under way to ensure these methods are accessible to the broader forensic community.

This presentation will impact the forensic science community by: (1) introducing a method to evaluate and express the significance of latent print examination results in quantitative terms; (2) discussing the progress of implementing this method into practice at the United States Army Criminal Investigation Laboratory; and, (3) exploring strategies to facilitate the transition of this method to other federal, state, and local forensic service providers.

Over the past several years, there has been significant emphasis on implementing reform in the pattern evidence domains by identifying, developing, and integrating relevant quantitative methods into laboratory procedures for the evaluation and interpretation of impression evidence. This emphasis has resulted in promoting awareness of the need for such methods, stimulated conversations and debates on how to effectively achieve such endeavors, and encouraged practitioners, statisticians, scientists and other relevant academia to partner to achieve a common objective. Over the past few years, the United States Army Criminal Investigation Laboratory has taken incremental steps forward to facilitate the transition from solely subjective, experience-based practices to integrating more robust, scientifically demonstrable, and data-driven practices for latent print examination. As part of this process, prototype software has been developed to quantify the correspondence between friction ridge impressions based on the geospatial arrangement of friction skin features and estimate the related likelihoods to assist analysts in their interpretation of source associations. Following robust evaluations of the method against ground truth data sets and pseudo operational trials using casework datasets, the method is being implemented into routine practice in a stepwise fashion. This presentation will provide a general explanation of the statistical methods employed, discuss policies and procedures governing its use in casework, and discuss possible strategies to transition the method to other federal, state, and local forensic service providers in an effort to assist the broader friction ridge community in its incremental progression toward reform.

The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.

Fingerprint, Probability, Statistics

B168 A Question of Context Within Fingerprint Examinations: Decision-Making Processes, Contextual Information, and Examiners' Motivation

Francisco Valente Gonçalves, MSc, University of Leicester, Dept of Criminology, 154 Upper New Walk, #S03, Leicester LE 1 1NB, UNITED KINGDOM*

After attending this presentation, attendees will have a different perspective regarding the accessibility of contextual information for fingerprint examiners. The goal of this presentation is to provide attendees with new suggestions for the practice of forensics, especially for fingerprint examinations; however, these guidelines will be provided from the examiners' point of view and examiners' performances from different countries. Taking this into consideration, attendees will receive input that will be of value for new implementations of guidelines and for a better understanding regarding the effects of contextual information.

This presentation will impact the forensic science community in three ways. First, the research conducted used only fingerprint examiners; although the sample is not extensive, no lay people were participants. This means the results were closer to the community of forensic professionals. Second, in addition to the computer-based experiment, this presentation provides qualitative input from examiners in different countries. There are some common points within participants' ideas, which need to be further acknowledged by the forensic community. Third, the mix methodology between quantitative and qualitative research is a very important point as the results will provide not only a functional view (the task), but also addresses a very important issue — the examiners' motivations.

Criminal investigation is an area of interest in which there is a need to systematically retain links with forensic science disciplines. Among those, the forensic community found various disciplines that have been the target of research within cognitive bias, namely fingerprints and DNA. Until 2004, after an erroneous decision by fingerprint examiners from the Federal Bureau of Investigation (FBI), this field received enormous focus on research relative to examiners' performances.

From all of the suggestions previous research proposed, the Analysis, Comparison, Evaluation (ACE) methodology has been given an independent phase (verification), changing the methodology into what is currently known as Analysis, Comparison, Evaluation-Verification (ACE-V). On the other hand, the vision on contextual information acquired great dimensions, making this type of variable appear negative for examiners' performances.

This presentation has a different perspective. Examiners from 12 countries (England, Scotland, the United States, Brazil, China, Belgium, Germany, the Netherlands, Portugal, Switzerland, Australia, and New Zealand) were asked to perform a computational experiment in their respective laboratories. Participants (n=65) with varying experience (from trainees to senior examiners) completed tasks similar to fingerprint examinations. Within the task, participants had different types of contextual information in four blocks (control/no context; type of crime; suspect's criminal record; and a previous conclusion from another examiner].

Examiners were also individually interviewed (n=50) on topics related to the ACE-V methodology, the current guidelines within their laboratories, contextual information, and their motivation to perform their work.

Quantitative results suggest that there are types of contextual information that affect examiners' performances in a more negative way, whereas some types of contextual information do not affect performance as much. These results contradict other research that suggested examiners will make misguided decisions in their casework when they have certain types of contextual information, such as the type of crime.

Qualitative data from interviews provided a view that has not been acknowledged to a great extent. Examiners have claimed that there are some guidelines that may not be useful or even possible to accomplish. Regarding their motivation, there are two distinct types of motivation, one of these being a motivation toward performing their work being linked with having some type of contextual information or instant feedback from other departments.

This presentation opens a dialogue on the accessibility of contextual information by examiners, on their motivation (which seems to be something that has been forgotten by research), and on future guidelines in a worldwide perspective. The latter item is included here as global crime is increasingly becoming an issue, and international partnerships have been part of the communication between forensic communities (e.g., the Prüm Treaty).

B169 Resolving Latent Conflict: What Happens When Latent Print Examiners Enter the Cage?

Alicia R. Rairden, MS, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002; Brandon L. Garrett, JD, University of Virginia School of Law, 580 Massie Road, Charlottesville, VA 22903; Daniel C. Murrie, PhD, Institute of Law, Psychiatry, & Public Policy, University of Virginia, Box 800660, Charlottesville, VA 22908; Sharon Kelley, PhD, Institute of Law, Psychiatry, and Public Policy, 1230 Cedars Court, Ste 108, Charlottesville, VA 22903; and Amy Castillo, PhD, Houston Forensic Science Center, 1301 Fannin Street, Ste 170, Houston, TX 77002-7010*

After attending this presentation, attendees will be better informed regarding consultation and conflict resolution methods used during the verification phase of the Analysis, Comparison, Evaluation-Verification (ACE-V) process at the Houston Forensic Science Center (HFSC). Attendees will also be advised of trends observed when this process is utilized via the study of approximately 2,000 completed latent print examination cases. The goal of this presentation is to use these results to inform policies regarding conflict resolution and case processing for other forensic disciplines.

This presentation will impact the forensic science community by fostering better understanding of consultation and conflict between examiners of different experience, training, and employment backgrounds. This study focuses on data gathered from two years and approximately 2,000 latent fingerprint examination cases completed at HFSC. The results will shed light on assessing the types of conflicts that arise and will more predictably and accurately resolve those disagreements.

Verification, which provides scientific validity and scrutiny to a reported conclusion, is the final stage of the latent print analytical process. Despite standard operating procedures and quality controls designed, in part, to mitigate differences, latent print processing and analysis inherently lends itself to conflict. This conflict arises when two latent print examiners, analyzing and comparing the same friction ridge impression, do not use or interpret the same points of data when formulating their conclusions.

In order to preemptively moderate potential conflict, HFSC's Latent Print Section has implemented a standard indicating the number of minutia required before a latent impression is deemed suitable for comparison. Despite this standard, differing levels of experience and training remain and the ability to identify minutia presence and type signals from competing factors, such as pressure and distortion effects, background interference, and processing technique, may create differences of opinion regarding the comparison conclusions. As a result, latent print examiners may consult with each other regarding the impression and the corresponding area(s) of an exemplar, noting both similarities and/or differences used to formulate their respective conclusions. From this point, a consensus agreement regarding the conclusion of the comparison may be reached; however, if the two examiners cannot agree amongst themselves, the conflict is escalated until either a supervisor or the collective decision of the examiners in the section determines the reported conclusion.

While studies have scrutinized latent fingerprint comparisons, past research has not thoroughly examined the verification stage of the process in a casework setting. This study presents an analysis of approximately 2,000 cases completed by HFSC latent print examiners. This analysis focuses on overall occurrence of consultation and conflict resolution over a two-year period with an emphasis on rate and trends of occurrence and outcomes in relation to examiner demographics, such as experience level. Inferences for policies to reduce trends in intra- and inter-experience-level conflict occurrences will be made.

Latents, Verification, Consultation

B170 The Evolution of Latent Print Testimony

Heidi Eldridge, MS, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709*

After attending this presentation, attendees will possess a long-range perspective of where latent print testimonial practices have been, where they are headed, and why they are headed there. Attendees will understand the hallmarks of the "dogma" versus the "transparent" expert and will be aware of the main arguments and literature supporting change in the way reports and testimony are presented. Attendees will also understand some potential barriers to this change and the research that is needed to reduce or remove those barriers.

This presentation will impact the forensic science community by embracing the American Academy of Forensic Sciences (AAFS) meeting theme, *Our Future Reflects Our Past: The Evolution of Forensic Science*, to examine both the past and the future of latent print testimony and reflect on how we are currently working to bridge that gap while still testifying every day during a time of change. This presentation will provide a context to the several philosophies of latent print reporting and testimony that are currently being used by different laboratories and practitioners.

Friction ridge comparison testimony in the United States has long been characterized by speaking in absolutes: fingerprints are unique, the Analysis, Comparison, Evaluation-Verification (ACE-V) methodology has a zero error rate, and the testimony presented by the expert should be regarded as an incontrovertible fact. Once the National Research Council released their watershed Report in 2009, questioning and criticizing these clear overstatements of the strength of the evidence, many commentators and professional organizations recommended that the friction ridge community rethink the way their evidence was presented in reports and in court. Yet change has been slow to come. While some agencies have begun a shift in the way they present their findings, many others still testify the same way, or nearly the same way, they always have. Differing schools of thought have evolved regarding how latent print conclusions ought to be presented, and these are causing a philosophical rift in the community.

This presentation offers the historical context of where American friction ridge testimony has been, lays out the arguments for why it needs to change, describes some recent efforts to improve, and highlights some likely directions for the future of friction ridge reporting and testimony in the United States. This presentation will include examples of some new modes of reporting and testimony, along with discussion of challenges that may accompany those new styles, such as concerns about juror comprehension and examiners' discomfort with leaving absolute source attribution behind without a quantitative model to support a probabilistic conclusion, and will also examine some of the recent literature that surrounds the issue of new styles of testimony.

Latent Print, Reporting, Testimony

B171 Reconstruction of Decompositional Events by the Use of an Arthropod Community on a Large Number of Partially Burnt Human Mummies in the Catacombe dei Cappuccini in Palermo, Italy

Mark Benecke, PhD, International Forensic, Research & Consulting, Postfach 250411, Cologne, NRW 50520, GERMANY*

After attending this presentation, attendees will understand not only how to perform a successful collection of biological stains on human corpses hundreds of years postmortem in a difficult environment that was rearranged and burnt, but also that it is possible to do so.

This presentation will impact the forensic science community by determining that entomological stains can not only be collected hundreds of years postmortem but can also be analyzed to reconstruct both decompositional events and the storage of corpses, even though the environment was burnt.

In July 2012, 622 mummies were examined in the basement of the Capuchin monastery in Palermo, Italy. Corpses were dated to between the 17th and 20th centuries. Their decompositional end state was termed "mummification" by the local population even though skeletonization and differential decomposition were much more abundant. In fact, the mummies must have passed through different, mixed stages of (often active) decomposition.

There were no statistical differences in the type of decay between mummies of males, females, monks, or regular priests nor between the mummies of persons with other occupations (lawyers, etc.). Some of the mummies were stuffed with straw (i.e., they did not contain relevant amounts of body tissue). Inside the skulls, insect remains could be collected.

Only 260 of the 622 mummies showed signs that may have been caused by insect activity (i.e., skin lesions in cases in which skin was intact). The insect remains found on those 260 partially burnt mummies were unusual. Very few blowfly remains (Calliphoridae) were seen even though this group of flies is usually very common in early decomposition. Instead, other arthropods were found (e.g., *Hydrotaea ignava* (Diptera: Muscidae), *Fannia scalaris* (Diptera: Fanniidae), *Conicera tibialis* (Diptera: Phoridae), *Leptocera* sp. (Diptera: Sphaeroceridae), *Necrobia rufipes* (Coleoptera: Cleridae), *Gibbium psylloides* (Coleoptera: Ptinidae), *Oryzaephilus surinamensis* (Coleoptera: Silvanidae), Alysiinae (Hymenoptera: Braconidae), *Tinea pellionella* (Lepidoptera: Tineidae), and a number of pseudoscorpions (Pseudoscorpionida, Arachnida)).

Certain coffins that could be opened also contained fragments of Clerid, Dermestid, and Staphylinid beetles. The insect findings were compared to arthropod recoveries from human corpses in similar climatical environments.

Comparing the mummies of males, females, virgins, monks, priests, and members of other professions, only priests and virgins showed a significant difference in insect colonization patterns (via the Wilkoxon test). This may be due to very different methods of mummification rather than a reflection of the life of the persons before death; however, the state of the teeth revealed significant differences between the health status of the groups (e.g., mostly missing teeth; also flat, filed-off teeth due to sand in baked goods — an indicator of age at death).

During further searches, a "colatoio" (preparation) room was found in which the fresh corpses had been stored, then dried and reassembled. The method of mummification was often not elaborate, and methods have changed several times over the centuries, as could be deduced from the insect remains.

Mummies, Arthropods, Decomposition

B172 DNA Recovered From a Victim's Pockets Solves a Cold Case: A Case Study

Laura Stanton, 11001 Cedar Avenue, Cleveland, OH 44106; Nasir A. Butt, PhD, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106; and Curtiss L. Jones, MS, Cuyahoga County MEO, 11001 Cedar Avenue, Cleveland, OH 44106*

After attending this presentation, attendees will understand the importance of utilizing techniques currently used in the field today to help aid in the re-examination of old evidence in unsolved cold cases.

This presentation will impact the forensic science community by encouraging the re-examination of the victim's pockets of clothing worn at the time of death in crimes in which robbery could be a possible motive. Evidence that is suitable for further testing should then be swabbed for the presence of touch DNA left behind by the perpetrator.

A case study will be presented that highlights this method of swabbing the victim's pockets for touch DNA left behind by the perpetrator, which ultimately aided in solving the case after 22 years. The perpetrator can deposit skin cells when reaching into the victim's pockets in the process of robbery. This touch DNA can then be collected and analyzed in order to develop a DNA profile.

On the night of November 6, 1993, a witness stated he saw a car driving down the street and then stopping. Minutes later, he heard gunshots and saw an individual exit the passenger side of the car and flee. A 17-year-old boy was found in the driver's side area of the car shot multiple times in the head. The victim's left front pants pocket was turned inside out and there was change lying on the ground next to the driver's door.

In 2015, a request was made by the prosecutor's office cold case unit to re-examine the victim's clothing worn at the time of death. The pants were examined and the pockets were swabbed on the inside for the presence of touch DNA. The swabs were extracted using organic extraction methods. The extracted DNA was quantified using the Quantifiler® Duo quantification kit using a Real-Time Polymerase Chain Reaction (RT-PCR) instrument. The DNA was amplified by using the PowerPlex® Fusion amplification kit. The amplified DNA was loaded onto the genetic analyzer for the detection of DNA fragments. Fragment analysis was performed using GeneMapper® ID software.

A Short Tandem Repeat (STR) DNA mixture profile was developed from the victim's left front pants pocket. The DNA mixture consisted of the victim and an unknown major contributor. This unknown profile was entered into the Combined DNA Index System (CODIS). The unknown profile hit to a convicted offender. After releasing the name to the agency, it was learned that this individual had been interviewed in the initial investigation and was a person of interest.

In conclusion, touch DNA in the victim's pockets that was left behind by the perpetrator over 20 years ago was still able to be collected and a DNA profile developed, which ultimately aided in solving the case.

Touch DNA, Cold Case, Criminalistics

B173 The Identification of Silk Forgeries

Mehdi Moini, PhD, George Washington University, Dept of Forensic Sciences, 2100 Foxhall Road, NW, Washington, DC 20007; and Christopher M. Rollman, MFS, George Washington University, 2100 Foxhall Road, NW, Somers Hall, L14, Washington, DC 20007*

After attending this presentation, attendees will better understand how to use Capillary Electrophoresis/Mass Spectrometry (CE/MS) to identify naturally aged vs. artificially aged silk.

This presentation will impact the forensic science community by introducing proteomics techniques and explaining how they could be used in forgeries.

Forgery in art and cultural heritage is almost as old as the objects themselves; however, cultural heritage forgery is seldom investigated in forensic settings. The identification of the forgery is similar to the forensic analysis of documents, inks, and paints and similar to age identification of proteinaceous specimens, such as hair or teeth. In this presentation, one of the most famous cases of silk forgery in the United States will be discussed as will the analytical techniques developed and used to identify the real and forged specimens. Forgery identification includes the identification of the materials, dyes, and age of the specimens.

In 1924-1925, a number of medieval Islamic silks were excavated from tombs at a site called Bibi Shahrbanu near Rayy, Iran. Although these silks were not necessarily all from the Buyid dynasty, as a collective they are referred to as the "Buyid" silks as they are thought to be from that approximate time period. Additional pieces surfaced in the 1940s, but doubts arose regarding the authenticity of some of the fragments, which led to discussions among curators, art historians and dealers. Accurate dating of many Buyid fragments has yet to be ascertained.

Recently, several new techniques for dating proteinaceous historical artifacts have been developed using modern separation/mass spectrometry and proteomics techniques.[1] By using these techniques, several biomarkers of natural aging in proteinaceous cultural heritage objects were identified. The dating study is based on racemization and deamidation of amino acids in proteinaceous specimens. CE/MS was used to measure D-amino acid/L-amino acid (D/L) of Aspartic Acid (Asp) and a proteomics technique was employed to measure the deamidation rate of asparagine in silk proteins. To test the authenticity of the Bibi Shahrbanu silk, 12 samples from the Textile Museum in Washington, DC, were analyzed and the change in racemization and deamidation in both authentic and unknown silk samples was compared. These results were also compared to the rate of racemization and deamidation of the artificially aged silk proteins. Modern silk samples were aged using pH, heat, and radiation. Thirteen silk fragments were HCl digested and analyzed by chiral CE/MS and the D/L Asp was measured. For the deamidation study, these samples were enzymatically digested and analyzed by proteomics techniques. Two of the fragments that were originally purchased by the museum were among these samples. One of these fragments was carbon dated and used as the control. The results were consistent with the skepticism regarding the authenticity of nine fragments and pointed to the possibility that they were artificially aged to look older. The results of this investigation will be discussed.

Silk Forgery, Proteomics, Racemization Dating

B174 Lessons From Inside the Barrel: A Forensic Case Report of a Double Gunshot Suicide

Eva Brencicova, MD, Insitute of Forensic Medicine, University of Bern, Bühlstrasse 20, Bern, SWITZERLAND; Julia Brünig, University of Bern, Institute of Forensic Medicine, Bühlstrasse 20, Bern, SWITZERLAND; Nicole Schwendener, HF, Institute of Forensic Medicine, University of Bern, Bühlstr. 20, Bern 3012, SWITZERLAND; Melanie Grabmüller, MSc, Institute of Legal Medicine, University of Bonn, Stiftsplatz 12, Bonn 53111, GERMANY; Christian Jackowski, MD, Institute of Forensic Medicine, University of Bern, Bühlstr. 20, Bern, Canton Bern, SWITZERLAND; and Christian Schyma, University of Bern, Institute of Forensic Medicine, Bühlstrasse 20, Bern CH-3012, SWITZERLAND*

After attending this presentation, attendees will understand the complexity and importance of the interpretation of biological traces in challenging forensic gunshot cases.

This presentation will impact the forensic science community by highlighting the value of precise and cross-sectional analyses of biological traces involving molecular methods in forensic settings and examinations.

A 45-year-old man was found dead, seated in the driver's seat of a vehicle parked next to a remote cemetery in the countryside. The right hand of the corpse was lying on its lap, closed around a .38 special Smith & Wesson® revolver. Behind the driver's seat, balanced between the front-seat pocket and the back seat row was a 9mm Glock® handgun, the barrel pointing toward the front. The corpse presented with a gunshot entry wound on the right temple with a corresponding gunshot exit wound above the left ear. Interestingly, a second gunshot entry wound was found at the back of the neck with an exit wound located on the chin, slightly to the left of the facial midline.

A thorough external examination of the corpse by forensic experts was performed onsite, during which backspatter was identified and collected on the right hand of the corpse, but not on the left. To complete the forensic investigations, an autopsy and post-mortem imaging (Computed Tomography (CT) and Magnetic Resonance Imaging (MRI)) were performed. In addition, both firearms seized onsite were subjected to endoscopy of the barrels, visualizing the biological stains inside and enabling their systematic and precise collection by DNA-free cotton swabs moistened with sterile, desalted water. Analysis of the collected biological material was performed in the context of a research project funded by the Swiss National Foundation which investigates the phenomenon of biological stains inside gun barrels after close-contact gunshots.

Interdisciplinary work involving forensic and criminal investigation experts allowed a reliable and comprehensive reconstruction of the incident, revealing that the two firearms had been fired simultaneously with close contact of both muzzles to the skin, confirming the act to be suicidal. Analyses of organ-specific regulatory RNA, more specifically microRNA (miRNA) in the biological traces collected from the right hand of the corpse and from the barrel of the .38 special Smith & Wesson® revolver, which had inflicted the shot to the right temple, revealed both blood-specific and brain-specific miRNA. Interestingly, on the swabs collected from the barrel of the Glock® handgun, which had equally been used with close contact to the skin at the back of the neck, causing extensive injury to the spinal cord, no organ-specific miRNA traces could be detected.

The presented case demonstrates the complexity of backspatter composition and distribution as a function of different gunshot wound locations, firearms, and munitions. Importantly, this case substantiates the reconstructive value of cross-sectional molecular analysis methods and points toward their increasing importance in forensic examinations in the future.

Firearms, Contact Shot, Backspatter

B175 Gunshot Residue (GSR) Identification Errors and Sample Significance

Bryan R. Burnett, MS, Meixa Tech, PO Box 844, Cardiff, CA 92007-0844*

The goal of this presentation is to describe analyst errors made in the interpretation of spectra by Energy Dispersive X-ray Spectroscopy (EDS) of GSR samples in the Scanning Electron Microscope (SEM), as well as population statistics as they relate to GSR sampling.

This presentation will impact the forensic science community by describing errors in the interpretation of EDS spectra in GSR particle analysis made in case work and in determining sampler significance for GSR.

SEM/EDS is being used by crime laboratories worldwide for the analysis of GSR samples in shooting cases. Unfortunately, the operators of these instruments often have inadequate training for the interpretation of EDS spectra, usually relying solely on software identification of peaks. Newbury analyzed this problem, but did not focus on mistakes made in GSR analysis.[1] Element peaks are misidentified, missed, or fabricated.

Case 1: Arsenic with the major sulfur peak confused for lead.

Case 2: Mistaken assignment of trace antimony in particles with major barium and trace calcium.

Case 3: Misreporting spectra due to software misplacement of element symbols on spectra.

Case 4: Missing element peaks that are obscured by peaks of other elements.

Case 5: Claim of trace element presence (antimony or lead) using presumptive (thumbnail) spectra listings without confirmation spectra.

Case 6: Assignments of particle spectra to consistent, "highly specific" (= characteristic), "unique" (= characteristic), and characteristic GSR.

Case 7: Ignoring a major contribution of iron (+ trace copper) in antimony/barium particle spectra (= friction-brake particles) and calling these particles GSR.[2]

Case 8: Failure to identify the source of trace elements represented in a GSR spectrum. Barium sulfate particles are ubiquitous in the urban environment and often well-populate a sampler. Thus, nearby barium-containing particle(s) may contaminate a particle's spectrum. This can occur for the consistent GSR particles composed of lead and antimony which produces an erroneous assignment of characteristic GSR.

For many crime lab analysts, there is a failure to consider statistical significance of a GSR particle burden of sampler. The SEM/EDS analysis results of the (usually) two samplers from a suspect (left and right hands) require statistical criteria for acceptance of these samplers as representative of a GSR population that existed on the suspect's hands prior to sampling. A single-characteristic GSR particle without supporting consistent GSR on a sampler cannot be separated from a rare contamination event or outlier.[3] This is especially true due to possible GSR contamination in the police environment from officers, who occasionally qualify their firearms, or GSR-contaminated suspects who have been in the police environment previous to the suspect. The criterion for a GSR sampler to have a significant burden of characteristic (Lead, Antimony, and Barium (PbSbBa)) GSR particles is three (except perhaps in military cases); however, the criterion for assigning significance to a sample when it has one characteristic GSR particle with two or more consistent GSR particles has not been established.[4]

There is no reason not to combine the two samplers from a suspect's hands for the determination of sampler significance.

B176 A Post-Incident Investigation of Ammonia Contamination of Food Products in a Cold Storage Facility

Kelly L. Wouters, PhD, Armstrong Forensic Lab, Inc, 330 Loch'n Green Trail, Arlington, TX 76012*

After attending this presentation, attendees will understand a protocol used to conduct a large-scale investigation regarding the sampling and analysis of numerous food products located in a cold storage facility, following an ammonia refrigerant leak. The protocol includes the development of statistically based sampling plans, sample collection procedures, and analytical methodologies.

This presentation will impact the forensic science community by providing examples and suggestions for dealing with similar incidents in the future. No published guidelines are available for this type of investigation. This presentation will illustrate the decisions and flexibility required to overcome the specific challenges associated with interfacing between numerous parties, including the business representatives, insurance companies, attorneys, and both state and federal governmental agencies.

This presentation will discuss an extended investigation following an ammonia refrigerant leak at a large-scale cold storage facility. Numerous types of food products were stored in the warehouse, including baked goods, meats, and seafood. Due to the variations in product compositions, packing techniques, exposure potentials, and requirements imposed by regulatory bodies, several different processes were utilized for sample collection and analysis.

The sampling plan for most of the products evaluated was based on a hypergeometric distribution, a statistically based sampling method commonly utilized by forensic scientists in other applications. The sampling plans were modified, as needed, to suit the needs and requests of the specific product owners. In total, more than 3,000 samples were collected for evaluation and analysis.

The primary instrumental analytical technique utilized for the investigation was Ion Chromatography (IC). Residual ammonia, when dissolved in the moisture contained in the product and/or extracted under acidic conditions, will be in the form of the ammonium cation. The IC technique is a sensitive method for detecting and identifying ionic species, including ammonium. For some products, organoleptic testing was employed at the request of regulating authorities. The organoleptic testing involved both taste and odor evaluations via a panel of analysts. All testing was based on published methodologies, adapted for use in this unusual application.

A summary of the analytical data and observations will be presented. Strategies for data interpretation will be discussed. Overall, the results of the investigation established the ammonia release had little to no impact on the food products stored at the facility. No health hazards were indicated, although ultimately, the decision regarding whether the products were suitable for public consumption was not made by the laboratory. The final decisions regarding the acceptability of the affected products varied greatly, depending on many factors. Over the course of this extensive investigation, numerous unexpected twists and challenges were encountered and overcome, and the narrative of the project should be both engaging and informative to other forensic investigators.

Ammonia, Food Products, Ion Chromatography

B177 The Indirect Detection of Bleach (Sodium Hypochlorite) in Bleach-Tainted Infant Eye Drops

David S. Jackson, BS, US FDA Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237; John B. Crowe, BS, US FDA Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237; Lisa A. Kaine, BS, US FDA Forensic Chemistry Center, 6751 Steger Drive, Cincinnati, OH 45237; Adam C. Lanzarotta, PhD, USFDA-FCC, 6751 Steger Drive, Cincinnati, OH 45237; and Heather A. McCauley, BS, 6751 Steger Drive, Cincinnati, OH 45237*

After attending this presentation, attendees will better understand the methodology that can be used to test a matrix for the presence of bleach (sodium hypochlorite), even if all of the active ingredient in the bleach has broken down, will learn how suspect eye drops were determined to be positive for bleach, and how this information was used in court to convict a mother of assaulting her daughter.

This presentation will impact the forensic science community by shedding light on bleach detection in difficult matrices and by illustrating the possibility of identifying bleach in a matrix even when all of the active ingredient in bleach has broken down.

An eye drop sample that reportedly left a pharmacist ill after inhaling its fumes, left a detective with a chemical burn on her skin after spilling it, and left a toddler blind after receiving it as treatment for a month from her mother was received for analysis at the Forensic Chemistry Center (FCC). The suspect eye drops tested positive for an oxidizer, had a pH of 6.1 when received, contained chloride and chlorate, but tested negative for bleach.

Sodium hypochlorite (NaOCl) is a strong oxidizer that is used as a bleaching agent, a sanitizer, a clothing whitener, and a deodorizer. It is readily available in most households. It is caustic, causes damage to tissues when it comes in prolonged contact with the human body, has chloride and chlorate as breakdown products, and rapidly degrades in matrices that can be oxidized. Methodology to characterize the stability of sodium hypochlorite in beverages has been developed and published by the FCC.

Twenty-three beverages were spiked at three levels with sodium hypochlorite and were monitored for sodium hypochlorite stability, pH, chloride and chlorate content, and visual and organoleptic characteristics over a 13-day period. This study revealed that sodium hypochlorite adulteration can be determined in a suspect matrix even when all of the active hypochlorite has broken down. This is accomplished using spot tests for oxidizing agents and Ion Chromatographic (IC) anion analysis for bleach degradation products. Based on the excess chloride found in the suspect eye drops, the amount of equivalent bleach was estimated and spiked into control eye drops to be used for comparison to the suspect eye drops. Comparisons were made using IC, Gas Chromatography/Mass Spectrometry (GC/MS), Stereoscopic Light Microscopy (SLM), Fourier Transform Infrared (FTIR) spectroscopic imaging, and Liquid Chromatography/Charged Aerosol Detection (LC/CAD). It was determined that the laboratory-fortified control eye drops were very similar to the suspect eye drops using the above-listed techniques. These results were presented in court and led to the conviction of the toddler's mother, who was sentenced to 40 years in prison for the assault.

Sodium Hypochlorite, Bleach, Eye Drops

B178 What Happened to Flight MH17?

Peter D. Zoon, PhD, Laan Van Ypenburg 6, The Hague 2497 GB, NETHERLANDS; Reza R.R. Gerretsen, MD, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague 2497 GB The Hague, NETHERLANDS; Mayonne Van Wijk, MSc, Netherlands Forensic Institute, Laan van Ypenburg 6, The Hague 2497 GB, NETHERLANDS; and Erwin Vermeij, Geer Ban 41, Amsterdam 1068ZW, NETHERLANDS*

After attending this presentation, attendees will better understand how the origin of an airplane explosion may be determined and, more specifically, what brought down Flight MH17 and how Disaster Victim Identification (DVI) processes can benefit from the inclusion of new technologies.

This presentation will impact the forensic science community by familiarizing attendees with some of the results of the initial investigation into the crash of Flight MH17. Non-accidental airplane crashes are relatively rare events. This presentation will discuss how to obtain and examine relevant materials from one of these events. This presentation will also explain the benefits of designing DVI processes to include forensic examinations; in particular, the novel inclusion of mobile Computed Tomography (CT) scanners, dual-beam X-ray scanners, and hand-held X-ray scanners.

At approximately 3:15 p.m. on July 17, 2014, Malaysia Airlines Flight MH17 from Amsterdam to Kuala Lumpur crashed in the vicinity of Hrabove in the eastern Ukraine province of Donetsk. All 298 passengers and crew were killed. Initial reports hinted of a non-accidental cause of the crash. At the time of the crash, an armed conflict between Ukrainian military and armed separatist forces was taking place in the crash area, which precluded the possibility of examinations at the crash site.

One week later, on July 23, 2014, the first human remains arrived in the Netherlands. At the military base in Hilversum, a disaster mortuary had been established at the Corporal Van Oudheusdenbarracks. The DVI process took place at this location.

Prior to start of the DVI process, plans were made to include forensic examinations within the DVI process, as this might be the only opportunity to obtain forensic evidence to determine what happened to Flight MH17; however, the DVI process took top priority as it could not be impeded as a result of the forensic examinations.

The multidisciplinary approach used at the Netherlands Forensic Institute (NFI) to examine invasive traumas led to a plan that included the use of a mobile Computed Tomography (CT) scanner, a dual-beam X-ray scanner, and a portable X-ray scanner to screen the human remains for foreign (metal) fragments.[1-3] It was thought that once recovered fragments had been identified as being non-airplane in nature, this information could be combined with a passenger seating map to determine the origin of the explosion.

The recovered fragments were sent to the NFI, where they were tested for explosive residues. After the fragments were cleaned, they were visually examined. Those of unknown origin were further analyzed with Scanning Electron Microscopy in combination with Energy Dispersive X-ray (SEM/EDX) analysis. This analysis confirmed that multiple fragments were unalloyed steel on which molten and resolidified layers were present. With the use of a Focused Ion Beam (FIB), local cross-sections were made and it became clear there were aluminum and glass layers present on the particles. The elemental composition of the glass layers revealed zirconium was present in the glass. A subsequent query of the NFI glass database disclosed only a single hit of glass containing zirconium: a cockpit window.

In December 2014, parts of the wreckage arrived at the Gilze-Rijen airbase in the Netherlands. From the wreckage, more fragments were recovered and analysis determined the same results as those obtained from the human remains. Reference samples from various glass sources in the airplane verified that only the outer and inner layers of the cockpit windows were made of zirconium-containing glass. This means that the steel fragments originated outside of the airplane and that probably a missile brought down Flight MH17.

B179 DNA Testimony in the Past, Present, and Future

Kristy Kadash, PhD, Jefferson County Regional Crime Lab, 200 Jefferson County Parkway, Golden, CO 80401; Christopher J. Plourd, JD*, Superior Court, 939 Main Street, El Centro, CA 92243; Ted R. Hunt, JD*, Jackson County (Kansas City) Prosecutor's Office, 415 E 12th Street, Fl 11, Kansas City, MO 64106; Christine Funk, JD*, Washington, DC 20024; Andrea M. Borchardt, MS*, 401 E Street, SW, Washington, DC 20024; Elizabeth A. Hewitt, MFS, Jefferson County Regional Crime Laboratory, 200 Jefferson County Parkway, Golden, CO 80401; Suzanna R. Ryan, MS*, Ryan Forensic DNA Consulting & Advanced Serology, 3548 Woodland Way, Carlsbad, CA 92008; and Robin W. Cotton, PhD*, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118*

After attending this presentation, attendees will be aware of various perspectives on the evolution of forensic DNA-related testimony, will realize what approaches are more effective for judges and juries, and will benefit from the opportunity of asking questions of the invited panel.

This presentation will impact the forensic science community by encouraging a dialogue between DNA experts and members of the legal system.

DNA fingerprinting, as it used to be known, was first applied to criminal cases in the late 1980s. Most notably, Dr. Alec Jeffreys used his technique in 1986 to exclude a 17-year-old boy as the perpetrator of two sexual assaults in the Leicestershire area of England and to later identify the true perpetrator, Colin Pitchfork. The first person convicted by DNA evidence in the United States was Tommy Lee Andrews, who was found guilty in 1987 in Orange County, FL. At the end of 1988, the Technical Working Group on DNA Analysis Methods (TWGDAM) held its first meeting to discuss the best approaches to implementing DNA analysis in crime laboratories, including quality control measures. This ultimately led to the Guidelines for a Quality Assurance Program for DNA Analysis in 1991 (updated in 1995). These guidelines have since evolved into the Quality Assurance Standards (QAS) required by the Federal Bureau of Investigation (FBI) for all forensic DNA laboratories that participate in the national DNA database system, Combined DNA Index System (CODIS). Due to the solid foundation provided by the QAS, DNA analytical techniques have successfully endured admissibility hearings and have been accepted in courts throughout the country over the last 30 years.

In those early days, most DNA testing was restricted to blood and semen. These types of stains yielded relatively straightforward Restriction Fragment Length Polymorphism (RFLP), and later Short Tandem Repeat (STR) Polymerase Chain Reaction (PCR), profiles. Mechanisms were established and promoted by TWGDAM and later the QAS to allow the objective comparison of evidence results to known references. If a match was determined, the statistical significance of the match was reported. In this way, DNA testimony differed from the more traditional police sciences of fingerprint analysis and firearms comparisons in which there were generally no qualifications made on putative identifications other than the expert's opinion.

As technology improved, the nature of biological evidence expanded beyond the rich sources of DNA to extremely trace level samples. This increased complexity of the resulting DNA profiles, their interpretation, and the statistical analysis applied to inclusions. Consequently, presenting DNA analysis to juries has shifted focus from describing the nature of DNA and its capacity to identify individuals to explaining how DNA can be transferred between objects and the intricacies of dropout and mixture ratios. Future technologies promise to provide additional levels of information from biological material beyond today's STR profile or Single Nucleotide Polymorphism (SNP) haplotype, such as the type of cell, the age of the stain, the physical description, and even the age of the donor. How will this impact future testimony?

A two-hour block of time has been devoted to explore the past, present, and future of DNA testimony. The panel convened for this session will provide the perspective of the judge, the prosecutor, the defense attorney, the DNA expert, and the independent consultant on effective testimony techniques and will discuss the pitfalls to avoid in light of the emerging changes in DNA interpretation and statistics.

DNA, Testimony, Statistics

B180 Ashes to Ashes: An Analysis of Enhanced Methods for Genetic Identification of Human Cremated Remains

Kelly Grisedale, PhD, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723; and Maureen Hickman, MS, Western Carolina University, 111 Memorial Drive, NSB 231, Cullowhee, NC 28723*

After attending this presentation, attendees will better understand the potential and limitations of genetic investigations of cremated human remains.

This presentation will impact the forensic science community by providing a way to gain maximum information from cremated human remains, which have historically been very difficult to identify.

Human cremation is a common funeral practice in many cultures throughout the world. In the United States, the preference for cremation continues to increase, with the rate of cremation soon expected to surpass that of burials. After cremation, there may be a need to confirm the identity of the remains for reasons including civil or criminal cases, paternity or kinship analysis, or identification of missing or deceased individuals. This has traditionally fallen to anthropologists, who can employ various metric analyses to assess whether the contents of an urn are in fact human cremated remains and can assist in determining a biological profile including sex, stature and weight.

Historically, genetic examination of cremated remains has been limited due to lack of remaining DNA and concerns regarding contamination. The cremation process involves burning at temperatures up to 1,000°C, reducing the corpse to skeletal remains or bone fragments, which are then often further ground to a sand-like consistency; however, depending on the method used to grind the remains, sizeable bone fragments may still be found in the urn returned to family members. Previous investigations into DNA analysis from cremated remains have shown limited success. Studies testing the sand-like portion of the remains found that small amounts of nuclear and mitochondrial DNA were recoverable, but the potential for contamination was too great to ensure reliable results, while examination of remaining bones or teeth resulted in little to no DNA recovery; however, advances in DNA extraction and detection methodologies may present an opportunity to re-examine the process of genetic identification from the remaining bone fragments.[1,2]

This work examines adjustments or enhancements along the entire DNA analysis workflow to improve identification methods from human cremated remains. DNA was extracted from bone fragments using either a commercial silica-based method or an enhanced extraction method that modifies the commercial kit to determine which process resulted in maximum DNA recovery. Multiple extracts from a single bone fragment were pooled, then concentrated using an Eppendorf Vacufuge™. All extracts were quantified using real-time Polymerase Chain Reaction (PCR) to assess nuclear or mitochondrial DNA (mtDNA) recovery. Concentrated extracts were then amplified using either the GlobalFiler® PCR Amplification Kit with an increased PCR cycle protocol and analyzed using capillary electrophoresis or an in-house-developed whole mtDNA genome multiplex for sequencing on the Illumina® MiSeq®. Multiple samples from individual sets of remains were examined to assess consistency across results.

Results indicate that low levels of nuclear DNA can be recovered from cremated bone, with partial Short Tandem Repeat (STR) profiles obtained from pooled and concentrated extracts; however, exaggerated stochastic effects such as increased stutter, allele drop-out, and peak-height imbalance were observed in some profiles due to the low amount of starting template and use of an increased-cycle PCR, thereby complicating the profile interpretation. Results also revealed that sufficient mtDNA can be recovered from cremated remains for whole mtDNA genome sequencing using a multiplex amplification approach. Massively parallel sequencing of amplified mtDNA yielded an average coverage of 10,500 reads across the genome, with 97% of the genome covered by at least 100 reads. Preliminary variant analysis suggests the remains are likely to be from a single source.

Cremated Remains, STR Profiling, MtDNA Sequencing

B181 The Short-Term Effects of Surface and Subsurface Burial on DNA From Human Skeletal Remains

Brianna B. Bermudez, BS, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824; and David R. Foran, PhD, Michigan State University, Forensic Science Program, 560 Baker Hall, East Lansing, MI 48824*

After attending this presentation, attendees will understand how mitochondrial and nuclear DNA quantities vary within the human femur and how they are affected by short-term soil surface exposure and burial.

This presentation will impact the forensic science community by providing insight into both the variable levels of DNA throughout human femora and the differential degradation after short-term surface and subsurface burial.

Forensic biologists utilize human skeletal remains as a source of DNA for identification purposes. In particular, the femur and other weight-bearing long bones are commonly sampled at the midshaft diaphysis for DNA analysis in a forensic setting; however, Mundorff and Davoren demonstrated that DNA quantities vary throughout the human skeleton, with cancellous bones such as the patella and tarsals producing greater profiling success than the midshaft of weight-bearing long bones, although only one location on each bone was tested.[1,2] Previous research conducted at Michigan State University using bovine and porcine models demonstrated that DNA quantity and quality vary widely within a femur, with higher DNA yields at the epiphyses than at the diaphyses.[3] In contrast to these animal models, DNA variation within human bones has yet to be rigorously examined.

