Among the “justifications” for such obviously unsafe heavy truck fuel system designs is the significantly greater size and weight of medium and heavy trucks relative to passenger vehicles, as well as the supposedly lower flammability of diesel fuel compared to gasoline. The extremely dangerous sidesaddle fuel tank design of the General Motors® 1973–87 pickups was ample proof of how such placement outside the frame rail was vulnerable to failure in relatively minor collisions with other vehicles or fixed objects. Some of the “justifications” for such hazardous heavy truck fuel systems are based more on incorrect assumptions, myths, and economic/political considerations rather than any reasonable safety engineering.

### D28 Electrical Homicide or Not?

*Helmut G. Brosz, BASc\*, Forensic Science International Group, Markham, ON L3P 3P2, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand that forensic engineers can play an important role in reconstructing the scene of an electrocution. These reconstructions assist criminalists in determining if a death could have been a criminal act that was perpetrated with the use of electricity, either intentionally (electrical homicide) or unintentionally (negligent homicide).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to an improved performance of criminalists and others involved in an investigation of a suspected electrical homicide by availing themselves of forensic engineers and their expertise.

In this presentation, cases will be presented in which the cause of death is electrocution. Electrocution generally means that current has passed through the heart and death ensued. Through investigation, one may discover whether this death was caused intentionally, by criminal negligence, or other causes.

Electrical injuries can be multifaceted, and in many cases can cause devastating trauma to the victim's body or no visible trauma at all. The severity of electrical trauma can range from gross loss of limb and tissue due to sustained high voltage and high current contact. Low voltage and low current contact may not leave any marks on the body, depending on contact area, duration, and other environmental factors. Since most electrical injuries involve marks on the body, there can be challenges in accurately assessing the pathway(s) of current and the modes and circumstances of contact. When an electrocution is being examined, investigators must inspect the scene and the body before concluding.

In some cases, it can be difficult to determine whether the incident was deliberate, an accident, or if an electrocution occurred due to lack of evidence. For example, if a victim were to be electrocuted by fallen electrical wires, there are many possibilities of what caused the wires to fall in the first place. One possible situation is if an electrical worker installs wires in such a manner that they could foreseeably cause an electrocution, then such a case could be considered negligent homicide or manslaughter. Another situation is that the electrical system was sabotaged in some way and, if so, this would be intentional electrical homicide. The incident could also be the fault of the victim, such as electrical suicide or misadventure. Natural causes, such as floods, winds or a storm bringing down power lines and poles, as well as lightning, are other causes of electrocution.

When investigators examine the scene of an electrocution, they cannot afford to make any assumptions. Although some instances may appear to have a clear cause, all possibilities must be taken into consideration first, with the assistance of a forensic electrical engineer and their expertise.

---

#### **Electrocution, Homicide, Electrical Injury**

### D29 Sabotaged Electrical Grid: Worse Than 9/11?

*Helmut G. Brosz, BASc\*, Forensic Science International Group, Markham, ON L3P 3P2, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will see that forensic engineers can play an important role in determining if criminal sabotage or an accidental sequence of events has occurred. The by-product of such an investigation is often an increase in the reliability of the electrical grid.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to an improved performance of criminalists and others involved in an investigation and postmortem of an intentional electrical grid failure by availing themselves of forensic electrical engineers.

This presentation is based on 50+ years of experience as a hands-on Electrical Engineer working for and with electric utilities nationally and internationally, and having caused accidental blackouts, experienced blackouts, investigating many blackouts, as well as breakdowns and failures of electrical equipment, including transmission lines, distribution lines, major power transformers, generators, and substations.

In addition, the study of major blackouts in the United States, Canada, Russia, Australia, Greece, Venezuela, Pakistan, and Jamaica, just to name a few, has caused one to pause and reflect on the dire consequences of a lack of electricity in our electricity-dependent world.

For example, on a small scale, an extended power failure in a high-rise condominium brings about the putrefaction of refrigerator contents, lack of circulating water, loss of heat and cooling, elevators, communication, and eventual evacuation. If we now scale this up to a city-wide outage, food stores will also close, gas stations will not pump fuel, the water supply will eventually dry up, police and emergency services will diminish, hospitals, banks, and credit card services will stop, cash will be king until barter and robbery takes hold, and so on. If we now scale this up to a region-wide outage affecting seven states and one province, as on Aug 14, 2003, then the outage effect really gains traction. The World Trade Center attack of 9/11 killed and injured several thousand people; a power failure of one week could kill as many, and a power failure lasting one month and longer will bring our society back to primordial behavior, much to the satisfaction of the perpetrators. The forecast will be left to psychologists and others in this field.