Following death, skeletal DNA begins to degrade, which can be exacerbated by unfavorable environmental factors such as temperature, moisture, pH, and burial conditions. Over time, this results in reduced DNA yields, potentially to a point where DNA is no longer retrievable; however, exactly when and to what extent DNA degradation occurs during the taphonomic process is unresolved. The goal of this study was to establish the short-term effects of surface and subsurface burial on human femoral DNA throughout the length of the bone.

Three unpreserved human bilateral femur pairs were obtained. The majority of soft tissue was removed manually, and the bones were subsequently macerated in a 0.5% Terg-a-zyme® solution. A Dremel® tool with a cobalt drill bit was bleached and Ultraviolet (UV) -irradiated and used to drill five locations on each femur (midshaft, proximal and distal diaphysis, femoral neck, and patellar groove). Bone powder was collected and its mass recorded. One femur was buried in approximately 30cm of soil, while its counterpart was placed on top of the soil, exposed to the elements. A large dog crate with the bottom removed was staked to the ground in order to protect the remains from scavengers. Femora were retrieved from the site after seven days and resampled. The powder was digested in a demineralization buffer and a 1:1 phenol-chloroform extraction was performed, followed by Amicon® column filtration. DNA extract volumes were measured prior to storage at -20°C.[4]

Mitochondrial DNA quantities at the five femoral locations were examined using an in-house, human-specific, TaqMan® assay. An internal positive control template was included to assess any Polymerase Chain Reaction (PCR) inhibition. A Quantifiler® Human DNA Quantification Kit was used to assess nuclear DNA quantity. For both mitochondrial and nuclear assays, samples that demonstrated signs of inhibition were diluted tenfold and re-tested.

Results demonstrate that prior to surface exposure or subsurface burial, mitochondrial DNA quantity was highest in the more distal femoral regions (distal diaphysis and patellar groove), whereas nuclear DNA quantity was greater at the proximal end (neck and proximal diaphysis). Both surface and subsurface burial usually resulted in sharp decreases in DNA yields, sometimes by as much as 90%, even after only seven days. Bones that were placed on the soil surface had overall higher mitochondrial and nuclear DNA yields throughout the bone than did their buried counterparts. Finally, the proximal diaphysis maintained higher mitochondrial and nuclear DNA quantities after surface and subsurface burials than did the more peripheral regions.

In conclusion, short-term burial can have a strong and extremely rapid degrading effect on DNA from human bone, the extent of which varies across the length of the femur. Contrary to conventional thinking, the midshaft diaphysis generally does not have higher DNA yields before or after burial. Owing to this, the midshaft diaphysis should not be viewed as the optimal location for DNA recovery from human femora.

DNA Quantity in Bone, Skeletal DNA and Burial, DNA Degradation

B182 A Specialized Workflow for Charred and Degraded Human Remains That Leads to Identifications

James Anstead, PhD, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Kelsy Lowther, MS, DNASolutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; Erica Reynaga, MS, DNASolutions, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104; and Brandt G. Cassidy, PhD, 840 Research Parkway, Ste 551, Oklahoma City, OK 73104*

After attending this presentation, attendees will learn how to obtain probative results from samples that have been degraded after prolonged exposure to fire. Attendees will see the effect of sample degradation and sample inhibition on forensic DNA cases and will learn about the tools that are available to address theses issues. Two cases, one from a recent transport disaster event and one from a missing persons' identification case from a 20th-century military conflict, will be presented to illustrate the typical condition of samples obtained from crime scenes and evidence exposed to fire.

This presentation will impact the forensic science community by identifying and sharing best practice methods that have enabled results to be generated from highly compromised samples that previously would have been unlikely to produce probative results. Attendees will learn bone and tissue preparation methods that can improve downstream success and, in these cases, led to positive identifications.

As a result of both the improved recovery of DNA from crime scene samples and increases in the sensitivity of forensic DNA testing systems, there is increased understanding of the robustness of DNA testing from degraded samples. Forensic analysts, therefore, are more frequently encountering challenging samples that require a specialized workflow to obtain probative data. These samples are often highly degraded and have been exposed to multiple Polymerase Chain Reaction (PCR) inhibitors from various environmental conditions. Degradation becomes one of the greatest challenges when processing evidence that has been subjected to fire. The length of exposure, the temperature of the fire, and preservation of evidence after collection affects the ability to recover a DNA profile with traditional Short Tandem Repeat (STR) testing systems.[1]

To improve the ability to maximize recovery from these complex tissue and bone samples, a specialized workflow has been developed. It involves combining efficient extraction, recovery, and subsequent analysis using commercially available technologies, including next generation autosomal STR marker systems, a highly sensitive quantification system, and an *Alu*-based maker system designed for highly degraded samples. This presentation will detail the proposed workflow, including tissue and bone preparation, analysis, and interpretation.

Two cases will be presented, one recent and one from a 20th-century military conflict. In both cases, samples were exposed to prolonged high-temperature fires. These cases will demonstrate the process that was used to achieve probative results from highly compromised samples exposed to and consumed by fire. In both cases, sufficient STR data was obtained to make a positive identification based on a family reference sample.

Degraded, Bone, Human Remains

B183 DNA-Protein Crosslink Reversal and Mitochondrial DNA Amplification From Formaldehyde-Treated Unknowns From the Korean War

Charla Marshall, PhD, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Jennifer L. Higginbotham, MFS, 115 Purple Heart Drive, Dover AFB, DE 19902; Cassandra R. Taylor, BS, 351 Stock Drive, Bridgeport, CA 93517; Erin M. Gorden, MFS, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Kimberly S. Andreaggi, MFS, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; Suzanne M. Barritt-Ross, MS, AFMEO/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; and Timothy P. McMahon, PhD, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover Air Force Base, Dover, DE 19902*

After attending this presentation, attendees will understand the concept of formaldehyde-induced DNA-protein crosslinks and their effect on Polymerase Chain Reaction (PCR). Attendees will further learn how to use heat denaturation to reverse DNA-protein crosslinks for successful DNA amplification. The downstream ramifications of heat denaturation will be explained, and protocol modifications to accommodate single-stranded DNA (ssDNA) will be discussed.

This presentation will impact the forensic science community by offering guidance on how to successfully reverse formaldehyde-induced DNA-protein crosslinks from embalmed human remains.

Of the more than 800 Korean War Unknowns that were embalmed in formaldehyde and buried in the National Memorial Cemetery of the Pacific in Hawaii, only a few dozen have been identified to date. The formaldehyde treatment of the remains inflicted DNA-Protein Crosslinks (DPCs) that inhibit standard PCR amplification. Since the 1990s, attempts to conduct DNA testing of these Unknowns have been largely unsuccessful until Next Generation Sequencing (NGS) technologies became available. In 2015, the Armed Forces DNA Identification Laboratory (AFDIL) validated a hybridization capture and Illumina® sequencing protocol to obtain mitochondrial genome data from these and other degraded DNA samples. While this method was shown to be nearly 100% successful when tested with traditional degraded samples, it proved to be half as robust for the formaldehyde-treated Korean War Unknowns (with a success rate of 47%). Moreover, the DNA that could be sequenced from these Unknowns was shown to be very short in length, approximately 65 base pairs (bp) on average. The observations made over the course of the NGS validation indicated that most of the endogenous DNA was unamplifiable due to the presence of inhibitory DPCs.

To bolster the success rate of DNA testing for this set of Korean War Unknowns, a novel DPC reversal and DNA extraction procedure was recently developed at the AFDIL. The procedure involves standard bone powder demineralization, DPC isolation and denaturation, followed by proteinase K digestion, and DNA extraction and purification. For this, 29 samples and 6 reagent blanks were extracted with varying DPC denaturation temperatures (65°C, 72°C, and 95°C) and DNA purification methods (QIAGEN® EZ1® DNA Investigator, Microcon®, and Amicon® Ultra-4). After DPC reversal extraction, DNA was quantified using the Qubit® fluorometric assay as well as the Plexor® HY System. Amplification was attempted using a modified AmpFℓSTR® Y Filer® technique as well as mitochondrial control region primers. The results indicate that higher temperature (95°C) improves DPC denaturation and enables amplification of 100bp-250bp mitochondrial DNA fragments. Furthermore, this study demonstrated that DPC reversal at high temperature renders DNA single stranded, which has downstream ramifications. Specifically, ssDNA can lead to DNA loss when silica-based and filter-based purification methods are employed. In addition, the validated NGS library preparation protocol at the AFDIL requires double-stranded DNA substrate. Consequently, DPC reversal requires DNA extraction techniques that are amenable to ssDNA, such as phenol chloroform extraction, as well as a complementary-strand DNA synthesis step prior to NGS library preparation. The results of the DPC reversal extraction and DNA amplification will be presented and future goals for protocol development will be discussed.

Crosslink, DNA Extraction, Heat Denaturation

B184 The Success of DNA Testing of Skeletonized Human Remains and the Comparison of Organic vs. Inorganic Extraction Protocols

Suni M. Edson, MS, Armed Forces DNA ID Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; and Stephanie R. Ah Sam, MS, DPAA Laboratory, 590 Moffett Street, Bldg 4077, Joint Base Pearl Harbor-Hickam, HI 96853*

After attending this presentation, attendees will understand not only the success of skeletal elements for DNA testing as a whole, but will also increase their knowledge regarding different extraction techniques.

This presentation will impact the forensic science community by providing information on different extraction techniques for DNA testing of skeletonized human remains. This presentation will also encourage attendees to be flexible in protocols and procedures to allow for greater success.

Since 1992, the Armed Forces DNA Identification Laboratory (AFDIL) has processed more than 16,000 skeletal elements received from the Defense POW/MIA Accounting Agency (DPAA) for multiple DNA testing platforms. These skeletal elements have typically been exposed to a variety of environmental insults postmortem and range in time of death from 40 years to slightly more than 80 years. While the initial testing strategy focuses on Sanger sequencing of the mitochondrial DNA (mtDNA) Control Region (rCRS), in the past ten years, autosomal Short Tandem Repeat (STR) testing has become an increasingly prevalent testing option. Currently, more than one-third of the casework reported each month is some form of STR analysis. These include Low-Copy Y-chromosomal Short Tandem Repeat (Y-STR) Analysis (LCN-Y) and a variety of STR testing kits.

With the shift in focus to STR analysis, in addition to a desire to use less dangerous chemicals, AFDIL implemented an inorganic DNA extraction procedure in 2013. Validation studies indicated inorganic extractions provided a cleaner DNA extract, which is more suitable for STR analysis; however, there was some concern that the extract was too clean for the existing mtDNA protocols which were adapted specifically for extracts that included low-quality DNA as well as some inhibitory materials.

Over the subsequent 3.5 years, sample types have been tracked to determine the efficacy of inorganic extractions. While the general trend in STR analysis has seen a marked improvement, from ~20% success to a current 44% success, mtDNA success has slipped, from 92% to 85%. Initial evaluation of the samples indicates that skeletal materials exposed to inhibitory materials, such as formalin or fuel, were less successful overall when extracted using an inorganic protocol. In such instances, samples were re-extracted using a Phenol-Chloroform-Isoamyl Alcohol (PCIA) -based organic extraction and generated successful mtDNA results. An organic extraction protocol has been re-incorporated into day-to-day testing for severely compromised skeletal remains.

Frequently, the forensic community is eager to adopt a single strategy for processing of casework samples. A workflow with minimal decision points is simpler, especially when faced with a large number of samples or complex cases. This is seen to be of one of the great appeals in the move toward automation; however, this evaluation of extraction protocols used for skeletonized remains indicates that a careful evaluation of the sample upon receipt and a selection of a workflow based on downstream needs may be valuable. It is also indicative of a need to maintain multiple protocols within a laboratory, rather than to suffer loss of success or capabilities by eliminating "outdated" protocols.

DNA, Extraction Techniques, Skeletonized Remains

B185 A Comparison of the Deconvolution and Likelihood Ratios (LRs) Produced Using a Continuous Probabilistic Software From Low-Level Samples When Amplifying the Entire Extract or Splitting the Extract

Todd W. Bille, MS, Bureau of ATFE, National Laboratory Center, 6000 Ammendale Road, Ammendale, MD 20705; and Michael D. Coble, PhD, NIST, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8314*

After attending this presentation, attendees will understand the potential benefits and differences of information gained from either a single analysis of a low-template sample versus splitting and combining replicate testing of the samples using a continuous probabilistic genotyping software.

This presentation will impact the forensic science community by demonstrating the range of LRs generated analyzing a single DNA profile versus splitting, then jointly analyzing, replicates of the DNA template.

Touch DNA samples typically contain much less than 1ng of total DNA. Strategies to maximize the genetic information from low-level samples is to: (1) concentrate the entire extract down to 10uL, then amplify the entire extract volume; or, (2) split the extract into multiple amplification reactions, then develop a consensus profile for interpretation.[1,2] Some laboratories may be hesitant to implement enhanced detection methods to increase the sensitivity of the amplification or analysis (e.g., increased cycle number, increased injection time/voltage, post-amplification de-salting, etc.) due to the potential for an increased detection of allele drop-in. Therefore, more information may be gained through replicate amplifications using standard protocols. Probabilistic genotyping software using continuous models of interpretation has the ability of analyzing replicates of the same DNA sample to produce a combined deconvolution and LR. This option poses the question, which analysis will produce a more informative result — amplifying and analyzing the entire DNA extract or splitting the extract and conducting a joint analysis? By splitting the DNA extract, the total DNA template used for the amplification is halved, but the replicate analysis may provide additional information for the statistical analysis.

In this study, DNA profiles were generated from a range of single source and two- and three-person mixed DNA samples in which the template DNA was amplified: (1) once with a determined quantity of template DNA; and, (2) in duplicate using one-half of the original quantity of template DNA in each amplification. All samples were amplified using the standard Polymerase Chain Reaction (PCR) amplification conditions and analyzed using capillary electrophoresis. The DNA profiles were then processed using a continuous probabilistic genotyping software. The duplicate DNA profiles generated from the split DNA extract were analyzed together, resulting in a single combined deconvolution and LR result. The information from deconvolved genotypes and the range of LR values for a single analysis compared to a joint analysis using replicate profiles will be presented.

B186 The Application of Short Tandem Repeat (STR) Sequence Variation for the Selection of Novel STR Markers to Enhance DNA Mixture Deconvolution: What Do We Know and Where Are We Headed?

Nicole M. Novroski, MS, UNT Health Science Center, 3500 Camp Bowie Boulevard, Fort Worth, TX 76108-3893; Jennifer D. Churchill, PhD, UNTHSC, 3500 Camp Bowie Boulevard, CBH-250, Fort Worth, TX 76107; Jonathan King, MS, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; and Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107*

After attending this presentation, attendees will better understand Massively Parallel Sequencing (MPS) of forensically related STRs, the value of capturing entire amplicon sequence information (primer-to-primer sequence data), and the potential impact increased allelic data will have on applications in forensic DNA human identification.

This presentation will impact the forensic science community by providing information on data that supports implementation of MPS and STRs into forensic laboratories, discussing best-practice analysis methods, and exploring the next steps in novel forensic STR determination for maximal DNA mixture deconvolution efforts.

DNA mixture deconvolution of crime scene samples remains one of the biggest challenges faced by forensic laboratories today. When DNA mixtures are encountered in a sample, the analyst would like to identify individual components of the mixture and characterize each component of the sample using mixture interpretation guidelines and statistical calculations. Once the different components of the mixture have been resolved, the analyst then is able to make comparisons of the mixture components to reference samples. Currently, the basis of forensic interpretations relies on the amplification of STR markers using the Polymerase Chain Reaction (PCR), allele sizes determined using Capillary Electrophoresis (CE), and the results used to query reference samples or existing profiles stored in the Federal Bureau of Investigation (FBI) Combined DNA Index System. DNA mixtures often complicate STR genotyping of samples, and complex mixtures of three or more contributors are being encountered routinely in forensic casework.

MPS is a novel yet robust technology for capturing large amounts of DNA data from minimal input DNA, which is useful for processing forensic evidence that is frequently limited in quantity and quality. Using MPS, multiplexing a large number of STR markers simultaneously is possible and will provide greater genetic information for STR genotyping of multiple contributors in mixture DNA samples. MPS also provides the opportunity to identify intra-allelic sequence variation within STRs not possible using conventional CE protocols. Although this technology offers promise, current panels that capture the core STR loci may not contain sequence variants that have sufficient variability to individualize components in a mixture sample. Additionally, the ability to capture flanking region sequence variation to exploit the full power of forensically relevant STR loci is needed. The application of such data will increase knowledge and understanding of each locus, increase the power of discrimination of a locus, and potentially aid in mixture deconvolution efforts. The underlying genetic variation needs to be described through studies on various population groups.

An in-depth examination of sequence variation in 58 STRs was performed on 780 individuals using the MiSeq® FGx™ Forensic Genomics System, STRait Razor, and in-house Excel® workbooks. A total of 747 autosomal, 228 X chromosome, and 324 Y chromosome STR alleles were identified by sequence compared to 357 autosomal, 107 X chromosome, and 188 Y STR alleles that were identified by length. Within the observed sequence variation, more than 500 novel alleles were identified and described. These population data illustrate the genetic variation that exists in the commonly used STR markers and suggest that a great deal of genetic diversity has yet to be uncovered in STR markers.

Continued efforts are focused on identifying substantially polymorphic STR loci for the creation of a novel STR panel. The characterization of novel STR markers containing high-resolution intra-allelic sequence variants will allow the forensic scientist to overcome certain challenges of interpretation of some complex mixture samples, increase the number of resolved profiles being compared to reference and suspect profiles, and expand the DNA database by increasing the number of forensic samples uploaded. The benefit from this revolutionary application will be an increase in the number of investigative leads and the overall resolution of more crimes.

Massively Parallel Sequencing, STR Sequence Variation, DNA Mixture Deconvolution

B187 Validation of Probabilistic Genotyping Software for Use in Forensic DNA Casework

Hinda Haned, PhD, Amsterdam, NETHERLANDS; Peter Gill, Norwegian Institute of Public Health, Oslo 0403, NORWAY; Kirk Lohmueller, PhD, Department of Integrative Biology, 3060 Valley Life Sciences, Bldg 3140, Berkeley, CA 94720; Keith Inman, MS, Dept of Criminal Justice Admin, Rm 412 Student Faculty Services, 25800 Carlos Bee Boulevard, Hayward, CA 94542; and Norah Rudin, PhD, 650 Castro Street, Ste 120-404, Mountain View, CA 94041*

After attending this presentation, attendees will better understand the scientific foundation of software validation. Attendees will receive both theoretical and practical guidance on implementing validation of probabilistic genotyping software in a forensic DNA laboratory.

This presentation will impact the forensic science community by assisting forensic DNA laboratories in validating probabilistic genotyping software, which fills a current and critical need.

Complex profiles may encompass a multitude of confounding factors resulting from DNA profiling of a low quantity and/or low quality biological sample. The resulting profile may contain multiple contributors, may lack information from the true contributors (allelic drop-out), may include extraneous information unrelated to the crime-sample information (allelic drop-in), and may suffer from degradation or inhibition. It is now accepted throughout the worldwide forensic DNA community that a likelihood ratio approach is required to reliably interpret these types of profiles.

Accordingly, recent years have seen a proliferation of probabilistic models, implemented via software, offered to the community as solutions to this problem. Acceptance of such software in the user community, and subsequent acceptance by the court, relies heavily on their validation. Although these probabilistic models rely on different assumptions and make use of different types of information, they all enable the evaluation of evidence within a likelihood framework. While these software programs have proven generally useful to facilitate the interpretation of complex DNA profiles, few guidelines exist that describe the appropriate and sufficient validation of such software used in forensic DNA casework.[1,2] The validation of probabilistic models for use in forensic casework is not straightforward because the true weight of the DNA evidence cannot be determined; there is no "right" answer. Indeed, the generated likelihood ratio always depends on the model's assumptions. No "gold standard" exists in the form of a true likelihood ratio that can serve as a comparison.

Forensic science is not the first discipline to face the challenges of model and software validation. Consequently, the field can draw on the collective wisdom of other disciplines to guide its inquiry. This presentation will discuss general principles of software validation and how they could be applied to the interpretation software now being introduced into the forensic community. This presentation will first introduce some general definitions of model and software validation taken from existing fields. Importantly, the relationship between a statistical model and its implementation via software will be clarified. This presentation will then illustrate how these ideas can be translated into use for forensic casework. A set of considerations that seek to provide guidance in validating probabilistic genotyping software for casework use will be offered.

Finally, this presentation will make the case for transparency in software. Concerns about the reliability and reproducibility of software used in scientific computing have grown over the past few years. There is a strong movement for researchers to make the source code used for analyses freely available to the community at the time of publication. Easily accessible source code implementing a statistical method will allow scientists to perform all aspects of software validation. Finally, such transparency will promote standardization and will facilitate improvements and extensions to existing software, which will be a further benefit to the community.

Probabilistic Genotyping, Software, Forensic DNA

B188 Assigning the Number of Mixture Contributors: A Fool's Errand

Charles H. Brenner, PhD, 6801 Thornhill Drive, Oakland, CA 94611-1336*

After attending this presentation, attendees will understand that the number of contributors to assume for a mixture calculation cannot be anticipated in advance, and frequently isn't even the same for competing hypotheses. Overlooking this possibility, as nearly all currently available advanced software does, entails a substantial risk of very misleading results.

This presentation will impact the forensic science community by illustrating the need to be decidedly more cautious about pushing the envelope with even moderately complicated mixtures.

Some standard advice about DNA mixture analysis is to begin by deciding the number of contributors. This advice is not only bad, it's impossible. The advice was memorialized in a careful and influential 1998 paper.[1] In the context of the times and the paper, practically speaking, the advice was merely: decide if the mixture is two-person, in which case the paper described how to perform calculations. The paper's authors didn't seriously consider more complicated mixtures. Presently, complicated mixtures are considered seriously. This is a good time to review and, without disrespect, to reject the old advice.

As a working definition, "complicated" means that the number of contributors isn't obvious. Sometimes the number doesn't even exist in any practical sense. Imagine a mixture of many contributors with contribution amount ranging from major by gradations down to undetectable. Clearly, an undetectable contributor isn't a contributor in a practical sense. How about barely detectable? A small contribution may or may not count as significant, depending on context.

A clear and concrete example will be presented explaining how the differing contexts of two competing (i.e., prosecution and defense) hypotheses may require the use of different contributor numbers. In the example, the only reasonable analysis for the prosecution hypothesis is as a four-person mixture, but the only fair analysis for the defense hypothesis is as a three-person mixture. The resultant Likelihood Ratio (LR), for four-person versus three, is close to one — neutral evidence. Calculating instead as a four-person mixture throughout manufactures the illusion of strong evidence; it frames the suspect. Conversely, calculating uniformly as three-person mixture per the defense generates the illusion that the suspect is virtually excluded. Correctly employing the unconventional calculation is vital; it makes a huge difference.

Examples are fairly common in practice, and do not follow a single pattern. It is not good to say, after studying the one example, "I see where the problem comes from; I'll just look out for that situation and I'll be okay." A counterexample doesn't simply mean, "Here's an exception." A counterexample to a rule means the rule is wrong.

What is to be done? Since there is no ground-truth number of contributors, it is impossible to begin by "deciding the number of contributors." What can and must be done instead is to calculate likelihoods for the range of possible contributor numbers, each for the prosecution and defense separately. Generally, there will be one standout number for each side — maybe the same number, maybe not — which can be used.

DNA Mixture, Number of Contributors, Bias

B189 The Use of Microhaplotypes in the Analysis and Deconvolution of Mixed DNA Samples

Lindsay D. Bennett, The George Washington University, Somers Residence Hall, 2100 Foxhall Road, Washington, DC 20007; Kelly E. Long, BSc, The George Washington University, 7308 Snowden Court, Springfield, VA 22150; Rebecca Walter, BS, 521 N Imboden Street, #402, Alexandria, VA 22304; Sharon C. Wootton, PhD, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Chien-Wei Chang, PhD, Thermofisher Scientific, 180 Oyster Point Boulevard, South San Francisco, CA 94080; Robert Lagace, BS, 850 Lincoln Centre Drive, Mail Stop #404-1, Foster City, CA 94404; Kenneth Kidd, PhD, Yale University School of Medicine, Dept of Genetics, 333 Cedar Street, New Haven, CT 06520; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will understand some of the advantages of using Massive Parallel Sequencing (MPS) of regions containing multiple Single Nucleotide Polymorphisms (SNPs), known as "Microhaplotypes (MHs)," to analyze and deconvolute complex forensic samples that are composed of DNA from multiple contributors.

This presentation will impact the forensic science community by providing further understanding of additional methods that can be used in the analysis of forensic DNA samples.

Short Tandem Repeats (STRs) have been the standard DNA markers used in human identification due to the ease of amplification and their highly polymorphic nature, which leads to a high power of discrimination. Additionally, several software packages have been developed that allow the analyst to easily identify and interpret the results. While STRs have been vital in forensic DNA analysis, several characteristics have led to limitations in their use. STR fragments are amplified and labeled using fluorescent probes; the number of loci that can be analyzed in one assay is determined by the size of the fragments and number of dyes. Current Capillary Electrophoresis (CE) methods allow determining the size of the fragment but not the sequence; however, STR loci have complex repeats that vary in sequence, making alleles indistinguishable by size discernable only by sequence. Lastly, during amplification of the repeats, stutter effects can occur for some loci over 20% of the time, leading to the production of n-4 (also n-8/+4) fragments indistinguishable from true alleles of the same size.

MHs are loci of two or more SNPs within a short distance of each other (<250 nucleotides (i.e., micro)) with three or more allelic combinations (haplotypes). Conventional Sanger sequencing does not allow determination of the *cis/trans* relationship between individual SNP alleles (i.e., the haplotype). In contrast, MPS methods, when SNPs are in the same amplicon, allow sequencing of individual strands and, therefore, the detection of haplotypes at a locus. As MHs are sequence variations, stutter effects are of no concern, making MHs a potential resource for the analysis and deconvolution of imbalanced mixtures. Other characteristics, such as small amplicon size and lower mutation rate, make these markers potentially effective on degraded samples and in familial cases, respectively. Numerous MHs have been identified that are promising forensic markers; these MHs are currently being further characterized for their use in mixture deconvolution.

In this study, synthetic mixtures and forensic type samples were genotyped using both MPS (Thermo Fisher HIDS Early Access Ion AmpliSeq™ GlobalFiler™ Mixture ID Panel) as well as CE size analysis (GlobalFiler™) and the results were compared. Results from samples first analyzed by CE suggested they were potentially composed of multiple genetic contributors, though the interpretation using CE alone was questionable as potential minor contributors fell below analytical or stochastic thresholds and into stutter ranges. MPS of STRs of these samples showed sequence variations that provided more support for the presence of a mixture; however, MH genotyping conclusively indicated the presence of multiple contributors in mixtures of two, three, and four persons at 40:1, 10:1:1, and 10:1:1:1 ratios, respectively. Additionally, several forensic-type samples were found to contain DNA from more than one contributor, with the minor contributor(s) more easily identified using MHs. Using preliminary MH allele frequencies, work is being conducted to determine random match probabilities for minor contributors found in mixed forensic samples.

These results illustrate the capabilities of MHs in the detection of mixtures and suggest the ability to genotype multiple contributors in complex forensic samples.

DNA, Sequencing, Microhaplotypes

B190 An Error in the Likelihood Ratio: The False Match Probability (FMP)

Mark W. Perlin, PhD, MD, Cybergenetics, 160 N Craig Street, Ste 210, Pittsburgh, PA 15213*

After attending this presentation, attendees will understand why the FMP is important in forensic science and how the FMP can be accurately and rapidly calculated.

This presentation will impact the forensic science community by describing how to quantify an error in forensic analysis and DNA mixture interpretation.

In identification science, there may many possible types. Observables that exist in the physical world can be conceptualized as random samples drawn from a type space. Probability and information statements made about observed types refer to the full sample space of all possible types.

A prior probability distribution describes the chance of observing a type before examining data. A posterior distribution over type space updates these probabilities based on examined data. The Bayes factor of a type in the sample space is a ratio of posterior to prior probabilities.

When stating a factor for a type exemplar relative to evidence, there is a chance of false match error. With a DNA mixture, this error is the probability of misidentifying a non-contributor type as a contributor, when the type coincidentally has a factor value at least as large as a given match statistic.

The probability of falsely matching a wrong exemplar by chance is the FMP. The error can be quantified by calculating the subset size of misidentified types having spuriously large factors.

The FMP can be costly to calculate exactly on a large type space; however, when a type is formed from independent subtypes, the factor is a numerical product of the subtype factor values. Independence helps with rapid and accurate calculation of the joint factor distribution. Evaluating the joint distribution's tail probability beyond a fixed factor value measures the type subset showing false matches.

A trier of fact does not want to make a mistake by wrongly convicting an innocent person. Most jurors do not know Bayes theorem or statistical independence. Few have studied mathematical probability, and fewer still have learned conditional probability. They rarely know about likelihood (the probability of data given a hypothesis), much less the Likelihood Ratio (LR) factor that contrasts two competing hypotheses. But they do understand the chance of error, and they want to avoid making a mistake.

Considering all the people in the world, what is the chance that a reported match statistic identifies the wrong person? DNA mathematics can randomly embed the 7.5 billion (10^{10}) people in the world in a dense space of a trillion trillion (10^{24}) possible genotypes. Population genetics can estimate prior genotype probability, while Bayesian update on evidence data can produce a posterior genotype distribution. Prior and posterior combine to provide a factor function over all genotype space.

The factor function's inverse connects extreme match values to an error subset of types. The one-dimensional tail probability of extreme match values is the multidimensional measure of non-contributor types. Actual objects in the physical world have types that are samples from the full type space. To determine an FMP relative to all the people in the world, it is computationally effective to reduce the function to a single variable and its tail probability.

The LR summarizes the probative value of evidence in forensic identification. The FMP puts an error rate to that LR value, customized to the evidence in a particular case. Both numbers are important to a trier of fact — the LR's strength of match, and the FMP's chance of error. While 1/LR is always an upper bound on LR error, calculating the FMP can provide an exact estimate of misidentification frequency. The FMP provides additional error information about an LR match statistic, simply expressed as the chance of making a mistake.

This presentation will introduce the FMP method and demonstrate its use in analyzing DNA in a sexual assault case and searching a DNA database. Understanding match statistic error will help an analyst better quantify the chance of making a mistake.

Likelihood Ratio, False Match, Error Rate

B191 Out of the "*Frye*" Pan and Into the Fire: KISS Your Judge and Defend Your Probabilistic Genotyping (PG) Software in Court

Melissa Mourges, JD, New York County District Attorney's Office, One Hogan Place, New York, NY 10013; and Martha Bashford, JD*, New York County District Attorney's Office, One Hogan Place, New York, NY 10013*

After attending this presentation, attendees will be better prepared to present evidence concerning the general acceptance and reliability of various PG software programs.

This presentation will impact the forensic science community by providing laboratory managers and lawyers with the skills necessary to successfully defend the use of PG programs, which have been increasingly adopted by accredited forensic laboratories to improve reliability of the statistics used in DNA testing.

When a laboratory manager introduces probabilistic genotyping software to generate statistics in casework, he/she can expect *Frye* or *Daubert* challenges in court. These are claims, generally by the defense, that the results should be precluded because the new techniques are not generally accepted as reliable in the relevant scientific community (*Frye*) or that the techniques are not based on sufficient facts or data and that the proposed testimony is not the product of reliable principles and methods (*Daubert*). These attacks are made even though PG software has been used to generate statistics that sometimes exonerate suspects, in both pre-trial and post-conviction settings.

Laboratories and prosecutors must partner up when faced with these challenges to scientific evidence. Together, they must create an educational package with one student in mind — the judge, who will decide whether the jury will hear results from the software on which the laboratory has spent enormous resources of time and money. The presentation to the judge will have to be comprehensive, yet simple enough for a non-scientist to understand, following the Keep It Simple Stupid (KISS) rule of thumb. Sometimes this challenge can be met on paper, and sometimes it will have to be battled out on the witness stand.

Based on successful experience defending the Office of the Chief Medical Examiner's (OCME's) Forensic Statistical Tool (FST) in New York City, suggestions for the best ways to prepare and present complex scientific evidence will be offered, including: peer-reviewed articles, conference presentations and workshops; validations; DNA and mixture interpretation fundamentals; recommendations from the Scientific Working Group on DNA Analysis Methods (SGWDAM), National Institute of Standards and Technology (NIST), and international bodies; other agencies and laboratories using them; and problems PG software will avoid.

An important aspect of these scientific admissibility hearings focuses on what to expect from experts. Because this is an adversarial system, lawyers on both sides of a *Frye* hearing can be expected to research expert witnesses and vigorously challenge them on the basis of expertise, bias (financial or otherwise), and whether they advocate the use of alternative software that can be manipulated by varying thresholds on a case-by-case basis instead of using one set of validated thresholds uniformly across the laboratory.

PG Software, *Daubert*, *Frye*

B192 United States Population Sequence Data for 27 Autosomal Short Tandem Repeat (STR) Loci, 24 Y-Chromosomal Short Tandem Repeat (Y-STR) Loci, and 7 X-Chromosomal Short Tandem Repeat (X-STR) Loci

Katherine B. Gettings, PhD, NIST, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Kevin Kiesler, MS, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Becky Steffen, MS, NIST, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Lisa Borsuk, MS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; and Peter M. Vallone, PhD, 100 Bureau Drive, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will better understand sequence-based STR allele frequencies, how this new data type can be implemented into statistical analysis, and which STR loci exhibit significant allelic gains by sequence in a large population dataset representative of four common United States populations.

This presentation and the availability of this data will impact the forensic science community by facilitating sequence-based statistical calculations when STR sequencing applications are utilized. Recent publications have been limited to smaller sample sizes, less loci, or populations less representative of the United States.[1-3]

STR loci allows for determination of repeat motif variations within the STR (or entire PCR amplicon) that cannot be ascertained by size-based Polymerase Chain reaction (PCR) fragment analysis. Sanger sequencing has been used in research laboratories to further characterize STR loci, but it is currently impractical for routine forensic use due to the laborious nature of the procedure in general and additional steps required to separate heterozygous alleles. Recent advances and cost reductions in Next Generation Sequencing (NGS), also known as massively parallel sequencing, have opened the door to routinely obtaining STR sequence data in the forensic laboratory, which may be particularly valuable in challenging cases of mixture interpretation or complex kinship. Thus, several commercial manufacturers have developed assays for sequencing various combinations of STR loci (autosomal, X, and Y), with some also containing Single Nucleotide Polymorphisms (SNPs) and mitochondrial DNA (mtDNA).

This sequence-based population study includes >1,000 DNA samples, divided among Caucasian, African American, Hispanic, and East Asian individuals, at 27 autosomal STR loci, 24 Y-STR loci, and 7 X-STR loci using an assay designed for NGS. Data analysis for genotyping was performed using the manufacturer's software and an alternate in-house pipeline based on freeware.[4,5] Allele calls for Capillary Electrophoresis (CE) and sequencing methods were compared for concordance at every locus. In the case of a discordant allele call, the cause was determined.

The resulting population data reveals general gains in discriminatory power per locus, as well as population-specific gains for some loci. Categorizing the 58 STR loci as simple or compound/complex based on the motif present in GRCh38 Human Genome Reference Sequence, the 22 compound/complex loci exhibit, on average, more than double the number of alleles by sequence compared to alleles by length, with some loci containing more than four or five times the alleles. The 36 simple repeat loci demonstrate a more modest increase in alleles by sequence compared to alleles by length, as expected. For the autosomal STR loci, the resulting sequence-based frequency data is applied to generate Random Match Probabilities (RMP) for each individual per locus and across the profile, and comparison to length-based RMP values reveals expected gains in statistics. Y-STR and X-STR loci are evaluated for gains in haplotype diversity.

This data is fundamental to implementation and support of sequencing technology, and the demonstrated gains in alleles and RMP values will assist laboratories in weighing costs/benefits.

B193 An Evaluation of the Discriminatory Power, Ancestry Prediction, and Practical Considerations of the ForenSeq™ DNA Signature Prep Kit Against Traditional Short Tandem Repeat-Capillary Electrophoresis (STR-CE) Methods

Rebecca Walter, BS, 521 N Imboden Street, #402, Alexandria, VA 22304; Michelle A. Peck, MFS, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902; Kimberly S. Andreaggi, MFS, ARP/AFDIL, 115 Purple Heart Drive, Dover AFB, DE 19902; Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007; and Charla Marshall, PhD, Armed Forces DNA Identification Laboratory, 115 Purple Heart Drive, Dover AFB, DE 19902*

After attending this presentation, attendees will better understand the differences in the discriminatory power, ancestry prediction, and practical considerations (i.e., processing and analysis time and cost) of the ForenSeq™ DNA Signature Prep Kit and Universal Analysis Software (UAS) versus traditional STR-CE methods.

This presentation will impact the forensic science community by illustrating how, as this community begins to embrace next generation sequencing, it is crucial to fully understand the differences in discriminatory power, ancestry prediction, and practical considerations between this new technology and the methods currently in use.

To this end, the ForenSeq™ DNA Signature Prep kit was evaluated for its usefulness with a set of 120 self-identified samples from African American, United States Caucasian, and United States Hispanic and Colorado population groups. The ForenSeq™ kit contains 27 autosomal STRs, 24 Y-chromosomal STRs (Y-STRs), 7 X-chromosomal STRs (X-STRs), 95 identity-informative Single Nucleotide Polymorphisms (iiSNPs), 56 ancestry-informative SNPs (aiSNPs), and 22 phenotypic-informative SNPs (piSNPs). The samples, which were previously analyzed for the mitochondrial control region, were processed according to the manufacturer's recommended procedure using Primer Mix B with minor modifications at the library purification step. Sample libraries were sequenced with an Illumina® MiSeq® FGx™, and sequence data were analyzed using the UAS. Concordance data were generated by typing the samples with an AmpFℓSTR® Y Filer® Polymerase Chain Reaction (PCR) Amplification kit and a PowerPlex® Fusion 5C System using an ABI® 3500xL and performing analysis with GeneMapper® ID-X software. This allowed for the comparison of sequenced STRs from the ForenSeq™ kit with autosomal STRs and Y-STRs typed on a traditional CE platform. Additionally, ancestry prediction from the UAS was compared with the self-identified ancestry, maternal ancestry determined from the previously obtained mitochondrial region haplogroups, and paternal ancestry determined from Y-haplogroups predicted from both the Y Filer® loci and the ForenSeq™ Y-STR loci.

These high-quality samples resulted in full autosomal profiles for all samples and full Y Filer® profiles for all male samples in both ForenSeq™ and CE kits. The data between PowerPlex® Fusion and ForenSeq™ were 99.46% concordant across overlapping loci. The ForenSeq™ data showed the presence of isoalleles, which are length-based homozygotes with different sequences due to SNPs that further distinguish same-size alleles. Both kits exhibited imbalance at D22S1045, although the imbalance was more pronounced in the data generated by the ForenSeq™ kit. Allelic calls for Y-STR markers were 97.77% concordant across overlapping loci for ForenSeq™ and Y-Filer®. Regarding the ancestry prediction from the ForenSeq™ data set, the majority of samples matched the self-identified ancestry. Discrepancies between the two measures of ancestry were observed with 6 out of 90 samples. The additional comparison of the ForenSeq™ ancestry prediction with the mtDNA and Y-STR ancestries allowed for improved characterization of the admixed samples.

Comparing the cost of both workflows at the reaction level, the ForenSeq™ method was approximately the same cost as the traditional CE kits used in this comparison. Additionally, start-up costs, such as the cost of instrumentation and a laboratory's particular throughput, need to be considered. Furthermore, the time needed to process the ForenSeq™ workflow, starting with prepared extracts, was approximately 36 hours, compared to approximately 8 hours for the traditional methods. In regard to analysis, the evaluation of the ForenSeq™ data with the UAS was particularly time consuming for two main reasons: (1) it required navigating to individual calls; and, (2) population statistics and phenotypic/ancestry prediction had to be performed for each sample individually with no report generated by the analysis software. Analysis of the CE data with GeneMapper® ID-X was generally straightforward with appropriate reports for the analyzed data and more rapid compared to analysis of STRs within

the UAS.

ForenSeq™ offers a higher discriminatory power than traditional STR CE kits and additionally provides ancestry and phenotypic prediction that can be used for investigative leads; however, the practical considerations of cost, time, and low-throughput analysis of ForenSeq™ may limit the implementation of this protocol into forensic crime laboratories since traditional STR CE kits still provide sufficient data for DNA identification in a rapid and affordable manner.

The opinions or assertions presented hereafter are the private views of the speaker(s) and should not be construed as official or as reflecting the views of the Department of Defense, its branches, the United States Army Medical Research and Materiel Command, or the Armed Forces Medical Examiner System.

Next Generation Sequencing, ForenSeq™, STRs

B194 An Evaluation of the ForenSeq™ System for Sequence-Based Y-Chromosome and Autosomal Short Tandem Repeat (STR) Typing

Rebecca Just, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA ; Lilliana I. Moreno, PhD, 15223 Leicestershire Street, Woodbridge, VA 22191; Jill Smerick, MS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22051; and Jodi A. Irwin, PhD, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will better understand the performance of the Illumina® ForenSeq™ Next Generation Sequencing (NGS) Assay and its associated Universal Analysis Software (UAS).

This presentation will impact the forensic science community by describing the current practical utility and usability of the ForenSeq™ NGS Assay and its associated UAS.

The recent commercial availability of massively parallel sequencing components and systems designed specifically for forensic use has improved the feasibility of sequence-based typing of nuclear DNA markers commonly examined for forensic applications. One such assay, the ForenSeq™ DNA Signature Prep kit (compatible with the MiSeq® ForenSeq™ FGx™ instrument), simultaneously targets 58 Short Tandem Repeat (STR) loci and up to 172 single nucleotide polymorphisms. The associated ForenSeq™ UAS performs all secondary and tertiary analyses and presents the resulting STR genotypes in both repeat and sequence-based formats.

The potential utility of the ForenSeq™ assay and software system for Y-chromosome and autosomal STR typing was evaluated based on the examination of high-quality DNA samples amplified at the target DNA input. The performance of the assay/software combination was considered with respect to marker recovery metrics. Genotype concordance was assessed both across sample or lineage replicates and with standard Capillary Electrophoresis (CE) -based repeat number data. To test both the ForenSeq™ autosomal STR (auSTR) and Y-STR recovery rates and the UAS performance with respect to the detection of poor quality or inconclusive data, UAS-determined genotyping results were assessed prior to and after analyst review of the ForenSeq data. ForenSeq™ UAS-determined genotypes were compared directly to the CE-based allele calls developed from PowerPlex® Fusion System and the Y Filer® Plus PCR Amplification Kit. A total of 4,111 auSTR and 1,296 Y-STR loci were targeted for the samples examined in this study. Five runs of the MiSeq® FGx™ system were performed, with each run varying in terms of the number of samples multiplexed. Apart from the single run (Run #2) with the largest number of multiplexed samples (61 samples total), greater than 99% of the auSTR loci and more than 97% of the Y-STR loci were recovered. The lower recovery rates in Run #2 clearly reflected lower overall read quantities per sample.

Among the 4,167 total loci ultimately compared between the ForenSeq™ and CE data (3,212 auSTR and 955 Y-STR), only two UAS allele calls were found to be inconsistent with the CE-based data and, additionally, did not trigger quality control indicators in the software. The first of these was a sample that also typed differently between the GlobalFiler® and Fusion™ CE assays. The second of these instances represented a null allele in the ForenSeq™ assay. Overall, the auSTR and Y-STR ForenSeq™ results indicated high concordance with CE data developed using commercially available assays and were similar to concordance rates reported for other CE kit-to-kit comparisons. In this presentation, results from the concordance assessments will be presented along with additional information on the general performance of the ForenSeq™ chemistry and software.

Next Generation Sequencing, Illumina® ForenSeq™, NGS Concordance

B195 Forensic Analysis of the Entire Mitochondrial Genome on Ion Torrent™ Massively Parallel Sequencing (MPS) Platforms

Jennifer D. Churchill, PhD, UNTHSC, 3500 Camp Bowie Boulevard, CBH-250, Fort Worth, TX 76107; Jonathan King, MS, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; and Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107*

After attending this presentation, attendees will possess a basic understanding of the mitochondrial genome sequencing process on an MPS platform. Attendees will also better understand the benefits of sequencing the entire mitochondrial genome in order for forensic laboratories to be able to generate the maximum amount of discrimination power and to improve mixture detection and resolution.

This presentation will impact the forensic science community by providing information on the progress toward validating and implementing MPS technologies into forensic laboratories.

The mitochondrial genome (mtGenome) has been well-established as a useful genetic marker for the analysis of challenged or degraded forensic samples; however, sequencing of the mtGenome in forensic laboratories has been limited to HVI and HVII of the sequence variation-rich control region. This is largely due to limitations with Sanger-Type Sequencing (STS) methodologies, the current gold standard of forensic DNA typing. MPS technologies offer an alternative to these STS methodologies. More specifically, the Ion PGM™ and Ion S5™ Systems are promising MPS platforms for forensic analyses. A large multiplex, short-amplicon system was developed for sequencing the mtGenome on these Ion Torrent™ MPS platforms. The Applied Biosystems™ Precision ID mtDNA Whole Genome Panel is comprised of two multiplexes each with 81 primer pairs (plus degenerate primers) that generate amplicons ≤175bps in length, which facilitates the analysis of challenged and degraded samples. When used with the Ion Chef™ System, an efficient and largely automated workflow is generated worthy of consideration for forensic casework. Sequence data for the entire mitochondrial genome can increase discrimination power when generating mitochondrial haplotypes, and the increased resolution afforded by MPS technologies allows for detection of heteroplasmy levels at each nucleotide and provides avenues for mixture interpretation. Samples were sequenced on the Ion PGM™ and Ion S5™ Systems to evaluate the quality and efficiency of the Precision ID mtDNA Whole Genome MPS workflow. Metrics such as concordance, amplicon success, coverage, strand balance, and noise were analyzed to evaluate the quality and reliability of the data produced.

MtGenome sequence data were generated for 120 reference samples, and these genomes displayed few instances of amplicon dropout. Haplotype calls for these samples were concordant with mtGenome data generated by long Polymerase Chain Reaction (PCR) on both the Ion PGM™ and Illumina® MiSeq® platforms. Read depths for these samples ranged from 259X to 8,579X, and strand balance calculations demonstrated that reads were generated from both strands of the DNA. Any reads not attributed to nominal nucleotide calls were termed noise and ranged from 0.002% to 9.03% of the total read depth across the genome. A dilution series ranging from 1ng to 1pg of input genomic DNA illustrated the sensitivity of detection for this multiplex. Successful analysis of challenged samples (including bones, aged buccal swabs, and hair shafts) and mixture samples demonstrated the multiplex's success with forensically relevant samples. When analyzing the mixtures, the major contributor's haplotype was successfully identified with nuclear DNA ratios of 1:1, 1:5, and 1:10. Overall, results indicated robust and accurate data were generated, which supports the need for full validation studies with this MPS workflow in order to move this multiplex and MPS technology closer to implementation into forensic laboratories for routine mtDNA analyses.

Massively Parallel Sequencing, Forensic DNA Typing, Mitochondrial DNA

B196 An Analysis of Highly Degraded DNA From Bone Samples Using Probe Capture Enrichment of the Entire Mitochondrial Genome and Next Generation Sequencing

Cassandra R. Taylor, BS, 351 Stock Drive, Bridgeport, CA 93517; Rachel M. Gordon, MS, 3388 Morcom Avenue, Oakland, CA 94619; Sarah Copeland, MS, Mitotyping Technologies, 2565 Park Center Boulevard, State College, PA 16801; George Sensabaugh, DCrim, University of CA, Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720; and Cassandra Calloway, PhD, 5700 Martin Luther King Junior Way, Oakland, CA 94609*

After attending this presentation, attendees will better understand the efficacy of using probe capture enrichment of the entire mitochondrial genome coupled with next generation sequencing to analyze highly degraded DNA from bone samples.

This presentation will impact the forensic science community by evaluating a method that can be used to successfully analyze highly degraded DNA samples from crime scenes and to identify victims of mass disaster situations.

Forensic DNA samples are often highly degraded, making them unsuitable for traditional methods of DNA analysis such as Short Tandem Repeat (STR) analysis because target sequences and primer binding sites are not intact. Mitochondrial DNA (mtDNA) is useful for analyzing degraded DNA because of its high copy number. Traditional methods of mtDNA analysis, including Sanger sequencing, are commonly used to only target only the HVI/HVII regions of the mtDNA genome, limiting the discriminatory power of mtDNA analysis. Probe capture is a novel technique that uses mtDNA-specific probes to enrich and capture the entire mitochondrial genome. Analyzing the entire mitochondrial genome would allow detection of discriminating information outside of the HVI/HVII regions and increase the discriminatory power of mtDNA. Next generation sequencing, a massively parallel, clonal, and high-throughput technique, is an excellent tool for analyzing the entire mitochondrial genome of degraded DNA and allows for mixture detection and resolution. The purpose of this project was to determine whether probe capture and next generation sequencing on the Illumina® platform could be used to successfully analyze highly degraded mtDNA from bone samples dating to approximately 100, 2,000, and 4,000 years ago.

This optimized probe capture method for enrichment of the entire mtDNA genome was tested on forensically relevant bone samples dating to 19-20 BC, 10-8 BC, and 4000-1000 BC. Seven bone samples recovered from a comingled tomb in Rijeka, Croatia, and dating to approximately 100 years ago were successfully sequenced with coverage of the mitochondrial genome ranging from 52%-100%. The average read length for these samples ranged from 73bp-79bp, demonstrating that the DNA is highly degraded. Six prehistoric bone samples dating to approximately 2,000 years ago were successfully sequenced with coverage of the mitochondrial genome ranging from 26%-100%. The last set of samples was recovered from a necropolis on the island of Korčula, Croatia, and dates to approximately 4,000 years ago. These six samples were successfully sequenced with coverage of the mitochondrial genome ranging from 75%-100%. In this presentation, the results of this study and the historical information gathered from these results will be discussed in further detail.

Degraded DNA, Mitochondrial DNA, Probe Capture

B197 The Evaluation of a Nanopore Sequencing Platform for Concordance and Reliability in Short Tandem Repeat (STR) Analyses

Clare M. Diester, BS, Virginia Commonwealth University, 1003 Kinney Street, Richmond, VA 23220; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, 1015 Floyd Avenue, PO Box 843079, Richmond, VA 23284; Reema Elshaer, BS, Virginia Commonwealth University, 1015 Floyd Avenue, Richmond, VA 23284; Amelia A. Bussell, MSFS, 2113 17th Street, Lubbock, TX 79401; Bonnie Brown, PhD, 1000 W Cary Street, Richmond, VA 23284-2012; and Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Dept of Forensic Science, PO Box 843079, Richmond, VA 23284-3079*

After attending this presentation, attendees will better understand current nanopore sequencing technology and its potential utility in the forensic science community, particularly with forensic STR analysis.

This presentation will impact the forensic science community by attempting to evaluate and determine the potential utility of a revolutionary small-scale nanopore sequencing platform for obtaining High-Throughput Sequencing (HTS) data.

The question in the forensic science community is not whether HTS will be implemented, but how and when. It is crucial to evaluate all potential avenues of HTS that can bring the forensic science community up to speed in the most cost- and time-efficient manner possible. This becomes increasingly imperative with the expansion of both the number of samples and the number of biomarkers per sample being employed in forensic laboratories today. This research works to evaluate and determine the potential utility of a revolutionary small-scale nanopore sequencing platform for obtaining HTS data for the forensic science community.

Research was conducted using the only nanopore platform currently commercially available: Oxford Nanopore's MinION™ nanopore system. Samples were extracted and amplified using STR amplification techniques currently used in forensic science laboratories. By evaluating the nanopore platform with commonly used, commercially available STR primers for amplification, implementation would potentially require fewer validations, implementation into the workflow would be more easily achieved, and the Combined DNA Index System (CODIS) data entry could be streamlined. In the MinION™ platform, DNA passes through a nanopore protein channel for sequencing. The unique amount of current blocked as each nucleotide moves through the channel is translated into a base call. It was posited that the 5' fluorophores incorporated during STR amplification would hinder this process and possibly block ligation of the necessary adapters for sequencing during the library preparation. Thus, STR amplicons were pretreated with ExoSAP-IT® reagent in an effort to remove the fluorophores for improved ligation efficiency and higher quality sequencing.

Products were analyzed by Capillary Electrophoresis (CE) after ExoSAP-IT® treatment to determine if the fluorophores were removed by the treatment. Data revealed incomplete cleavage of the 5' fluorophore mobility complex from all amplicons. One specific locus, D8S1179, had STR alleles detected on the CE, indicating the continued presence of the fluorophore; however, sequence data was still obtained upon analysis on the MinION™ nanopore sequencing device. These results demonstrated that the removal of the fluorophore is not necessary, and STR sequencing data is obtainable with fluorophores still attached. Alternatively, it is possible that the majority of the sequence data is originating from the non-tagged strand.

Overall, sequencing with the nanopore device yielded a total of 3,053 sequence reads less than 500bp in length, with the following loci identified: CSF1PO, FGA, TH01, TPOX, D5S818, D7S820, and D13S317. Additional sequence reads were identified for CSF1PO, TH01, and D7S820 but did not pass Quality Assurance (QA) thresholds. Only six of the identified loci were concordant with reference profiles obtained by CE analysis. Thus, an accuracy rate of less than 50% was observed. While these results are promising, they also illustrate that some additional work is needed to fully evaluate this HTS method. Continuing work will include replicate runs on an updated MinION™ platform, which includes a redesigned nanopore protein flowcell and improved bioinformatics software to address these exact error and accuracy issues. Also, additional concordance and accuracy data will be analyzed and compared to reference data obtained from CE, which may serve to further streamline and improve MinION™ data analysis.

This research works to provide information to the forensic science community about a small, portable HTS

platform that is potentially both time- and cost-efficient. The preliminary data determines that, with further improvements in error and accuracy rates, the potential uses of nanopore sequencing devices in forensics are tremendous.

Nanopore, Short Tandem Repeat, High-Throughput Sequencing

B198 The Development of a Nuclear Single Nucleotide Polymorphism (SNP) Probe Capture Assay for Massively Parallel Sequencing (MPS) of Degraded and Mixed DNA Samples

Nikhil Bose, BS, 2121 Glacier Drive, Unit 11, Davis, CA 95616; Katie Carlberg, MD, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Junior Way, Oakland, CA 94609; George Sensabaugh, DCrim, University of CA, Berkeley, School of Public Health, 50 University Hall, MC 7360, Berkeley, CA 94720; Henry Erlich, PhD, Children's Hospital Oakland Research Institute, 5700 Martin Luther King Junior Way, Oakland, CA 94609; and Cassandra Calloway, PhD, 5700 Martin Luther King Junior Way, Oakland, CA 94609*

After attending this presentation, attendees will better understand a novel method of enrichment called probe capture that can be used to enrich targeted SNP regions in degraded DNA samples as well as DNA mixtures for MPS.

This presentation will impact the forensic science community by demonstrating that extremely fragmented DNA can be captured and sequenced by an SNP probe capture assay targeting a large number of SNP regions. Further, the SNP probe capture assay designed in this project introduces the combined usage of tri-allelic SNPs, tetra-allelic SNPs, lineage SNPs, and micro-haplotypes, thereby improving the capability of detecting mixtures even if the minor contributor percent is extremely small.

Mini Short Tandem Repeat (miniSTR) primer kits are used for STR analysis when DNA samples are degraded; however, in some cases such as mass disasters and missing persons, the DNA is extremely degraded and miniSTR primer binding sites may not be intact. In such cases, mitochondrial DNA (mtDNA) can be analyzed, but since mtDNA is maternally inherited and the "product rule" is not applicable, it is not as discriminatory as nuclear DNA analysis. SNPs can be viable markers for degraded DNA analysis since the region of interest is only a single base; however, primer extension assays used in conventional SNP typing methods have limited multiplexing capabilities and require intact primer binding sites. Recently, MPS methods have been shown to sequence up to 172 SNPs across multiple samples simultaneously with high read depth per sequence. Also, the method of targeted DNA library preparation using probe capture enrichment has proved successful in enriching extremely degraded mtDNA for MPS without the need of intact primer binding sites. Therefore, the goal of this project was to design and test a probe capture assay targeting forensically relevant nuclear DNA SNPs for MPS of degraded DNA samples and mixed DNA samples.

A total of 451 SNPs were selected in the design and development of this forensic SNP probe capture assay. These SNPs include 136 Identity Informative SNPs, 41 Ancestry Informative SNPs, 24 Phenotypically Informative SNPs, 25 X chromosome SNPs, 81 Y chromosome SNPs, 31 Tri-allelic SNPs, 39 Tetra-allelic SNPs, and 36 Micro-haplotypes. The custom probe panel was developed and tested for read depth, sensitivity, capturing size-selected and degraded DNA, and detecting two-person mixtures at different ratios. The results of the coverage test consisting of 16 samples at 25ng indicated that 448 SNPs out of 451 showed coverage ≥10X in each sample. Three SNPs dropped out consistently and were excluded in later studies. The sensitivity of this capture system was tested by determining the number of SNPs with a read depth of at least 10X for sample DNA amounts ranging from 50ng to 50pg. For amounts of 5ng and greater, the percent of SNPs covered (measure of sensitivity) was 100% for all SNPs, and the correct SNP genotype assignment was at least 99.78%. The percent of SNPs covered and percent of SNPs with correct genotype assignment decreased as the sample amounts reduced from 1ng to 50pg. Next, the performance of the system was tested with size-selected DNA samples and mock-degraded DNA samples at varying sample amounts. With 0.5ng, size-selected sample DNA ≤75bp obtained coverage for 96.65% of all SNPs, and 95.09% of all SNPs obtained the correct genotype assignment. Mock-degraded samples at 10ng, 1ng, and 0.5ng with an average size of 150bp were sequenced. The coverage results for all SNPs were as follows: 100% for 10ng, 94.87% for 1ng, and 75.67% for 0.5ng. The mixture test contained samples at ratios ranging from 60:40 to 97.5:2.5. The X SNPs, Y SNPs, Tri-allelic SNPs, Tetra-allelic SNPs, and Micro-haplotypes detected 90% of the minor contributor SNPs for ratios between 60:40 and 90:10, and approximately 85% of minor contributor SNPs for ratios 95:5 and 97.5:2.5.

Based on these results, highly fragmented DNA samples can be successfully captured and sequenced for DNA samples fragmented to ≤75bp. Also, minor contributor ratios as low as 2.5% can be detected in mixtures. Therefore,

it is expected that this system can be successfully applied to analyze highly degraded DNA obtained from mass disasters and missing person cases as well as mixed DNA samples.

Single Nucleotide Polymorphism, Probe Capture, Massively Parallel Sequencing

B199 Toward a Vision of a National Forensic Science Academy Specializing in Leadership and Management

Barry A.J. Fisher, MS, MBA, 81620 Avenida Estuco, Indio, CA 92203; John Morgan, PhD*, RTI Center for Forensic Science, 3040 Corwallis Road, Research Triangle Park, NC 27709; Jody M. Wolf, MS*, Phoenix Police Department, Laboratory Services Bureau, 621 W Washington Street, Phoenix, AZ 85003; and Martina Bison-Huckaby*, 150 Clay Street, Ste 215, Morgantown, WV 26506-6528*

After attending this presentation, attendees will better understand how the concept of a leadership academy developed, the steps being undertaken to develop a curriculum, and future efforts to make the project a reality.

This presentation will impact the forensic science community by providing a process for supervisors and managers to gain skills in leadership and management to assist them in becoming better leaders.

Forensic scientists are typically promoted into higher-level positions in a forensic science laboratory because the individual is good at casework and may volunteer for special projects; this becomes the basis of the promotion. Once scientists become supervisors, managers, or crime laboratory directors, they discover their new position requires a different set of skills, which they have not had the opportunity to acquire. "Flying by the seat of one's pants" all too often becomes the solution to the problem.

Unlike police ranks, which may often have leadership and management training programs, mentorship programs, and colleagues in other command positions within the agency to provide guidance, forensic scientists placed into management roles may have little training or support.

One of the more sought-after programs for leadership/management training within policing is the Federal Bureau of Investigation (FBI) National Academy (NA). The NA began July 29, 1935, and was created in response to a 1930 study by the Wickersham Commission that recommended the standardization and professionalization of law enforcement departments across the United States through centralized training. With strong support from the International Association of Chiefs of Police and with the authority of Congress and the Department of Justice, the "FBI Police Training School" was born.

A similar study for forensic science that recommends elements of standardization and professionalism is the 2009 National Academy of Sciences (NAS) Report, *Strengthening Forensic Science in the United States: A Path Forward,* which stated, "First-line supervisors need training in quality assurance, case file review, and basic supervision skills; and managers need training in fiscal management, quality systems management, leadership, project management, human resource management, and customer service."

The concept for a National Forensic Science Academy (NFSA) was proposed by Research Triangle Institute (RTI) International and the American Society of Crime Laboratory Directors (ASCLD) to The Laura and John Arnold Foundation (LJAF), who agreed that a need existed and funded a start-up effort to develop the curriculum for the program.

There exists a number of leadership and management programs directed toward crime laboratory managers: ASCLD and West Virginia University are two of many. RTI decided that rather than start from scratch, they would work with existing programs with the intention of integrating the different efforts into an interconnected, national program of blended learning and certification with minimum standards and flexibility for individual student needs.

This panel is made up of persons with broad expertise in the forensic science community and management/leadership training program who will provide a context to the development and implementation of the NFSA.

Leadership, Management, Continuing Education

B200 Data From the Federal Bureau of Investigation (FBI) Review of Microscopic Hair Comparison Laboratory Reports and Testimonies

Cary T. Oien, MS, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135; and Marc A. LeBeau, PhD, FBI Laboratory, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will be better informed concerning current results from the review of the FBI laboratory reports and testimony in the discipline of Microscopic Hair Comparison Analyses (MHCA).

This presentation will impact the forensic science community by providing data from the FBI's MHCA review with details on statements that were marked as "inappropriate" in the review.

In 2012, the FBI, in conjunction with the Department of Justice, the Innocence Project, and the National Association of Criminal Defense Lawyers, engaged in a review of laboratory reports and testimony provided by FBI Laboratory examiners in cases involving MHCA. To the extent possible, the review has covered the period from the early 1970s through the end of 1999, when mitochondrial DNA testing of hair was fully utilized within the FBI Laboratory. The process this study used was to identify statements made by hair examiners that, when viewed alone, the FBI interpreted as not meeting accepted scientific standards for the discipline of MHCA. In April of 2015, the FBI issued a joint press release acknowledging that more than 90% of testimonies and 50% of laboratory reports in the MHCA cases reviewed had been identified as containing at least one scientific error. While these statistics are accurate, the press release did not contain the underlying data regarding these errors, nor how the FBI conducted its review. For example, when conducting the review of individual statements, language which has more than one interpretation was often conservatively marked as an error. The impact of single statements in the larger context of the examiner's complete testimony or report was not considered. The inclusion of language that properly described the boundaries of the science elsewhere in the testimony or report was not considered in deciding if a statement exceeded the limits of the science.

This presentation will provide the definitions of scientific errors used by the FBI and examples of statements that were marked as inappropriate in the FBI's review. The data will reveal that all 26 examiners that provided testimony on MHCA had at least one testimony statement flagged as inappropriate. Further, 24 of 34 examiners who issued laboratory reports on MHCA had at least one report with a statement marked as erroneous; however, it is noted that 26% of the total testimonies reviewed that contain inappropriate statements, as well as 26% of the total laboratory reports reviewed that contain inappropriate statements, were from a single examiner. It is also noted that two-thirds of testimonies with inappropriate statements were offered from the mid-1980s through the early 1990s.

More than 63% of statements marked as errors in testimony reviews and 99% in laboratory report reviews fell within the "Type 2" category in which it was deemed that the examiner offered or inferred a probability or a likelihood that a questioned hair originated from a particular source. Of these, nearly all of the Type 2 errors in laboratory reports and nearly one-half of the Type 2 errors in testimony were marked because the examiner indicated that a questioned hair was "consistent" with coming from an individual. Additionally, 20% of Type 2 errors marked in testimony were when the examiner used terms such as "rare," "unusual," or "highly unlikely" in describing the likelihood that two different people may have the same microscopic hair characteristics.

Twenty-five percent of statements marked as errors in testimonies were in the "Type 1" category. Type 1 errors involved a statement implying "the evidentiary hair could be associated with a specific individual to the exclusion of all others." Use of the words "match," "associate," or "unique" were the phrases most-often flagged for this category.

Error Type 3 required the examiner to "cite their experience of the number of cases or hair analyses worked in the laboratory and the number of samples from different individuals that could not be distinguished from one another as a predictive value to bolster the conclusion that a hair belongs to a specific individual." Approximately 12% of the statements marked as testimonial errors fell within this category.

Forensic Science Review, Microscopic Hair Comparison, FBI

B201 The Organization of Scientific Area Committees (OSAC) for Forensic Science Highlights Recent Standards and Baseline Documents for Many Disciplines

John P. Jones II, MBA, National Institute of Standards & Technology, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899*

After attending this presentation, attendees will understand the latest standards and guidelines reviewed by the OSAC for Forensic Science, recent baseline documents added to the OSAC Subcommittees webpages, and a summary of OSAC's 50+ Research and Development Needs. The OSAC is comprised of 34 operating units and more than 200 task groups populated by more than 560 OSAC members and 250 affiliates, all working on specific standards activities. The OSAC facilitates collaborations among forensic science practitioners, researchers, statisticians, and measurement scientists to bolster existing standards and guidelines, develop new standards from scratch, highlight the "state of forensic science disciplines," and identify research needs for the forensic science community.

This presentation will impact the forensic science community by educating attendees on the standards and guidelines reviewed by the OSAC, describing the purpose of the OSAC baseline documents listed on the OSAC website, and identifying existing research gaps in specific disciplines. Instructions will also be provided describing how individuals can become involved with the OSAC and have an impact on standards development efforts.

The OSAC has been fully operational since January 2015 and continues to transition the fragmented standards development efforts in the forensic industry to a unified process of recognizing valuable standards and guidelines that have both scientific merit and wide-based community acceptance. The OSAC Subcommittees have started to add baseline documents to their specific subcommittee webpages that describe the "state of the discipline" at this point in time while they work to develop new or updated standards for listing on the OSAC Registry of Approved Standards. These baseline documents contain practical information regarding forensic science disciplines that can help forensic scientists, judges, lawyers, researchers, other interested parties, and the general public to better understand the nature, scope, and foundations of the individual disciplines as they are currently practiced. This presentation will highlight some of the key baseline documents listed on the website.

The OSAC continues to implement the OSAC Registry Approval Process of Published Standards and Guidelines, which includes criteria against which existing standards and guidelines will be analyzed before being approved for posting on the OSAC Registries. This includes an analysis of technical merit, openness of the development process (to ensure balanced interests are represented), consensus, harmonization, and impact on the forensic science community. This presentation will highlight all the standards and guidelines currently listed on the OSAC Registries.

Another of the OSAC's objectives is to inform the forensic science community of research needs that are discovered during the OSAC's standards development activities. These research recommendations may be considered by other agencies and organizations when they develop their own agency research needs and when soliciting funding for forensic science research. The 25 OSAC Subcommittees have identified more than 50 research and development gaps that need to be addressed by the forensic science and academic community. This presentation will highlight some of the critical research needs identified in the OSAC.

Standards, OSAC, NIST

B202 Demolishing Divides: A Discourse on the Dearth of Discipline Differences Between DNA and Dactyloscopy

John M. Butler, PhD, NIST, 100 Bureau Drive, MS 4701, Gaithersburg, MD 20899; and Heidi Eldridge, MS*, RTI International, 3040 E Cornwallis Road, Research Triangle Park, NC 27709*

After attending this presentation, attendees will observe commonalities between different forensic disciplines, will understand that these disciplines struggle with the same issues, and realize that there is much the disciplines can learn from one another by breaking silos and abandoning an "us-against-them" attitude.

This presentation will impact the forensic science community by encouraging forensic science practitioners to reach across disciplinary lines and share their struggles and successes with one another. Many disciplines are facing the same questions, yet often approach them differently. Open and frank discussions concerning the similarities between disciplines can help everyone in problem solving.

Forensic science is often thought of as a conglomeration of separate disciplines, each residing in its own silo. In larger laboratories where each analyst specializes, this perspective can manifest in negative ways, with some analysts exhibiting an "us-against-them" attitude in which members of different disciplines keep to themselves, rarely converse, and at times exhibit hostility and jealousy toward one another. How many times have you heard members of a discipline describe themselves as the "red-headed stepchildren" of the laboratory or lament that "DNA gets all the money and all the good stuff"?

Not only are these attitudes divisive, but they also rob each discipline of the opportunity to grow and gain strength from the knowledge possessed by the others. When disciplines are compared with the intention of discovering commonalities, it may be surprising to realize how many exist. Many disciplines share similar principles. For instance, nearly all forensic disciplines involve comparing an unknown material to a known material and looking for similarities and differences in patterns, whether those patterns are fingerprints, shoe impressions, signatures, or tool marks, or two chemical spectra or DNA profiles. Many disciplines share the same critics who are saying similar things about them. Many are considering the same statistical frameworks for presenting their evidence or struggling with the same questions of how to interpret noise or report conclusions.

Using DNA and latent prints (a field originally known as dactyloscopy) as a model, this presentation will offer insight into the many ways in which these two disciplines are remarkably similar. Latent prints, once considered the "gold standard" of forensic evidence, and DNA, the current reigning champion, are both considered to be rock-solid evidence when there is a high quantity of high-quality information (such as a clear tenprint card or a complete single-donor profile). Yet once the signal becomes degraded (such as in a distorted partial latent fingerprint or a several-donor DNA mixture), the interpretation required increases dramatically, along with the chances for error and the exposure to criticism.

These two disciplines will be discussed from beginning to end, breaking the issues into Deposition, Detection, and Description (which incorporates database use, documentation, and dissemination of findings). Discover the "Dearth of Discipline Differences" in this eye-opening lecture.

Latent Prints, DNA, Breaking Silos

B203 The National Institute of Standards and Technology (NIST) Trace Evidence Data Workshop: Discussions on a Path Forward for Trace Evidence Analysis

Shannan Williams, MA, 100 Bureau Drive, Gaithersburg, MD 20899*

After attending this presentation, attendees will be informed about current efforts at the NIST to expand and improve the accessibility of reference collections, materials, and databases for trace evidence analysis. This presentation will discuss the content of a workshop that took place at the NIST on July 19-20, 2016, in addition to key takeaways, related upcoming projects, and preliminary findings being crafted into a report to be released in 2017.

This presentation will impact the forensic science community by summarizing the content of the NIST meeting, describing future plans for follow-on projects, and reviewing preliminary recommendations obtained from the various discussions that took place. The ultimate goal of this effort is to assist in coordinating a multi-agency push to strengthen data in trace evidence in order to provide better tools to assist practitioners in conducting analyses and interpretation of their casework.

In 2012, the NIST Forensic Science Research Program, with sponsorship from the National Institute of Justice (NIJ), worked to develop a comprehensive list of databases, reference materials, and standard reference collections used by forensic scientists in laboratories at the state and local levels. The main goals were to identify existing data for forensic practitioners and to discover prevailing limitations. The results of the search identified 228 state, federal, and commercially run databases, which are all available to view at http://www.nist.gov/oles/forensics/forensic-database.cfm. Since that time, the NIST has been involved in several efforts to assist in expanding the availability of data and reference materials for various disciplines, including biometrics and firearms.

On July 19-20, 2016, the NIST held an event titled, "Trace Evidence Data Workshop: Improving Technology and Measurement in Forensic Science." This event was part of an effort at the NIST to gather feedback from the practitioners and researchers in the forensic science community on further improving access and expanding the development of datasets useful for trace forensic evidence. The main objectives of the event were to: (1) identify major gaps in the availability and accessibility of data for major areas of trace evidence analysis; (2) discuss possible solutions to addressing current gaps and determine future resource needs; and, (3) develop a road map of next steps to strengthen data in trace evidence.

Over the course of two days, attendees heard presentations from several renowned experts, scientists, and practitioners on the importance of references and data in trace evidence analysis. Many pointed out the struggle that forensic laboratories have faced in maintaining trace evidence units with the reductions in submissions and budgets for staff and training. Stakeholders from various levels of government verbalized the role that data could play in the development of new strategies for trace evidence analysis, in support of new approaches to interpretation, and in the development of standards. Presentations during the event covered broad topics, in addition to focused, moderated panels on fiber, hair, paint, tape, glass, explosives, and other miscellaneous particle analysis. Representatives from the private sector also contributed in a panel discussion.

This presentation will summarize the content of the meeting, describe future plans for follow-on projects, and relate preliminary recommendations obtained from the various discussions that took place. The ultimate goal of this effort is to assist in coordinating a multi-agency push to strengthen data in trace evidence in order to provide better tools to assist practitioners in conducting analyses and interpretation of their casework.

Trace Evidence, Data, Criminalistics

B204 What Can We Learn From the Coverdell Grants? Data Mining the Coverdell Grants to Assess Their Impact on the Forensic Community

Luther S. Schaeffer, MSc, Office of Investigative and Forensic Science, NIJ, Office of Justice Programs, 810 7th Street, NW, Rm 6271, Washington, DC 20531*

After attending this presentation, attendees will better understand, through the analysis of the data collected from the Coverdell awardees, that much can be learned about the contribution of the Paul Coverdell Forensic Science Improvement Grants Program (the Coverdell program) to the greater forensic science community.

This presentation will impact the forensic science community by providing an evaluation of the Coverdell program.

The Paul Coverdell National Forensic Science Improvement Act (NFSIA) became Public Law 106-561 on December 21, 2000. This Act authorized grants to states to improve the quality, timeliness, and credibility of forensic science services for criminal justice purposes. Beginning in 2002, the Coverdell program has been perennially offered through the National Institute of Justice (NIJ) and is relied upon by many forensic laboratories and organizations throughout the United States and its territories. Coverdell grants may be used to eliminate a backlog in the analysis of forensic evidence, to purchase instrumentation and/or equipment, and to train and employ personnel in forensic science laboratories and medical examiner/coroner offices. As of 2014, more than $184,000,000 has been awarded for more than 1,000 awards. Broadly, this evaluation will include a review of data collected by the NIJ through the life of the program to elucidate the impact the grants have made throughout the forensic science community. Trends studied include: (1) determining whether the Coverdell grant program has supported the implementation of new technologies by analyzing what trends existed in purchases (e.g., did any major shifts in equipment occur that might demonstrate a discipline-wide shift to a new technology and has it contributed to establishing new technologies in the field?); and, (2) if there were measureable effects on laboratory backlogs (i.e., has the program reduced the evidence backlog in the forensic laboratories and/or has the turn-around time decreased?).

To conduct this retrospective study, a sampling of the final budgets for completed Coverdell projects will be examined to determine if and what equipment was purchased. A review of the supplies purchased in relation to technology (not typical laboratory consumables) and relevant Contracts/Consultants (e.g., services related to evaluating or validating new technologies) will also be completed. Reviews will be conducted of the budget narratives to track the discipline(s)/forensic unit(s) for which those purchases were made, as well as the training purchased for laboratory staff. Additional metrics considered will be whether the Coverdell grants were used to pay overtime or hire new laboratory staff; the relevant dates in relation to the program, such as the initial award date, project starting date, and project completion date; and lastly, the source of the funds — whether they were formula or competitive grants.

Paul Coverdell, Backlog, NIJ

B205 Polymer Replication of Cartridge Cases for Proficiency Testing and Evidence Transfer

Thomas B. Renegar, BS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Xiaoyu A. Zheng, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Michael T. Stocker, National Institute of Standards and Technology, 100 Bureau Drive, #8212, Gaithersburg, MD 20899; Robert M. Thompson, BS, NIST, Special Programs Office-Forensic Sciences, 100 Bureau Drive, MS 8102, Gaithersburg, MD 20899; Theodore V. Vorburger, PhD, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Junfeng J. Song, MS, NIST, 100 Bureau Drive, MS 8212, Gaithersburg, MD 20899; Johannes A. Soons, PhD, NIST, 100 Bureau Drive, MS 8223, Gaithersburg, MD 20899; and James H. Yen, PhD, NIST, Statisical Engineering Division, 100 Bureau Drive, MS 8980, Gaithersburg, MD 20878-8980*

After attending this presentation, attendees will understand the polymer replication process as applied to the replication of cartridge cases. Attendees will be able to perform the basic steps required in replication, as well as perform measurements/analysis of casing replicas to quantify the degree of similarity to the original masters.

This presentation will impact the forensic science community by aiding in the production of large proficiency testing sets that have a very high similarity between sets. This will help reduce errors introduced by variations between sets, thereby improving their effectiveness. Casing replicas can also be used for evidence transfer where chain-of-custody requirements inhibit the transfer of forensic evidence between agencies.

For the past several years, the National Institute of Standards and Technology (NIST) has worked on developing a validated polymer replication process for fired bullets. Quantitative analysis of bullet replicas has shown that polymer replication is a viable option for producing quality replicas that are virtually identical to the master bullets.

The NIST is now developing a process for replicating cartridge cases. Similar to bullet replication, it consists of a two-stage process in which a negative mold is first produced using silicone, then a positive cast replica is produced using polyurethane. While the process is similar to bullet replication, there are several key differences due to the specific geometries of the cartridge case surfaces being replicated. These will be described, as well as the measurement and analysis methods used in quantifying the degree of similarity of the replicas to the master cartridge cases.

Proficiency testing sets are commonly used to ensure forensic examiners are trained and qualified to examine forensic evidence. Typically, these testing sets are produced by repeatedly firing well-marking guns to produce the large number of samples required; however, even well-marking guns still have slight variations from one firing to the next. This can negatively influence the results of proficiency testing. Having the ability to replicate a master set of cartridge cases to a high level of detail is extremely beneficial. This allows multiple sets to be produced without significant differences between them. Using the polymer replication process, this can be achieved.[1] Large sets of casings can be produced and distributed, and the true results of the proficiency testing can be compared without any additional error introduced due to variations between sets.

Another important use for polymer replication is the transfer of forensic evidence. In many cases, evidence that is part of an ongoing investigation cannot be transferred to other agencies; however, due to the nature of violent crimes, it is sometimes necessary to exchange evidence with neighboring agencies to determine if there are additional links to other criminal cases. By using polymer replication, replicas of the original evidence can be shared with other agencies while maintaining chain-of-custody requirements.

Polymer Replication, Cartridge Case, Proficiency Testing

B206 We're Not as Good as We Think, But We're Not as Bad as They Say: The Need for an Objective Look at the Challenges and Perceived Issues Within Forensic Sciences

Vincent J. Desiderio, Jr., MS, United States Postal Inspection Service, 22433 Randolph Drive, Dulles, VA 20104*

After attending this presentation, attendees will have an appreciation for both sides of the debate over the validity of the forensic sciences and its role in investigative and legal proceedings.

This presentation will impact the forensic science community by highlighting and addressing the divide that exists between forensic practices and the view of those practices from critical outside perspectives.

The forensic sciences are currently facing unprecedented challenges. Over the past several years, a series of high-profile missteps have exacerbated the perception that forensic scientists operate in a culture devoid of science. Stoked by a series of DNA exonerations, high-profile fingerprint misidentifications, newsworthy accreditation issues, and a litany of rogue scientists falsifying results, some of our most outspoken critics have generalized the entire forensic field as something that is unworthy of participation in our judicial process. On the opposite side of the debate, there are some among forensic scientists who have dug in their heels and taken the position that such claims are entirely false, everything is fine, and there is no reason to change anything that is currently being conducted.

As with any other scientific endeavor, forensic science is not perfect and is in serious need of improvements in a wide range of areas. To think that it will be fine to proceed in a "business as usual manner" is naive at best. Practices are not as good as some would believe and critics do raise some valid points that need to be seriously considered. Fortunately, rational scientific thought is winning out and a great deal of effort is being expended to make improvements throughout the forensic field. Unfortunately, our critics do not seem to be impressed with many of these efforts. Potentially tainted by environments that only highlight the negative, many of the critics appear unwilling to step outside of their spheres to take an objective look at the efforts toward change that are being put forth.

It is the objective of this presentation to demonstrate that both points of view, each heavily influenced by their own forms of confirmation bias, are incorrect. The opposite extremes of each group select only the information that supports their position yielding a two-way unwillingness to objectively evaluate the merits of each other's position. We may not be as good as we think, but we are certainly not as bad as they say.

Forensic Malpractice, Confirmation Bias, Forensic Validity

B207 The Importance of a Combined DNA Index System (CODIS) DNA Hit Follow-Up: A Case Review of Secondary DNA Transfer and the Individual Wrongfully Charged With Murder

Tahnee Nelson Mehmet, MSFS, Santa Clara County, Crime Lab, 250 W Hedding Street, San Jose, CA 95110*

The goal of this presentation is to share the case specifics of likely the first documented case of secondary DNA transfer of an innocent individual at a crime scene. The discovery of this individual's DNA profile on the fingernails of the decedent incorrectly implicated him as one of the perpetrators of the homicide, consequently forcing him to serve several months in county jail before his alibi was discovered. This case highlights the extreme importance of conducting proper follow-up investigations once an individual is associated to a crime scene via DNA evidence.

This presentation will impact the forensic science community by sharing a case review in which DNA transfer wrongfully implicated an individual of murder and by explaining how the presence of an individual's DNA profile, especially when first determined through a CODIS DNA hit, must be properly investigated.

DNA transfer is the presence of an individual's DNA profile on an item even though the individual never directly came into contact with the item. The mode of transport can be secondary or tertiary in nature and has been documented in mock crime scene scenarios in the relevant literature. DNA transfer has long been discussed in the context of forensic evidence and used to theoretically explain the presence of DNA profiles at crime scenes. This concept has become increasing important, especially with the rise of contact DNA testing of very small amounts of DNA.

The homicide case discussed in this presentation is likely the first documented case of secondary transfer of DNA evidence on an actual crime scene sample. The robbery-homicide rattled the quiet community, especially since there were no leads and the victims initially appeared to be completely random targets. The Santa Clara County Crime Laboratory was tasked with examining several items of evidence from the scene, including samples collected from the decedent's body, duct tape used to bind victims, and several disposable gloves found throughout the house. The identity of the individual, Lukis Anderson, whose DNA was transferred to the fingernails of the decedent, was discovered through a DNA hit. At the time of the homicide, he was a transient of downtown San Jose with a petty criminal history. Two other individuals were also associated to the crime scene through DNA hits on various items of crime scene evidence, including duct tape and disposable gloves. The latter two individuals had extensive criminal histories and were known gang members from Oakland, CA, with clear ties to the victim once further investigations were conducted. On the other hand, follow-up investigations revealed that Anderson did not have any known associations with the other two individuals or with the victims. Further investigation by his defense attorney revealed that he was incapacitated at a local hospital at the time of the homicide, thereby proving his innocence.