The criminalists and other investigators will be busy trying to survive.

So far, it is believed that most outages have been accidental or, let's say, not deliberate. However, there is a fine line between those two terms. "Accidents" can be staged and created. Without turning this presentation into a "how to," let it be said that we are very vulnerable today despite the various protection and backup systems that have been put in place after each blackout. These vulnerabilities still need to be addressed.

---

#### Electrical Grid, Sabotage, Blackout

### D30 American Association for the Advancement of Science (AAAS) Forensic Science Assessments: A Quality and Gap Analysis of Fire Investigation

Jose R. Almirall, PhD\*, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will be familiar with the July 2017 report published by AAAS on the quality and gap analysis in the field of fire investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing conclusions and recommendations reported by the AAAS fire investigation working group.

The AAAS, the world's largest scientific society, recently commissioned a quality and gap analysis on the topic of fire investigation. The AAAS staff and a working group composed of a fire investigator and academic scientists reviewed the current practice and available scientific literature in the field and reported their findings in July 2017.<sup>1</sup> The working group was asked to identify gaps in the body of knowledge within fire investigation and make recommendations for future research that would fill the gaps and "inspire greater confidence in the criminal justice system." The report was divided into two parts, fire scene investigation and fire debris analysis, and includes conclusions and recommendations related to the different aspects of each of these methodologies. Fire scene investigation covers the topics of origin and cause determination, locating ILRs in fire debris, reliability and validity, cognitive bias and education, certification and experience. The fire debris analysis section of the report covers topics that include potential improvements in locating and analysis of ILRs at the scene using more advanced analytical chemistry tools, applying analytical methods in the laboratory, advances in the standardization of analytical practice, challenges in the analysis of Ignitable Liquid Residues (ILRs), including the interpretation of the analytical data collected from fire debris analysis and, finally, reporting language.

The report is formatted to include specific recommendations for both the fire scene investigation portion and the fire debris analysis portion. The report also includes conclusions drawn from the review of the available literature to aid policy makers and funding agencies in developing a strategy to facilitate research where gaps in knowledge are identified. The fire scene investigation portion of the report includes recommendations in the areas of origin and cause determinations, locating ILRs in fire debris, reliability and validity, cognitive bias and education, certification, and experience.

The recommendations and conclusions drawn from the fire debris analysis portion of the report include improving the identification and, hence, collection of ILRs in the field through the use of portable instrumentation, trained canines, and other means, improving the application of analytical chemistry tools in the laboratory (sampling, extraction and analysis), addressing the current challenges in analyzing ILRs, such as the classification of ILRs in a standardized way, a study on the limitations on the current methods, and the need to know the performance of the current standard methods in use by the fire debris analysis community (global and local error rates).

### D31 A Case Report on a Cable Car Stoppage Accident Caused by Wild Mice

*Youngsu Kong\*, Department of Physical Engineering in Gwangju, Jangseong, Republic of Korea; Jaehak Lee, PhD, Jangseong-gun, Korea, SOUTH KOREA; Gie-tae Lee, MS, National Forensic Service, Gwangju Institute, Jangseong-gun, SOUTH KOREA; Jae-mo Goh, PhD, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; Nam-Kyu Park, PhD, National Forensic Service, Wonju, SOUTH KOREA*

**Learning Overview:** After attending this presentation, attendees will be informed about a special case of a cable car stoppage accident caused by wild mice and will thus be informed of more possibilities to be considered when investigating cable car accidents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a case report for a non-typical case of a cable car stoppage accident caused by wild mice.

With technology development and urbanization, accidents caused by wild mice are gradually disappearing in South Korea. Nonetheless, buildings in the countryside and mountains of a famous place occasionally have accidents caused by wild mice. In one case, a cable car that was normally running suddenly stopped due to wild mice. On November 5, 2015, at Duryun Mountain in Haenam, South Korea, the cable car, which was operating normally with passengers, was suddenly stopped by a power failure.

The site of the accident consisted of a cable car, a cable car platform, a machine room, and a cab. The machine room was equipped with the main power and the Automatic Transfer Switch (ATS) panel, a generator to supply spare power, a motor to drive the cable car, and a wire rope pulley. The ATS installed on the ATS panel was partially destroyed due to electrical fault. After replacing the ATS, the operation test for the cable car system was performed and the cable car system operated normally. The ATS operates as follows: the ATS is in contact with the main power terminal when the cable car is operating normally, but it automatically contacts the backup power terminal of the ATS when there is a problem with the main power supply of the cable car. Through scene investigation, it was found that the cause of sudden stoppage of the cable car was the ATS breakage. As a result of the inspection of the ATS, the main and backup power indicators of the ATS were both on and the ATS conversion switch had been moved to the backup power side. Two mice bodies were found on the R phase and the S phase between the main and backup power terminals of the ATS, respectively. Many electric arc marks were observed on the R phase, the S phase, and the T phase of the main power and standby power terminals.

According to the results of the scene investigation and ATS inspection, the cause of the cable car accident was the breakdown of the insulation due to the intrusion of the wild mice between the R phase and the S phase of the main power and standby power terminals of the ATS. Such a situation, with buildings in rural and mountainous areas of famous places, can still cause accidents due to wild mice. This case report can be used as a reference for future similar accidents.

#### Wild Mice, Automatic Transfer Switch (ATS), Cable Car

### D32 Data Center Failures, Losses, and Litigation

*Helmut G. Brosz, BSc\*, Forensic Science International Group, Markham, ON L3P 3P2, CANADA; Ralph A. Ruffolo, BSc\*, Clearwater, FL 33766*

**Learning Overview:** After attending this presentation, attendees will understand some of the common causes of data center failures, which often lead to litigation, and preventive remedies of such failures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping experts to identify in data center failures: (1) cause; (2) origin; (3) responsibility; (4) preventability; and (5) how to assist with insurance and legal claims.

Data centers require reliable electrical power, Uninterruptable Power Supply (UPS) systems, batteries, back-up generators with reliable and sufficient fuel, cooling systems, transfer switches, and switchgears, including reliable protection systems.

**Case 1:** Water pipe and valve failures-flooding—Water cooling and circulating systems are required to withstand certain pressures, temperatures, and flow velocities in order to keep electronic equipment cooled. Pressure tests are usually conducted soon after installation. However, in-plant inspections of pipes, shut-off valves, and fittings before they are shipped to a site are seldom performed. Inspection in a manufacturer's plant can go a long way toward catching defects before shipment.

**Case 2:** Back up diesel engine/generator failures—In some cases, improperly manufactured oil filters have allowed metal particles to bypass such filters and damage bearings. In other cases, defective diesel engine fuel injectors were found to leak and cause explosions in the exhaust system. Most emergency diesel generators are turbocharged and are sometimes not manufactured to tight tolerances. As a result, they have been known to fail and start lubricating fires since they operate at very high temperatures. Fuel supplies have been found to contain water and cause malfunction of diesel engines. In-plant inspections and review of specifications of diesel engines during manufacture are an important prevention remedy.

**Case 3:** Electrical protection failures—In large data centers, 480-volt switchgears usually contain overcurrent relays only. Directional overcurrent relays are often not used but should be used. Also, in many instances fuses and relays are not properly coordinated, thus causing larger outages in a system than necessary.

**Case 4:** Small UPS failures start fires—Small under-the-desk UPS units have been known to fail due to defective solder joints.

**Case 5:** 480-volt switchgear/4,000-amp circuit breaker failure and Automatic Transfer Switch (ATS) failures—Drawout circuit breakers require current-carrying contact fingers that can carry not only rated current but also fault current for a prescribed time, otherwise they may overheat, arc, and fail. Finger contacts are often improperly machined and thus have insufficient contact surface. There may also be insufficient contact pressure and misalignment. Corrosion on contact surfaces can also contribute to overheating.

**Prevention Remedies:** In-plant inspection as well thermography at various intervals during the testing and commissioning process can go a long way toward failure prevention.

In an actual case, a 1,600-amp ATS failed for the following reasons: the racking assembly roller was bent out of position by almost one-half inch, so that upon racking in the switch into its connected and operating position, the main finger contacts did not properly mate with the fixed plated copper stabs of the switchgear. Thus, only a few fingers in the contact cluster made contact. This had the detrimental effect of de-rating the current carrying capacity of the finger cluster-stab contact. Overheating over a period of time led to arcing within the contact, which melted the remaining contact surfaces. This was followed by an explosion where conducting copper vapor was produced which then created a phase to phase-to-ground fault. If the prevention remedies set out above had been followed, this loss would not have occurred.

#### Data Center, Failure, Litigation

### D33 Propane Explosions: The Result of Failed Water Heater Gas Control Valves—Manufacturing Flaws Brought on by Design Changes by an Outsourcer

Tim G. Dunn, MS\*, Dunn Laboratories, Inc, Roswell, GA 30076

**Learning Overview:** After attending this presentation, attendees will be familiar with some basic principles on the safety features of gas control valves, as well as how changes in valve component, by a third-party vendor, can lead to gas fires and explosions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how unilateral design changes by outsourcing vendors of critical subcomponent parts, unknown to the control valve manufacturer, can affect the product's overall safety.