Following the discovery of this information, Anderson was promptly released from county jail and cleared of all charges. The crime laboratory conducted additional Y-chromosomal Short Tandem Repeat (Y-STR) testing that confirmed Mr. Anderson wasn't connected to this crime via an adventitious, or false, DNA hit. Once news of this circumstance became public record, the media began to speculate on the explanation of the presence of Anderson's DNA on the decedent's fingernails, including accusing the DNA criminalist of using improper techniques and contaminating the fingernails with Anderson's DNA profile. Ultimately, the Santa Clara County District Attorney's Office discovered that the same paramedics that responded to the homicide scene also treated Anderson earlier that evening. It is thought that a medical apparatus called a pulse oximeter, which attaches to the fingertip of the patient, was the mode of transport of Anderson's DNA profile to the decedent. Without the proper follow-up investigations, it is unclear what Mr. Anderson's fate would have been, as he likely could have been wrongfully convicted of murder. Thankfully, the truth was discovered and he was cleared of all wrongdoing. The forensic science community must learn from this case that DNA transfer is not just a theory used to distract juries, and thorough investigations following a CODIS DNA hit should be undertaken by the proper authorities to provide supporting information as to the individual's criminal involvement.

DNA Transfer, CODIS, Wrongful Arrest

B208 Exploring the Relationship Between Quantitative Polymerase Chain Reaction (qPCR) and Short Tandem Repeat (STR) Data for Compromised, Low-Template DNA Samples

Lauren Elizabeth Alfonse, MS, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Rm L805, Boston, MA 02118; Amanda D. Garrett, MS, Boston University School of Medicine, 72 E Concord Street, Rm R806, Boston, MA 02118; and Catherine M. Grgicak, PhD, Boston University, School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Rm R806D, Boston, MA 02118*

The goal of this presentation is to provide attendees with an understanding of how information obtained from the qPCR reaction, such as the degradation index and Internal PCR Control (IPC) Cycle threshold (C_t), may relate to the resultant electropherogram. This will be accomplished by examining qPCR and STR data obtained from pristine, enzymatically degraded, sonicated, Ultraviolet (UV) -damaged, and humic acid-inhibited DNA extracts.

This presentation will impact the forensic science community by demonstrating that the correlation between qPCR and STR data varies and depends upon the way in which the DNA was compromised. Although results from the qPCR reaction are often used to inform downstream processing and interpretation, the data presented indicate that under certain circumstances, and particularly for low-template, compromised extracts, information obtained from the qPCR reaction is only an approximation of the amount of amplifiable DNA. The information garnered from qPCR becomes less informative as the DNA becomes more compromised and as the extract contains fewer copy numbers.

With the implementation of increasingly sensitive detection systems, compromised (i.e., damaged, degraded, or inhibited), low-template DNA samples are often encountered in forensic casework. During forensic DNA processing, quantitation via qPCR precedes STR amplification. Data obtained from the quantitation reaction, which now include a measurement of total human DNA content, an assessment of the level of degradation, and information pertaining to the amplification of an Internal PCR Control (IPC), may inform downstream processing steps.[1,2] Ideally, with well-paired qPCR and STR amplification kit chemistry, these metrics may be used to optimize the amount of sample added to the amplification reaction or indicate that additional treatment may be worthwhile.

This study seeks to relate and compare information obtained from the qPCR reaction to the resultant STR Electropherogram (EPG) using both pristine and compromised DNA samples obtained from whole blood. Compromised samples were generated via enzymatic degradation, sonication, UV damage, and inhibition with humic acid. For each type of compromised extract, three levels were produced by varying concentration (DNase and humic acid) or reaction time (Fragmentase, UV, and sonication). Extracts were quantified then amplified using 29 cycles at 0.25ng and 0.03ng. Fragment analysis was completed using common electrophoresis settings and an analytical threshold of one Relative Fluorescence Unit (RFU).

Three phenomena were observed: (1) the correlation between the Degradation Index (DI) obtained from the qPCR assay and the peak height slope observed across increasing molecular weight loci in the EPG varied with different types of compromised extracts. Sonicated samples displayed the highest correlation between DI and slope, and the remaining sample types in order of decreasing correlation for 0.25ng templates were: DNase/Fragmentase, UV, and humic acid. For all compromised extracts, this correlation became worse as the template mass decreased; (2) with the exception of inhibited extracts, a decrease in RFU at the lowest molecular weight loci was observed with all compromised extracts as the DI increased despite the target mass remaining constant (0.25ng). The concentration of the 80bp target in compromised samples may be an overestimate of the amount of amplifiable product available for STR amplification. Although the STR amplicons tested range in size from ~80bp-450bp, the low molecular weight region is largely composed of rare autosomal alleles and non-autosomal markers with low discriminating power.[3] Preliminary results obtained with sonicated extracts quantified with a 140bp target and amplified with STRs that range in size from ~100bp-400bp suggest that using a longer qPCR target more representative of the size of the shortest high-frequency STR alleles may result in a more informative EPG for certain sample types; and, (3) with regard to extracts inhibited with humic acid, no correlation was observed between the DI and IPC C_t obtained from the qPCR assay and the resultant EPG. In the worst-case scenario, characterized by an out-of-range or undetected IPC C_t and an undefined degradation index, the corresponding EPGs exhibited no discernable peak height slope

across loci and a drop-out rate of 0% for 0.25ng template samples. Cumulatively, these data indicate that for low-template, compromised extracts, information obtained from the qPCR reaction provides only some predictive value regarding the final EPG and may not be an appropriate method by which to decide whether a sample is likely to produce an EPG with substantive levels of signal.

DNA Quantification, DNA Degradation, PCR Inhibition

B209 Touch DNA: "Touch" Time and Resiliency

Francesco Sessa, MS, Ospedale Colonnello D'avanzo, Viale Degli Aviatori 1, Foggia 71100, ITALY; Benedetta Tomaiuolo, BS, University of Foggia, Viale Ofanto, Foggia 71122, ITALY; Stefania C. Bello, MD, Ospedale Colonnello D'Avanzo, viale degli Aviatori, Foggia 71100, ITALY; and Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Dept of Forensic Pathology, Viale degli Aviatori, 1, Foggia 71100, ITALY*

After attending this presentation, attendees will better understand touch DNA, the variation in quantity of DNA related to touch time, and what type of methodology can best be used to collect touch DNA.

This presentation will impact the forensic science community by providing information regarding the collection of samples of touch DNA from garments and by clarifying the major aspects of these forensic techniques.

With every touch of the skin on a surface, cells are left behind; with every cell, the genetic code can be found. People touch doors, tables, and so many other surfaces every day, often with multiple people touching the same object throughout the course of a day.[1] New research has found that touch DNA analysis can erroneously implicate a person who had no contact whatsoever with the crime scene as the main contributor of the DNA on its handle.

When a swab is used for evidence collection from a surface, the investigator may not know how many people may have touched this evidence in the past or what level of persistence DNA may have on touched objects over time. Though every touch leaves cells containing DNA, most contact leaves only a few cells if minimal pressure is used. These trace levels of DNA may remain undetected or, if detected, may be at such low levels that only stochastic effects and low levels of allele drop-in are observed.[2]

The goals of this study are to evaluate how much time (in term of seconds) is necessary to leave touch DNA on a dress and to determine what type of technique maximizes the DNA recovery by evaluating swabs, cuttings, and adhesive tape to sample an area of interest.

To acquire a greater knowledge of the rate of a detectable wearer as well as touch and background DNA, 30 females wore their brassieres for 12h. Subsequently, the lateral regions of each brassier were handled by one of five male volunteers for different lengths of time: 60s, 45s, 30s, 20s, and 10s.

Every experiment was conducted in triplicate. In the first case, the sample was collected by swabbing. The second case employed cutting the area for testing. The third case was sampled with adhesive tape. The quantity of recovered DNA was determined using real-time Polymerase Chain Reaction (PCR) with Alu-based targets and SYBR® Green detection. The samples were also analyzed using capillary electrophoresis-based Short Tandem Repeat (STR) typing to determine the percentage of recoverable alleles. Touch DNA is an emulation of the Locard exchange principle, in that any time a person is in a location, they may leave DNA evidence of their presence.

The results revealed that the best technique to recover touch DNA is to cut the area of interest. The "toucher" was detected as a single profile in samples handled between 60s and 45s. The "wearer" was present in the mixtures obtained from the 30s to 10s samples, but the "toucher" was always observed as the major contributor.

Greater knowledge of the frequency of detection of reportable wearer DNA and toucher DNA allows scientists to evaluate the likelihood of observing a matching profile if an individual wore a garment rather than touched it in disputed case scenarios. Everyone in the medicolegal community — forensic scientists and technicians, DNA analysts, potential jurors, and judges and lawyers for both the prosecution and defense — must know and understand the potential for mistakes.

Touch DNA, DNA Recovery, Touch Time

B210 Increasing DNA Recovery With Nylon Flock Swabs and One-Step Spin Baskets

Angela Ambers, MA, 1319 Windstream Street, Denton, TX 76209; Rachel E. Wiley, MFS, University of North Texas Health Science Center, Dept of Molecular and Medical Genetics, 3500 Camp Bowie Boulevard, Fort Worth, TX 76107; Nicole M. Novroski, MS, UNT Health Science Center, 3500 Camp Bowie Boulevard, Fort Worth, TX 76108-3893; and Bruce Budowle, PhD, UNT Health Science Center, Forensic & Investigative Gen, 3500 Camp Bowie Boulevard, EAD 310, Fort Worth, TX 76107*

After attending this presentation, attendees will understand the salient features related to DNA recovery from forensic samples. Since swabbing is a routine method of sample recovery, the important features include collection efficiency, recovery of DNA from the collection device, elution strategies, and purity of the DNA.

This presentation will impact the forensic science community by stressing the importance of collection and extraction. Indeed, it is these processes that contribute substantially to the success of DNA typing, especially for low-quantity samples. Success of DNA typing is related to the amount of target material recovered from an evidentiary item.

While not considered as dynamic as the analytical phase, recovery and extraction of DNA are critical to the success of DNA typing. Successful typing can be increased by recovery of greater quantities of suitable-quality DNA. The features that favor collection of a stain at the crime scene often are the same ones that reduce successful recovery of DNA from a swab medium. The primary collection device in current use, the cotton swab, is designed to recover biological stain evidence with reasonable efficacy and is relatively inexpensive; however, the release of DNA from cotton is rather inefficient. There are other devices, such as the 4N6FLOQSwab™, composed of short nylon fibers arranged in a perpendicular fashion by flocking, which will not trap DNA within its matrix as cotton does. In addition, swab heads are often subjected to multi-step manipulations involving a spin basket device. One improvement on the process is the use of the Nucleic Acid Optimization (NAO™) basket, an insert which allows for one-step processing of the swab tips. This approach yields more DNA, reduces labor/processing time, and decreases the likelihood of sample contamination. These various devices have been compared to assess the efficiency of DNA recovery by direct deposit and/or swabbing of neat blood and diluted blood; dried blood, semen and saliva at various dilutions; and trace touch samples. In all cases, DNA recovery and, thus, typing results obtained with the 4N6FLOQSwab™ outperformed that of the cotton swab. These alternate devices also contribute to an efficient workflow.

This presentation will describe the important features to consider for an efficient process of DNA recovery and will present results from comparative testing. Attendees will benefit by becoming more aware of methods to enhance DNA typing success.

Swab, Basket, DNA Recovery

B211 Alternative Reducing Agents for DNA Extraction

Megan E. Grimes, MFS, 5187 Salt Pond Place, Woodbridge, VA 22193; and Mark F. Kavlick, MPhil, 2501 Investigation Parkway, Quantico, VA 22135*

After attending this presentation, attendees will understand how reducing agents can improve forensic DNA extraction, that there are alternatives to the commonly used reducing agent Dithiothreitol (DTT), and how to easily substitute these agents into an established casework workflow.

This presentation will impact the forensic science community by introducing and describing alternative reagents to improve DNA extraction from semen samples. The reduction of disulfide bonds is a critical step in the extraction of DNA from sperm cells, which may be improved using alternative reducing agents compared to DTT.

A commonly utilized reducing agent in forensic DNA extraction is DTT, which facilitates the isolation and purification of DNA from proteins within a biological sample by reducing disulfide bonds, thereby enhancing proteinase K digestion. Additionally, an alkylating agent, such as Iodoacetamide (IAM) may be employed as a secondary step to prevent reformation of disulfide bonds.

DTT has many disadvantages as a reducing agent, in that it is unstable in air, requires refrigeration, and has an unpleasant odor. During a previous study, it was observed that alternatives to DTT *alone*, such as DTT followed by alkylation with IAM or replacement of DTT with Tris(2-Carboxyethyl)Phosphine (TCEP), improved DNA extraction yields.[1] Therefore, this study focused on identifying other alternatives to DTT to improve/enhance DNA yields from semen samples. Three alternatives to DTT and TCEP were identified and evaluated. These included Dithiobutylamine (DTBA), Glutathione (GSH), and Tributylphosphine (TBP).[2-4] Specifically the following conditions were compared: (1) DTT alone (Standard Operating Protocol (SOP)); (2) DTBA; (3) DTBA followed by IAM; (4) GSH; (5) GSH followed by IAM; (6) TBP; and, (7) TBP followed by IAM. DNA yields were measured using a nuclear DNA-specific quantitative Polymerase Chain Reaction (qPCR).

All reagents tested were water-soluble and easily incorporated into a semi-automated SOP workflow. In brief, the SOP involved lysis of the semen specimen in buffer G2, proteinase K, and DTT, followed by purification on an EZ1™ BioRobot®. Each alternative reducing agent simply replaced DTT during the initial lysis stage. Alkylation by IAM, where tested, involved a separate incubation for 30 minutes in the dark at room temperature.

Results demonstrated that the alternative reducing agents provided increased DNA yields over the SOP. DTBA, DTBA followed by IAM, GSH, and GSH followed by IAM showed significant increased yields of 25%, 25%, 65%, and 61%, respectively, compared to the SOP. In conclusion, DTBA and GSH may be considered superior reducing agents to that of DTT for forensic DNA extraction. In particular, these alternatives may prove invaluable for challenging samples, such as low template, or those which are recalcitrant to extraction, such as spermatozoa.

DNA Extraction, Dithiobutylamine, Glutathione

B212 An Analysis of an Internal Validation Dataset for the New Core Short Tandem Repeat (STR) Loci

Sarah Riman, PhD, The George Washington University, 5500 Friendship Boulevard, Apt 2429N, Chevy Chase, MD 20815; Erica L. Romsos, MFS, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; and Peter M. Vallone, PhD, 100 Bureau Drive, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will better understand the open source interpretation tools for analyzing large internal validation data sets.

This presentation will impact the forensic science community by exploring different means to parse the output from internal validation experiments designed and performed in forensic laboratories to demonstrate the reliability, reproducibility, and robustness of the current larger STR DNA genotyping chemistries.

In March of 2015, the Federal Bureau of Investigation (FBI) published the expansion of the original core 13 loci to a new Combined DNA Index System (CODIS) core containing 20 loci.[1] Following validation guidelines outlined by the Scientific Working Group on DNA Analysis Methods (SWGDAM) and the European Network of Forensic Science Institutes (ENFSI) DNA Working Group, an internal validation dataset was generated to assess the PowerPlex® Fusion™ 6C STR multiplex chemistry.[2,3]

Organization and analysis of internal validation data is often performed manually within an Excel® spreadsheet format within laboratories. Thorough analysis of validation data sets for the new STR typing kits and/or new technologies within forensic laboratories may appear daunting, but it is essential for robust data interpretation to generate the most accurate results for producing a laboratory's standard operating procedures and technical manuals.

To illustrate the analysis of an internal validation data set, 44 reference and known samples were used in experiments designed to validate PowerPlex® Fusion™ 6C, which is comprised of 23 autosomal STRs, 3 Y-chromosomal Short Tandem Repeats (Y-STRs), and amelogenin. Results obtained from the internal validation experiments provided data to extract and evaluate parameters, such as sensitivity, stochastic effects, sizing precision, allele calling accuracy, repeatability and reproducibility, DNA mixture performance, and contamination detection.

This presentation will describe the process of interpreting internal validation experiments for PowerPlex® Fusion™ 6C using several open source software tools. Data analysis were conducted using the in-house software programs developed at the National Institute of Standards and Technology (NIST) (http://www.cstl.nist.gov/strbase/software.htm), as well as *STR-validator*, a software created by Oskar Hanson at the Norwegian Institute of Public Health.[4]

This presentation will illustrate: (1) the specific data formatting for import into software tools; (2) the calculations of analytical and stochastic thresholds manually as well as in *STR-validator*, which examines multiple published calculation methods; and, (3) the data output of stutter percentage calculations, peak height ratios, base-pair sizing precision, mixture detection, genotyping concordance, reproducibility, and sensitivity.[5-7] The goal is to share the findings of this study with forensic laboratories and introduce the community to open source programs that can be utilized during the internal validation process.

Autosomal STR Markers, Internal Validation Studies, Software

B213 A Survey on Serological and DNA Typing Methods in United States Forensic Laboratories

Jeannie Do, BS, 21072 Spurney Lane, Huntington Beach, CA 92646; and Daniele S. Podini, PhD, Department of Forensic Science, 2100 Foxhall Road, NW, Washington, DC 20007*

After attending this presentation, attendees will better understand the most common serological tests and DNA typing kits in use in a representative sample of forensic DNA laboratories in the United States. This presentation will discuss the amount of variation that exists with the laboratories' chosen methodologies, the trends toward new methodology and instruments, and the knowledge that forensic professionals want new employees or recent graduates of forensic programs to possess prior to entering the field.

This presentation will impact the forensic science community by informing United States forensic practitioners about their community's trends and the methods in use. This will help determine the variation present among laboratories. The results will also act as guidelines for educators in developing course content in their forensic science programs to maximize students' pertinent knowledge prior to entering the workplace.

There are approximately 400 public forensic laboratories in the United States, of which 59% perform serological and DNA typing analysis on evidence. Each laboratory selects the methodologies and kits, then validates corresponding Standard Operating Procedures (SOPs) based upon their needs and expertise. The differences among laboratories lead to variation and a lack of SOP standardization within the community, which is a major concern, particularly with DNA mixture interpretations. A 2013 study by the National Institute of Standards and Technology (NIST) found discrepancies in how laboratories were interpreting artificially generated mixture profiles. The results highlighted significant variation among the conclusions reached, not only by different laboratories, but also within a single laboratory between different analysts. Understanding and characterizing the basis of this variation will benefit the community.

The variation in public forensic laboratories is also reflected considerably among forensic biology educational programs in the United States, whose purpose is to develop and effectively prepare pertinent content to maximize employment opportunities for their students.

To address the aforementioned concerns, a survey was developed to receive feedback from laboratories on various areas of testing. Topics ranged from collection methods and presumptive and confirmatory tests for different body fluids to the type of kits laboratories use for extraction, quantitation, and amplification. For example, laboratories were asked to select which tests are used for the presumptive and confirmatory testing of blood and to describe their workflow process for blood evidence screening. In addition, there was a section for comments and advice for educators. The survey was distributed to 198 National DNA Index System (NDIS) laboratories through Qualtrics, an on-line survey-making platform. One hundred seventeen responses were collected, but 17 responses were incomplete and therefore excluded from the analysis. With 100 complete responses, the response rate of the survey was 50.5%.

Results from the survey not only highlight the most popular serological methods and DNA kits, but also provided insight to the forensic DNA community. For example, results revealed that phenolphthalein (the Kastle-Meyer test) was the most common presumptive test (71%) and the ABAcard® HemaTrace® was the most common confirmatory test (64%) for blood. Variation was observed more frequently with the laboratories' serological methods and workflow processes, especially for sexual assault evidence. Several laboratories process blood evidence with a visual examination, followed by a presumptive test; if the presumptive test is positive, the evidence is processed for DNA. Sexual assault workflow, on the other hand, is dependent on the type of evidence given the different items present in a sexual assault kit, such as swabs, slides, and clothing. Consequently, the evidence may be processed differently. One possible workflow is to process the evidence first with a microscopic sperm search and, if the search is negative, with a confirmatory test for p30, indicating the presence of seminal fluid. Another approach is to perform a differential extraction to isolate the male DNA, then a microscopic sperm search on the evidence from which the male profile was obtained. Furthermore, laboratories were surveyed on additional analysis capabilities, such as mitochondrial DNA (mtDNA) analysis and Massively Parallel Sequencing (MPS) capabilities.

The survey provided a significant amount of information from several laboratories. This allows for the identification of commonly used methods and an understanding of how these vary across laboratories. This information will inform laboratories on the most popular current, and potentially future, methods used by forensic practitioners, allow laboratory directors to be better prepared for the future, and help educators develop their programs to produce knowledgeable graduates.

Survey, Serological Tests, DNA Typing

B214 The PROVEDIt Initiative: The Development and Release of a Collection of Computational Tools and a Large-Scale Empirical Data Set for Forensic Research and Validation

Lauren Elizabeth Alfonse, MS, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Rm L805, Boston, MA 02118; Amanda D. Garrett, MS, Boston University School of Medicine, 72 E Concord Street, Rm R806, Boston, MA 02118; Harish Swaminathan, PhD, Boston University School of Medicine, 72 E Concord Street, Boston, MA 02118; Kelsey C. Peters, BS, Boston University Biomedical Forensic Sciences, 72 E Concord Street, Rm R806, Boston, MA 02118; Genevieve Wellner, MS, Illumina Madison, 5602 Research Park Boulevard, Ste 200, Madison, WI 53719; Lauren M. Taranow, BA, 7 Price Road, #1, Allston, MA 02134; Jennifer L. Sheehan, BS, Boston University School of Medicine, 72 E Concord Street, Rm R806B, Boston, MA 02118; Sarah E. Norsworthy, BA, RTI International, Center for Forensic Sciences, 3040 E Cornwallis Road, Bldg 7, Rm 222, Research Triangle Park, NC 27709; Desmond S. Lun, PhD, Rutgers University, Center for Computational & Integrative Biology, Camden, NJ 08102; Ken Duffy, PhD, Hamilton Institute, Maynooth, IRELAND; Muriel Medard, ScD, Massachusetts Institute of Technology, Dept of Elec Engineering & Computer Science, 77 Massachusetts Avenue, Cambridge, MA 02139; Robin W. Cotton, PhD, Boston University School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, R 806, Boston, MA 02118; and Catherine M. Grgicak, PhD, Boston University, School of Medicine, Biomedical Forensic Sciences, 72 E Concord Street, Rm R806D, Boston, MA 02118*

After attending this presentation, attendees will be aware of the release of a large-scale database of DNA samples containing up to five contributors. Attendees will also have knowledge of five software-based applications that can be utilized during forensic research, validation, or pedagogical pursuits.

This presentation will impact the forensic science community by providing an easily accessible large-scale database of compromised, mixed DNA samples of varying templates. This will allow all members of the forensic science community to test software implementations and various hypotheses from a single, well-characterized data set.

The interpretation of forensic mixtures is difficult and becomes increasingly more difficult as: (1) the number of contributors increases; (2) the number of copies decreases; and; (3) Polymerase Chain Reaction (PCR) becomes less efficient because of PCR inhibitors or DNA damage. Several interpretation tools, analysis techniques, and interpretation standards/recommendations have been developed and released. In the case of software solutions, all of these systems rely upon assumptions and have computational nuances associated with their algorithms; thus, there is considerable interest in comparing their performances.

In an effort to provide support to the community and to foster growth in both forensic research and operations, the Project Research Openness for Validation with Empirical Data Initiative (PROVEDIt) is announced.

PROVEDIt comprises 25,000 .fsa and .hid profiles as well as a suite of analysis, interpretation, and *in silico* software systems/procedures and models developed in a variety of environments. The profiles and tools are available to the community on Boston University's DNA Mixture Website (www.bu.edu/dnamixtures).

The collection of computational systems includes: (1) Computational Evaluation of Evidentiary Signal (CEESIt) — outputs the likelihood ratio, likelihood ratio distribution, and p-value for an unknown; (2) Number of Contributors (NOCIt) — outputs the a posteriori probability distribution for the number of contributors; (3) Genotype Generator & Evaluation Tool (GGETIt) — a simulator that outputs the minimum number of contributors based on allele counts; (4) Simulating Evidentiary Eletropherograms (SEEIt) — a dynamic model that simulates the entire forensic process and produces well-characterized electropherograms for up to six contributors; and, (5) CleanIt — an automated procedure for filtering bleed-through, complex bleed-through, and minus A from an electropherogram.

The collection of .fsa and .hid profiles includes one- to five-person DNA samples, amplified with targets ranging from 1ng to 0.007ng, with varying levels of damage and contributor ratios.

The usefulness of large data sets is demonstrated by plotting a histogram of the empirical signal for each locus and confirming that signal from one copy is detected. These histograms exhibit at least three seemingly distinct

peaks. For example, for the D8S1179 locus, the first signal group (median 4 Relative Fluorescence Units (RFU)) consists largely of instrumental noise; the second group (median 24 RFU) is the signal obtained when one copy of DNA is amplified; and the third (median 47 RFU) is the signal obtained when two copies of DNA are amplified. Next, the signal obtained when these same samples were injected for twice as long is presented. The same multi-modal pattern is observed but, with doubled injection time, the first and second signal groups appear at 4-11 RFU and 36-65 RFU, respectively. These data suggest that single-copy DNA signal is regularly detected using modern forensic laboratory implementations.

This project was partially supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice, and the Department of Defense, Army Research Office, Rapid Innovation Fund. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the author(s) and do not reflect those of the Department of Justice or Department of Defense.

PROVEDIt, DNA Mixtures, Low-Template DNA

B215 The Development of the National Institute of Standards and Technology (NIST) Standard Reference Material (SRM) 2391d: The Next Iteration of the Polymerase Chain Reaction (PCR) -Based DNA Profiling Standard

Becky Steffen, MS, NIST, 100 Bureau Drive, MS 8314, Gaithersburg, MD 20899; Margaret C. Kline, MS, 100 Bureau Drive, Gaithersburg, MD 20899; David L. Duewer, PhD, 100 Bureau Drive, Gaithersburg, MD 20899; Michael D. Coble, PhD, NIST, 100 Bureau Drive, MS 8312, Gaithersburg, MD 20899-8314; and Peter M. Vallone, PhD, 100 Bureau Drive, Gaithersburg, MD 20899-8311*

After attending this presentation, attendees will understand the benefits and potential differences of the next iteration of the NIST SRM 2391d: PCR-Based DNA Profiling Standard.

This presentation will impact the forensic science community by demonstrating what is involved in developing and characterizing a NIST SRM, as well as what will be different about this SRM when compared to the current 2391c version.

The first NIST Standard Reference Material (SRM) 2391: PCR-Based DNA Profiling Standard was developed in 1993 and produced in 1995 when it became apparent that a standard reference material was necessary to ensure accurate and comparable measurements between laboratories in the DNA forensic community.[1] In fact, it was eventually used to address the United States Federal Bureau of Investigation's (FBI's) Quality Assurance Standards (QAS) for laboratories conducting forensic DNA testing that were published in 2000 and updated in 2011 (Sect. 9.5.5): "The laboratory shall check its DNA procedures annually or whenever substantial changes are made to a procedure against an appropriate and available NIST standard reference material or standard traceable to a NIST standard."[2] Since then, several iterations of the SRM have been made available as the prior versions were depleted. SRM 2391c is the current version and is expected to be depleted in February 2018 based on reported sales.[3] Work has begun on planning the next iteration: SRM 2391d, so it is available to the community when SRM 2391c is completely exhausted. The historical significance of these standards is important and will be briefly discussed.

There is a great deal of planning and strategizing involved when beginning the process of producing an SRM. The technology and needs of the DNA forensic community are constantly changing and evolving and these need to be considered when selecting samples and determining what techniques will be used for certification. The thought processes behind the development and production of SRM 2391d will be explained and input from the community will be addressed.

Because of the advances in technology and new Short Tandem Repeat (STR) markers recently required for Combined DNA Index System (CODIS), new information will be included and certified with SRM 2391d. The samples that are chosen will have certified genotypes/haplotypes for the commercially available STR markers via characterization by capillary electrophoresis, Sanger sequencing, and next generation sequencing. Concordance between the results of the fragment-based and sequence-based methods will serve as validation for the certified values that will be assigned for each marker run with the chosen SRM samples/components. A summary of what is planned for SRM 2391d will be presented.

Forensic DNA, Standard Reference Material, STR Markers

C1 The Development and Preliminary Application of the New ForensicSW Software for Image Analysis

Kim Younsu, PhD, 769-2 Gasuwon-dong Seo-gu, Deajeon, SOUTH KOREA; and Jin Young Lee, Dunsanlo 155, Daejeon, SOUTH KOREA*

After attending this presentation, attendees will understand the new ForensicSW software for image analysis.

This presentation will impact the forensic science community by describing how ForensicSW can be utilized easily and intuitively as a suitable method of semi-quantitative analysis in Thin-Layer Chromatography (TLC) plate and may be applied to other forms of forensic analysis.

Recently, many analytical methods using image analysis software with more intuitive, simple, and highly practical applications have been developed to produce the quantitative data from qualitative results by combining the image analysis function.[1] Many types of image analysis software have been utilized in various parts of forensic, medical and analysis science as needed and requested, including TLC, drug test, fingerprint, age estimation, soil granules, blood vessel pattern, Computed Tomography (CT), and many others.[2-4]

Image analysis software is frequently used as a semi-quantitative method in TLC, however, many automatic TLC analysis systems are expensive and not as easy to use as High-Performance Liquid Chromatography (HPLC) or Gas Chromatography/Mas Spectrometry (GC/MS); therefore, general use in the small laboratory is limited.[5-8]

Consequently, several open-source image analysis software tools were developed by universities or government institutions for easier use and lower cost; however, as most of the software has been developed for analysis of images of electrophoresis gel, the software needs to be installed and requires large storage space. Additionally, they consist of macro expansion for less installation capacity, and a programming background is required to utilize the software.

This study is related to the development of image analysis software with a new algorithm named ForensicSW. This software can be utilized easily and intuitively for semi-quantitative analysis in TLC plates and applied to other forensic analysis. It is also compared with two other software products, CP ATLAS 2.0 and ImageJ. To explore the possibility of its use in forensic science, fingerprints and letters written in pencil were analyzed using the newly designed software.

ForensicSW is simple and easy to use with an intuitive User Interface (UI) for the semi-quantitative image analysis based on Windows® OS, written in the C++ language, and mounted with only the minimum functions for easy use and rapid analysis of an image.

The area calculation algorithm of ForensicSW is the sum of the horizontal line of the color density in each pixel ranged from 0 to 255, which corresponds to the y-axis of the plot profile. It can provide more accurate results than other software that use an integral sum algorithm. The automatic recognition of background color is a useful function for rapid analysis without further adjustment of the images digitalized under UV_{254}, $UV_{365,}$ visible light, and any other light source. The calibration curve and R^2 values can be obtained with a built-in function for statistics.

The images of TLC plates of five derivatized PEs with four derivatizing reagents were analyzed with ForensicSW and two other software products.

The result of Repeatability Standard Deviation (RSD) and linearity (R^2) from the analysis using three software products was compared. The evaluation of the semi-quantitative method based on the combination of derivatization in TLC and image analysis was acceptable for identification of amine compounds derivatized with derivatization reagents. The RSDs were 0.69 ~ 5.87 analyzed by CP Atlas 2.0 and 0.72 ~ 11.20 by ImageJ. The R^2 values were

R^2>0.99 on average, depended on the concentration of PEs.

The R^2 value of derivatized EP with FMOC-NHS was 0.9732 when analyzed by CP ATLAS 2.0, 0.9185 by ImageJ, and 0.9842 by ForensicSW. The RSDs were 5.96 ~ 6.88 analyzed by CP ATLAS 2.0, 5.12 ~ 8.35 by ImageJ, and 3.71 ~ 3.82 by ForensicSW. It was proven that ForensicSW demonstrated a rapid, easy, and sensitive semi-quantitative analysis result compared to the other two software products.

The similar patterns of plot profile from the image analysis represented in the fingerprints imprinted twice under the same conditions (about 1kg·f for five seconds) on the A4 paper of the same person were demonstrated by ForensicSW. ForensicSW could be helpful to evaluate fingerprints when combined with Automated Fingerprint Identification System (AFIS) through additional research.

Also, ForensicSW was applied to the analysis of handwriting. The characteristics of writing habits such as the writing pressure of each letter with a pencil, was examined with a plot profile by ForensicSW.

Based on the fact that ForensicSW showed acceptable results in R^2 and the RSD value of the TLC image analysis, the algorithm of ForensicSW was suitable for semi-quantitative analysis of TLC images. The applicability of ForensicSW for other areas of forensics can be studied. This new image analysis software has many merits in the field of forensic science. In addition, the UI of ForensicSW is easier and more intuitive for the user than other image analysis software. Therefore, ForensicSW can be considered as a new alternative for the image analysis.

C2 An Analysis of a Photocopier Hard Drive for Forensically Relevant Artifacts

Trevor Bobka, BS, Marshall University, 2950 Auburn Road, Apt A7, Huntington, WV 25704; Ian Levstein, MS, Marshall University, 1401 Forensic Science Drive, Huntington, WV 25701; Nevin Westurn, BSc, Superior Office Services, Inc, 108 Eight Avenue, Huntington, WV 25701; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will feel more confident in their ability to analyze photocopier hard drives and will better understand what files can and cannot be recovered. Attendees will also be more confident using their own forensic tools to retrieve such information.

This presentation will impact the forensic science community by providing information regarding forensic artifacts that can be recovered from a photocopier hard drive during four stages: (1) a blank hard drive; (2) a hard drive with an Operating System (OS) installed; (3) a hard drive with data generated; and, (4) a hard drive that has been initialized or wiped by the photocopier. The goal of this project was to determine which stage yields the most data and to see how accurate the photocopier's wiping process is. It is believed that data files can be recovered due to the nature of hard drives themselves.

In the world of digital forensics, many people fail to recognize photocopiers, or Multifunction Peripherals (MFPs), as having any probative value. These machines actually contain a hard drive to aid in processing or sorting multitasking functions. Thus, the hard drive acts as a storage media and saves the documents sent to it for the various jobs the machine performs. These machines are heavily used in many offices (businesses, government, universities, etc.), and the devices can potentially be a gold mine if the data falls into the wrong hands. Contrary to popular belief, the hard drives are fairly easy to obtain if the photocopier breaks or gets replaced by a newer model. This is due in part to some offices simply tossing out the old copiers and paying no attention to the hard drive left in the machine, thus making the hard drive available to anyone who wants to take the time to remove it.

The project involved removing the hard drive from a Canon® imageRUNNER ADVANCE 4035 photocopier during the four stages of its life cycle and analyzing the content obtained. The hard drive was cloned twice at each stage using a Disk Jockey PRO Forensic Edition to provide an actual and working copy to use during analysis. The results suggest that data generated on the machines was able to be recovered using forensic software programs such as FTK® 5.6.13 and Autopsy® 4.0.0. The files that were obtained corresponded to time stamps for the various jobs performed, phone numbers for faxes, email addresses, and other log files. In one case, an exact document matching the original was found as a PDF file. After initializing the photocopier, the data was overwritten by the machine and only the files associated with the working OS remained.

Photocopier, Hard Drive, Forensics

C3 A Text-Independent, Automatic Speaker Recognition System Evaluation With Males Speaking Both Arabic and English

Safi S. Alamri, MS, PO Box 91904, Riyadh 11634, SAUDI ARABIA*

After attending this presentation, attendees will better understand how to compare text-independent samples of speakers using different languages against a single-language reference population.

This presentation will impact the forensic science community by illustrating how conducting a study to better understand a design may be beneficial in further developing software that can complete accurate, text-independent, automatic speaker recognition for bilingual speakers against a single-reference population. All samples were taken from a text-independent speaker recognition system and enhanced to optimal performance. The data obtained were processed by a BATVOX 4.1, which deploys the Mel Frequency Cepstral Coefficients (MFCCs) and Gaussian Mixture Model (GMM) methods of speaker recognition and identification. The results of testing through BATVOX 4.1 was a likelihood ratio for each sampled voice that was evaluated and the problems experienced. This presentation provides a brief overview of the area of text-independent, automatic speaker recognition system evaluation with males speaking both Arabic and English. The purpose is to compare text-independent samples of speakers using different languages against a single language reference population.

Automatic speaker recognition can be classified into speaker identification and speaker verification. Speaker identification deals with determining who the speaker is in the provided sample. The speaker usually lacks identity, so it is assumed the unknown speaker must come from a set of known speakers fixed from the system. Speaker verification deals with determining whether or not the speaker is the claimed person. In this research, the emphasis is on text-independent automatic speaker recognition; however, the process can be classified as either text-dependent or text-independent. But it depends on the cooperation of the involved parties and the available data. The text-dependent application is designed to identify the speaker through the recognition systems regardless of what they say.[1]

Automatic speaker recognition has several applications, both commercially and forensically. Some of the commercial applications entail telephone banking, voice mail, prison call monitoring, voice dialing, and biometric authentication.[2] The emphasis on the current study is on forensic applications, which includes systems such as BATVOX. It can be applied to both investigative and evidential purposes. The systems have two main processes, which are feature extraction and classification. Feature extraction takes small portions of samples that will be stored and used later for speaker identification. The most common technique for feature extraction is the MFCCs.[3] Classification is a two-phase process that starts with speaker modeling, which is the features of a new speaker, then uses speaker matching, which includes the features saved in a database.[4]

For text-independent applications, there must be a speaker model in place. The speaker model is a recognition system that has trained speaker samples stored in a database that used acoustic feature vectors extracted from each trained samples comparison to any given sample. This is what allows the text-independent application to have no restrictions on the words the speaker can use, but also makes it a more challenging method of automatic speaker recognition because of differences in linguistic content and potential phonetic mismatch.[5] Many models are available, such as Hidden Markov Model, MFCCs, Vector Quantization, GMM, Neural Networks, and Radial Basic Functions.[6]

In this study, the MFCCs and GMM-Universal Background Model (UMB) models are used. Nonetheless, MMFCs are the most notable features in automatic speaker recognition. The goal of the MFCC is to model the vocal tract's spectral envelope, consisting of the formants and a smooth curve connecting them, and using them as an identifier. This takes place by taking the spectral envelope and applying a filter based on human perception experiments, which applies filters to the spectral envelope and creates the spectrum known as the Mel-Spectrum. Cepstral transformation is then performed on the Mel-Spectrum, and the outputs are the MFCCs and speech then represented as a sequence of cepstral vectors.[7] The GMM is a weighted cumulative of the features observed from a sample when compared to the trained model, the outcome being the Log Likelihood (LL). The higher the value of the LL the higher probability that the mode and evidence are the same speakers. The GMM is a representation of the cumulative observed features from the speaker taken from the underlying model. Forensic automation speaker

recognition was created to make it easier and more accurate to conduct speaker recognition. This involved creating an algorithm that then makes a quantitative analysis of the speech signal.[8]

Automatic Speaker Recognition, Likelihood Ratio, Arabic and English

C4 Closing the Performance Gap in Forensic Speaker Recognition

Reva Schwartz, MA, NIST, Forensic Science Research Program, 100 Bureau Drive, Stop 8102, Gaithersburg, MD 20899*

The goal of this presentation is to educate the broader forensic community about current capabilities in forensic speaker recognition and National Institute of Standards and Technology (NIST) activities to support progress in this field.

This presentation will impact the forensic science community by providing an overview of what is possible in the field of forensic speaker recognition, an update on research activities, and a description of future directions.

Speaker recognition is the process of determining whether two (or more) speech samples (live or recorded) are from the same person or different people. While speech recognition seeks to answer what is being said, speaker recognition attempts to answer who is talking. Forensic speaker recognition isn't called upon very often as a forensic technique, but when it is, there are a variety of methods in use.[1]

In forensic casework, analysts are asked to perform speaker comparison tasks from evidentiary recordings that typically exhibit a high degree of variability. The forensic speaker recognition research community has spent a great deal of time and resources in an attempt to study and address these sources of variability. Most of the benefits have played out in algorithm development and, when tested with the type of high-quality speech data that is usually unseen in forensic settings, technology performance has improved greatly.[2] Yet, very often these tools do not perform well when confronted with the type of data encountered in forensic casework.[3] This performance gap is real and significant when compared to performance under optimal conditions. The path forward to address this gap has taken time to come into view.

The Organization of Scientific Aea Committees (OSAC) Speaker Recognition Subcommittee and the European Network of Forensic Science Institutes (ENFSI) Forensic Speech and Audio Analysis Working Group have been developing guidelines and best practice documents, separately, for various aspects of forensic speaker comparison.[4] Their work also seeks to answer some of these lingering questions about how to harmonize practice across the discipline due to the myriad forms of variability present in case data and the differing approaches used in comparison.

Ultimately, any forensic system must be tested under the conditions seen in casework.[5] This means we need to assess performance of these systems using a variety of data types.

While the use of automation in forensic practice has grown, laboratories tend to rely on human practitioners for various aspects of the examination process. How any of these systems — human, automation, hybrid — perform under forensic conditions, remains unclear.[6-8]

To illuminate future paths for forensic speaker comparison, NIST will focus on a series of research activities in the near term, which will be described in detail during this presentation: (1) improvement of underlying technology; (2) assessment of performance across listener types; (3) comparison of performance between listeners and state-of-the-art automated systems; (4) focus on data that bears a close resemblance to that seen in forensic conditions, through the use of: (a) new experimental data collections dedicated to a different set of variables than in the past; (b) operational data for: (i) system testing; (ii) new development of reference datasets; and, (iii) system calibration; and, (5) development of a new Speaker Recognition Evaluation focused on issues inherent to forensic practice.

Speaker Recognition, Reference Data, System Performance

C5 "HAND-ling" *Daubert*: A Photographic Comparison Case Study

Christina A. Malone, MFS, 2460 Peachtree Road, NW, #1013, Atlanta, GA 30305; and Carl R. Kriigel, MA, US Army Criminal Investigation Laboratory, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have an understanding of: (1) the importance of forensic photographic comparisons; (2) a case example in which skin detail was used in such a comparison; and, (3) the *Daubert* challenges that were presented at the court-martial.

This presentation will impact the forensic science community by demonstrating, through a case study, how images retrieved from a computer's hard drive can be linked to a suspect. The challenges encountered in a forensic photographic comparison and the associated legal proceedings will also be discussed as they pertain to a specific case example.

Photographic comparisons are a part of forensic image analysis. In such examinations, the analyst will determine whether the subject or object that is depicted in a questioned image is the same as the subject or object depicted in a known image/photograph. While any number of objects depicted in imagery (photographs) may be the focus of a photographic comparison, skin detail has become of particular interest in forensic casework. The importance of skin detail becomes paramount when a suspect's face is not visible in an image (photograph). For instance, in the present case, an individual's hands and forearms were visible, but a face was not.

In this case, 318 images (photographs) were recovered from a computer hard drive. These images depicted child pornography and the sexual assault of a child by an unknown individual. The individual photographed the assault to include his hands and forearms in the process. A suspect was identified, and sixteen known images (photographs) of a suspect were submitted. It was requested that the known photographs of the suspect (hands and forearms) be compared to the photographs of the assault containing an unknown individual's hands and forearms. A photographic comparison was conducted on the skin detail present on the individual's hands and forearms visible/depicted in the photographs. The photographic comparison conducted visually presented the similarities between the individual in the recovered images (photographs) and the suspect in the known images (photographs).

Prior to the military court-martial, the defense counsel requested a *Daubert* hearing in an attempt to limit the admissibility of the photographic comparison analysis. As such, preparations were made to demonstrate in what manner the photographic comparison met the *Daubert* criteria of: testability, peer review, error rates, standards, and the degree of acceptance in the community. The *Daubert* criteria response materials were presented to the judge and included numerous research articles supporting photographic comparison analysis. The result of the *Daubert* hearing was successful in that the judge ruled that the photographic comparison analysis met the *Daubert* criteria, citing the methods were sound and reliable. The court-martial continued, allowing the photographic comparison to be admitted. The court-martial concluded with the accused being sentenced to life in prison.

Through examining this case example, the ability of photographic comparisons to link a suspect to recovered images is established. Additionally, examiner performance is demonstrated through the analysis conducted and the compelling testimony to educate the court on the photographic comparisons process as it relates to the *Daubert* criteria and the examination involved in this case.

Photographic Comparison, Image Analysis, *Daubert*

C6 Tool Testing and Comparison: Recovery of Snapchat™ Pictures From Mobile Device Unallocated Space

Joseph Levi White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will expand their general understanding of the value of utilizing multiple forensic tools and techniques to recover deleted graphical content from mobile devices, specifically those utilizing the Snapchat™ application, which is designed to clear transmitted content from the receiver's mobile device after a designated time frame.

This presentation will impact the forensic science community by providing a comparison of the abilities of various software packages in recovering deleted Snapchat™ content from mobile device unallocated space.

Forensic analysis of mobile devices is one of the most quickly evolving areas of Digital and Multimedia Sciences (DMS). With the development and release of mobile devices occurring at a very rapid pace, Digital Forensic Examiners (DFEs) and mobile forensic software companies are faced with the task of determining how to extract and interpret data from the constantly evolving hardware and software of mobile devices. As each new iteration of mobile device and/or mobile device Operating System (OS) is released, it must be determined how to not only extract data from the device, but how to convert the raw data into a format that makes sense to the end user. The use of mobile device applications, or apps, further complicates data analysis of mobile devices. Not only is the base OS of mobile devices under constant development, but individual application developers release and update apps at a surprising pace.

Snapchat™ is a mobile device application that allows users to send and receive multimedia content, such as pictures and video, between specified individual contacts. The transferred multimedia is termed a "Snap." Settings within the sender's Snapchat™ application determine how long the sent content will be viewable on the receiver's mobile device, from one to ten seconds. After the time limit has expired on the receiver's device, an attempt is made by the Snapchat™ software to delete the data. Security features of the Snapchat™ application are also designed to prevent users from taking screen captures of received content through other mobile device applications.

A previous presentation on this topic provided an overview of the examination of an Android-based mobile device submitted for examination to the United States Army Criminal Investigation Laboratory (USACIL) in a case involving the Snapchat™ application. Upon completion of this case, it was determined that at that, time, traditional mobile device forensic software packages were unable to extract any deleted Snapchat™ pictures from the mobile device; however, traditional computer forensic software was successful at recovering the pertinent content. This presentation will provide the results of a research study developed as a result of this case, comparing various (computer and mobile device) forensic software packages and their ability (or lack thereof) to recover deleted Snapchat™ content.

The opinions or assertions contained herein are the private views of the author and are not to be construed as official or as reflecting the views of the Department of the Army or the Department of Defense.

Names of commercial manufacturers or products included are incidental only, and inclusion does not imply endorsement by the authors, DFSC, OPMG, DA, or DoD.

Snapchat™, Data Recovery, Digital Evidence

C7 Forensic Image and Video Enhancement: Methodology for Improved Efficacy and Error Mitigation

Spencer Ledesma, MS, 20525 Cypresswood Drive, #4301, Cypress, TX 77433*

After attending this presentation, attendees will develop an understanding of how the fidelity of image processing results can be profoundly impacted by the order in which image and video enhancement filters are applied. This presentation will entail discussion of commonly available forensic image and video enhancement techniques, fundamentals regarding their inner workings, and the complex interactions that can occur when multiple image processing techniques are applied in succession. Through this discussion and a series of practical examples, attendees will be prepared to evaluate a proposed order of operations for image enhancement, which seeks to maximize the effectiveness of forensic image enhancements while reducing spurious artifacts created throughout the image processing pipeline.

This presentation will impact the forensic science community by raising awareness of potential causes of image artifact creation and by offering methodology to mitigate such errors so that the best available information can be extracted from image data used in forensic investigations. The research presented will aid in the development of improved quality assurance standards for laboratories and individuals practicing forensic image and video enhancement. Furthermore, attendees who do not engage in image enhancement but are nevertheless impacted by the practice, such as law enforcement and legal professionals, will gain a better understanding of modern image enhancement techniques as well as their strengths and limitations.

Image enhancement is an accepted practice in the field of digital and multimedia forensics and heavily relied upon in many forensic disciplines, such as crime scene reconstruction, photogrammetry, questioned documents, and biometric analysis, including facial and fingerprint identification. Images used in these applications often undergo several concurrent image processing operations. It is significant to note that when multiple processing operations are applied to an image, like a falling stack of dominoes, each operation that an image undergoes will have an effect on any future processing on the image. Even when applying identical enhancement techniques, at the same exact settings, to the same image, applying them in the incorrect order can lead to an overall loss in image fidelity, loss of data, and the creation of features that are non-existent in the original image data, including artifacts such as image noise or false edges.

Visual components of digital images are, in principle, matrixes of numerical values. Image processing operations use algorithms to manipulate these numerical values mathematically. Since these algorithms operate in predefined ways, it is possible to predict their behavior. By studying the underlying processes of enhancement algorithms, it is therefore possible to predict how they react in relation to different image properties and thereby establish an ideal order for their application.

Currently, the digital and multimedia forensics community has not universally agreed upon the order in which image enhancements should be applied. Since the needs of every enhancement case is unique and can require different combinations of image processing operations and settings, it has often been seen as impossible, or at the least, impractical, to establish an order of operations for image enhancement. This presentation advocates that an order of operations for forensic digital image enhancement is both possible and readily applicable to forensic casework.

Image, Video, Enhancement

C8 Structure and Format Analysis of Lossy Compressed Audio Files

Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217*

After attending this presentation, attendees will have a better understanding of multimedia metadata analysis and how it can benefit investigations which audio authenticity and source attribution are important questions.

This presentation will impact the forensic science community by revealing the latest results in a large study of digital audio recordings that are lossy compressed such as MPEG-1 and/or MPEG-2 Audio Layer III (MP3), Advanced Audio Coding (AAC), and more.

This presentation introduces a study on the format and structure of digital audio files, with an emphasis on lossy compression algorithms like MP3, Windows® Media Audio (WMA), and AAC. Lossy compressed audio files are common in real forensic cases, can be produced with digital audio recorders, digital video cameras, mobile phones, tablets, computers, and other digital systems, and their forensic authentication can be crucial in the courtroom or other extrajudicial investigations. As was presented at the 2016 AAFS Annual Scientific Meeting, in conjunction with other analyses largely involving time and frequency domain measurements/plots (e.g., Quantization Levels/ Bit Depth, Long-Term Average Spectrum, Modified Discrete Cosine Transform coefficients, etc.), a framework for digital audio authentication includes analysis of the file structure and format as well as investigation of the suspected recording device itself, when available.[1-3] Previous papers presented the results of MP3 and WMA digital lossy audio format analysis for forensic purposes.[4,5] This study reports an investigation of more than 50 different digital audio recorders and mobile phones from over ten years of data collection, validates the previously mentioned studies on MP3 and WMA, and extends the research on iPhones recordings and AAC files as well. In the interest of authentication and establishing digital provenance of recordings, examples of traces left by different digital audio editors (e.g., Adobe® Audition, GoldWave, Sound Forge™ Pro) and converters (e.g., ffmpeg) are also presented.

Preliminary results indicate that while, in most of the cases, the original files contain references of the make, model, recording timestamp, and/or OS version, the digital lossy recompression process affects files' headers and removes this information. The following tables illustrate different examples of the structure analysis results for: original MP3 and WMA files from Olympus® and Sony recorders; original AAC files from different iPhone® OS versions; and digital audio converted/edited MP3, WMA, and AAC files. The conclusion of this study is that structure analysis can be very effective in forensic audio authentication. It can be used to: (1) reveal similarities or inconsistencies between evidence and original reference recordings produced with the suspect digital audio recording system; (2) to verify the evidence file(s) against original reference recordings created with the suspect recorder or another same make and model device; and, (3) to identify the recording system when a database of original recordings is maintained and available.

The following tables provide examples of the material and results collected in this study.

Forensic Audio, Metadata, Digital Evidence

C9 Media Forensics and Microphones

Eddy B. Brixen, BA, EBB-Consult, 108 Aeblevangen, Smorum DK-2765, DENMARK*

After attending this presentation, attendees will better understand microphone transducer principles that can be applied in audio forensic examinations. Basic specifications/limitations, performance of pressure vs. pressure-gradient types, beamforming, and the influence on recorded audio will be discussed.

This presentation will impact the forensic science community by highlighting microphone performative characteristics which are important for those working with media forensics.

Nearly all acoustic recordings include a microphone in the recording chain. Recordings may stem from dashboard cameras, cell phones, smartphones, car phones, dispatcher headsets, video cameras, surveillance systems, dictaphones, computers of all sorts, and others.

It is very seldom that the result of a forensic examination of a recording device includes any findings related to the microphone/microphones; however, the microphone may add valuable information to findings of the recording.

A microphone is not just a microphone. Devices responsible for the majority of recordings that become subject to forensic examination are either electret condenser types or Micro-Electro-Mechanical Systems (MEMS). The sound quality in good electret microphones is clearly superior to the MEMS types; however, the MEMS are extremely inepensive and can more or less directly deliver a digital code (density modulation). As with most coding, this may leave traces in the signal.

Any microphone can be specified by different data (i.e., sensitivity or how much output for a given Sound Pressure Level (SPL), self-noise (all microphones have a noise floor), max SPL (the SPL at which the microphone will start clipping/distorting), and frequency response (how wide is the range of the given microphone).

The directivity of microphones are especially of great interest. Two ways of coupling the diaphragm to the surrounding air are responsible for the directivity.

Pressure microphones (the sound can only access the diaphragm from one side) are by definition omnidirectional; however, this also depends on the practical mounting in/on the device or in the room. For instance, mounting on a surface changes the directivity dramatically, depending on the size of that surface. Pressure microphones are the least sensitive to wind and vibrations. In regard to frequency response, it decreases to DC and lets one consider whether to open or close doors in rooms due to the pressure variation.

Pressure gradient microphones can provide a variety of first-order directional characteristics: figure eight (bi-directional), super cardioid, cardioid, subcardioid, etc. The final directivity is primarily determined by the relationship between the front and rear inlet. The pressure gradient microphones normally have "looser" diaphragm to reproduce some amount of low frequencies. This fact also leads to a higher sensitivity (approximately 10-15 dB) to vibrations, wind-noise, and handling-noise.

Pressure gradient microphones exhibit proximity effect. This means that the low frequencies are boosted as the microphone gets closer to the sound source (i.e., point source). On the other hand, sound sources moving away from the microphone lose bass. This is practical in phone calls; however, it also provides information on distance when examining the spectral changes of recordings' content.

When applying more than one microphone capsule in a device, arrays can be formed.

Two-channel recordings contain directional information depending on the directivity and angling of the microphones (XY stereo) or the distance between them (AB stereo and near-coincident set-up). Here, there is considerable information to extract. This also provides possibilities of signal enhancement when one channel can be utilized to improve the other (i.e., cross-lattice filtering and the like). Shot-spotting systems also form a type of array, although with much larger distances between the microphones.

Arrays can be used for directivity beamforming. Today, most computers and smartphones contain two or three microphones for this purpose. This means that certain frequencies coming from certain angles are either boosted or cut. This is why it is essential to gain as much knowledge as possible of the recording devices to include/exclude sound sources. Accordingly, the difference in the individual microphone's sensitivity provides information for the authentication of the device or for the scene.

Casework (test sound-files to be presented) has shown that the characteristics of the recording devices, and the microphone in particular, have provided evidence or led to the better choice of enhancement technique.

Which (fixed-line) phone was used for the emergency call? Why was the background sound lower than expected? The saturation of the input was pure microphone clipping; hence, de-clip was possible. Crime scene analysis has been made possible because of the wide frequency range of the microphone.

Examiners sometimes neglect the characteristics of the microphone; however, microphone specifications and implementation influence the signal recorded. For the purposes of selecting the right microphone for forensic recordings, rescuing bad recordings, authenticating recordings, and extracting valuable crimescene information, practitioners in media forensics should acquire a basic knowledge regarding microphones.

Microphones, Forensic Recordings, Audio Forensics

C10 An Analysis of Apple® iOS® Version Effects on Format and Metadata Structure of Audio Files Recorded Using the Native "Voice Memos" App

Jeff M. Smith, MS, National Center for Media Forensics - CU Denver, 1150 10th Street, Ste 177, Denver, CO 80217; Douglas S. Lacey, BS*, BEK TEK LLC, 9 Kingsland Drive, Ste 111, Stafford, VA 22556-1353; Catalin Grigoras, PhD, 1020 15th Street, Ste 8I, Denver, CO 80202; and Bruce E. Koenig, MFS, BEK TEK LLC, 12115 Sangsters Court, Clifton, VA 20124-1947*

After attending this presentation, attendees will better understand the critical aspects of audio format and metadata analysis that can inform audio authentication examination of recordings made with Apple® iOS® Voice Memos app and how a similar approach can be applied to other recording devices. A preliminary determination of an iPhone® Voice Memos recording's originality and integrity can be assessed through the use of a decision tree that takes into account how different editing processes and recording interruptions affect the resulting audio file.

This presentation will impact the forensic science community by disseminating a decision tree for authenticity analysis of audio recordings from iOS® Voice Memos. This procedure demonstrates the initial results of a large study into changes in the format and metadata structure of audio files recorded using the native Voice Memos app. This presentation will also impact the forensic science community by shedding light on how certain recorder operations and interruptions modify the native format and structure of embedded metadata within the Voice Memos recordings.

This presentation will describe the ongoing study into the authentication of audio recordings originating from an Apple® iPhone® using the Voice Memos app, which comes built-into the iOS® operating system. The data collection procedure for producing test recordings from iPhones® will be described. These test recordings will account for various capture, editing, and interruption scenarios, based on the inherent functionality of the Voice Memos app. Metadata analyses of these test recordings were conducted, and any modifications to the format and structure as a result of an editing process or recording interruption were documented. For example, the bitrate of the recorded audio information may change as a result of an editing process having been applied to the original recording or due to an interruption in the recording caused by an incoming call. Based on the collected data and metadata analyses, a decision tree, aimed at helping guide authentication examinations involving recordings purported to have originated from the iPhone® Voice Memos app, was developed and will be shared during the presentation. Additionally, a study based on the practical application of the decision tree to real-world examples was undertaken and will be discussed.

The materials used during this study involved 20 recordings made with various iPhones® running on various versions of the iOS® operating system. The materials were prepped for testing employing the various types of editing processes and record interruptions that can be conducted directly on the phone on some recordings, while leaving others in their original, unaltered state. These materials were then disseminated to test subjects and examiners, who each worked in blind testing the recordings for authenticity against the proposed decision tree. In order to assess the efficacy of the decision tree, the accuracy of examiner decisions made in blind were tabulated. Results will be shared at the presentation and recommendations for further research will be discussed.

Audio Forensics, iPhone® Forensics, Digital Evidence

C11 An Analysis of Digital Forensic Units

Kaitlyn Gurule, BS, Purdue University, 401 N Grant Street, West Lafayette, IN 47907; Kathryn C. Seigfried-Spellar, PhD*, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907; and Marcus Rogers, PhD, Purdue University, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will have learned about the operations of digital forensic units, what can be improved upon, and what tactics have succeeded.

This presentation will impact the forensic science community by providing a basis point for analyzing digital forensic units and also confirms the findings of previous research within the digital forensic community.

Computer technology is growing rapidly, and law enforcement has seen an increase in the number of criminal cases that involve digital evidence. Nearly all crimes, including both cybercrimes and traditional crimes, include some type of digital media.[1,2] In fact, it is becoming more common to see multiple forms of digital evidence in a single criminal case, such as texts from a mobile phone, travel coordinates on a GPS, and saved photos on a computer.

Law enforcement agencies are having a difficult time processing all of the digital media in an effective and efficient manner.[1] As the volume of digital data increases, so does the amount of time it takes to examine the data for evidence, resulting in a backlog. In addition, this backlog is exacerbated when there are multiple parties involved with multiple digital devices.[3] Thus, law enforcement is overwhelmed with the number of cases that involve digital evidence, as well as the number of devices and variety of devices which may be involved in a single case, adding to the backlog of cases.[2]

In order to overcome the backlog created by cases involving digital evidence, some states have created computer crime or digital forensic units that investigate and/or process the digital evidence obtained in criminal cases. For the purposes of this study, specialized cybercrime units were defined as units that work only on digital media forensics and complete the forensic investigation within their own unit. Non-specialized units were defined as any other unit that did not fit the specialized unit criteria. The current study assessed the effectiveness of specialized vs. non-specialized units.

Two surveys were completed: a phone interview and an online questionnaire. Twelve specialized and eight non-specialized units completed the phone interview. Eight specialized and eight non-specialized units completed the online survey. The data was aggregated and anonymized so the respondents felt comfortable reporting information about their units. Respondents answered a variety of questions about the unit, such as the unit's history (e.g., Why was it created? What were the original goals?), their past and/or current backlog, number of cases worked, and types of digital evidence examined, just to name a few. The study suggested the specialized units operated more effectively than the non-specialized units. This study also revealed the lack of knowledge regarding standard procedures/best practices in digital forensics, as well as the lack of consistency in the standards reported among the cybercrime units community. Finally, the current study also supported previous research regarding the need for more training, funding, and personnel in digital forensics.

C12 Image Correction and Enhancement With the Apparatus for Actual Measurement of Image Degradation Properties in Security Cameras

Kenji Kurosawa, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Ken'ichi Tsuchiya, PhD, 6-3-1 Kashiwanoha, Kashiwa, Chiba 2770882, JAPAN; Norimitsu Akiba, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Kenro Kuroki, PhD, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Daisuke Imoto, MS, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Physics Section, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; and Manato Hirabayashi, MS, National Research Institute of Police Science, 6 3 1 Kashiwanoha, Kashiwa 277-0882, JAPAN*

After attending this presentation, attendees will better understand the method to measure actual image degradation properties in security cameras as well as better enhanced and/or corrected images that can be obtained using the measured properties.

This presentation will impact the forensic science community by providing information about methods and an apparatus for measuring degradation properties in security cameras. The experimental results showed better images by using the measured actual properties in comparison with modeling methods. This information will be useful for forensic image analysts.

Videos or images that are recorded by security cameras can be objective evidence leading to criminal investigations; however, in some cases, the recorded images cannot be effectively utilized due to insufficient image quality. Thus, image processing, such as image enhancement or image correction, is expected under the circumstances. In the image processing procedure, some types of functions or parameters describing image degradation characteristics in cameras are required; for example, Point Spread Function (PFS) is used for image deblurring.[1] The Gaussian function is commonly used as an approximate model for PSF; however, the optimal deblurred image cannot be obtained with the Gaussian PSF because there is a difference between the actual PSF of a camera lens and the Gaussian function. Therefore, another approach for image enhancement/correction method is proposed in this presentation, which uses actual measured image degradation properties in security cameras.

An apparatus to measure the image degradation properties in security cameras was developed. The apparatus consists of an industrial high brightness Liquid Crystal Display (LCD) panel (19 inches, 1500cd/cm^2), three-joint flexible arm, a single board computer (Raspberry Pi 2 model B), a wireless control circuit, a small stand on casters, and a battery. The total weight was approximately 28kg. After putting the apparatus into place in view of a security camera, a series of basic graphics, such as dots, lines, color patches, and digits, were displayed on the LCD panel by the single computer board. During that time, the images of the LCD panel are recorded by the security camera. Because the recorded images of the basic graphics were distorted according to the degradation properties of the security camera, the degradation properties were obtained by analyzing the recorded images. This is the principle of the proposed method and the following are expected: (1) image deblurring using the measured PSF; (2) geometric correction of lens distortion; and, (3) measurement of color characteristics of the camera and color correction. Furthermore, the apparatus can be used for identification of digits/characters on a car license plate image and scale estimation of objects in images.

Experiments were performed using a security camera (Victor VN-H137B) in terms of 1, 2, and 3 as mentioned above. By displaying dot patterns, the PSF was successfully measured. When the Wiener deblurring filter was adopted to a blurred image taken by the camera, the restored image with the measured PSF was clearer than those with the Gaussian PSF or the circular PSF. By displaying a lattice pattern, the property of the geometric lens distortion was successfully measured. A corrected image was synthesized with the measured lens distortion data. Furthermore, the composed non-linear chromatic transfer characteristics of the camera and the recording device were successfully measured by displaying 861 color patches.

Security Camera, Image Enhancement, Camera Properties

C13 Automatic Removal of Face Features in Video for Purposes of Visual Anonymity Using Statistical Learning and Meaningful Face Color Detection

Leonid I. Rudin, PhD, Cognitech, 3871 E Colorado Boulevard, Ste 100, Pasadena, CA 91107*

After attending this presentation, attendees will understand how the use of color information may permit the fast detection and removal of faces from video sequences.

This presentation will impact the forensic science community by demonstrating the effectiveness of the proposed method for preserving the anonymity of individuals in real-life videos.

The need for personal anonymity in video surveillance footage imposes the use of face hiding techniques on these videos.

The manual removal of people's faces is time consuming, while automatic face detection techniques exhibit low performances when applied on videos recorded in emergency situations. Motion induced by shaking cameras, people in motion, etc., blurs the faces and makes most of these algorithms unable to correctly detect them.[1]

For these reasons, an automatic technique for face removal is proposed based on the color characteristics of the faces, not on the face features usually considered by the face detection methods. This has the advantage of making the method invariant to deformations of the face geometry (rotations, side views, partial occlusions, etc.).

The proposed approach consists of: (1) representing image colors using their Hue, Saturation and Intensity attributes (the so called HSI color space), instead of the usual Red, Green, Blue (RGB) space. This representation is more intuitive and perceptually relevant and has the additional advantage of separating the pure color information (represented by the hue and saturation values) from the illumination information (i.e., the intensity); (2) statistically learning the meaningful (statistically robust) ranges of hue and saturation associated to the color of human faces. Intensity information is not taken into account because the goal is to detect faces independently on the illumination conditions of the scene (dark or bright). Such ranges have proven to be quite robust to ethnic variation of the features, thus being equally successful in any subject population; and, (3) selectively bluring image pixels whose hue and saturation values fall in the learned range.

Of course, besides faces, several other objects in the scene may have a color in the learned range. In order to prevent the blurring of non-face objects, the previous algorithm is refined by introducing two additional steps: (1) use a background extraction algorithm to discern between background and foreground parts of the scene, then apply the blurring method only to the foreground pixels; and, (2) use an anisotropic blurring filter. This will preserve the main image edges, while blurring the small details (e.g., faces). The scale of this filter is a critical parameter of the method.[2,3]

The results of the proposed algorithm are promising. Moreover, since only color information is used, computations are fast and a real-time implementation has been produced. The algorithm is parallelizable and an open-source implementation has also been developed.

Face Removal, Face Detection, Color Features

C14 Open Source Automatic Facial Comparison Algorithms' Potential Application in Forensics

Angeliki Fydanaki, MFS, Ohmstraat 8-III, Amsterdam 1098ST, NETHERLANDS; and Zeno J. Geradts, PhD*, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS*

After attending this presentation, attendees will understand several open source initiatives that exist for facial comparison as well as a test on forensic images.

This presentation will impact the forensic science community by introducing algorithms that are open source for facial comparison and discussing how they can be used in research.

The face is considered to be one of the main organs used in biometrics. It is a relatively stable part of the human body that has proven to be a great instrument in forensics. Over the past decade, the automatic facial analysis algorithms are at the center of the interest in the biometrics community. Recent facial comparison algorithms have illustrated significant growth regarding their performance; however, none were able to fill the gap between software and the significant high human accuracy. OpenFace is an algorithm that is trying to fulfill the aforementioned need. The center of this research is to determine the efficiency of the automatic OpenFace system as it relates to relevant forensic data. OpenFace is an open source toolkit based on the FaceNet algorithm, which has been created by Google®; however, it has been developed and shared as open source by Brandon Amos at Carnegie Mellon University. The main advantages of OpenFace are its online availability (which makes it a low-cost option), the limited need for human resources, and its reported performance on the Labeled Faces in the Wild (LFW)benchmark.

OpenFace requires specific products in order to operate, which are all open source as well; namely, OpenCV®, Torch, GitHub™, Docker, Dlib™, and a few libraries used in Python™. These products contribute to the three main tasks of OpenFace, which are verification, recognition, and clustering of faces on stable images and on real-time web videos. FaceNet, and hence OpenFace, are based on Euclidean embedding per image. Furthermore, they use the squared L2 distance in order to determine the face similarity of the query pair of faces. Then, by the use of one of the well-known techniques of K-means or agglomerative clustering, the recognition of the similar faces is achieved. Additionally, there is a triplet-based loss function used during training, which assures that the output of the algorithm is a compatible 128-D embedding. This sets a positive respective distance limitation. In general, this function minimizes the relevant distance when the same face is present on both query images and maximizes the relevant distance when different faces are present on the pair of query images. OpenFace could have multiple forensic applications. It could be used for facial recognition of suspects based on a query image and a reference; it could provide a connection of criminals by the use of images between multiple crime scenes; and it could be used with surveillance cameras in order to recognize specific individuals, as terrorists or a person reported as missing. Moreover, it could be used for the identification of corpses in mass disasters.

Based on the four OpenFace models and LFW benchmark, the verification of the reported results is achieved. The nn4.small2.v1 model outperforms the other three models in accuracy. For that reason, the further examination of nn4.small2.v1 model is selected. The experiments on OpenFace with the use of LFW-raw, LFW-deep funneled, SCface, and ForenFace datasets reveal that as the resolution of the input images is getting worse, the performance of nn4.small2.v1 OpenFace model is getting low. Moreover, the performance of OpenFace detector depends on the quality of the input images. This is due to the fact that it is unable to detect a face or align the input low-analysis image. Furthermore, the runtime of OpenFace depends on the specifications of the machine in use and the quality of the image. This includes the fact that the detector processes images of low resolution more slowly. Hence, the intervention of the quality of the query images to the efficiency of OpenFace is forthright. Therefore, OpenFace proved inadequate in its current condition for forensic application. Notwithstanding, there are possible proposed improvements that are promising.

OpenFace, Open Source, Automated Facial Comparison

C15 Accurate Video Reconstruction and Metadata Extraction From a Self-Executing Video File

Matthew Case, PhD, Audio and Video Analysis Unit, 1426 Saint Joseph Boulevard, Rm 1340, Ottawa, ON K1A 0R2, CANADA*

After attending this presentation, attendees will understand how video files can be wrapped inside proprietary Windows® executable video players and how the native video data can be extracted to ensure accurate playback and analysis.

This presentation will impact the forensic science community by demonstrating that native video data and metadata can be extracted from proprietary Windows® executable video players, thus allowing for a proper forensic analysis of the video.

Forensic video analysis has evolved in recent years to eschew the use of proprietary video players wherever possible in favor of independent playback using open source multimedia frameworks, such as FFmpeg, that can decode native video data. When analyzing native formats directly rather than through opaque proprietary third-party viewers, accurate metadata, such as storage aspect ratio and frame-level timing data, can often be established explicitly in a reliable and repeatable way, thus allowing for accurate playback and analysis; however, this approach is hindered when video data and player data are wrapped together as a single executable file and the native video data is not immediately identifiable.

This presentation will introduce two ways in which native video data can be contained within Windows® executable files. The first method is when the video data is written directly into the payload of the video player executable, so extraction relies simply on recognizing the video format start codes and carving out the data. With the second method, the executable is simply a data decompression utility, while its payload contains compressed video data along with other compressed files required for playback, such as the player executable itself, associated Dynamic Link Libraries (DLLs), and text files containing supplementary video information. As a result, directly carving out the (uncompressed) video file is not possible.

This second case will be discussed in detail using the "MP4Extract" class of video files as a case study. It will be shown, for this class of videos, how the compressed data can be identified within the executable, carved out and decompressed to yield a non-conforming (i.e., non-playable) MPEG-4 (Part 2) format video file. The metadata of the resulting video file can be fully decoded so all proprietary video information, such as camera number, accurate frame-level timing data and supplementary overlay data, can be exported for reference purposes. Furthermore, the extent of the video file's non-conformity will be presented and a solution to produce a fully conformant, readily playable video file will be outlined.

The approach outlined in this study also has broader implications for forensic video analysis. In particular, application to the authentication of digital video and metadata analysis of proprietary video file formats more generally will be discussed in the time remaining.

Data Carving, Metadata Analysis, Video Reconstruction

C16 Pokémon™ GO® Forensic Artifacts: An Exploratory Study

Joseph Levi White, MS, US Army Criminal Investigation Laboratory, Digital Evidence-CFI, 4930 N 31st Street, Forest Park, GA 30297; Carl R. Kriigel, MA*, US Army Criminal Investigation Laboratory, Defense Forensic Science Center, 4930 N 31st Street, Forest Park, GA 30297; and Julie Robyn Constantine, MS, US Army Crime Lab (DFSC), 4930 N 31st Street, Forest Park, GA 30297*

After attending this presentation, attendees will have obtained the results of research regarding the availability of forensic artifacts maintained by mobile devices specific to the Pokémon™ GO® application.

This presentation will impact the forensic science community by providing potential sources for data relevant to criminal investigations maintained within user data associated with the Pokémon™ GO® mobile device application.

Digital Forensic Examiners (DFEs) are responsible for extracting data from a growing number of different electronic device types and performing analyses on a multitude of different resultant data types. It is up to members of the Digital and Multimedia Evidence (DME) field (DFE's and researchers) to search out and interpret new sources of potentially important data to aid in future investigations. This responsibility includes mining for potentially pertinent data stored within mobile device applications, such as the game Pokémon™ GO®.

Pokémon™ GO® is a location-based augmented reality mobile game released in July 2016. There was enormous controversy upon the release of this game due to potential privacy issues and threats to personal property and personal safety. Even with the concerns, Pokémon™ GO® quickly became one of the most popular mobile device games for both Android™ and Apple® iOS®. Active game players are required to physically visit specified locations in order to refill energy, gather objects necessary for game play, and capture Pokémon™ characters. Global Positioning Satellite (GPS) technology tracks the location and progress of game players to determine their physical proximity to designated Pokéstops (locations for players to collect Pokéballs and other items necessary to continue game play and to capture Pokémon™ characters) and Gyms (locations set by game developers to join together with additional players as teams and battle for virtual control of the designated Gym).

Pokémon™ GO® game play requires users to utilize a Pokémon™ Trainer Club, Google®, or Facebook® account for login identification and to provide permissions for the game to monitor player GPS location. The Pokémon™ GO® application also stores information on game play activities within mobile device memory. This presentation will provide the results of an exploratory study into forensic artifacts left behind on Apple® iOS® and Android™ mobile devices specific to the mobile device game Pokémon™ GO® and explore how these artifacts may be used to aid in criminal investigations.

C17 Digital Stratigraphy: Analyzing File Allocation Methods to Uncover Concealment Behavior

Eoghan Casey, PhD, University of Lausanne, Batochime, CH-1015 Lausanne-Dorigny, Lausanne, Vaud, SWITZERLAND*

The goals of this presentation are to: (1) increase knowledge of file allocation methods and traces; (2) review contextual analysis of file allocation traces (digital stratigraphy); and, (3) raise awareness of potential limitations of digital stratigraphy.

This presentation will impact the forensic science community by illustrating how advances in the practice of file system analysis will enable forensic examiners to perform contextual analysis of file allocation traces in order to differentiate between concealment behavior and normal system activity.

When computing devices are used to conceal digital evidence by deleting, reformatting, wiping, or backdating files, it can be challenging to prove concealment behavior versus normal system activity.

There is a common misconception that new files are saved onto storage media in a predictable fashion. Certainly, in the simplest scenarios, such as on a memory card in a digital camera when files are saved in quick succession, there can be a predictable next-available allocation; however, there are situations that will cause file allocation to deviate from predictable or deterministic allocation strategies. In one case, a forensic examiner misinterpreted gaps between allocated files as indications of file wiping.

Furthermore, file initialization can exhibit itself in various ways when different applications, operating systems, and file systems are involved. In one case, a new file system entry was initialized but nothing was saved to disk, leaving untouched data from a prior deleted document in the space allocated to the new file system entry, making it seem like backdating (i.e., a file system entry created in 2015 seemingly containing information dated 2014). To avoid confusion, great care must be taken when interpreting the provenance of deleted data that is recovered from a partially initialized file.

Understanding file allocation methods can provide insight into such concealment behavior, but real world computer use introduces complexity that complicates forensic analysis. Each file system tells a story about the use of that storage media, and analyzing the allocation of files over time can sometimes provide insight into deletion or other concealment activities. As a result, general understanding of file allocation methods can only be used as a starting point, and it is necessary to take the overall context into account when analyzing traces of such concealment behavior. Contextual analysis of file allocation traces is called digital stratigraphy because it has similarities to the concept of stratigraphy in archaeology.

Using examples of forensic analysis from past cases, this presentation demonstrates how digital stratigraphy has been used to address questions of concealment behavior. The challenges, successes, and limitations of this form of forensic analysis are discussed.

File System Forensics, Digital Concealment Behavior, Digital Stratigraphy

C18 Paired Apple® Watch® Forensics

Yoshitaka Takase, MS, National Police Agency of Japan /Purdue University, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will be more familiar with paired iPhone® examinations. The implications for iPhone® examinations when paired with an Apple® Watch® will also be discussed.

This presentation will impact the forensic science community by providing information on the Apple® Watch® and paired iPhone® forensic artifacts.

An Apple® Watch® paired with an iPhone® provides not only precise time but also unique functions operating with installed applications and embedded equipment. There were some differences from conventional iPhone® examinations that could be recognized based on some research on an Apple® Watch® and the paired iPhone®. Factors changing the procedures are categorized into three groups, which are named influence, independence, and uniqueness for descriptive purposes. Influence is referred to as the pairing of an Apple® Watch® and an iPhone® and the influences the two devices have on each other. The interaction between them and the storage of Apple® Watch® data on the paired iPhone® are two examples. Independence is defined as separately processing and storing data on an Apple® Watch® and the paired iPhone®. Uniqueness encompasses Apple® Watch's® unique functions added to the paired iPhone®. These factors would bring new steps, new analyses, and new information, which is used for an iPhone® analysis to iPhone® examination processes. In the seizure phase, an Apple® Watch® should be isolated in order not to alter both data stored on the Apple® Watch® and the paired iPhone® because they communicate with each other via a wireless network. Also, the step to seize the Apple® Watch® needs to be added to the phase. In the collection phase, Apple® Watch® data should be extracted from the two devices; therefore, the step to extract the data from the Apple® Watch® needs to be conducted in this phase.

In this research, a manual extraction method (e.g., taking pictures or notes) was employed for the Apple® Watch®; also, an iTunes® backup method was used for the paired iPhone®. In the analysis and examination phase, the extracted data should be confirmed. The data from the Apple® Watch® were easily understood because the extracted data were pictures of applications displayed on the screen; however, there was extra work to figure out the data from the paired iPhone® because the backup contained a lot of files. Additionally, health data such as heart rates and active calories, which were sourced from the Apple® Watch®, could be analyzed by making more detailed charts than the charts displayed on the iPhone®. Also, information remaining on the Apple® Watch®, which has been deleted from the paired iPhone® could be applied to an analysis of the iPhone® in certain instances. The research concluded that pairing an Apple® Watch® and an iPhone® makes iPhone® examinations more complex and creates valuable data for forensic examiners.

Apple® Watch®, iPhone®, Wearable Device

C19 Experience Validating Disk-Imaging Tools With Computer Forensic Tool Testing (CFTT) Federated Testing

James R. Lyle, PhD, NIST, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899; Barbara Guttman, BA, National Institute of Standards & Technology, Mail Stop 8970, Gaithersburg, MD 20899-8970; and Benjamin R. Livelsberger, MS, 100 Bureau Drive, Mail Stop 8970, Gaithersburg, MD 20899-8970*

After attending this presentation, attendees will be aware of the CFTT Federated Testing forensic tool-testing environment utility that is used for validating disk-imaging tools.

This presentation will impact the forensic science community by increasing awareness of the capabilities of Federated Testing when applied to real imaging tools. This presentation will provide examples of Federated Testing on actual disk-imaging tools, in the same manor as a digital forensics laboratory would conduct validation testing. In addition, by documenting the resource commitment required to perform the tool testing, forensic practitioners will be able to estimate the cost in time and effort to test disk-imaging tools in their laboratory. This presentation will aid the forensic practitioner choosing to use Federated Testing by providing examples of using Federated Testing to test actual disk-imaging tools, much as a digital forensics laboratory would conduct validation testing.

The CFTT project at the National Institute of Standards and Technology (NIST) develops methodologies for testing computer forensic tools. Currently, there are CFTT methodologies for testing the following: disk imaging, write blocking, deleted file recovery, file carving, forensic media preparation, and mobile devices.

A variety of tools in each of these categories have been tested and observed flaws in the tools have been reported by the National Institute of Justice (NIJ) and the Department of Homeland Security (DHS). These results can be used as a basis for identifying the types of likely failures that occur in forensic tools. Currently, CFTT has implemented testing disk imaging into Federated Testing.

Using Federated Testing has several advantages: (1) it relieves a forensic laboratory of the task of developing a test plan for tool testing because Federated Testing generates a test plan based on selections made by the user describing how the laboratory uses the tested tool: (a) a list of test cases (based on user input); (b) tools and detailed procedures for creating test drives (adding known content); (c) detailed procedures for running each test case; (d) tools to evaluate test results; (e) tools to generate a skeleton test report that can then can be finished in the style favored by the laboratory; (2) the test reports can be shared with other laboritories; and, (3) completed test reports can be submitted to CFTT for administrative review and if no issues are found, the report is passed on to the vendor for comment. The final report is published by the DHS.

In this round of testing, the following tools were tested, making slight variations in feature selection:

Tool	Version
FTK	3.4.2.6
Guymager	0.8.1
Logicube Falcon	2.4U1
Logicube Falcon	3.0U1
Paladin/ewfacquire	6.09/20160403
Paladin/dc3dd	6.08/7.1.614
X-Ways	18.8
dc3dd	7.2.641
Ditto FieldStation	2016 Mar01
Tableau TD2u	1.1.2.3948-4270f9c

Temporal and physical resources to measure the level of commitment that was required to test each tool were tracked. It was found that with two PCs, a single practitioner could set up test drives in just a few hours. The drives

can be set up faster if more Personal Computers (PCs) were devoted to the task. After the test drives are set up, running the tests takes less than two days. The most time expended is actually taking the generated skeleton test report and adding laboratory-specific information.