Following two propane explosions, it was concluded that the source of the fugitive gas was the failure of water heater control valves. Additional incidents came to light during these investigations. All shared these common threads: (1) out of gas conditions or a pilot outage. The victims were burned while trying to relight the appliance pilot; (2) same brand water heater control valves; (3) the failure of the valve's internal safety magnet to properly close off flow following the gas outages; (4) the same basic safety magnets used with gas appliance control valves since the 1930s; and (5) a common mode of failure: a peeling off of the rubber seat from the top mount on the valve's safety magnet, such that once off, the seat would not provide closure. The consequence being that on the occasions of an interruption of gas service or pilot flame outage, this insidious failure would permit raw (unburned) gas flow—absent a lit pilot light—to the constant (or standby pilot), and when called on (i.e., tank water temperature dropped below the desired set point), a much larger discharge of fugitive gas through the main burner.

In recent years, the safety magnet had been supplied to the valve manufacturer by an outsourcing (third-party) vendor: unbeknownst to the valve manufacturer at the time, this third-party vendor had changed (reduced) the dimensions of the magnet's top metal tip (referred to as a nesting button), where the donut-shaped rubber seat was nested, thus leaving the seat susceptible to being peeled off.

Even as more incidents occurred, the valve manufacturer maintained inexplicably that the separation (peeling off) of the seat from its magnet mount was a direct result of overpressure conditions. However, testing of the subject (incident) pressure regulators and later, high pressure testing in lab conditions, disproved this failure mode.

Residing within the valve's inlet chamber, the primary purpose of this safety magnet is to shut down gas flow to both pilot and main burners in the event of pilot flame outage. A failure of this safety magnet will allow unburned or raw gas to flow to the appliance burners in absence of a lit pilot. A thermocouple, with its head impinging upon the pilot flame, will feed a small (millivolt) electrical current into the safety magnet, sufficient to energize the magnet. Following the pilot lighting steps, the valve's reset button is manually depressed, which draws the safety magnet's rubber seal down and away from its metal closure opening, which in turn pushes the attached spring-loaded stem so that its mating plate bottoms-out against the magnet; once the pilot flame is established and the thermocouple is generating current, the energized magnet should hold the mating plate down, thus permitting gas (or gas flow) into the other valve chambers.

In these incidents, the peeling off of the rubber seat would have occurred during previous pilot lightings, when the control valve was operated as described: while properly aligned and in place, the affinity (or sticking) of the closed rubber seat to its metal closure was the cause of the failure. This failure only occurred in the more recently manufacture valves, specifically magnets provided by the third-party vendor with reduced-sized top (nesting) buttons.

Review of the valve manufacturer's documents and drawings of the safety magnet assembly reflected an inexplicable change in dimension of the top (nesting) button. The 10/20/94-dated drawing depicts a 0.472-inch diameter button, while the 2/23/02 drawing reflects a 0.421-inch diameter, with no engineering change order. Again, measurements of the failed control valves revealed safety magnets with 0.42-inch diameter top buttons. Related to the alleged overpressure theory, in the drawing, the rubber seats are flush against the base metal disk: in other words, there is no excess rubber hanging off the base disk and exposed to the directional gas flow, whether it is nominal or high pressure.

In deposition testimony, the valve manufacturer's senior principal engineer explained that in previous drawings, the diameter of the top (nesting) button was incorrect: the outsourcer had always supplied safety magnets with a 0.421-inch diameter top (nesting) button.

The relevant section of deposition testimony follows: Question: Why? Answer: We were told by the outsourcing vendor that was not (1) correct; that the dimension had never been .472. It had (2) always been .421. So, it was to update our drawing, and, (3) correct it to what it should have been. Question: Okay. So ... so, in other words, the .472 never existed. Answer: That's correct. That's correct.

In contradiction to this testimony, notwithstanding previous drawings, the earlier vintage of same brand control valves, both had top (nesting) buttons with the larger (0.472) diameters. An unmarked magnet (possibly not from this outsourcer) with a red rubber seat has a date code 9427, while the other, safety magnet (supplied by the same third-party vendor) has a date code 9405.

This presentation will briefly discuss the basic design of appliance gas valves, the critical role that safety magnets play, relevant aspects of the incident investigations and testing, as well as the conclusions reached.

After this presentation, attendees will be familiar with how subtle changes in the design of a subcomponent can affect the integrity of a key component of a pilot-ignited gas appliance.

#### Propane Explosion, Water Heater, Control Valves

## D34 An Explosion of a Primitive Industrial Oven in India: A Forensic Analysis

Jatin Bodwal, MD\*, Deen Dayal Upadhyay Hospital, New Delhi 110064, INDIA; Anil Aggrawal, MD, Maulana Azad Medical College, New Delhi 110002, INDIA

**Learning Overview:** After attending this presentation, attendees will understand the workings of a primitive type of industrial oven and the various causes behind its explosion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the workings of a primitive type of industrial oven and the various causes behind its explosion.

The explosion of an industrial oven results in an extremely devastating outcome, which usually claim the lives of people who unfortunately are present in proximity of the blast site.

Invariably, inadequately trained and impoverished people who migrate to New Delhi (the capital city of India) from poor states such as Bihar and Uttar Pradesh are the ones who risk their lives every day while working in a factory where these primitive industrial ovens operate.

**Working of an industrial oven:** (A seven-minute video will be shown to explain the working of a primitive industrial oven.) A typical industrial oven has two doors, one entry and one exit. Both the entry and exit doors can be used interchangeably (Figure 1). Inside this oven is chamber in which there are two parallel rods that are placed at the bottom of the chamber. These rods have multiple holes that light up due to the supply of Liquefied Petroleum Gas (LPG) and generate a high degree of temperature inside the chamber. The temperature monitoring is done by a thermometer that hangs on the ceiling. The usual temperature generated for optimum working of the oven is ranges between 120°C to 170°C. Surprisingly the source from which the oven get its heat is a typical household LPG cylinder (Figure 2). The sliding fashion assembly of metallic plates or other circular-shaped table fan tops or ceiling fan tops go inside the chamber and both the doors are closed (Figure 3). The assembly of metallic plates is usually arranged in the row. This assembly of objects remain inside the chamber for about 15 to 30 minutes. The purpose of this oven is to get the metallic paint firmly stuck to the surface of these objects.

Presented here is the case of a worker who died on the spot due to an oven blast while working. The main reason that can be attributed to the blast will be thoroughly discussed. In this instance, a worker was working in the factory when a fellow worker rushed to the oven when they heard a loud blast sound. They found a worker lying on the floor, injured. They rushed him to hospital, but he was declared dead on arrival.

At autopsy, the deceased was found to have suffered both burn injuries in the form of superficial burn and blunt injuries, in the form of a fracture (Figures 4 and 5). Death was attributed to the head injury and multiple fractures.

The chief reason for an oven blast is an extremely high temperature inadvertently generated if a worker forgets to switch off the supply of LPG gas or open the gates. Most of the modern sophisticated industrial ovens are equipped with safety valves, which function to alleviate excess heat. If the valve become dysfunctional owing to some clogged pipe or the oven is not equipped with safety valves, then excess temperature causes an oven blast.

India is a developing country where ill- or inadequately trained youths jump into factory work where these primitive types of oven are being used, without knowing the potential hazards of their job. Safety gears, which should be essential while working, are hardly ever provided by the employer to these poor workers. Only certified persons who take formal training from recognized institutes for working in factory should be hired.

### D35 A Framework for the Cost Evaluation of Deforestation Based on the Habitat Equivalency Analysis (HEA) Principle

David Domingues Pavanelli, PhD\*, Brazilian Federal Police, São Paulo 05038-090, BRAZIL; Nickolaos Voulvoulis, PhD, Imperial College London, London, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand the role of financial evaluations in Brazilian environmental forensic reports and the methods used by forensic experts to calculate the total economic value of environmental damages.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential of the framework to inform the forensic science community, improving the ability to evaluate interim losses, perpetual damages, and propose better approximations of the total economic value of deforestation.

Under Brazilian law, environmental damages are considered criminal offenses. During the criminal process, environmental forensic experts normally are expected to appraise the damage to set bail, a fine, and the minimum value for its repair. The final financial damage valuation is defined during a civil process and trial, in line with the valuation described in the criminal process.

Deforestation is a typical Brazilian environmental crime. Environmental forensic experts typically evaluate the damage caused by deforestation using the commercial value of the wood extracted plus the cost of reforestation. However, many non-marketable ecosystem services provided by forests are rarely considered in this process. Well-described examples of these include erosion control, water supply, nutrient cycling, pollination, biological control, and many other ecosystem services. Not including these services in valuations of environmental damages is misleading public perception of the true total environmental costs and potentially puts at risk law enforcement and the implementation of environmental policies.

To ensure that ecosystem services are evaluated from the initial damage assessments, a framework for deforestation cost evaluation has been developed, based on Habitat Equivalency Analysis (HEA), as first described by the National Oceanic and Atmospheric Administration (NOAA) and in line with the European Union Liability Directive.<sup>1,2</sup> The framework considers remediation costs as proxies for evaluating ecosystem services, and it enables the calculation of interim losses (i.e., the time elapsed between the loss of ecosystem services caused by deforestation and the return of these ecosystem services after damage recovery).