If a laboratory uses (or just wants to test) more than one imaging tool, the drive set up only needs to be executed once and can be reused for additional tool testing.

Digital Forensics, Tool Testing, Disk Imaging

C20 An Anatomy of a Knockoff

Mark D. Guido, MS, The MITRE Corporation, 7515 Colshire Drive, Mclean, VA 22102; Justin Grover, MS*, The MITRE Corporation, 7515 Colshire Drive, M/S T240, Mclean, VA 22102; Eric Katz, MS, 4435A Beechstone Lane, Fairfax, VA 22033; and Kyle Anthony, MS, The MITRE Corporation, 7515 Colshire Drive, Mclean, VA 22102*

After attending this presentation, attendees will be more knowledgeable of the motivations to create knockoff mobile devices, the forensic characteristics of knockoff mobile devices, and how much they differ from the real thing.

This presentation will impact the forensic science community by directly analyzing a topic that is typically underresearched (i.e., knockoff devices) due to the international and criminal aspects of this described consumer supply chain problem.

This case study involves the technical examination of three international Samsung™ devices purchased through an official Samsung™ reseller. The devices ordered were Samsung™ Galaxy™ S5 phones, model SM-G900F. These devices have a Snapdragon™ processor and are typically used on mostly European carrier networks. Upon receiving the order, each devices' boxes were found to be in a pristine state in which they appeared to be factory sealed within the expected packaging, with stickers denoting the device model SM-G900F. During an examination of two of the devices while in Samsung's™ Download Mode, it was immediately noticed that the devices identified themselves as SM-G9006V and that each device had its warranty bits tripped. Further inspection while in the Android™ operating system revealed that the devices reported a device type of SM-G900F and the bootloader threw an error when an SM-G900F update file was attempted. Having believed that the research team may have been responsible for the warranty bit trips, the third device was unpackaged and inspected. It too exhibited the same behavior and its warranty bit was also tripped.

The Samsung™ GS5 SM-G900F and Samsung™ GS5 SM-G9006V have very similar hardware sets and it appears that in this case, the model SM-G9006V is used as a "knockoff" device for the model SM-G900F. The team was able to identify more knockoff devices with similar characteristics purchased from other authorized resellers, indicative of a more regional supply chain problem. Based on the research team's observations, the existence of a supply chain problem in both Europe and Asia manifesting itself through authorized Samsung™ resellers in the United States is assumed. This study focuses on the technical changes made to mask the original hardware and hypothesizes on the possible motivations for knocking off these particular device models. Using the Periodic Mobile Forensics tool suite, a suite of tools previously discussed at AAFS Annual Scientific Meetings, the research team examined these SM-G900F knockoff devices and will report on its hardware, the shape of the bootloader, the system partitions, and the state of the secure booting integrity. Results will be discussed.

Periodic Mobile Forensics, Android™, Knockoff

C21 A Forensic Investigation of Drones

Niels Ter Bork, BS, NFI, Laan Van Ypenburg 6, Den Haag 2288GD, NETHERLANDS; and Zeno J. Geradts, PhD, Netherlands Forensic Institute, Laan van Ypenburg 6, Den Haag, SH 2497 GB, NETHERLANDS*

After attending this presentation, attendees will learn what type of data can be extracted from drones after they have been used.

This presentation will impact the forensic science community by highlighting several methods for the digital investigation of drones. Since the number of drones is rising, they are also being used in criminal activities.

Drones come in all shapes and sizes and are becoming more accessible to individuals. Drones are increasingly popular among criminal organizations due to their ease of operation and the different functions they offer. Criminals use drones to explore unseen locations and to transport illegal cargo.

Because little is known about what data is stored on different types of drones, it is important to focus on an exploratory study. The Netherlands Forensic Institute (NFI) wanted to know what research questions regarding drones to take into consideration. For this purpose, six different types of drones popular in 2016 were purchased. These include drones from the DJI®, 3DR®, and Align, and Yuneec brands. These drones have assistance systems, making it easy to control the drones. The auxiliary systems themselves handle a large amount of data that can be useful for forensic examination.

Data extraction is divided into two categories: destructive testing and non-destructive testing. For destructive testing, chip-off may be used. Non-destructive testing consists of extracting data from forensic software using a Joint Test Action Group (JTAG) method. This study uses the least intrusive method, namely Forensic Toolkit® (FTK®). The study consists of an external examination, which looks at possible access ports on storage media (e.g., USB, SD card) and an internal examination, which looks at the printed circuit boards inside the drones. Raw data that is acquired is converted from the drones and ground stations to a readable file. There are many converter programs that are specifically designed for these specific drones. A disadvantage of many of these converter programs is that data must be uploaded to a site, which is not possible for case-related data.

The Align M690L is the only drone that stores any data unless a data logger has been purchased. The other drones include all data that have been extracted and analyzed using standard forensic software. It includes data about various assistance systems such as Global Positioning System (GPS), Gyro, Accelerator, and a barometer. The GPS coordinates can be plotted on a map to provide an escape route. The 3DR® IRIS+ contains waypoints that are pre-programmed and can be downloaded at any time. Imports logged on the remote controls are visible so that a statement can be made about a possible driver.

For several drones, the route flown can be extracted; however, the owner could not be found from the data extracted from the drone. Conventional forensic methods such as DNA and fingerprints of the drone might be used to find the owner of the drone. In further research, chip-off will be tested to determine if more information pertaining to the drone owner can be obtained.

Drone Forensics, UAV, Digital Investigation

C22 Joint Task Action Group (JTAG) Phone Forensics

William Charles Easttom II, MBA, Chuck Easttom Consulting, 5605 Woodspring Drive, Plano, TX 75093*

After attending this presentation, attendees will better understand what it means to use JTAG techniques to access the raw data from a phone. Attendees will also receive an overview of when JTAG is the appropriate approach to phone forensics. This presentation will cover the types of techniques, equipment needed, and skills required to JTAG a phone. This presentation will also cover the limitations of JTAG and help forensic examiners know when this is the appropriate technique and when it is not. The goal of this presentation is to provide attendees with an understanding of JTAG phone forensics techniques.

This presentation will impact the forensic science community by defining how JTAG phone forensics techniques are a very critical topic in the area of mobile forensics.

It is a common occurrence for digital forensic investigators to require data from a phone that is locked or even physically damaged. When one of these situations occurs, common phone forensics tools are not adequate for the task of extracting data from the phone. In many cases, investigators in this situation will determine data cannot be extracted from the phone and will simply stop the investigation; however, there are techniques that allow a forensic examiner to directly access the computer chip on a phone (at least for an Android™ or Windows® phone), then to extract that information in a hexadecimal format.

Many law enforcement agencies lack personnel trained in JTAG techniques. Many forensic examiners assume that JTAG is very complex, exceedingly difficult, and is beyond their skillset. Some even suppose that an electrical engineer is required to JTAG a phone; however, these assumptions are inaccurate. There are a variety of inexpensive kits designed for testing of chips that can be applied to JTAG techniques on a phone.

Forensic investigators need a better understanding of the process, techniques, and procedures in order to begin to leverage JTAG techniques in their phone forensics investigations. This presentation will provide that fundamental knowledge that will allow forensic examiners to take the next step to implementing JTAG in their own investigations.

This topic is very important to digital forensics. As any examiner can attest, it is common to find a phone related to a case but be unable to access the data on that phone. This impedes investigations in all areas. Phone forensics itself impacts not just traditional cyber crime investigations but also violent crimes, drug trafficking, and even terrorism investigations. The ubiquitous nature of smart phones makes phone forensics one of the most critical aspects of digital forensics. Both civilian and law enforcement forensic examiners need to expand their technical skillset in order to provide the possibility of extracting data from a phone, even if that phone is locked or damaged.

JTAG, Mobile Forensics, Phone Forensics

C23 Joint Task Action Group (JTAG) Data Extraction and Analysis

Jenise Reyes-Rodriguez, BS, NIST, 100 Bureau Drive, Gaithersburg, MD 20899; and Richard Ayers, MS, 100 Bureau Drive, MS 8970, Gaithersburg, MD 20899-8970*

After attending this presentation, attendees will better understand the importance of JTAG data extraction, analysis research, and testing conducted within the Computer Forensic Tool Testing (CFTT) project at the National Institute of Standards and Technology (NIST).

This presentation will impact the forensic science community by providing awareness of the capabilities and limitations for data extraction and digital forensic tools supporting JTAG binary file analysis.

As mobile device usage and sophistication continues to grow, the need for rigorous research and testing conducted across a variety of forensic tools and techniques is critical.

JTAG, an Institute of Electrical and Electronics Engineers (IEEE) standard, began as a method to verify the design and testing of printed circuit boards after manufacturing. The JTAG interface provides forensic examiners with numerous advantages, such as a non-destructive byte-for-byte memory dump from supported mobile devices whose data contents are typically examined using a traditional digital forensic tool. Additionally, the JTAG interface provides examiners with the ability to bypass mobile devices with disabled USB ports and the ability to extract data from devices that may have been subjected to liquid, thermal, or structural damage.

JTAG research conducted within the CFTT program begins by populating a set of supported mobile phones with a known data set containing active and deleted data. A known data set yields a way for results to be measured across several extraction solutions, techniques (i.e., solder, jig), and tools capable of parsing JTAG binary files. The memory contents are acquired across supporting JTAG extraction tools using a variety of connectivity techniques (e.g., solder, solderless). Data extractions begin with methodically disassembling a supported mobile device and identification of the copper Test Access Ports (TAPs) located on the Printed Circuit Board (PCB). The TAPs across various makes and models of supported mobile devices will vary in location and size. The TAPs are generally about the size of the tip of a thumbtack. Once the TAPs have been identified, various techniques can be utilized to establish connectivity and begin data extraction from the mobile device's internal memory, resulting in a JTAG binary file. After JTAG extraction, the data contents are examined by importing the JTAG binary into supporting analysis tools and comparing the results against known content.

The goal of the research and testing within the CFTT program is intended to provide the forensic community with an understanding of the capabilities and limitations of various JTAG extraction techniques and analysis tools. These results provide insight into any pros and cons across a combination of supported hardware, techniques, and tools capable of performing JTAG data analysis.

This presentation provides a summary of findings and lessons learned during the research and testing process of tools capable of extracting and analyzing memory contents from a mobile device using the JTAG interface.

Certain trade names and company products are mentioned in the text or identified. In no case does such identification imply recommendation or endorsement, nor does it imply that the products are necessarily the best available for the purpose.

JTAG, Mobile, Forensics

C24 Personality Characteristics of Computer Hackers: A Systematic Review and Meta-Analysis

Marcus Rogers, PhD, Purdue University, 401 N Grant Street, West Lafayette, IN 47907; and Kathryn C. Seigfried-Spellar, PhD*, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will have a better understanding regarding personality characteristics of computer hackers.

This presentation will impact the forensic science community by increasing understanding of the personality characteristics of computer hackers through a systematic review and meta-analysis.

According to Symantec™, there was a 23% increase in the number of data breaches as well as an all-time high of 24 discovered zero-day vulnerabilities, with a combined 295 days passing until vendors released patches for the top five zero-days in 2014.[1] In addition, small- to medium-sized organizations were the victims of 60% of all targeted attacks. Verizon® reported an estimated 79,790 security incidents and 2,122 confirmed data breaches in 2014, and 55% of insider incidents involved abuse of privileges.[2] Regarding software security, Veracode™ reported that the government sector only remediates 27% of application vulnerabilities and 80% of healthcare sector applications suffer from cryptographic issues.[3] Finally, Abellera reports that the 16 critical infrastructure sectors in the United States (c.f., Presidential Policy Directive 21) are constantly defending against cyber-attacks.[4]

It is clear that escalating cyber threats and vulnerabilities are a serious concern for both small and large organizations as well as the private sector and general public. For the past decade, empirical studies exist that focus on the human element of computer crime; that is, trying to understand the personality characteristics of computer hackers.[5-7] Studies suggest that not only are there personality differences between computer criminals and non-criminals, but there are personality differences between different types of hackers, such as virus writers and identity thieves; however, researchers have yet to combine the results of these studies in order to better understand the overall relationship between computer criminal behavior and personality.[6,7]

After a decade of research, enough studies exist for a systematic review of the literature in order to conduct a meta-analysis.[8] A meta-analysis is a statistical approach to combining the results of multiple studies in order to understand the estimates of the effect or relationship under investigation. The specific goal of the current study is to conduct a meta-analysis of the literature, by including published and unpublished studies, to improve the overall understanding of the personality characteristics associated with computer criminal behavior. The systematic review of the literature will include unpublished works in order to account for publication bias, which should also result in a more accurate representation of the overall effect size estimate.

The results will be discussed in addition to the limitations of the study, final conclusions, and suggestions for future research.

C25 Detecting Causality Through Fine-Grain Logging in Digital Investigations

Golden G. Richard III, PhD, University of New Orleans, Dept of Computer Science, New Orleans, LA 70148; and Aisha Ali-Gombe, MS, University of New Orleans, Computer Science, 308 Mathematics Bldg, 2000 Lakeshore Drive, New Orleans, LA 70148*

After attending this presentation, attendees will understand the impact of attribution on multi-app systems such as Android™. Storage and access of sensitive system data like contacts on SQLite databases by applications does not leave any trace of the causal relationships that will attribute the target app to the database object(s). Attendees will also learn how this problem can be solved by enforcing fine-grained access control on the SQLite database using static bytecode rewriting. The methodology is backed by a practical experiment that analyzed the 64 most-downloaded free apps on Google® Play™ and evaluated them based on application crashes, static, and runtime overhead.

This presentation will impact the forensic science community by discussing how fine-grained logging mechanisms can aid investigations by providing clear causal relationships between apps and database objects. Practical scenarios will be illustrated on how these casual relationships can be vital in supplementing memory and disk forensics to enhance digital investigations.

In a digital forensics investigation, how data gets written onto a device is as important as who writes the data. Often, research has shown that malicious software can write incriminating evidence on digital devices, thereby putting users at risk, as in the child pornography case against Michael Fiola.[1] The problem presented in this study illustrates how data written onto SQLite databases via the Android™ native providers cannot be linked to any specific application. While READ/WRITE accesses on the database are restricted and granted based on exclusive user permissions, general log files and typical digital evidence sources do not affiliate any app to the written data at any time.

With WRITE permission for instance, update, insert, and delete database operations can be performed by an application with very little data available to support attribution. This is primarily because SQLite is a single-user system and is not designed to keep track of who performs what operations on a system. For forensics investigation, this makes it very difficult to ascertain if a particular entry in the database is added or updated by the user or by a malicious application.

Thus, to aid digital investigation, a fine-grain logging technique that uses bytecode weaving to statically weave in extra auditing code after the return of specific Android™ database Create, Read, Update, and Delete (CRUD) functions (insert, update, delete, and query) is presented. The presented technique uses aspect-oriented programming to instrument Android apps. This instrumentation process does not require any modification to the operating system and/or framework code, thereby making it easily adoptable by average users. The experiment also revealed the system incurs an average of 15 seconds of static overhead and 58 nanoseconds runtime overhead across a range of test apps.

Causal Relationships, Fine-Grain Logging, Bytecode Weaving

C26 Supervisory Control and Data Acquisition (SCADA) Forensics: Network Traffic Analysis for Extracting a Programmable Logic Controller (PLC) System and Programming Logic Files

Irfan Ahmed, PhD, University of New Orleans, 2000 Lakeshore Drive, New Orleans, LA 70122*

After attending this presentation, attendees will understand the message format of the Allen-Bradley Programmable Controller Communication Commands (PCCC) protocol and how the network traffic of the protocol can be analyzed for extracting ladder logic program and system files. Ladder logic is a popular programming language for a PLC that is an essential and critical component for the automation of industrial processes such as gas pipelines, chemical and nuclear plants, and power generation and distribution.

This presentation will impact the forensic science community by providing an overview of a parsing and recovery technique for a ladder logic program and system files from the network traffic of the Allen-Bradley PCCC protocol. The protocol is supported and widely used by the PLCs of the vendor, Allen-Bradley, for transferring configurations and programming logic and control data (such as sensor readings, current state of actuators, counters, and timers). When the programming software, such as Studio 5000® and RSLogix 500™, transfers a ladder logic program from an engineering workstation to a PLC, it transfers system files along with the program.

In order to extract these files, the technique takes into account the PCCC message format allowing the identification and filtering of packets based on the protocol header fields. The fields include byte-count, file-number, file-type, element-number, and sub element number. In particular, the file-type field is used to identify the type of data in a packet. For instance, "O" represents output file data. Each packet contains headers of three industrial protocols in the following sequence: Ethernet/IP, Common Industrial Protocol (CIP), and PCCC. The technique for recovering the files involves parsing the PCCC header, then further filtering out the packets containing the chunks of system and program logic files, which are then combined in a logical sequence to reproduce the files being transferred through the network.

A prototype implementation (tool) of the technique will also be provided in the presentation. The tool can play an important role in the forensic investigation of a SCADA system. For instance, a forensic investigator can determine the presence of any ladder logic code and system files in a network packet capture and further obtain the whole code from the capture in a file for further analysis. The investigator can compare the hash values of the code extracted from the network trace to the original code of the PLC created and downloaded from PLC programming software.

Ladder Logic, SCADA Forensics, Network File Carving

C27 Assessing the Psychological Well-Being and Coping Mechanisms for Law Enforcement Investigators and Digital Forensic Examiners of Child Pornography Investigations

Kathryn C. Seigfried-Spellar, PhD, Purdue University, Computer and Information Technology, 401 N Grant Street, West Lafayette, IN 47907*

After attending this presentation, attendees will understand the significant differences of psychological well-being, job satisfaction, and coping mechanisms for individuals working as either digital forensic examiners and/or investigators of cases involving child pornography.

This presentation will impact the forensic science community by highlighting this first study to assess the psychological well-being, as well as attitudes toward psychological services, for individuals working as either digital forensic examiners and/or investigators of cases involving child pornography.

The United States has seen an increase in the number of law enforcement officers investigating child pornography cases as well as the number of digital forensic examiners involved in the analysis of child pornography-related digital evidence.[1] Specialized task forces or units that focus on child pornography cases exist. Some are nationwide, such as the Internet Crimes Against Children (ICAC) task force, whereas others exist at the state or local level. In some units, there is a clear division of labor — computer forensic examiners analyze and index the child pornography collections, while the investigators work directly with the offender and the victim/family; however, in other units, the investigators are also the examiners, meaning they not only work alongside the offender and/or victim, but they also analyze the digital evidence in child pornography cases. Overall, criminal justice occupations are associated with high work stress leading to psychological illnesses (e.g., depression, anxiety) and high turnover rates, especially for officers dealing with child investigations.[2,3] Previous research has assessed the level of job satisfaction and coping mechanisms for digital forensic examiners; however, research has yet to compare the psychological well being of individuals who work as either digital forensics examiners, investigators, or both, while working child pornography cases.

The current study was the first to compare the psychological well being, job satisfaction, coping mechanisms (i.e., strategies for dealing with stress), and attitudes toward psychological treatment (e.g., therapy) for individuals working as either digital forensics examiners and/or investigators of child pornography cases. This study had three specific goals: (1) explore the psychological wellbeing and job satisfaction; (2) identify any differences in coping mechanisms; and, (3) assess attitudes toward psychological treatment as well as the availability of psychological resources for examiners/investigators working child pornography cases.

A snowball sample of law enforcement officers and digital forensic examiners were solicited to participate in the anonymous, online survey through a variety of means, including the ICAC task force listserv. Based on their current, self-reported duties, 20 respondents were classified as digital forensic examiners only, 71 respondents as investigators only, and 38 respondents as both digital forensics examiners and investigators of cases involving internet child pornography. Results suggested significant differences in the psychological well being, job satisfaction, and coping mechanisms for individuals working as either digital forensic examiners and/or investigators of cases involving child pornography.

The results will be fully discussed as well as suggestions for future research.

Digital Forensics, Law Enforcement, Child Pornography

C28 A 3D Study of Facial Mimicry: A New Approach for the Identification of Missing Children

Niccolò Barla, MD, Department of Public Health and Pediatrics, Corso Galileo Galilei 22, Torino 10126, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP - Univ. TO, C So Galileo Galilei N 22, Torino 10121, ITALY; Guglielmo Ramieri, MD, Maxillofacial Surgery Section, Turin, Corso Bramante 88, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Dept Public Health Sciences, Sezione di Medicina Legale, Corso Galileo Galilei 22, Torino 10126, ITALY; and Laura Verzé, MD, Department of Public Health and Pediatrics, Turin, Corso Galileo Galilei 22, Torino 10126, ITALY*

After attending this presentation, attendees will better understand how to improve the possibility of facial recognition of missing subjects by exploiting the memory for facial expressions.

This presentation will impact the forensic science community by highlighting an important 3D facial analytical method that can extract invariant features from the 3D face template. The results could be very helpful in the interpretation of 2D images, given that the 3D verification of the mimicry in childhood/adolescent samples revealed the persistence of highly individualizing facial expressions.

The assessment of facial morphology is mainly used in the facial identification of missing subjects when photographs and videos are available; however, in everyday life, faces are in constant motion and often a person is recognized for distinct facial expressions. Facial morphology also is altered with age and environmental conditions. Even a simple instantaneous contact captures the image of a moving face. For this reason, researchers have begun to consider how facial motion affects memory for faces. The face provides a distinctive indication of the individual identity and previous studies demonstrated that memory for a moving face can help personal recognition.[1] Moreover, in previous studies conducted with 3D methods, adults undergoing reconstructive facial surgery retained the same mimic movements one year after surgery, despite the changes to the underlying bones. This study proposes a method for personal identification of missing children, at a period of time after their disappearance, using 3D analysis of facial movements.

New technologies enable presentation and manipulation of digital videos, techniques that are fundamental in the efforts to identify subjects, including minors. The identification of facial expressions can implement the effectiveness of recognition of missing persons. Three boys and three girls aged 7-14 years of age in T1 and 14-21 years of age in T2 were recruited for the study. Facial surface data were acquired by a 3D laser scanner (Cyberware 3030RGB™) and transferred to Geomagic Design™ X software for data elaboration. In previous studies, the development of a specific protocol resulted in a mean scanning error of 1mm–1.2mm and a recording error of 0.3mm–0.4 mm on repeated scans of human subjects. The patients were registered in a resting position and after movements of the upper, middle, and lower area of the face. They were frowning, grimacing, smiling, and pursing their lips. To study the modifications of these faces during growth, an anthropometric evaluation was conducted using 3D points to discern distance measurements in a resting position.

Statistically significant results were obtained in longitudinal and oblique 3D measurements ($p<0.05$). In T1 children, the motion was easier and spontaneous in the lower area of the face, while the movements of the upper area were not intuitive. The amplitude of the movements of the lower area of the face was augmented with age. In T2, spontaneous movements in the upper area of the face appeared more evident (i.e., grimace). This is consistent with the literature. Two observers separately evaluated the soft tissue displacements during the facial movements of T1 and T2. The 3D morphological study of the mobility of the soft tissues of the lower part of the face of the subjects demonstrated that the same parts of the soft tissue were involved in the same areas of the face. A unique and characteristic facial morphology was generated, different in every subject, but similar and consistent in the subject during repeated trials. In particular, the mouth, cheeks, and nosewing presented the same morphological displacement, and nose-lip sulks and asymmetries of the lower area of face were consistent over time. The maxilla-facial bone structures, especially in children, vary significantly over time, but facial movements do not.[2]

The 3D technology is useful for facial recognition. Nevertheless, facial modifications may pose problems for automatic individual identification and recognition, and more work needs to be conductede on a larger sample, including more variations in age categories.

3D Mimicry, Facial Recognition, Missing Children

C29 Behavioral Forensic Analysis, Biometrics, and Social Media — A New Investigative Tool

Paola Giannetakis, PhD, Link Campus University, Viale Gregorio VII, Rome, ITALY; Walter Quattrociocchi, PhD*, IMT Lucca Institute for Advanced Studies, Lucca, ITALY; Vinicio Pelino, MS*, Aeronautica Militare, Roma, ITALY; and Luigi Saravo, PhD*, Dalmonte Street, Rome 00123, ITALY*

After attending this presentation, attendees will understand that tracking online behavior makes it possible to understand, to deeply explore, and to predict the evolution of the users' activities. This study introduces the different modeling strategies and their peculiarities. Also being proposed is an integrated demolition tool.

This presentation will impact the forensic science community by providing information regarding how the use of a solid framework of computational social science combining biometry and online users' behavior for the detection and classification of specific behavioral patterns is useful in investigating single and mass phenomena.

The wide availability of social and mobility traces on online Social Media (SM) represents an opportunity for the quantitative analysis of human behavior for investigative and forensic purposes.

The recent advances in the computational social science field may provide an unprecedented set of tools able to disentangle social dynamics at both the micro and macro level, from behavioral and cognitive profiling of single users to forecasting massive social trends and viral phenomena.

Currently, modeling human behavior has become a priority, especially as it applies to social network behaviors as well as the proper use of behavioral biometrics to define and detect strategically hidden identities. Therefore, it is strategic to combine identification tools based on behavior implemented within structures that allow tracking, control, and the potential demolition of assets of dangerous activities. The study of human behavior, especially applied to behavioral analysis in the forensic field, offers new and interesting application perspectives; this study explores two main areas of application by combining them.

This stydy's goal is to use the solid framework of computational social science to combine biometry and online users' behavior for the detection and classification of specific behavioral patterns. By means of the proposed approach, behavioral analysis can become an active tool. On the one hand, the precision and speed of anomaly detection and user identification can be improved. On the other hand, through mathematical modeling, user behavior at the individual and social level can now be forecast. Furthermore, the application of mathematical tools for the understanding of users' behaviors on SM can reveal critical information to be exploited for security purposes.

Users online, tend to join polarized groups of like-minded people and to acquire information that only adheres to their belief system. Such a tendency, known as confirmation bias, plays a pivotal role in online social dynamics and reflects the users' personality traits.

The analysis, therefore, allows us, on the one hand, to explore behavior of the media in order to extrapolate information susceptible and sensitive information. On the other hand, it provides a useful tool for the identification of the subject. By tracking online behavior, it is possible to understand, to deeply explore, and to predict the evolution of the users' activities. This study introduces the different modeling strategies and their variences and proposes an integrated demolition tool.

Behavior, Forensic Analysis, Behavioral Biometrics

C30 Advances in Automated Content Carving

Michael Haaf, MS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090; Eric Shirk, BS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090; Chris Poldevaart, BS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090; Eoghan Casey, PhD, University of Lausanne, Batochime, CH-1015 Lausanne-Dorigny, Lausanne, Vaud, SWITZERLAND; and Joseph Lewthwaite, BS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090*

WITHDRAWN

C31 Challenges in Determining End-User Actions Based on Cloud Repository Metadata

Darcie Lynn Winkler, MSFS, Stroz Friedberg, 1150 Connecticut Avenue, NW, Washington, DC 20036*

After attending this presentation, attendees will better understand the challenges involved in drawing conclusions based on metadata from cloud repositories, such as Google® Drive™ and Dropbox™ Paper, in addition to how end-user actions affect the available metadata.

This presentation will impact the forensic science community by providing a clear and concise summary of how end-user actions impact the metadata maintained in cloud-based environments and how this information can be used to make reliable conclusions in digital forensic investigations.

Metadata, or "data about data," is a critical artifact relied upon in many digital forensic investigations and extensive research has been conducted by the digital forensic community to better comprehend how dates of files relate to actions taken by the user; however, cloud metadata is stored and updated differently than metadata on a physical file system, and, thus, the need to understand this tracking system is of the utmost importance. Therefore, this presentation will describe recent research and analysis performed on data stored in Google® Drive™ and Dropbox™ Paper repositories, with a specific emphasis on the analysis of metadata to determine user activity.

The use of various cloud repositories to create, edit, and store documents is becoming more and more commonplace, and the data in these repositories has become increasingly relevant in both civil and criminal digital forensic investigations. Google® Drive™ and Dropbox™ Paper were researched in order to determine what types of metadata are stored and how they relate to common user actions. To replicate as many user scenarios as possible, the web-based interface was used in conjunction with the downloaded applications on a Windows® desktop computer and an Apple® mobile device. Several typical user actions were completed, such as creating, editing, downloading, and uploading documents, while changes made to the metadata were documented.

This presentation will describe how various actions performed by the user can change the metadata between different platforms: the web-based interface, the application on a Windows® machine, and the application on an Apple® iPhone®. For example, while Google® Drive™ maintains date metadata to an extent within the web interface, the created time of the file is overwritten by the time of download, regardless of how it is downloaded; however, the modified date remains unchanged except for the fact that it is represented in Pacific Standard Time despite Google® Drive™ settings being set to Eastern Standard Time. Unlike the original Dropbox™, Dropbox™ Paper allows for the creation and editing of documents and only shows the dates of recent edits within the web-based interface. Once the file created within Dropbox™ Paper is downloaded, the modification date is overwritten with the time of download. Many other situations will be discussed to enhance analyst comprehension of how metadata is affected by common end-user actions.

Forensic analysis of cloud metadata is especially challenging, as new features and versions are constantly being introduced by cloud providers. To overcome the challenges of ever-changing metadata tracking systems, digital forensic analysts need to be aware of the versions and features relevant to their case and, if necessary, verify their understanding of the relationship between user actions and the changes in the metadata in the same environment. Without this comprehension, analysts may be unable to make knowledgeable and accurate conclusions when translating the metadata of a cloud repository file into user-attributable actions.

Cloud Forensics, Google® Drive™ Metadata, Dropbox™ Paper Metadata

C32 The Acquisition and Analysis of Evidence From Cloud and Internet of Things (IoT) Services

Vassil Roussev, PhD, Computer Science, 2000 Lakeshore Drive, 308 Mathematics Bldg, New Orleans, LA 70148*

After attending this presentation, attendees will better understand the qualitative differences between working with traditional and cloud-based evidence sources. Attendees will also gain methodological insight into the inherent limitations of the currently prevalent client-side analysis of cloud services as well as a preliminary notion of how IoT forensics is likely to take place.

This presentation will impact the forensic science community by clearly demonstrating: (1) the need to develop new approaches to investigating cloud services; (2) a summary of early results in the field, including new data sources that are not available on client devices; and, (3) several new types of capabilities that forensic tools already need.

The rapid transition to a cloud-centric delivery of Information Technology (IT) services is having a profound, and currently underappreciated, impact on the acquisition and analysis of digital evidence. Namely, the switch from deploying "software as a product" to using it "as a service" changes both the legal environment and the technical requirements for search, seizure, and evidence analysis operations. Considering the technical side, it is shown that digital forensics needs to move away from the idea that physical acquisition is the gold standard and transition to the concept of acquiring evidence from an authoritative source, such as a cloud service. It is argued that digital forensics, as a whole, is on the verge of transitioning to a new mode of operation in which large-scale automated data analysis will dominate and mainstay data recovery and reconstruction techniques will rapidly diminish in importance.

Several case studies of cloud acquisition and analysis tools that work with cloud drive and online collaboration services to illustrate both the limitations of client-side analysis and the new opportunities presented by rich historical data collected by services will be discussed. Examples include direct acquisition from Dropbox™, Box, Google® Drive™, and Microsoft® OneDrive®, and analysis of native Google® Docs artifacts, including the extraction of user biometric signatures based on keyboard dynamics.

This presentation will also briefly consider the forensic analysis of IoT devices, which are placed in several capability classes. The argument will be made that for a large class of low-end devices, the only meaningful forensic analysis will be based on the data acquired from the cloud service backing the devices.

Based on the above reasoning and experiences, the argument is made that the next generation of forensic tools will be primarily focused on working with network Application Programming Interfaces (APIs) and the forensic community will need to develop completely new capabilities for (semi-) automated reverse engineering and will describe the semantics of network protocols and data APIs.

Cloud Forensics, Cloud Evidence, IoT Forensics

C33 Representing and Exchanging Cyber-Investigation Information in a Standard Format

Sean Barnum, BS, MITRE, 7515 Colshire Drive, McLean, VA 22102; Eoghan Casey, PhD, University of Lausanne, Batochime, CH-1015 Lausanne-Dorigny, Lausanne, Vaud, SWITZERLAND; Ryan Griffith, BS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090; and Jonathan Snyder, BS, DC3, 911 Elkridge Landing Road, Linthicum, MD 21090*

After attending this presentation, attendees will have learned about the community-driven standard format for representing digital evidence and other cyber-investigation information. Uses and benefits of this standard are presented and initial implementations are demonstrated.

This presentation will impact the forensic science community by demonstrating how the adoption of this standard by forensic laboratories, tool developers, and other members of the digital evidence community will enable sharing, increase efficiency, enhance analysis, and reduce linkage blindness.

Any type of investigation can have a digital dimension, ranging from computers as a source of information in homicides and terrorist attacks to computers as instrumentalities of fraud and cyber-attacks. Offenders, violent and white collar alike, including drug dealers making simple use of cell phones and organized criminals making sophisticated use of computer networks, use technology in various ways. As a result, cyber-investigations are complex, multifaceted, and have specific applications within broader contexts of criminal justice systems, enterprise governance, and military operations.

Furthermore, investigations of cybercrime can involve multiple investigating entities, forensic tools, and jurisdictions that each have pieces of information needed to solve the case. It is important to bring these pieces of information together to support forensic analysis and reduce the risk of overlooked linkages. Current approaches to sharing cyber-investigation information are ad hoc, inconsistent, and inefficient. Where standardized structures are used, they are typically focused on only an individual portion of the overall cyber-investigation process, they do not integrate well with each other, or they lack coherent flexibility. Many existing information-sharing activities involve conversion of proprietary formats and are human-to-human exchanges of unstructured or semi-structured descriptions of cyber-investigation traces and analysis. Correlating results from digital forensic tools can be a time-intensive and error-prone process, largely due to the inconsistent export formats.

This presentation details a community-driven standard format to support interoperability between organizations, jurisdictions, investigations, and tools. This initiative is called Cyber-investigation Analysis Standard Expression (CASE). The intended benefits for this standard format include increased efficiency when combining and deduplicating output from multiple tools and reduced linkage blindness between investigations and jurisdictions.

Core features of this standard are presented, including how traces, actions, relationships, and provenance are represented. Examples are provided of the initial JavaScript™ Object Notification (JSON) serialization of the underlying information model. Use cases for the standard format are discussed, including collaboration and sharing, correlation and analysis, and tool comparison and interoperability. An initial proof-of-concept implementation of CASE is demonstrated using the open source "plaso" forensic framework.

Attendees are invited to join this community effort, using the standard in their organizations and tools, and proposing improvements to the standard.

Digital Evidence, Cyber-Investigation, Information Sharing

C34 Vehicle Forensics: A Tale of Two Cars

Celia Whelan, 1018 Eighth Street, Apt 3, Huntington, WV 25701; John E. Sammons, MS, 18 Quail Drive, Ona, WV 25545; Brian K. McManus, BS, National White Collar Crime Center, 5000 NASA Boulevard, Fairmont, WV 26554; and Terry Fenger, PhD, 1401 Forensic Science Drive, Huntington, WV 25701*

After attending this presentation, attendees will recognize the capabilities and potential for vehicle forensics to uncover valuable digital evidence. Attendees will also understand the basic capabilities of the only commercial vehicle forensics tool currently available.

This presentation will impact the forensic science community by demonstrating the ability of vehicle forensics to unearth valuable digital evidence in an innovative manner.

The analysis of mobile devices and hard drives has been the focus of the digital forensics world for years; but, there is another source of potential evidence that is not often considered: vehicles.[1,2] In fact, vehicle forensics is so new that attorneys, investigators, or law enforcement may not even realize the wealth of digital information cars can provide. Many of today's digitally "connected cars" have infotainment and telematics systems that function like computers, storing information that they process, including user data from mobile phones and devices that have been synced to the system.[2,3] These systems have been said to store unique identifying information originating from mobile devices such as call logs, contacts, sent/received text messages Short Message Service (SMS), and even social media feeds that remain on the system even when the phone is detached.[2,4] User artifacts such as these can point to suspects or witnesses and/or play a role in corroborating or disproving someone's alibi. There has been little-to-no research conducted regarding how long these artifacts remain on the system and whether or not the user can remove those artifacts.

Additionally, there has been minimal research conducted regarding the types of user artifacts that can be left on vehicle systems by mobile devices. This is understandable since vehicle forensics is new and there is currently just one commercially available tool: Berla Corporation's iVe.[2,4] Furthermore, due to the differences between various makes and models of infotainment systems, it stands to reason that the user information obtained from one system by iVe may be different than that obtained from another. Little research has been done regarding certain systems potentially providing more information than others.

This research seeks to answer the following research questions: Which user artifacts can be found on vehicle infotainment systems?; How long will those artifacts remain on the system?; Will any of those artifacts remain on the system once the devices are removed or unpaired through the on-screen interface?; and will different infotainment systems allow for recovery of different artifacts? For this study, two different makes and models of vehicle infotainment systems were used for the data acquisition process: a Uconnect® system and another with a Toyota® Extension Box. It was found that the Toyota® system provided a significant amount of user information (contacts, call logs, media files, locations, and unique identifiers), while the Uconnect® system only provided locations. Additionally, it was found that even when these paired devices were unsynced from the Toyota® system using the on-screen interface, a significant amount of acquirable information remained behind on the system: contacts, call logs, and media files were recovered from devices that were not currently connected to the system. When devices were unpaired from the Toyota® system using the on-screen interface, the mobile phone identifying information (i.e., International Mobile Equipment Identity (IMEI)) was unable to be recovered, but contacts, call logs, media files, last sync time, and phone version could still be seen. Even after selecting the "Remove Personal Data" option on the Toyota® system, the same identifying information (contacts, call logs, etc.) could still be retrieved; call logs dating back several years were still recoverable from the system. While this study provides valuable insight into artifacts that can be found using vehicle forensics, future work should include the performance of physical acquisitions on vehicle systems, as well as analyzing data from other types of infotainment systems.

D1 Can Gait Recognition Using Coupled Non-Linear Oscillators Overcome Intra-Individual Variability?

Daisuke Imoto, MS, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Kenji Kurosawa, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Ken'ichi Tsuchiya, PhD, 6-3-1 Kashiwanoha, Kashiwa, Chiba 2770882, JAPAN; Kenro Kuroki, PhD, 6-3-1 Kashiwanoha, Kashiwa, JAPAN; Norimitsu Akiba, PhD, National Research Institute of Police Science, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; Hidetoshi Kakuda, PhD, National Research Institute of Police Science, Physics Section, 6-3-1 Kashiwanoha, Kashiwa, Chiba 277-0882, JAPAN; and Manato Hirabayashi, MS, National Research Institute of Police Science, 6 3 1 Kashiwanoha, Kashiwa 277-0882, JAPAN*

After attending this presentation, attendees will understand how to formulate and implement gait recognition schemes using Central Pattern Generator (CPG) -based coupled non-linear oscillators for overcoming the problems of false rejection due to intra-individual variability.

This presentation will impact the forensic science community by providing a novel gait recognition scheme using a coupled non-linear oscillator model. This study will also initiate discussion regarding which gait-relevant parameters can potentially be used to solve the problem of intra-individual variability.

Gait recognition is a recently developed and still evolving technique by which individuals can be recognized based upon their gait. Two different approaches are used: (1) silhouette-based; and, (2) model-based.[1-5] The first, using silhouette information, is being tested for forensic identification purposes in Japan.[1] The second uses body-model information, such as joint coordinates or angles, and is not yet in general use. Because conventional model-based methods mainly compare similarity of joint dynamics, gait recognition is adversely affected by intra-individual variability arising from environmental or mental changes.[3,4] False rejections (i.e., incorrectly identifying the same person as "different") therefore sometimes occur due to these alterations. It is a difficult but necessary and urgent task to overcome these problems to allow expanded application of this technology. To simulate and reconstruct foot joint dynamics, previous studies have successfully demonstrated the usefulness of non-linear oscillator models, which are one of the representations of the CPG framework.[6] Gait recognition schemes incorporating those models may offer the solution to false rejections arising from intra-individual variability.

This study compares different methods using a coupled non-linear oscillator model.[6] This study involves lower extremity joint trajectories (two hips, knees, and ankles) in a model which includes three Degrees Of Freedom (DOF) for one hip, one DOF for one knee, and two DOF for one ankle. Evaluations were performed using 3D joint trajectories to focus the possibility and usefulness of the suggested method. To fit these parameters to a non-linear oscillator model, a Levenberg-Marquardt algorithm was used that evaluates errors as sum of squares of joint coordinate differences. This study examined and compared four ways of selecting features described below: (1) using all fitted parameters; (2) using some fitted parameters; (3) using simulated joint trajectories; and, (4) using dynamic properties featured as a phase-response curve, which consists of the relationships between phase changes and perturbation timings when a perturbation is added.

The 3D joint trajectories of 20 subjects were measured by Microsoft® Kinect® v2 sensors. The data was obtained from four walks obtained during each of a two-day experiment. The error rate of conventional methods used to analyze the data from two days of experiments was greater than the error rate obtained from the date of a one-day experiment. This confirmed that intra-individual variability can cause false rejections. The results of these studies and suggested methods will be presented and error rates obtained from each of the four methods of selecting key

joint relevant features will be examined. The results will provide information regarding which joint parameters can or cannot be used to solve the problem of intra-individual variability.