Four study areas of the Brazilian Atlantic rainforest biome were evaluated using the framework. All four study areas involved a forest structure at the intermediate stage of regeneration prior to the damage: two areas had been converted to pasture; one area had been converted to a *Eucalyptus spp.* Plantation; and one area had had its soil removed by mining activities, causing the damage to be considered perpetual.

The application of the framework resulted in an increase in environmental valuation by 38%–43% in pasture areas, 33% in the *Eucalyptus spp.* area, and 232% in the mined area, without considering land acquisitions. Ratios between adapted forest ecosystem services values described by Costanza et al. and framework values were 1.65–2.23 in pasture areas, 1.75 in *Eucalyptus spp.* areas, and 4.85 in mined areas.<sup>3</sup> The inclusion of land acquisitions in these calculations would push these ratios toward 1.

The results demonstrate the potential of the framework to inform the forensic science community, improving the ability to evaluate interim losses, perpetual damages, and propose better approximations of the total economic value of deforestation. Considering the extent and consequences of deforestation in Brazil, the proposed framework reveals the actual cost of environmental damages and the negative economic impacts of deforestation.

### D36 A Fatal Injury Caused by a Scissor Jack in a Rear-End Collision

*Kurt D. Weiss, MS\*, Automotive Safety Research, Santa Barbara, CA 93111-2326*

**Learning Overview:** The goal of this presentation is to discuss a crash in which a seat belt-restrained occupant in a Sports Utility Vehicle (SUV) was fatally injured in rear-end collision. The physical evidence and the interior configuration of the vehicle will be detailed, and the mechanism of the fatal injury will be clearly explained.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the process of examining the physical and photographic evidence, and the vehicle interior configuration, that lead to the conclusion that vehicle occupants may be exposed to unwanted injury in foreseeable collisions.

Vehicle traffic had stopped for several minutes due to a previous traffic collision ahead. The three lane Interstate with a posted speed limit of 70mph had become a parking lot. Near the back of the line of cars, the operator of a long-haul tractor-trailer switched on his rig's four-way emergency lights. Stopped right behind his trailer was an SUV. Tragically, the driver of the SUV had no way to avoid the impending rear-end collision.

The SUV was struck by a small sedan, the driver of which claims to have fallen asleep. His speed control was set to 70mph–75mph. Contrary to his statement, he attempted to avoid the impact by steering left, evidenced by an approximately 31-foot-long angled tire friction mark. The right front area of the sedan struck the left rear area of the SUV in the offset rear-end collision. The maximum penetration to the SUV centerline was approximately 28in.

Upon impact, the sedan continued forward and entered the natural desert terrain of the center median, where it slowed to a rest. The SUV rotated clockwise and was pushed into the left rear corner of the trailer, evidenced by hinge hardware impressions to the SUV's left side. The frontal and left side curtain shield and torso airbags had deployed. The slack webbing confirmed the driver's seat belt was fastened at the time of collision. Vehicle rotation continued until the SUV's left rear corner struck the trailer's left side.

The SUV driver was extricated and flown by air ambulance to the local trauma center with a Glasgow coma scale of 3, and radiological findings of subdural and subarachnoid hemorrhages. A brain flow study showed the absence of circulation and death was pronounced. In the county coroner's opinion, the driver of the SUV died as a result of blunt force head trauma. The coroner's report noted a defect to the superior aspect of the occipital region of the head, at the superior point of the lambdoid suture. The report also noted multiple emanating linear skull fractures from this defect.

The SUV was examined, and it was discovered the rear damage profile involved the bumper reinforcement beam, lower edge of the liftgate, suspension components, and tire assemblies. Intrusion at the floor level compromised the convenience spare tire well located in the rear cargo area.

Collision forces overwhelmed the wing bolt and thrust the spare tire into the vehicle compartment. This fact was supported by finding the deformed wing bolt and a corresponding hole in the spare tire support.

Additionally, numerous rubber transfers were observed to the front of the spare tire well.

An eye-witness stated they had moved the spare tire from the driver's head and neck area to open the airway. However, the head injury is inconsistent with impact solely by the spare tire.

Investigator photographs taken at the collision scene show the driver's seat back reclined.

However, it is unknown if the seat back was reclined to facilitate extrication or if the recline mechanism failed as a result of the collision. On the floor behind the driver's seat is the spare tire, and next to the seat back is a blood-covered scissor jack.

An exemplar vehicle was examined to evaluate the spare tire storage hardware. It was determined that the scissor jack was secured beneath the spare tire.