Model-Based Gait Recognition, Intra-Individual Variability, Coupled Non-Linear Oscillators

D2 A Forensic Analysis of Flora Damage Caused by an Environmental Disaster at Mariana, Brazil

Carlos Alberto Trindade, Polícia Federal, Rua Ouro Preto, 1681, Santo Agostinho, Apto 1202, Belo Horizonte-MG, Minas Gerais, BRAZIL*

After attending this presentation, attendees will understand several of the techniques used for the characterization of damage to flora that occurred in a large area.

This presentation will impact the forensic science community by detailing the environmental expertise activities undertaken to assess the extent of flora damage in large areas.

On November 5, 2015, the worst Brazilian mining accident occurred in the city of Mariana, Minas Gerais, Brazil. This occurred as a result of a dam (Fundão) breach that produced a mud torrent for more than 600km along Vale do Rio Doce, affecting all the cities and communities along the way and impacting approximately 1.2 million people between the dam and the sea. An estimated 18 victims died; one person remains missing.

The Forensic Unit of Environmental Crimes of the Federal Police was assigned to examine the damaged area. Experts from this group were divided into teams according to specific types of damage, including vegetation, animals, drownings, causes of the dam collapse, and more. The purpose of this presentation is to describe the activities undertaken to assess the damaged vegetation.

The wave of mining waste caused contamination of mining tailings over the watercourse gutter limits, thereby destroying the existing vegetation. This wave reached the grassy vegetation, herbaceous-shrubby vegetation, and treed areas. Damage to vegetation encompassed a region approximately 117km in length, extending from the Fundão dam head to the beginning of the Risoleta Neves Hydroelectric Plant dam lake.

High-resolution satellite images of the damaged area were unavailable following the catastrophe. Later images were available from the Landsat 8 satellite, but the spatial resolution (15m) of these images limited the ability to quantify the extent of the damage.

Commercially available micro- Unmanned Aerial Vehicles (UAVs) were not an option to image and assess the damage as the range of these vehicles was limited to 6km, a distance incompatible with the location of the affected area. Thus, manned helicopter-based aerial surveillance was conducted over the affected riverbeds. A total of 940 aerial photographs were obtained by using a GoPro® HD2 camera equipped with a wide-angle lens to survey a large area in a single flight path. The photographs recorded approximately 80% of the available area viewed. Using these data, experts employed a photogrammetric technique of Structure from Motion (SfM) for generating 3D terrain models and, from these models, obtained georeferenced orthophotos (spatial resolution of approximately 30cm). Distortions due to geophysical relief and photographic angles were accounted for in these models by using a Geographic Information System app.

Simultaneously, a multispectral classification of high-resolution satellite images, taken before the dam disaster, was used to define the topography prior to the incident and provide "baseline" information. The processed information was verified by the use of data gathered in the field and with other prior aerial photographs. Atlantic forest, eucalyptus forest, woods, crops, pastures, and disturbed areas (roads and built-up areas) of physiognomy vegetation were characterized.

It was concluded that the extent of the destruction totaled 1,176,44 hectares (ha), distributed as: 240,880ha of Atlantic forest; 45,000ha of Atlantic forest with eucalyptus; 174,300ha of natural vegetation; 39,110ha of pasture areas; 1,380ha of commercial forests (eucalyptus), and 86,006ha of disturbed areas. This presentation offers attendees a learning experience regarding the methods available to quantify the extent of affected vegetation of large-scale environmental disasters.

Photogrammetry, Flora Damage, Remote Sensing

D3 An Environmental Forensic Analysis at the Doce River Estuary: A Tool for Damage Assessment in a Major Tailings Dam Break in Brazil

Alexandre Klotz, MD, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL; Leonardo Resende, BA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL; Daniel Domingues, MD, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL; Rodrigo Mayrink, MA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte, Minas Gerais 30.441-170, BRAZIL; and Luiza Teixeira, BA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL*

After attending this presentation, attendees will better understand the important aspects of environmental forensic examinations as applied to industrial disasters of major proportions.

This presentation will impact the forensic science community by illustrating modern techniques and an integrated approach to geoprocessing and environmental chemistry.

The goal of this presentation is to present the forensic examinations used to assess the extent of environmental damage at the mouth of the Doce River in Brazil, caused by mining tailings discharged by the disruption of the Fundão dam.

Estuary, a coastal environment of transition between river and sea, is considered an area of high environmental sensitivity, since it is a breeding and feeding area for several river and marine species. On November 21 2015, the Doce river estuary was affected by a plume of tailings originating from a mining company dam that had broken 16 days earlier. Some consider this the greatest dam collapse in mining history.

To assess the damage to the estuarine ecosystem, a forensic team from the Brazilian Federal Police conducted environmental examinations at the mouth of the Doce River. The examined site consisted of an area of natural occurrence of various endemic species of mangroves, typical wetlands plants, and endangered animal species. The marine zone adjacent to the mouth of the river is a reproduction and migration area of marine cetaceans and turtles, many of them endangered.

Forensic experts monitored the area before and after the arrival of the tailings plume, using boats, aircraft, and Unmanned Aerial Vehicles (UAVs). Field inspections and laboratory analyses were conducted to check water quality indices. Experts measured the dispersion of the tailings plume through the sea by daily helicopter overflights arranged using photographic and Global Positioning System (GPS) data. The plume advance was also tracked by images produced by orbital sensors (WorldView 02, WorldView 03, GeoEye-1, and Landsat 8, the latter having a specific band for sediment analysis in water). UAVs were used to obtain high-resolution images of a nearby coastal Federal Conservation Unit, another highly sensitive area in the region.

Normally, turbidity levels of the mouth of the Doce River were lower than five Nephelometric Turbidity Units (NTUs). The tailings plume resulted in the turbidity of mouth waters exceeding 2,000 NTUs, with peaks exceeding 5,000 NTUs and well above the legal Brazilian limit (100 NTUs). Water pollution resulting from mining tailings caused serious environmental damage, such as modification or elimination of wildlife niches, refuges, and breeding sites. Mortality of aquatic animals and migratory marine birds was also observed. Socioeconomic activities in local villages were affected due to the interruption of the drinking water supply and the decrease of tourism and fishing.

Expert examinations allowed a precise characterization of the site before and after the arrival of the tailings plume, thus enabling quantification of the environmental and socioeconomic damage caused by dam break. The current forensic examinations were crucial for proving the environmental crime caused by the dam break, revealing the deleterious effects of pollution on the Doce River estuary.

Dam Break, Estuary, Pollution

D4 Low Price or High Performance?

David Pienkowski, PhD, University of Kentucky, AB Chandler Hospital, Rm MN 564, Lexington, KY 40536-0298*

The goal of this presentation is to increase awareness of the role of economics regarding choices made in materials, designs, or workmanship of everyday devices that humans interact with and depend upon for satisfactory performance and personal safety.

This presentation will impact the forensic science community by discussing how human injury or death is always a tragedy, but these tragedies are exacerbated when their cause can ultimately be attributed to intentional choices made between low cost or high performance in materials, designs, or workmanship of the everyday devices relied upon to provide service. This presentation provides an overview of a session devoted to this topic and sets the basis for the concluding panel discussion.

Reliable performance of safety helmets, air bags, automotive seats, and seat buckles, as well as vehicle body designs, etc. are taken for granted by virtually all consumers. Yet reports often reveal that the risk of injury or death from these and other everyday devices of modern society is more than would ordinarily be expected. Although risk is a necessary accompaniment of a modern technological society, elevated risk arising from economic choices made in the materials, design, or workmanship of these devices merits the attention of consumers, regulators, and legislators.

This session features a compendium of presentations by experts who have spent a considerable portion of their professional careers investigating human injury or deaths that have occurred in conjunction with devices posing elevated risks to society from economic-driven compromises to football helmets, automobile seat backs, buckles, and fuel tanks as well as body and chassis design.

Information presented in this session is useful for forensic investigators as it will highlight design or material shortcomings in such devices and direct the attention of the investigator to these weaknesses, thereby promoting efficient, thorough determination of mishap etiology.

This session is important for attendees with regulatory or legislative responsibilities because lacking government regulation, organizations often choose a path which minimizes expenses to maximize profits at the cost of human safety. Decisions attending design of the Ford® Pinto® or General Motors® (GM) ignition lock provide noteworthy examples. Furthermore, information presented during this session will provide a basis for all attendees to improve their ability to understand mishap etiology.

This session will conclude with a panel discussion that attempts to raise societal awareness of the decisions governing material selection, device design, or manufacturing processes that compromise the performance of everyday items upon which society depends and takes for granted. This panel discussion may also result in technology-based suggestions for reducing such risks. Elected representatives in attendance may use the information provided as a point of departure for introducing new legislation designed to enhance societal safety and protect the public from economic-based compromises to devices upon which humans depend for safe performance.

Material Compromise, Design Flaw, Economics

D5 Vehicle Fuel Systems: Low Performance at a High Cost to Motorists

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; and Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661*

The goals of this presentation are to explain how and why a variety of automotive safety defects exist, along with effective countermeasures and safer alternative designs. The effects of low cost vs. high performance in automotive designs will be demonstrated by analyzing and discussing fuel leakage and ignition designs attending otherwise preventable human injuries.

This presentation will impact the forensic science community by illustrating how to recognize and prevent unsafe fuel system designs as well as by introducing forensic evidence associated with fuel system failure, including puncture and separation of fuel system components, ignition sources, fire burn patterns, and effects on vehicle occupant survivability. Attendees will learn how and why fire occurs in readily survivable collisions in passenger cars, light trucks, and heavy trucks.

Vehicle fuel systems have presented extreme hazards to motorist safety since the creation of motor vehicles. One gallon of gasoline has sufficient energy to propel a vehicle many miles; therefore, it can have instantaneous life-threatening consequences on occupant survivability if ignited due to fuel leakage occurring during an otherwise survivable collision.

Many early vehicle designs employed gravity-feed fuel tanks located between the engine and windshield. This design often caused non-collision-related fires due to fuel leakage onto hot engine and exhaust components. Fuel tanks were then relocated underneath seats and elsewhere inside occupant compartments and, with rare exceptions, along the exterior vehicle perimeter. This general practice continued well into the 1960s and, in some designs, even later.

The earliest efforts involving automobile fuel system evaluation involved ground vehicle safety testing conducted by the United States Air Force in the 1950s, eventually leading to the 1966 creation of Federal Motor Vehicle Safety Standard (FMVSS) 301. By the late 1960s and early 1970s, sufficient research had been performed at the University of California Los Angeles in the Department of Transportation (DOT) Experimental Safety Vehicle program and at independent laboratories, such as Dynamic Science Inc., to develop properly mounted, crashworthy vehicle fuel systems that were sufficiently cost-effective to enable wide-scale adoption in mass-produced vehicles sold to the public.

The theme of low price vs. high performance clearly reared its head as, unfortunately, automakers have, to the present time, resisted efforts to implement improved high-performance fuel systems in favor of those with low cost, despite the continuing evolution of design improvements in racing vehicles and military aircraft fuel system integrity. These high-performance design improvements are significantly more advanced than those found in current mass-produced automobiles. Such design improvements are not only far more crashworthy, they often contain fire-preventive materials or protection systems that were validated via analysis and testing by researchers. This knowledge was disseminated in the Department of Defense *Crash Survival Design Guide* and other technical safety engineering literature published decades ago.

Unfortunately, the quest for low price is manifested in numerous examples in which automakers built vehicles that ignored well-established fuel system safety design guidelines. Specifically, fuel tanks have been located in vulnerable areas aft of the rear axle, inside cabs on pickups and utility vehicles, and outside frame rails (i.e., “sidesaddle”) on millions of light-duty pickup trucks manufactured through 1987. The lessons that should have been learned from these low-cost, dangerous designs were ignored by automakers who continued to produce unsafe vehicles well into the new millennia. These designs persist with fuel tank locations aft of the rear axle, fuel tanks with no check valves or tethers on filler necks, and fuel tanks lacking effective impact shields or interior bladders to resist fuel leakage if the tank is compromised. This has resulted in a significant number of fire deaths and recalls involving late-model production vehicles. With rare exception, there are no automaker efforts to test production fuel systems in real-world collision conditions, such as vehicle-to-vehicle crash testing at foreseeable highway speeds. Government efforts to improve FMVSS 301 still do not include designs to mitigate fuel tank leakage caused by “underride effects” commonly seen in many vehicle-to-vehicle collisions. Fuel system failures have also

been caused by contact with guardrails, signs, and other common roadside fixed objects. None of these events are considered or evaluated by the DOT or any automaker.

Fuel system design flaws persist in heavy trucks as well, as plainly evidenced by designs clearly showing fuel tanks mounted outside the frame rails of large commercial trucks. Little evolution has occurred in this design since the 1950s. Diesel tanks constructed of thin-walled aluminum are extremely vulnerable to mechanical compromise, content leakage, and disastrous fire. While comparatively safe in bulk liquid form, diesel fuel readily ignites when atomized into a fuel/air mist as commonly occurs during a collision. Fuel tanks on these trucks have exposed filler valves that are vulnerable to impact by vehicles and relatively benign collisions against fixed objects. Collision-induced malfunctions in vehicle electrical systems can provide ignition sources for some time following the impact(s) of the initial collision.

Fuel System, Fire, Safety

D6 Richard III — Finding a King: High Performance and Low Cost

Sarah V. Hainsworth, PhD, University of Leicester, Dept of Engineering, Leicester LE1 7RH, UNITED KINGDOM; and Kevin Schurer, PhD, University of Leicester, School of History, University Road, Leicester , UNITED KINGDOM*

After attending this presentation, attendees will understand elements of planning a major undertaking and using information to guide decision making.

This presentation will impact the forensic science community by illustrating how a major multidisciplinary project can be planned and managed to achieve a successful outcome.

The Richard III project received worldwide attention and clearly demonstrated how multidisciplinary teams can collaborate to demonstrate the efficacy of skillful planning together with modern forensic techniques to efficiently identify the location of a 500-year-old British king's remains. This endeavor was managed like a textbook example of a forensic missing person case from the outset.

The first step involved identification of the known facts and listing the information known with certainty regarding the circumstances surrounding Richard III's death. These facts were that Richard III was in Nottingham when he learned of Henry Tudor's (Henry VII) landing in Milford Haven. Richard III's army rode into Leicester on August 20, 1485, passing through the North Gate, continuing along the High Street, and spending the night at the Blue Boar Inn. The next morning, he rode out of Leicester across Bow Bridge toward Market Bosworth, 12 miles to the east of Leicester. On August 22, he was killed in battle at Bosworth while fighting against the army of Henry Tudor.

After Richard III was killed, his body was stripped naked, thrown over the back of a horse, brought back to Leicester, where his corpse was taken through the town to the Newarke (a religious precinct and home to a college of priests), then displayed in the Church of the Annunciation of the Blessed Virgin Mary. Two or three days later, Richard III's body was taken from the church and hastily buried in the choir of a Franciscan friary church known as Greyfriars.

The Greyfriars monastery was dissolved in 1540 and the exact location of Richard's grave was lost; however, analyses of historical records have suggested the approximate location of the friary and its likely situation in relation to the modern urban landscape of the town of Leicester.

These analyses indicated that the likely site of Greyfriars was under a car park belonging to the Social Services at Leicester. Open spaces constituted 17% of the total friary precinct. Because both access to this site and financial resources for research were limited, only approximately 1% of the friary precinct could be excavated. The key decision involved where to utilize scarce resources needed for expensive excavation (typically trenches dug by large hydraulic earth-moving machinery) on the site. Ground-penetrating radar was used to survey all three of the most likely open spaces in the hope that one of these trenches would identify some portion of the friary walls. Excavation of the first two trenches identified only anomalous spreads of rubble and modern service lines. Six hours and 43 minutes into excavation of the third trench, a skeleton was discovered. Only after much additional research did the significance of this find become evident: the site where this skeleton was found meant that the skeleton was likely a person of significance.

The second step involved identifying the known anatomical facts concerning Richard III. Richard was 32 years of age at the time of his death. Contemporary accounts described him as being of slender build, "small of stature," and having "unequal shoulders, the right higher than the left." Because Richard III died in battle, his body should have had forensic evidence of trauma consistent with combat of this era.

A key element to the efficient success of this project involved managing the team from Leicester, who were involved with identifying, organizing, and disseminating historical information obtained from the relevant academic literature. Team members were responsible for interacting with other individuals from Leicester City and the Richard III Society to aid in locating his remains. A further aspect to the project involved management of the intense media interest and public scrutiny of the endeavor.

This presentation will discuss the elements of: planning a major undertaking; identifying, collecting, and assimilating both known facts and information that may not be accurate; operating under a constrained budget;

managing a large multidisciplinary project and the various personnel involved; and controlling the dissemination of information at key times. All of this resulted in a highly successful outcome that exceeded expectations.

Richard III, Multidisciplinary, High Performance

D7 A Comparison of Modern Youth Football Helmet Design Impact Attenuating Performance With Measurements Made in 1992 for the Helmet Design of a Fatally Injured High School Player

Kenneth J. Saczalski, PhD, 1440 W Bay Avenue, Newport Beach, CA 92661; Mark C. Pozzi, MS*, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336; Joseph L. Burton, MD, 13784 Highway 9, Alpharetta, GA 30004; and Mark N. West, BS, Environmental Research & Safety Technologists, 1440 W Bay Avenue, Newport Beach, CA 92661*

The goal of this presentation is to demonstrate the means for comparing and assessing designs of current youth football helmet impact performance in front, side, and rear locations versus impact results of a high school football helmet design tested decades earlier (i.e., 1992) in relation to the forensic analysis of a fatally injured 17-year-old high school football player.

This presentation will impact the forensic science community by informing attendees that helmet Severity Index (SI) test data certification measures of new and reconditioned youth football helmets should be made available to the public so parents, coaches, school administrators, and forensic researchers can compare SI impact safety performance levels and identify those helmets that provide uniformly optimum safe levels, throughout all regions of a youth helmet, when tested at realistic impact energies consistent with the speed of players. This type of evaluation would be beneficial for improving youth football player safety and would assist in improving helmet designs.

Head injury and concussion risk to high school and youth football players has recently received attention, including interest by the United States Congress, due to research by Omalu and McKee regarding repeat impact brain damage to professional football players diagnosed with Chronic Traumatic Encephalopathy (CTE).[1-4] Testimony by the National Football League (NFL) before Congress in 2009 suggested "optimism" regarding the safety of newer helmets, compared to older helmets used by CTE-injured players.[1] Unfortunately, research on contact-impact safety of current youth football helmet designs reveals similarities to non-uniform, dangerously high head impact loads seen in older helmets, such as those worn by athletes diagnosed with CTE, when compared to 1992 tests on the helmet of a deceased high school player.[5-7] Energy-absorbing padding in the frontal area of a forensically examined football helmet consisted of a dual-density elastomeric foam (Fig. 1.) Linear contact-impact testing used a certified National Operating Committee on Standards for Athletic Equipment (NOCSAE) drop-impact fixture. Repeat impacts were conducted at 5.5m/s (6.6 second 40-yard dash) with energy of 108 Joules (J). Figure 1 illustrates 1992 helmet compliance with NOCSAE head SI limit of 1,200, but the frontal helmet padding provided the least amount of protection in comparison to the side and rear. More importantly, the SI frontal measures were at or above current National Highway Traffic Safety Administration (NHTSA) Head Injury Criteria (HIC) Injury Reference Value (IRV) of 700 (denoting approximately 7% of the United States population would be at risk of severe head injury with this HIC value).[8] Data also demonstrated a wide disparity of SI measures from front-, side-, and rear-impact locations by approximately 30%. A safe design should not have such wide disparity in injury measures for a given impact energy, but should provide low SI values uniformly at all helmet impact locations.

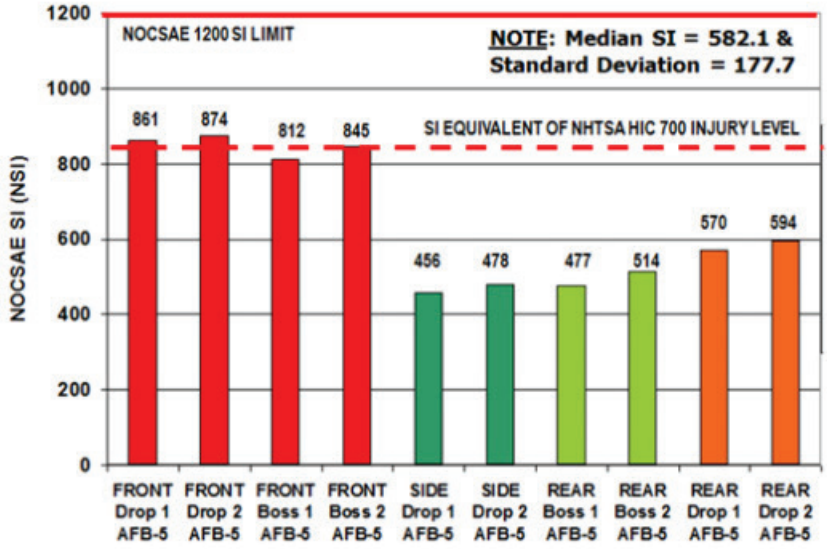

Fig-1. NOCSAE Severity Index Data from 1992 Helmet Design Used by a Fatally Injured High School Player

Comparison of the 1992 NOCSAE SI test data measures for the helmet (Fig. 1) of the fatally injured high school player with recent NOCSAE SI test data of a 2014 Youth Helmet design (Fig. 2) demonstrate that both helmet designs have impact regions exceeding NHTSA HIC 700 IRVs. The danger region of the helmet shown (Fig. 1) was the frontal area, the injury location of the high school player; the danger region of the helmet show in Fig. 2 was the rear (occipital) area. In both cases, the high SI measures deal with response from elastomeric foam impact attenuating "Energy Absorbing" (EA) materials. A positive, or "optimistic," aspect of the 2014 Youth helmet was the incorporation of a newer EA "Thermoplastic-Urethane" (TPU) waffle-pattern material in the front of that helmet (blue frontal material in helmet on left of Fig. 2). While this newer TPU material provides some improvement for direct contact-impact, recent studies by Saczalski et al. indicate head injury risk from rotational accelerations remains a problem with these materials, and that the rotationally induced danger and injury measures are still not part of the NOCSAE helmet safety performance criteria injury evaluation.

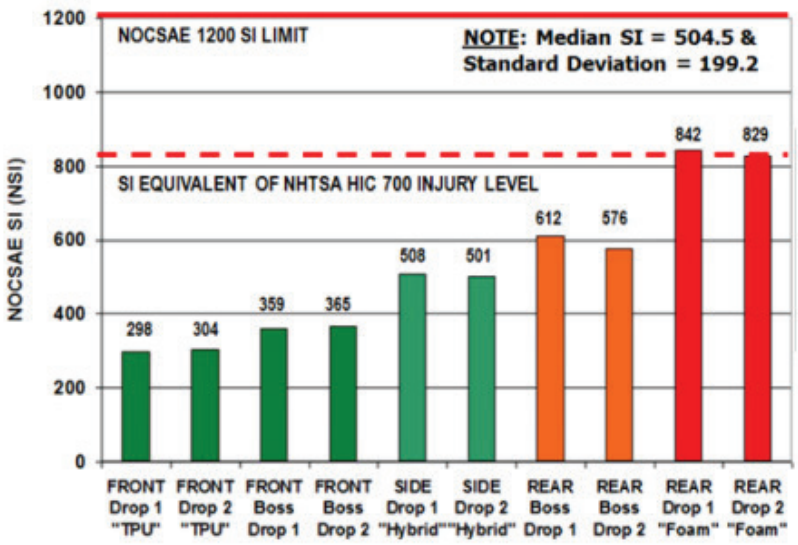

Fig-2. NOCSAE Severity Index Data from 2014 Peewee Youth Helmet Design Approved for Peewee Play

Summary: "Optimism" regarding the efficacy of football helmets to attenuate concussive level impact forces should, unfortunately, be tempered by the reality of recent research, rather than relying solely upon the assurances of NOCSAE and football helmet manufacturers using outdated safety certification testing and injury reference levels.[1,5,6] Ultimately, the NFL and the sport of football need a more rigorous engineering approach to design safer helmets, such as "multi-variable" methods enabling performance assessment for linear impact and rotational injury

measures, plus ambient, high-humidity, and temperature conditions.

Impact: NOCSAE helmet test data should be made readily available so the public can compare SI impact performance levels and identify helmets providing uniformly optimum safety in all regions, when tested at realistic impact energies consistent with actual player speeds. This would benefit football player safety and facilitate improvements in helmet design or materials.

D8 Visibility and Lighting Aspects of Perceiving a Liquid Slip Hazard on a Walkway Surface: A Case Study

James B. Hyzer, PhD, Hyzer Research, 1 Parker Place, Ste 330, Janesville, WI 53545-4077*

The goal of this presentation is to discuss how visibility and lighting influence human ability to visually perceive a liquid slip hazard on a walkway surface.

This presentation will impact the forensic science community by illustrating how conspicuity, expectancy, lighting, and measurable floor surface properties, such as gloss, influence the probability that an individual will visually perceive a liquid slip hazard in time to avoid a slip-and-fall accident.

A common cause of slip-and-fall accidents is liquid on floors. Accident avoidance in such cases, in the absence of prior warning, requires that the individual is able to visually perceive and avoid the hazard before stepping on it. At a minimum, the visual detection of a liquid hazard on the walkway requires that it be either more or less luminous than its immediate background and with sufficient contrast to be distinguishable from its background; however, it will be shown that even though a hazard may be in plain sight and visible, to be seen in sufficient time by all individuals, it must also be conspicuous relative to its surroundings. An object is *conspicuous* if it attracts or tends to attract the attention of an observer so as to be readily discovered. Conversely, an object is *inconspicuous* if it is not readily noticeable or discoverable. The term *conspicuity* refers to the capacity of an object to stand out in relation to its background so as to be readily discovered by vision. Liquid hazards that are more conspicuous are going to be perceived more quickly and therefore at greater distances than hazards that are less conspicuous. At the extremes, hazards that are highly conspicuous should be seen at the greatest possible distances and hazards that are perfectly camouflaged will not be seen at all. For example, colored liquids are generally more conspicuous than liquids that are clear.

It will be shown that the type and orientation of overhead lighting are significant factors affecting the conspicuity of liquids. In particular, some clear liquid hazards can only be seen as a reflection of overhead lighting, and then only when the overhead lighting is in an optimum orientation relative to the individual who will benefit from perceiving the hazard.

A case study involving a slip-and-fall accident at a retail shopping facility exemplifies the points made. At issue was whether the plaintiff should have been able to visually perceive a pool of clear detergent on what defense documents described as a “wet-look” commercial vinyl tile floor. It will be shown that a clear liquid hazard on a “wet look” high-gloss floor would be visually camouflaged under the lighting conditions that are typical in a large retail facility. Additionally, an individual exercising reasonable care regarding where they are walking would not visually perceive an unexpected clear liquid hazard on the surface of a “wet-look” high-gloss floor.

Numerical characterization of wet-look high-gloss floors will be discussed. “Gloss” is quantified in Gloss Units (GU) using an instrument called a glossmeter. Gloss quantifies the shininess of a surface; waxed and polished smooth tile floors have high gloss and unwaxed non-polished floors have low gloss. The GU for the subject “wet-look” dry floor was measured at 75GU-80GU. When wet with clear detergent, it measured 69GU-72GU. The unfinished tile measured 11GU and a typical commercial ceramic tile measured 2.2GU.

It will become obvious that some floors and floor finishes are better suited for exposing liquid slipping hazards by rendering them more conspicuous. The analogous case of ice on outdoor pavement will also be discussed.

Visibility, Lighting, Slip-and-Fall

D9 A Forensic Engineering Review of Vision in Automobile Crashes: Part I

Adam Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will better understand the general complexity of the human visual system and how fundamental characteristics affect human performance under common conditions, often with fatal results.

This presentation will impact the forensic science community by assisting attendees in assessing future cases they may encounter and by offering guidance in distinguishing confounding factors in visual system investigations.

Study of the human visual system and how its fundamental characteristics affect performance under common conditions is an element of Human Factors Engineering. It has a role in defining the design aspects of the human mobile environment as well as deficiencies due to human visual system limitations. Although there is a dominant theme in forensic engineering dealing with the design of products for human use, and associated cost and performance issues, there is also a subset that is less obvious — the overall mobile environment.

Humans have altered their mobile environment, one that was formerly dominated by low-speed walking and running performed for thousands of years, to (over a few generations) one that now also includes driving, skiing, and flying, all accompanying high-speed permutations. Humans have also created other fast-paced environments in which we rely on our visual system to function; however, the human visual system is simply not designed or evolved for optimal performance in such high-speed and high-complexity regimes. Currently, artificial intelligence systems are being tasked to intervene, presently with mixed results, and eventually take over substantial parts of these visual and cognitive functions.

In nearly every investigation involving a visual perception mishap, the following key questions arise: (1) What was there to be seen?; (2) Why was this not seen?; and, (3) How did this contribute (if at all) to the mishap? The short answer is that the human visual system is extremely complex and the human visual system is not a camera!

There are literally tens of thousands of design standards for automobiles, roads, controls, visibility, materials, lights, luminaires, and all their subsystems. Despite these design standards, hundreds of thousands of accidents, crashes, and mishaps occur each year across the globe.

This brief overview of multiple forensic engineering visibility cases will provide different explanations regarding why the scenes and situations were not sufficiently defined by the participants to avoid mishaps. This sets the basis for the matrix of causative factors to be discussed in Part II of this presentation.

This presentation will touch on fundamental concepts, including Gibson's visual world, the visual field, optical projection to the retinal structure, foveal vision, peripheral vision, processing by specialized receptor sensors, translation into bio-electrical signals, feed-forward to the visual cortex, processing and integration by neural-brain system, short-term memory, further cognitive processing and perceptual responses transmitted to specific muscle response groups, and feedback to complete a control loop.

Additionally, the discussion will include (as time permits) inclusion of the following elements as part of the eight-case analysis: perception-response time, attention and limited attention capability, illusions and perceptual traps, scanning of the visual world, human-designed visual aids, mirrors, devices, geometry, contrast, conspicuity, luminance, illumination, pattern recognition, driving search patterns, visual flow, focus of expansion, eye tracking, saccades, scans, fixations, blinking, combining images, contrast sensitivity, line of sight, foveal vision, peripheral vision, perception of color, rods and cones, human error, risk assessment, "inattentional blindness," driver expectancy, time to collision, looming, and alerted and non-alerted observers. These topics will assist attendees in assessing future cases they may encounter and offer guidance in distinguishing the confounding factors in visual system investigations.

Human Factors, Visual World, Attention

D10 A Forensic Engineering Review of Vision in Automobile Crashes: Part II

Adam Aleksander, PhD, Aleksander & Associates, PA, PO Box 140558, Boise, ID 83714*

After attending this presentation, attendees will be aware of the general complexity of the human visual system and how fundamental characteristics of this system affect human performance under common conditions, often with fatal results. This second of a two-part presentation examines specific instances of collisions and crashes and incorporates the principles and elements outlined in Part I.

This presentation will impact the forensic science community by helping attendees identify specific characteristics attending the cause of these vision-related incidents and the interaction of potentially causative factors. The ability of attendees to investigate other incidents involving human visual systems will be aided by attending this presentation.

The presentation of these cases will include discussion of the matrix of causative factors that may be reasonably considered in the analysis.

The cases include: (1) the State vs. JT involving an auto pedestrian fatal collision. A driver hit two elderly pedestrians in a crosswalk, despite the fact that he should have clearly seen these two pedestrians. In this case, a medical condition led to a scene-scanning behavior that allowed adequate driving behavior, except when faced with this critical situation; (2) Estate of L vs. CPM, a pedestrian vs. a backing asphalt truck resulting in a fatal collision. The driver should have seen the pedestrian, but did not. Elements to be considered in this case include mirror system design, signaling, night environment, illumination, and attention and illumination issues; (3) B vs. S, a high-speed skier who impacted another skier in a serious injury collision. The skier should have seen the impending cross traffic. Elements include perception reaction time, gradients, visual field, and foveal vision; (4) P vs. CJ, a young female who was assaulted in a complex playground with hidden playground features. The argument was made that the child should have been seen. Elements include line of sight, contrast, conspicuity, masking, and position of viewer; (5) B vs. ICG, an underground mine scoop was moving in a mine passageway and was involved in a fatal collision with another scoop. The impacted scoop was supposedly visible, yet an analysis of the line of sight, contrast, visual field, attention, and perception reaction demonstrated essentially blind driving. (6) H vs. IT, a pedestrian walked into a right-turning truck in a crosswalk collision. The pedestrian should have seen the large moving truck and trailer. Visibility issues were assessed, as well as distraction, and inattentional blindness-related issues. (7) H vs. R, a motorcycle rider on an unfamiliar road approached a modified T intersection and went straight, resulting in a crash. It was deemed that he should have seen the intersection, yet an analysis of the signs, scene, and visibility factors revealed a perceptual illusion (a visual trap); (8) K vs. ST, a pickup struck the back of a semi-truck on a clear road, resulting in multiple fatalities. An analysis considered the looming effect, attention, foveal vision, and perception reaction time as well as other motorists that avoided the hazard.

In these and other similar cases, no single factor fully explains the visual system or cause of mishap nor can the investigator place himself/herself in the eyes of any of the participants or witnesses involved. The matrix of factors presented will assist in developing potential explanations. Furthermore, cameras, whatever their modern features, cannot capture the events as they happened from the involved individual's perceptions. They can only memorialize the observations of the forensic engineer or investigator, who must understand the visual system to render opinions to assist the court.

Attendees will benefit from the identification of specific dominant characteristics of the proximate causes of the incidents and the interaction of other factors. This information may assist them in investigating other visual system cases.

Inattentional Blindness, Distraction, Line of Sight

D11 A Computer Simulation for Use in Impact Force Evaluations: Studies on the Correlation Between Impact Force and Finger Bone Fracture

Momoko Watanabe, University of Yamanashi, B-7, rapport-hosaka, 122-1, iwakubo-cho, Kofu-si, Yamanashi 4000013, JAPAN; Yasumi Ito, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu 400-8511, JAPAN; Yoshiyuki Kagiyama, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu-shi 400-0001, JAPAN; Tatsuya Fukuoka, University of Yamanashi, 4-3-11 Takeda, Kofu, Yamanashi 400-8511, JAPAN; Shohei Daimaru, 4-3-11 Takeda, Kofu-shi, Yamanashi-ken 400-0001, JAPAN; and Tetsuya Nemoto, PH.D, 36-3, Gengo, Morioka, Obu 474-8522, JAPAN*

After attending this presentation, attendees will better understand the relationship between impact force and finger bone fracture to establish a safety assessment index. In addition, attendees will learn the potential use of the Finite Element Method (FEM) for evaluating human finger bone fracture risk.

This presentation will impact the forensic science community by providing an example of computer simulation for human body injury assessment and by illustrating how safety assessment can be used to prevent accidents from a variety of devices.

Establishing relationships between external force and human injury is needed to estimate intent and certify negligence in various incidents or accidents. Recent research revealed that there exists a relationship between bone density and certain types of fracture risk. Techniques that evaluate fracture risk by individual bone shape and bone density are in the process of being developed and some are being used in medical care in Japan. Non-injurious evaluation of individual bone fracture risk is important, but difficult to achieve given variations in individual physical characteristics. This is particularly important when considering finger and hand injuries involving interactions with power windows in motor vehicles. Accurate estimates regarding the relationships between external force magnitude and finger injury risk are needed, but few studies address even the basic biomechanics of this issue due to the low risk to human life and perceived relative unimportance.

This study used a pig tail model of human finger bones during static compression and dynamic drop tests to determine the relationships between external force and injury level. Varying edge shapes were used to consider this covariate in the injury risk determinations. Furthermore, Finite Element Methods (FEM) were also employed to estimate bone fracture risk so relationships between human fingers and pig tail bones could be developed.

The results demonstrated that actual fracture loads (approximately 1,100N to 1,400N) varied significantly with impact velocity, contacting edge shape, and the amount of soft tissue present. FEM simulation demonstrated estimated finger failure loads of approximately 870N to 980N. The role of these finger fracture parameters was confirmed in addition to the usefulness of computer simulation as an effective tool for the evaluation of finger bone fracture risk.

Human Injury, FEM Analysis, Finger Fracture

D12 Basic Research on the Development of Crash Dummy Skin for Risk Evaluation of Fracture and Skin Injury

Yasuhiro Nishio, University of Yamanashi, 4-3-11Takeda, Kofu City, Yamanashi pref. 400-8511, JAPAN; Yasumi Ito, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu 400-8511, JAPAN; Ryotaro Kishida, University of Yamanashi, 4-3-11, Takeda, Kofu-shi, Yamanashi Prefecture 400-8511, JAPAN; Shohei Daimaru, 4-3-11 Takeda, Kofu-shi, Yamanashi-ken 400-0001, JAPAN; Yoshiyuki Kagiyama, PhD, University of Yamanashi, 4-3-11 Takeda, Kofu-shi 400-0001, JAPAN; Tatsuya Fukuoka, University of Yamanashi, 4-3-11 Takeda, Kofu, Yamanashi 400-8511, JAPAN; and Tetsuya Nemoto, PH.D, 36-3, Gengo, Morioka, Obu 474-8522, JAPAN*

After attending this presentation, attendees will better understand techniques for evaluating the dynamic mechanical properties of soft tissue.

This presentation will impact the forensic science community by providing a physical model of personal injury evaluation that accounts for the dynamic mechanical properties of soft biological tissue.

It is known that the presence of soft biological tissue such as skin and muscle has a large effect on the presence or absence of bone fracture resulting from a dynamic load such as impact from a blunt object; however, this effect has not been quantified since data quantifying the dynamic mechanical properties of soft tissue is unavailable. In addition, the dynamic properties of soft tissue are essential to evaluate damage due to external forces. The Hybrid III 50th Percentile Anthropometric Test Dummy (ATD) is commonly used to measure human injury in vehicular accidents. This is used not only in automotive frontal collision tests, but also in human body damage evaluations that were caused by impacts, drops, falls, vibration, etc.; however, the mechanical properties of the simulated soft biological tissue in this model have not been reproduced with high accuracy. The next-generation dummy has a much higher human being enhancement degree than existing dummies, and the soft biological tissue will be incorporated; therefore, substitute materials reproducing a soft biological tissue must be examined. This study seeks to quantify impact properties and dynamic viscoelastic properties for the development of alternative substitute materials which can reproduce the dynamic mechanical properties of soft biological tissue.

This study used urethane gel as a physical material of ATD skin. The surface of the urethane gel was covered in a simulated epidermis. The dynamic viscoelasticity was measured using a rheometer. Two-axis loading of this simulated skin revealed good correlation with the dynamic viscoelasticity measured from the human skin of 20-year-old men.

Dummy Skin, Dynamic Viscoelasticity, Human Body Damage Evaluation

D13 Multivariate Analysis Applied to Sawed-Off Shotgun Pellet Dispersion

Diva Carcamo, BS, Policia de Investigaciones Chile, Los Acacios 2140, Viña del Mar, CHILE; Erica Sepulveda, BS, Policia de Investigaciones Chile, Avda. Carlos Silva Vildósola N°9783, La Reina Santiago, CHILE; Cristian F. Lizama, BS, Policia de Investigaciones, Aldunate 620 8vo Piso, Temuco, Araucania, CHILE; Alejandra Figueroa, BSc, Policia de Investigaciones de Chile, Aldunate 620, Temuco, CHILE; and Ramiro Diaz, Universidad Católica de Temuco, Rudecindo Ortega 2950, Temuco, CHILE*

After attending this presentation, attendees will understand how statistics can model the dispersion of birdshot fired from a 12-gauge sawed-off shotgun and will also learn that the spread of lead birdshot depends only slightly on the barrel length and mainly on the firing range.

This presentation will impact the forensic science community by providing attendees with an appreciation of the fact that, in contrast to previously published works, the dispersion of lead birdshot is best described by a second-order polynomial expression rather than a linear relationship.[1-3]

Statistical techniques have been used to establish a mathematical relationship enabling estimation of the distance from which a shotgun was fired with buckshot ammunition.[4] In the present study, pellet dispersion accompanying the discharge of lead birdshot was analyzed. Shotguns are easy to obtain in several countries as they are considered hunting devices, including sport hunting or pest elimination such as hare, mice, or mink plagues occurring in the fields of southern Chile. Due to their low cost and capability to inflict injury, shotguns (especially those with substantially shortened barrels, also known as "Recortadas" in Chile) are sometimes the preferred weapons for criminal activities. A long-held belief was that pellet dispersion varied greatly with barrel length, hence the motivation for the present study. The objective of this study was to analyze the effects of barrel length and pellet size on pellet dispersion at several distances using two 12-gauge FAMAE™ shotguns. A two-level factorial design was used to analyze the effect of pellet size (5cm-7.5cm), barrel length (33cm-72cm), and the firing distance on pellet dispersion (evaluated as the area of the figure enclosing all leads on the target, the square root of such area, and finally the Matto and Nabar effective radius method, which requires the measurements of x and y coordinates for every single impact on the target).[1] The results demonstrated that pellet size has a dominant influence on pellet dispersion, but barrel length has a nearly negligible influence on pellet dispersion. The effective radius was the best parameter, reaching R2 values of 99.9% vs. 89.x% of the area of the minimum figure around the birdshots and 99.x% for the root of the area.