The rear seats of the SUV permit full reclining, and additional cargo space may be created by folding each rear seat to each side wall separately. In this case, the left rear seat assembly was stowed along the side wall, whereas the right rear assembly remained upright.

This rear seat configuration allowed a clear path for the scissor jack to be propelled directly into the head, killing the driver.

---

### SUV, Scissor Jack, Blunt Force Head Trauma

### D37 Positional Asphyxia

David Pienkowski, PhD\*, University of Kentucky, Lexington, KY 40536-0298

**Learning Overview:** After attending this presentation, attendees will: (1) review the musculoskeletal mechanics of breathing, (2) examine known mechanisms of positional asphyxia, (3) review two cases involving different mechanisms of positional asphyxia, and (4) gain a broader perspective on the biomechanics of death not otherwise associated with penetrating injuries or other mechanisms that disrupt human ventilation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new insights into death caused by positional asphyxia, specifically those attributable to accidental external ventilation restrictions.

Living organisms energized by oxidative phosphorylation of Adenosine Triphosphate (ATP) require oxygen (O<sub>2</sub>) for cellular (internal) respiration. O<sub>2</sub> is provided by circulating blood that exchanges cellular by-products (Carbon Dioxide (CO<sub>2</sub>)) with O<sub>2</sub>-rich air in the lungs. Breathing (external respiration) involves active cyclic muscle-force generated, O<sub>2</sub>-rich atmospheric air induction into the lungs followed by passive exhalation of CO<sub>2</sub>-rich gas. The lungs are incapable of self-movement and rely on volume changes of the upper chest cavity for CO<sub>2</sub> and O<sub>2</sub> transport. Contraction of the diaphragm and intercostal muscles pull the ribs superiorly and anteriorly, thereby increasing chest cavity volume. This expanding lung volume creates a negative internal pressure resulting in air inhalation. Exhalation is a passive process whereby these muscles relax, the ribs move inferiorly and posteriorly, the volume of the chest cavity decreases, and gas in the lungs is expelled. Sustenance of adequate cellular respiration requires removal of CO<sub>2</sub> and delivery of O<sub>2</sub>, which requires movement of a specific volume of air in the respiratory system. This volume must also include sufficient additional to compensate for the “dead air space” in the mouth and trachea. Air in this dead air space does not participate in effective exchange of CO<sub>2</sub> and O<sub>2</sub>.

Positional asphyxiation occurs when expansion or relaxation of the ribs cannot occur to a sufficient extent to provide adequate gas exchange. Positional asphyxia may occur with flexed or extended torsos such that adequate musculoskeletal chest movement is prohibited or when immovable external objects obstruct such movements. Positional asphyxia has occurred in industrial accidents, infants belted in some automotive child seat designs, and prisoner restraint. The following describes instances of positional asphyxia for which inhalation or exhalation was inhibited.

**Case 1:** An 18-wheel truck carrying coil sheet steel, estimated weight approximately 38,000 pounds, struck the rear of a second 18-wheel truck. Delta-V of this collision was approximately 35mph–40mph. Intrusion of the bullet tractor into the target trailer crushed the bullet tractor and limited space forward of the bullet tractor driver. Restraints securing the coiled steel cargo failed and, upon impact, this cargo translated forward and deformed the back of the bullet tractor cab. The back of the cab behind the driver pressed the driver’s seat forward into the area already compacted by impact of the bullet tractor with the target trailer. Although the driver of the bullet tractor sustained no rib fractures, the combined forward and rearward intrusion of the cab flexed his hips and knees toward his chest. This position, in conjunction with the driver’s surfeit of adipose tissue, restricted adequate ventilation of the driver. Eyewitness reports indicated that shortly after the collision, the driver was alert and urgently requested extrication. Unfortunately, the necessary equipment did not arrive in time. The victim expired on the scene *in situ*. Positional asphyxia occurred due to the inability to adequately inhale.

**Case 2:** A young man was reaching over the third-row seat of a Honda® Odyssey® minivan. Unable to reach the item of interest, he rose from the seat, turned 180°, placed his knees on the seat, leaned over the seat back, bending forward at the waist. The seat rotated toward the back bumper of the van, resulting in pinning the man upside down with the top of the back seat pressed against the inferior aspect of his ribs. The victim was unable to right himself and simultaneously rotate the seat to the normal position. The position of the seat against the ribs partially inhibited diaphragmatic relaxation and inferior rib movement. Adequate gas volume exhalation did not occur. First responders did not arrive in time, and the man expired on the scene due to positional asphyxia believed attributable to the inability to adequately exhale.