The second stage involved the development of a response surface methodology to obtain a graphical relation between barrel length and firing range, assuming a second order polynomial as response evaluated for the same functions described above for the pellet dispersion. The chosen method for the experimental design was a Box-Behnken model covering ranges of 33cm, 45cm, and 72cm for the length of the shotgun barrel and 5m, 10m, and 15m for the firing range. After conducting the experiments using only Nº 5 pellets (the most commonly used in Chile), a second degree equation describing lead pattern as a function of the two variables studied was obtained, and an Analysis of Variance (ANOVA) test demonstrated a very good fitness for the effective radius, with R2 values of 99.7% of agreement. Results again exhibited that pellet dispersion is not directly influenced by the length of the weapon's barrel but depends strongly on the distance from muzzle to target. According to these results, the senior method of Matoo and Nabar revealed this is a very good way to estimate the firing range for 12-gauge shotguns, but by using a parabolic curve instead of the linear approach initially proposed. Surprisingly, the square root of the area enclosing the impacts is a very easy method to calculate the approach to the distance of the firing distance; meanwhile, the ANOVA test showed that it is a statistically acceptable approach to the firing range.

D14 Wildlife Forensic Examinations in the Largest Dam Collapse in the History of World Mining

Rodrigo Mayrink, MA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte, Minas Gerais 30.441-170, BRAZIL; Daniel Domingues, MD, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL; Ana Luiza Queiroz, BA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL; Marcus Vinicius de Oliveira Andrade, MSc, Brazilian Federal Police, R. Nascimento Gurgel, 30, Bairro Gutierrez, Belo Horizonte, Minas Gerais 30441-170, BRAZIL; and Marcela Nishimoto, BA, Federal Police of Brazil, Rua Nascimento Gurgel, 30, Gutierrez, Belo Horizonte 30441-170, BRAZIL*

After attending this presentation, attendees will better understand the important aspects of wildlife forensics as applied to environmental disasters.

This presentation will impact the forensic science community by informing attendees about modern techniques and integrated approaches in wildlife and environmental forensic examinations.

The goal of this presentation is to describe the assessment and extension of the environmental damage caused by a huge mining dam break that occurred on November 5, 2015, in Minas Gerais, the state with the highest concentration of industrial mines in Brazil.

The dam, owned by two of the biggest mining enterprises in the world, has been considered the biggest disaster of its kind in mining history, given the volume of waste released (50-60 million cubic meters of tailings extending along an affected area of 600km and costing an estimated $ 5.2 billion (United States dollars) in environmental damage.

Since Brazilian law considers water pollution an environmental crime, the Brazilian Federal Police established an investigation into the causes and consequences of this disaster. From November 2015 to March 2016, a multidisciplinary team of environmental forensic experts made technical inspections along 600km of the Doce River to determine the damage on local wildlife caused by the waste discharge. Furthermore, the experts examined more than 70 technical reports written by government agencies and consultancy companies in charge of monitoring the effects of the catastrophe. Moreover, the Federal Police forensic service established technical partnerships for the exchange of information with the Brazilian federal environmental agency (Instituto Brasileiro do Meio Ambiente E Dos Recursos Naturais Renováveis (IBAMA)), research centers such as the Continental Fish Center of the Brazilian Institute for Biodiversity Conservation (ICMBio), and universities.

The forensic investigation determined the environmental impact on crustaceans, amphibians, reptiles, mammals, birds, invertebrates, and domestic animals. At least 29,300 fish carcasses (more than 13.9 tons) were found and collected at more than 60 sampling points along the river. The disaster occurred just before spawning, killing a large number of fish that went up the river to reproduce. Thus, the forensic analysis also estimated the effects of the pollution on the depletion of fish stocks for the following years.

In addition, more than 1,500 water and sediment samples were submitted for ecotoxicological tests during the first four months following the disaster. This set of data was analyzed to monitor acute and chronic damage caused by the tailings plume to the aquatic fauna.

Some of the species that suffered acute and chronic effects are officially classified as endangered or critically endangered, such as the endemic marine catfishes *Genidens genidens* and *Potamarius grandoculis*, the blue land crab (*Cardisoma guanhumi*), and the sea turtles *Dermochelys coriacea* (leatherback sea turtle) and *Caretta caretta* (loggerhead sea turtle). Forensic veterinarians and biologists analyzed approximately 130 records of animal health care and performed dozens of necropsies and histopathological analyses.

The current forensic examinations were crucial for proving the environmental crime caused by the dam break, showing the deleterious effects of pollution on the Doce River wildlife. In addition to registering and interpreting the evidence to press criminal charges, the forensic reports warned about the importance of continuous monitoring of chronic effects in aquatic, terrestrial, and migratory animals.

Dam Break, Wildlife, Environmental Forensic

D15 Data Integrity in Forensic Science and Engineering

David Pienkowski, PhD, University of Kentucky, AB Chandler Hospital, Rm MN 564, Lexington, KY 40536-0298*

The goal of this presentation is to increase awareness of the existence of data fabrication or falsification perpetrated by a small subset of scientists and engineers and to help the ethical forensic investigator develop robust analyses and conclusions that account for this unfortunate reality.

Scientists and engineers have historically been among the most trusted and respected professionals in society, but increasing reports of data fraud generate cause for alarm. This presentation will impact the forensic science community by raising awareness of this unethical behavior and will review the ways in which data is fabricated or falsified.

The Internal Revenue Service is an effective supervisory agency ensuring honest and accurate self-reporting of income upon which taxation is based. No such organization exists for the data self-reported by scientists or engineers. None has been needed because these professionals have historically told only the truth, and for this reason society holds scientists and engineers in high esteem and implicitly trusts the data they report.

Unfortunately, a small subset of scientists and engineers has deliberately invented or altered data for ill purposes. This behavior is particularly troublesome in matters concerning forensic investigations in which wrongful conviction (or failure to correctly convict) in a criminal case or an inappropriate settlement in a civil case may result. Regardless of the reason, any attempt to alter the reality of an experiment or observation is wrong and unethical. Such alterations take many forms and fall chiefly under the subheadings of fabrication and falsification.

Fabrication refers to ill-intentioned "invention" of data where none exists. This blatant act occurs by: (1) "dry-labbing" — reporting the results of calculations or experiments that never occurred; (2) adding "invented" data to actual experiments (so that mean values are altered) — this can also include physically or digitally adding objects to crime scene images (where no such objects existed in reality) or the opposite — removing or materially repositioning such objects; or, (3) reporting actual data, but from an inflated sample size (thereby misrepresenting the population estimated by a falsely reported sample size).

Falsification, while equally wrong and unethical, is subtler and has more manifestations. Falsification refers to taking actual experimental data and modifying it for ill purposes. This includes, for example: (1) undocumented measurement system "recalibration" to achieve a desired outcome; (2) biased (and undocumented) study subject selection; (3) unjustified data rejection; (4) exaggerated experimental measurement precision; (5) wrongfully identifying results as "typical" when, in fact, the results were the best ever observed; and, (6) confusing sample or subject identification numbers to obscure tracing.

It is important to add that discussions, including disagreements, regarding data interpretation are healthy and acceptable in ethical forensic science and engineering; however, the data itself should never be in question.

In summary, data fabrication and falsification are despicable acts diametrically opposed to the ethics of moral people and violate the trust society places in scientists and engineers. Such acts waste time and money, can endanger human life, and besmirch the vast majority of forensic scientists and engineers who behave according to high ethical standards. The panel discussion concluding this session will explore the means by which forensic scientists and engineers can be alert to acts of fabrication or falsification by others and thereby improve the credibility of their reports and the robustness of their conclusions.

Data Fabrication, Data Falsification, Data Interpretation

D16 The Deaths of Children in Moderate-Speed, Rear-End Impacts — Are They Unfortunate Accidents or Manslaughter? Discussions on the Ethical and the Moral Obligations of Manufacturers and Government to the Consumer

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661; and Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336*

The goal of this presentation is to demonstrate safety defects in vehicles and safer alternative designs. The effects of low costs resulting in predictable seat and belt failure in foreseeable survivable crashes and the effects on adult and child vehicle occupants are presented in tests and case studies.

This presentation will impact the forensic science community by informing attendees regarding the predictable dangers of unsafe seats, slackened belts, and intrusion of rear seat survival space, as well as by presenting associated forensic evidence.

The *Code of Ethics for Engineers*, published by the National Society of Professional Engineers, states in the first section entitled Fundamental Canons that "Engineers, in the fulfillment of their professional duties, shall: (1) Hold paramount the safety, health, and welfare of the public; (2) Perform services only in the areas of their competence; (3) Issue public statements only in an objective and truthful manner; (4) Act for each employer or client as faithful agents or trustees; (5) Avoid deceptive acts; and (6) Conduct themselves honorably, responsibly, ethically and lawfully so as to enhance the honor, reputation and usefulness of the profession."

Is there any valid reason why the above Fundamental Canons should not be adhered to by the manufacturers of products, like automobiles, that are intended for use by trusting consumers? Likewise, is there any valid reason why government agents, who are assigned to regulate and insure the safety of such products so that they provide the utmost level of protection and safety to the trusting citizens who purchase them and use such products, should not also follow similar Fundamental Canons?

Even if unwritten, the ethical and moral practices following implicit adherence to such Fundamental Canons by manufacturers and the governing regulators should be obvious as far as understanding the importance of the obligations needed to provide the utmost protection and care for its trusting citizens, in particular the most innocent citizens such as the infants and children, who are often exposed to the dangers of defectively produced products that are added to the stream of commerce.

Unfortunately, there are several real-world examples of failure of manufacturers and government regulators to follow such Ethical Canons. This discussion will present one such example entitled, "The Death of 8-Month-Old JF: A Properly Seated and Restrained Infant in a Middle Row Who Was Fatally Injured in a Moderate-Speed Rear-Impact Crash to the Family Minivan, While All Other Occupants, Including the Third-Row Seated Occupants Located Closest to the Impact Escaped Without Serious Injury."

In 1954, United States Air Force (USAF) tests proved that human tolerance to frontal impact was 46G. In 1958, a human volunteer in a crashworthy seat withstood 83G in a rear-impact test without loss of consciousness or significant injury. Static and dynamic testing from the 1960s to the present by researchers have consistently demonstrated the clear need for strong, crashworthy seats capable of absorbing predictable occupant crash loads. Weak, collapsing seats allowed by meaningless "safety standards" continue to defeat seat belts and demonstrate predictable life-threatening consequences to front and rear seat vehicle occupants in otherwise readily survivable crash tests and real-world collisions.

Based on the foregoing human tolerance testing, Federal Motor Vehicle Safety Standard (FMVSS) 210 requires vehicle seat belts to withstand 6,000 pounds static frontal loading. FMVSS 207 ignores the presence of a human in the seat and only requires 275 pounds of static load capacity, much less than the American Society for Testing and Materials (ASTM) safety standard for office chairs. There are no FMVSS regarding occupant protection for rear impacts or rollovers. This is why vehicle seat and seat belt failures predictably occur in minor rear crashes, resulting in severe injury and death to adults and rear-seated children. Yet automakers admit that stronger, crashworthy seats would cost "around a dollar."

Since 1996, automakers and the National Highway Traffic Safety Administration (NHTSA) advised placing children in rear seats to avoid airbag hazards, while ignoring predictable seat, belt, and intrusion failures. Research published in 1997 by the Insurance Institute for Highway Safety proved that children are 61% more likely to be severely injured or killed in rear impacts than in other collisions. Despite more than 50 years of crash test research and petitions proving the dangers of weak vehicle seats that defeat safety belts, no action has been taken to prevent these hazards.

Seat Failure, Child Fatality, Rear Impact

D17 Data Integrity in Forensic Engineering — Spoliation and Loss of Evidence

Helmut G. Brosz, BASc, PEng, Brosz Forensic Services, 64 Bullock Drive, Markham, ON L3P 3P2, CANADA*

After attending this presentation, attendees will be aware of the various practices used to further the legal success or outcome of one party at the expense of another.

This presentation will impact the forensic science community by exposing examples of the trickery practiced by unscrupulous parties in civil and criminal litigation involving willful or careless loss, destruction, or alteration of evidence.

Case 1: Loss of evidence — an electrician was electrocuted in his own workshop while testing a motor that he had rewound. He connected the motor to the test terminals and was immediately electrocuted at 480 volts. The two 50-ampere test clips he used had a protective insulating cover (boot) designed to provide insulation and protection from electrocution when handling. The attorney for the deceased claimed that the insulating boot was defective (i.e., had unspecified cuts or holes which permitted contact with the spring-loaded test clips. The plaintiff filed a product liability complaint against the manufacturer of the boot. The expert witness, upon being retained and asked to examine the boot, clips, and cable, was informed that this evidence was "lost" by the deceased's attorney. The only evidence available was autopsy photos of the deceased's hand. This was sufficient to generate a favorable outcome for the defense.

Case 2: Spoliation and failure to collect evidence — downed power line cases that involve electrocution or electrical injury require that utility companies that own the conductor that came down often do not collect the downed conductor or identify it properly. Most large utility companies have incident investigation procedures that call for such evidence to be retained. Often the conductor is discarded, "misplaced," or re-used by splicing (and thus non-identifiable). In many jurisdictions, the State Public Utilities Commission requires the utility companies to thoroughly investigate and record all incidents involving public contact cases. The utility investigators sometimes willfully take no or deficient notes or photos, even though their investigation procedures require these actions. Some conductors that were spliced and re-used, if they can be identified, must be removed to be examined inch by inch at the cost of the parties involved. Sometimes, such identification and removal cannot be conducted without an order from a judge.

Spoliation, Loss of Evidence, Electrocution

D18 Scientific Data Integrity and Engineering Ethics: Test Manipulation, Data Alteration, Elimination of Safety Regulations, and the Theft of Scientific Records

Mark C. Pozzi, MS, Sandia Safety Sciences, 2 Marietta Court, Ste A, Edgewood, NM 87015; Kenneth J. Saczalski, PhD*, 1440 W Bay Avenue, Newport Beach, CA 92661; and Todd Saczalski, BSMET, 140 Calle Irena, Sedona, AZ 86336*

The goals of this presentation are to alert forensic professionals in the ways that testing, data, and safety standards have been manipulated and the manner in which multiple records of taxpayer-supported research have been intentionally suppressed, stolen, or destroyed. This loss of critical information negatively affects public safety and efforts to improve technology. This loss also allows defective, dangerous products to continue to be produced, placing the public at risk. None of this could happen if those involved followed the *Code of Ethics for Engineers*.

This presentation will impact the forensic science community by increasing awareness of how automakers, government officials, and others who are responsible for generating and maintaining objective and reliable scientific information have failed in many instances to properly carry out this responsibility in an ethical manner.

Since the 1940s, countless research projects were performed to advance scientific and engineering knowledge affecting the performance and safety of transportation vehicles for personal, occupational, or recreational pursuits. The present era, especially since the 1960s, showed the advent of many performance and safety regulations and related compliance testing. This includes thousands of scientific tests performed by manufacturers and independent researchers working for government agencies such as the Department Of Transportation (DOT), Department Of Defense (DOD), National Aeronautics and Space Administration (NASA), Consumer Product Safety Commission (CPSC), Occupational Safety and Health Administration (OSHA), the insurance industry, National Operating Committee on Standards for Athletic Equipment (NOCSAE), and others. These include functional, durability, and static tests on consumer goods, ground vehicles, aircraft and spacecraft components and structures, braking/handling/rollover tests, full-scale crash and sled tests of production and prototype vehicles, and full-scale dynamic flight tests of production and experimental aircraft and spacecraft.

The First Canon of Engineering and Scientific Ethics states: One's first duty is to the public. The vast majority of the foregoing test work was conducted in an ethical and scientifically reliable manner, resulting in improvements in the performance and safety of ground vehicles, aircraft, spacecraft, and consumer goods. Unfortunately, during the course of this work, there have also been numerous examples of engineering ethics violations. This has typically occurred when sufficient money and political influence affect interpretation of the often huge gaps between "state of the art," a "reasonably safe, reliable design," and what is "legal to sell" under minimal, often outdated, safety regulations. This conflict has affected forensic investigations and the safety and welfare of the public. These ethical violations and poor engineering judgements have occurred despite civil and criminal laws intended to prevent dangerous products from being sold to unsuspecting consumers. Such violations have also delayed and otherwise affected the safety interpretation, rule-making, and enforcement process. Despite *Daubert* and other gatekeeping rules, unethical "junk science" occurs with regularity in courtrooms.

Examples include: (1) suppression/destruction/sale of scientific records and/or experimental prototypes from taxpayer-funded research, which were supposed to be returned to government safekeeping; (2) manipulation of test conditions, alteration or fabrication of test data (e.g., conducting a "proof" rather than a "test"; (3) diminishing or eliminating safety standards, with no possible public safety benefit, ignoring the National Transportation Safety Board and others opposing such changes; (4) stopping research on improving regulations that the responsible safety agency had admitted were "flawed and inadequate"; (5) conflict among government agencies (e.g., one DOT agency declaring a safety device unreliable and unsafe with another finding "no defects," despite multiple failures in crash testing and field investigations; and, (6) the theft or destruction of original taxpayer-funded test records or classified information from otherwise entrusted archives with subsequent cover-ups by institutions and individuals charged with upholding public safety.

The foregoing was witnessed or learned of during work on government safety research and defect investigations, private sector forensic investigations, and while performing testing with manufacturers, independent test laboratories, and government test facilities. One independent researcher physically searched government archives for extensive

testing he had performed for that agency, relevant to critical safety issues affecting millions of vehicles; he was told "no such testing exists." If the author of unclassified test reports cannot gain access to them, how would another researcher, or ordinary citizens, possibly learn of their existence, let alone the implications for current and future safety issues?

Data Integrity, Engineering Ethics, Test Manipulation

D19 Checking Canine and Handler Credentials Entering a Crime Scene and Evidence Contamination

Jen Hickok, BS, Hickok Consulting, LLC, 5864 Pebble Beach Place, Westerville, OH 43082*

After attending this presentation, attendees will understand the techniques of checking cadaver canine credentials before entering a crime scene, what the cadaver canine credentials are, and how they affect the case. Cadaver canine handlers receive national certification by taking courses that are accepted by the National Incident Management System (NIMS). Attendees of this presentation will discover what happens when a cadaver canine personnel spoils the scene by intentionally dropping physical evidence onto the scene that is not related to the case, only to have it turned over to police personnel as physical evidence.

This presentation will impact the forensic science community by demonstrating the importance of relying on the real physical evidence at hand and by illustrating how to treat unrelated spoiled evidence brought into the scene by someone else.

This case involves a single motor vehicle accident. The vehicle traveled off the right side of roadway, missed the guardrail, went down a ravine, and struck the embankment. The creek was full of water and no body was recovered with the vehicle. A cadaver canine with handler was called into the scene to check for the driver. The cadaver canine personnel "planted" a human toe on the scene when no one was looking. The canine alerted the handler to the human toe. The toe was submitted as evidence to police personnel. Eight weeks later, the body surfaced approximately one mile down the river. This body had work boots on and all toes were accounted for by the medical examiner. Two medical examiners were working on this case and neither would sign the death certificate due to foul play, not knowing whose toe was in police possession. It was difficult to confirm if the body was correctly identified as the driver of the vehicle, because the body was decomposed. As the driver in question had only visited the dentist twice in the driver's life, dental records were unable to confirm the driver's identity. Cross-parenting DNA was then utilized to determine the identity of the driver. The next step was to determine whose toe the police had and whether it pertained to the crash.

The investigator examined the body and the interior of the vehicle for cross-matching evidence to confirm the driver's movement inside the vehicle. Also, the investigator needed to determine how the body exited the vehicle after impact with the embankment. The vehicle had a clothing imprint transfer to the "A" pillar. This "A" pillar was cut from the vehicle and shown to the medical examiners to assist in the investigation. The investigation turned to the canine cadaver handler and a search warrant was issued for the canine handler's residence. The toe was not a part of the collision. The canine cadaver handler was charged with planting physical evidence on several crime scenes in many different states.

When evidence is found, it is accepted as fact without question by the forensic community. Once accepted, it is part of the investigation and submitted to the pertinent parties. In this case, the evidence was accepted and ruled out. In general, tampering with evidence leads to disciplinary action. The body that was found with ten toes was a crucial finding, leading to the discovery of evidence planting t the scene. Accepting the toe as physical evidence made it difficult to complete what should have been an easy investigation of a single-death motor vehicle crash.

Canine cadaver handlers have certifications for both the canine and the handler. These certifications should be checked upon entry to the scene. If the scene involves water, there are water Human Remains Detection (HRD) certifications available for both the handler and the canine. Canines have a special enhanced ability to recover human remains when trained to do so. Canines do an outstanding job in covering large amounts of area in detecting human remains, with the canine and the handler generally working together as a team. The certifications are not transferable between handlers.

Cadaver Canine Credentials, Scene Spoilation, Trusting Scene's Real Evidence

D20 May the Best Liar Win! Lies, Fraud, Intimidation, Deception, Bias, Error, and Incompetence at Work Within Our Courts

John Nixon, CEng, MBA, ARC, PO Box 66, Bippus, IN 46713*

After attending this presentation, attendees will better appreciate what can go wrong with scientific analyses and testimony, what enabling mechanisms are at work, what motivates practitioners to indulge in unethical and/or illegal behavior, and what strategies may be employed to avoid or minimize such problems.

This presentation will impact the forensic science community by alerting attendees to the diversity and extent of forensic expert intimidation, bias, and dishonesty. The forensic science community will be motivated to consider more effective alternatives to the current purely adversarial, process-governed system.

Expert forensic testimony is so widespread that it now often forms the backbone of criminal cases, and almost always plays a critical role in civil litigation. Some disciplines rely on conclusions derived primarily from hard data (test results or recorded observations, for example) while other disciplines rely on subjective opinion that is based upon experience, hypotheses, individual theories, and judgement. Virtually every discipline involves at least some subjective judgment, and that leaves plenty of scope for an apparently scrupulous process to go awry.

The continuing viability of industries, huge sums of money, and entire lives are often at stake. The outcomes of trials change the lives not only of the parties involved, but potentially of huge numbers of people for many years to come. With so much at stake, it is imperative that society ensure the integrity of the system — it should be beyond reproach. Unfortunately, we are falling short of that ideal. The court's role as gatekeeper and the application of *Daubert* and *Frye* standards have advanced keeping unreliable expert testimony out of the courtroom, but even these safeguards fall far short of desired ideals. Frye, for example, requires that testing protocols and underlying scientific principles be accepted by the relevant scientific community — but how does one identify who the relevant scientific community is? The application of a *Frye*-type standard in 16th century Italy resulted in the incarceration of Galilei Galileo because he said the earth was round and rotated around the sun, while the "relevant scientific community" dismissed his work as fantasy. How can we be sure that similar errors are not being made in courtrooms today?

Incompetence can largely be overcome by remedial education and stringent staff selection policies. Errors will never be eliminated completely, but can be minimized by the adoption of procedures such as independent peer review; however, there are far more sinister forces at work within the injustice system (lies, fraud, intimidation, deception, bias, etc.) and these can be difficult to detect and very difficult to eliminate.

Historically, the legal system appears to have dismissed the aforementioned acts as so rare as to be insignificant; however, a review of cases, and especially criminal cases, reveals that the problem is not as isolated as the layperson may assume. Perhaps there is more motivation to eliminate such acts in civil litigation in which huge sums of money are often involved, and less motivation in the criminal arena, where the high volume of cases and society's perception of criminal defendants as thieves, junkies, rapists, murderers, and general "street scum" results in far less scrutiny. The post-conviction process does little to discourage these behaviors as the review system is geared toward errors of process, rather than errors of fact or opinion, and the attitude of the courts is often one of "tough, the defendant should have hired his own expert and challenged this testimony first time around – he gets only one bite of the cherry." These undesirable expert behaviors have essentially been encouraged by the attitude of the legal community, by experts themselves, by the adoption of poor procedures, and by the creation of innocuous names for unethical or illegal activities. Generating fictitious test data (fraud) is usually described as "dry labbing," and false and misleading testimony is often described as "he misspoke," even when it leans solely in favor of the hiring party.

Case studies will be used to illustrate the points discussed and perhaps identify the motivations of the guilty parties. It will be demonstrated that while some instances of wrongdoing are the acts of individuals, others indicate conspiracy. It is concluded that the systemic failures that enable these practices to continue will not be changed without significant and concerted effort on the part of the legal system and lawmakers.

Systemic Failure, Witness Intimidation, Witness Dishonesty

D21 Proper (and Improper) Handling of Data and Analysis in Forensic Linguistics

Carole E. Chaski, PhD, ALIAS Technology, LLC, Institute for Linguistic Evidence, 25100 Trinity Drive, Georgetown, DE 19947*

After attending this presentation, attendees will be able to evaluate proper or improper handling of data in forensic linguistics (forensic stylistics, forensic computational linguistics, or forensic natural language engineering).

This presentation will impact the forensic science community by providing principles for proper data handling for forensic linguistics and other pattern recognition techniques and ways to recognize when data is being improperly handled or analyses are improperly conducted.

Improper handling of linguistic data and analysis impedes the progress of forensic linguistics and its acceptance as a legitimate forensic science. Data management can affect admissibility based on case law and federal/state rules of evidence because proper data handling enables methods to meet legal standards. This presentation covers principles of data management in linguistics, computer science, and forensic science, including ground truth data, human subjects protection, data scarcity, data ill-formedness, data contamination, and statistical analysis. Linguistic (text) data has specific requirements for proper management, but these principles apply to many kinds of forensic techniques.

What kind of data is needed? Ground truth data has known characteristics relevant for a specific task. In authorship identification work, ground truth data would be a set of texts whose authorship is known and verified. It is important to secure ground truth data, but difficult to do. At least one State Superior Court excluded the Federal Bureau of Investigation's (FBI's) Behavioral Analysis Unit (BAU) Communicated Threat Assessment Database (CTAD) due to ground truth problems (*New Jersey v McGuire*). Some advocate using the internet for authorship Identification (ID), but electronic authorial suspicions arise precisely because screen names are pseudonymous.[1-2] Alternative ground truth datasets do exist and are still needed for validation testing.[3-5]

What regulations apply to data sources? Human Subjects Protection (45 Code of Federal Regulations (CFR) 46) defines the standard practice for linguists, but sharing forensic linguistic data must follow both CFR restrictions as well as policing and legal policies. Ethical issues arise in the collection of suicide notes, threats, and predatory chats, including data collection methods, legality, and chain of evidence. Further, discussion of any case while it is still in adjudication is unethical and a potential obstacle to a fair trial. In *Tennessee v Potter*, a forensic stylist was excluded from testifying but presented a talk about the case while the case was in trial. In the JonBenet Ramsey case, a forensic stylist working for the prosecution provided his analysis to *The New York Times* during the grand jury.

What qualities of text data affect method? Three qualities are important: scarcity, ill-formedness, and contaminant-free. Data scarcity is a fact of forensic casework, so methods must select analytical levels to exploit information in minimal amounts of text. Forensic data is measured in the tens and hundreds, not hundred-thousands of words. Analytical levels are thus constrained. In the smallest samples, lexis isn't reliable for authorship ID but grapheme and syntax are.[4, 6-11] Lexis, grapheme, and syntax are standard analytical levels; prescriptive grammar is not.

Ill-formedness is another fact of forensic casework, so analytical procedures must perform on messy input while still preserving it. Spelling, syntax, or punctuation should not be "corrected" by the linguist because this changes the data, but some have. Standard sociolinguistics preserves data, no matter how ill-formed it may seem to the analyst.[12] In a habeas corpus case, two forensic stylists were engaged by the plaintiff and calculated wildly different sentence lengths; when questioned, one explained that he had "corrected the punctuation" of the data. This is not standard practice in linguistics or forensic science.

Correcting ill-formedness is close to contamination, which occurs when multiple unknowns are assumed to be from the same source and treated as known examples of one unknown source. Data should remain contaminant-free. Samples, whether blood or text, should never be mixed, although stylists regularly mix texts.[13] Alternatively, multiple unknowns can be hypothesized to come from one source, but not assumed to be; they can be tested for internal consistency as a single-source, but only if the expert report makes it clear that such a test has occurred, as in *BWI v John Doe*.

Finally, what statistical practice is required? Statistical analysis should proceed by normal rules for particular statistical procedures. While it is true that a few statistical procedures will still work well even if a requirement is violated, the multiplication rule will not work accurately if its requirement of independence is violated. In an immigration case, a computational linguist applied the multiplication rule on dependent data so that he could get, in his own words, the probability that the attorney requested, below .05. After being questioned about this, the analyst called it, in print, "statistical hand-waving."

Forensic Linguistics, Text Mining, Data

D22 Forensic Microscopy and Reverse Engineering in Asbestos-Containing Building Product Identification

James Millette, PhD, Millette Technical Consultants, 220 Cricket Walk, SW, Lilburn, GA 30047*

The goal of this presentation is to inform attendees how microscopic analysis of building products can be used to identify the manufacturer of a product.

This presentation will impact the forensic science community by informing attendees regarding how forensic microscopy can be used to identify the manufacturer of a product by reverse engineering a sample (determining its constituents) of the product, then comparing the resulting list of ingredients with product formula information obtained from a number of sources.

In the late 1980s, President Reagan signed into law the Asbestos Hazard Emergency Response Act (AHERA) to address the problem of asbestos in building materials in the nation's schools. To fund asbestos abatement or removal from existing structures, several school systems and state attorney generals sued the manufacturers of asbestos-containing building products. Determination of which specific manufacturer had produced a particular asbestos-containing building product was an important part of this endeavor. The analysis of thousands of individual samples and matching them to their manufacturer (commonly called Product Identification or Product ID) was a large forensic investigation involving thousands of samples from buildings across the United States and Canada.

There were two general objectives of this project. The first was to collect, decipher, and collate information concerning the formula components of asbestos-containing products, and the second was to develop, modify, and apply forensic microscopic methods to identify components in samples of building products.

There were several sources of manufacturers' product formula information. These included court-ordered releases in a number of cases, the 1990 Federal Register publication of the Environmental Protection Agency (EPA) Asbestos Information Act, Mealey's Litigation Reports, and analysis and deformulation of samples from building applications in which the manufacturer claimed ownership. In one of the first cases, a court order from Maryland's attorney general resulted in thousands of pages of formula documents from former asbestos product manufacturers. Although it was a daunting task to organize this massive amount of information so that it could be used efficiently, it soon became apparent that the majority of the products could be classified on the basis of the type of asbestos present and which of about two dozen binders and fillers were used to construct the products.

Forensic microscopy and chemistry methods were developed or modified from classical procedures to identify the product ingredients, which included: perlite, vermiculite, mineral wool, bentonite clay, kaolin clay, Portland cement, precipitated lime, gypsum, sand, limestone, diatoms, talc, starch, cellulose, mica, wollastonite, titanium dioxide, lithapone, sodium silicate, calcium silicate, magnesite, and sodium nitrate. These methods were used to deformulate known samples of product materials.

A comprehensive Excel® spreadsheet database of the asbestos-containing building material product compositions and their manufacturers was constructed. This database was used with forensic microscopy analysis and chemical testing to identify the manufacturer of the majority of asbestos-containing building products. Development of the database could not have been conducted without extensive investigation into brand names and industry-wide or company-specific terms used to identify each of the components listed on a manufacturer's batch production sheets. For example, an ingredient listed as "Staramic" is a trade name for starch and an ingredient listed as "Snowflake F" is wet-ground limestone (calcium carbonate). This research effort to identify ingredients listed in manufacturers' documents led to the publication of a dictionary of terms in 1999.[1]

This presentation will provide a detailed description of the processes by which the product formula database was developed and specific examples of the practical application of the forensic microscopy techniques used.

Building Product, Microscopy, Asbestos

D23 Why Engineers Are Named in Construction Defect Lawsuits: When Conflicts Arise Between the Building Code, Engineering Judgment, and Common Sense

Michael D. McDowell, MS, 24665 E Ontario Place, Aurora, CO 80016*

After attending this presentation, attendees will better understand some of the common reasons engineers are named in construction defect lawsuits, various aspects of the building code, situations in which using engineering judgment may be problematic, and the challenges facing forensic engineers when a conflict arises between engineering recommendations, engineering plans, and the applicable building code.

This presentation will impact the forensic science community by sharing experience gained through involvement in nearly 500 construction defect claims (and expert testimony in more than 200 construction defect lawsuits). This presentation will also increase engineers' awareness of various conditions that should be assessed at the time of design and construction. Multiple case studies will be presented and the relevant findings and opinions on each matter will be discussed.

The building code provides relevant guidance for design professionals and contractors. Experience has shown that many design professionals and contractors are not well acquainted with some portions of the building code. In these instances, the variation between the engineering design and the applicable building code can become problematic. Engineers are frequently named in lawsuits when conflicts arise between the building code, engineering judgment, and common sense.

Many parties acknowledge that when multiple standards specify differing requirements for the same aspect of construction, the more stringent (or restrictive) standard shall apply; however, experience has shown that the more stringent standard is not always the "applicable" standard. The Building Code states: "Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall be applicable." In more complicated litigated matters, engineering plans sometimes provide details which are less stringent than the adopted building code or general notes to a set of plans. In these cases, the specific requirement may be the "applicable" requirement, but not the more stringent (or restrictive) requirement implemented for construction. In situations such as these, engineering judgment and common sense should be used.

When variations between engineering design and the adopted building code exist, the arguments issued by opposing parties generally relate to engineering judgment. In some instances, engineering judgment may be inconsistent with the current or applicable building code. Perceived deviations, or inconsistencies, within engineering plans will frequently lead to lawsuits because forensic engineers may argue the relative importance of the building code versus engineering judgment.

Based on the review of numerous cases, differences are frequently found by outside parties who scrutinize the pre-design engineering recommendations, the engineering plans and the adopted building code. Differences between engineering plans and building codes can be one of the primary causes for a construction defect lawsuit.

Engineer Lawsuit, Building Code, Engineering Judgment

D24 The Fire Marshal and Forensic Fire Investigation

S.B. Addison Larson, BA, Sherman, CT 06784*

After attending this presentation, attendees will be able to identify the legal and statutory duties of the local fire marshal in a science-based fire investigation, understand a number of ethical and forensic implications associated with reporting a fire, discuss the jurisdictional limits of a fire marshal, and be able to identify some ethical and forensic limitations associated with data collection and reporting when the legal or statutory duty of the local fire marshal does not extend to root-cause or engineering failure analysis. This presentation is accompanied by a case study.

This presentation will impact the forensic science community by providing case facts meant to highlight how the duties of the local fire marshal can provide important testimony regarding culpability, yet still fall short of determining responsibility in civil or criminal litigation. Increased liability is of interest in situations in which there is a loss of life or property due to non-compliance with codes and standards, when the nature of the responsibility is a deliberate omission or an unintentional act. The information presented will be beneficial to fire investigators and public officials responsible for life safety in the local community.

Insofar as forensic fire investigation, it is the duty of the fire marshal to determine the cause, origin, and development of a fire within a jurisdiction and report findings to the state. His or her conclusion will determine whether a crime may have been committed, as in cases of arson or criminal negligence. If there is no evidence a crime may have been committed, then the fire marshal classifies the fire as natural, accidental, or undetermined. This will close the official investigation and no further attempt will be made to gather empirical data. Information reported is pertinent; however, it is limited to data required to fulfill the fire marshal's obligation to the state.

Fire investigations more commonly result in civil litigation than criminal prosecution. Although the local fire marshal or another public service agent may be deposed or must otherwise testify in a civil matter, it is the root-cause failure analysis performed by an engineer or private sector fire investigator that will usually point to civil responsibility. Insurance companies and independent forensic firms are better funded and can often bring a particular case further along to determine specific liability. An investigative engineer can avoid misinterpretation of evidence at the fire scene by studying the local fire marshal's incident summary, photo documentation, and investigative report. The fire marshal receives emergency dispatch notifications and begins data collection concurrent to the arrival of fire and rescue services. He or she should be able to provide a first-hand incident summary, from the initiation of emergency response to the termination of the incident at headquarters, and a written report based on the guidelines, published in the National Fire Protection Association document NFPA 921, for conducting a science-based fire investigation.

The case study that will be presented details the total destruction of a 4.5-million-dollar home in rural Connecticut. This case will show the progression of litigation after criminality was dismissed by the local fire marshal. Facts to be presented will illustrate how reports made by the Office of the Fire Marshal can provide data on origin, development, and proximate cause; confirm exculpatory statements during civil litigation through exclusion; and articulate how the scientific method was used to determine fire cause and origin within the scope of his or her investigation. Ethical implications regarding specific requests for data or statements that exceed the parameters of such an investigation (e.g., complete failure analysis of an appliance or system and testimony regarding the degree of engineering certainty in determining root causation) will be discussed.

Fire Marshal, Fire Investigation, Failure Analysis

D25 Vaginal and Colorectal Injuries From a Personal Watercraft Jet Stream Versus Falling Into the Water at Speed

Michelle R. Hoffman, MS, Forensic Injury Analysis, LLC, 9920 S Rural Road #108-19, Tempe, AZ 85284; and Carley C. Ward, PhD, Biodynamics Engineering, Inc, 3720 E La Salle Street, Phoenix, AZ 85040*

The goal of this presentation is to demonstrate, with a case study and analysis of the relevant literature, how vaginal and colorectal injuries caused by the high-pressure water jet emitted by personal watercraft become more severe with increasing power of these machines and how the pattern of these injuries differs from those typically observed due to falling into the water at speed.

This presentation will impact the forensic science community by demonstrating how the severity and type of vaginal and colorectal injuries can differ due to proximity to the high-pressure water nozzle of personal watercraft versus entering the water at speed by falling off a craft but not landing near the nozzle.

A Personal Watercraft (PWC) is generally defined as a vessel which uses an inboard motor powering a water jet pump as its primary source of motive power. The majority of PWC's manufactured in the United States are designed to be operated by a person sitting on the vessel in a straddled configuration, like a snowmobile or a motorcycle. According to the United States Department of Transportation, 1.2 million PWC's were in use in the United States in 2014. Since their advent, PWC's have become faster and more powerful. Current models can have 300HP engines and the pressure from the water jet emitted from the PWC nozzle can exceed 800psi.

Although relatively rare, serious orifice injuries may occur to the vagina, perineum, anus, rectum, or colon when the rider or passenger of a PWC falls (or is ejected) from the back of this watercraft and lands in proximity to the nozzle with both legs abducted, such that these anatomical structures are directly in the path of the PWC's high-pressure water jet.

A case study is presented whereby two young women (a 17-year-old female seated immediately behind the operator and a 16-year-old female seated behind the 17-year-old) were passengers on a 2007 model year PWC. When the 21-year-old male operator accelerated rapidly from rest with no warning, both female passengers (wet from prior water immersion) were ejected from the rear of the PWC. They landed in the water near the jet nozzle, each with both legs abducted. The 17-year-old sustained a 6cm defect at the left pararectal space inferior to the vaginal mucosa; detachment of the perineal body; a 5cm-long vaginal laceration extending caudally along the left lateral posterior vagina, and a 4cm superficial deficit in the left ischiorectal fossa. The 16-year-old sustained a significant anal tear at the midline 12:00 o'clock position anteriorly and completely through the internal and external sphincter, as well as a posterior anal tear through the interior and external sphincters.

A question that often arises in litigation related to PWC orifice injuries is whether the injuries were more likely to be caused by the pressure from the jet nozzle or if it would have occurred regardless, due to falling into the water while traveling at a given velocity.

Freeman, et al. reported that the average New Injury Severity Score (NISS) a scale based on threat-to-life values for reported PWC falls and other water sports and activities was about half of those values reported for PWC jet nozzle injuries.[1] This study adds to that database by analyzing the extent and type of injuries reported in the literature and in the subject case to determine if certain types of injuries are more likely related to the jet stream or simply falling into the water at speed. By examining the structures disrupted and the severity of each disruption, it may be evident that more force would be required to produce a given injury, even if threat-to-life is not increased. For example, it would take more force or pressure to lacerate the tough fibrous anal sphincter than to make a tear in the inner wall of the colon or vagina.

Analysis of the injuries from this case study, together with a review of similar injuries in the literature, lead to the conclusion that as power and thrust of the PWC increases, injury patterns will become less like those typically seen from falling into water at speed and the severity of injuries observed will increase.

Personal Watercraft, Colorectal Injury, Vaginal Injury

D26 The Time Needed to Exit a Stationary Vehicle and the Forces Required, at Highway Speed, for a Passenger to Open a Vehicle Door Wide Enough to Exit

Robert L. Anderson, MS, PO Box 1208, Scottsdale, AZ 85252; Robert D. Anderson, MS, Biomechanics Analysis, PO Box 7669, Tempe, AZ 85281-0023; Russell L. Anderson, MS, PO Box 7185, Tempe, AZ 85281; and Michael Rosenfield, BS, 2420 E Hermosa Vista Drive, Mesa, AZ 85213*

After attending this presentation, attendees will better understand how to quantify exit time from a stationary vehicle and the forces required to open the door of a vehicle that is traveling at highway speed.

This presentation will impact the forensic science community by providing quantitative data regarding the time for a passenger to exit a stationary vehicle as well as providing quantification of the force required to hold an automobile door open wide enough to allow a person to exit while traveling at highway speeds.

In an accident sequence, a pickup truck occupied by two adult males lost control and rolled over. The passenger sustained fatal injuries. Rather than being ejected during the rollover, it was alleged that the passenger elected to jump out of the pickup truck while it was traveling in excess of 60mph just as it began losing control immediately before the rollover. Because the scenario allowed for only a very short time interval between the beginning of the rollover event and the passenger's claimed egress, both the length of time required to accomplish this type of maneuver and the magnitude of force that must be simultaneously applied to the door to keep it open to exit were the objective of this study.