### D38 Seat Belt Load Marks on Aged Restraint Systems

*Mike Markushewski, BS\*, ARCCA, Inc, Penns Park, PA 18943*

---

**Learning Overview:** The goal of this presentation is to show that loading patterns on aged restraint systems are lighter as compared to new systems when exposed to the same crash forces.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating the relative difference in restraint system loading patterns on new versus aged restraint system components. A difference in loading patterns is expected as a result of typical aging characteristics on polymer materials and their respective response to impact loading.

Polymer-coated components used on the typical seat belt system are the D-ring or B-pillar guide loop and the latch plate which inserts into the buckle. The D-ring provides a turning and load surface for the webbing as it exits the locking retractor and forms the upper anchor for the shoulder belt. The latch plate controls the confluence of webbing between the lap and shoulder belt. The primary purpose of the coating is to provide a low-friction surface for the polyester seat belt webbing to slide on. The polymer surface on the D-ring and latch plate permits the webbing to slide freely in response to normal occupant motion while driving in addition to providing proper coupling of the occupant to the vehicle during a crash.

A dynamic horizontal accelerator test program was conducted to evaluate documented older seat belt systems as compared to new replacement restraint systems in a controlled manner. In an effort to isolate the differences in loading patterns on the restraint systems, as many variables as possible are to be controlled. New seat belt systems and older seat belt systems are mounted on the horizontal accelerator platform using identical generic, but typical, restraint system geometries. Two surrogates are used and ballasted to a 50th percentile male or approximately 167 pounds.

The main purpose of this study is to attempt to show the difference in loading patterns on aged seat belt polymer components that have been exposed to the same crash forces compared to new seat belts. Physical properties of polymers typically will change as a result of exposure to heat, humidity, ultraviolet light, and sunlight through, in some part, the photo-oxidative degradation process. Leaching of plasticizers, if used, whose purpose is to maintain flexibility of polymer chains, also results in increased surface hardness as the material ages.

It is suggested that because the new polymer materials are softer, the load surfaces will be more prominent and heavier loading patterns will be visible on surfaces that have been exposed to crash forces, as compared to aged and therefore harder, seat belt components for a given acceleration and delta-V. Conversely, the presumption is that aged polymers tend to increase in surface hardness and therefore will display lighter load marks as compared to new seat belts for a given impact.

#### Seat Belt, Load Marks, Polymers

### D39 Shared Anchor Seat Belt Buckle Self-Release

Kurt D. Weiss, MS\*, Automotive Safety Research, Santa Barbara, CA 93111-2326

**Learning Overview:** After attending this presentation, attendees will understand about a seat belt-restrained occupant in a Sports Utility Vehicle (SUV) who was ejected and fatally injured in a rollover collision. The physical evidence will be detailed, and the mechanism of inadvertent seat belt buckle release will be clearly explained.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how a shared anchor seat belt component design can be susceptible to inadvertent release.

Federal safety standards require that seat belt assembly hardware shall be designed to prevent attachment bolts and other parts from becoming disengaged from the vehicle while in service.<sup>1</sup> Failure of seat belts at or near the anchor points can render vehicle occupants unrestrained and particularly vulnerable to ejection. It is not uncommon for two adjacent seat belt assemblies to share an attachment bracket and anchor point. A previous study demonstrated how a design change of a shared anchor buckle component subjected to reasonably anticipated forces resulted in catastrophic failure and occupant injury in a rollover collision.<sup>2</sup> The current study highlights another shared anchor design that is susceptible to inadvertent release.

Four occupants of an SUV were northbound at approximately 65mph. A vehicle eastbound at approximately 26mph failed to stop at a stop sign and struck the SUV in the left rear corner. After the initial contact, both vehicles began to yaw counterclockwise. The SUV tipped on its right-side wheels and overturned on the passenger side, leading 4¾ times. By all accounts, the occupants of the SUV were wearing their type-2, lap and shoulder belts. Physical evidence, one in particular, a paint transfer to the seat belt webbing matching the vehicle's exterior color, validated claims of belt use for the second-row left occupant.

Despite this fact, the left rear occupant was ejected and sustained a fatal blunt force head trauma, including skull fractures, brain hemorrhages, and near-complete transection of the brain stem. Occupant ejection while wearing a seat belt is not a unique occurrence.<sup>3-5</sup>

Vehicle inspection revealed the second-row left buckle was a shared anchor component with the adjacent center buckle.

The left buckle is attached to a stiff metal bracket whereas the center buckle is attached by a webbing strap. When installed, the left buckle is slightly recessed while the center buckle lies atop the seat cushion.

In this case, the second-row left and center seats were both occupied at the time of collision.

Design considerations of seat belt buckles involve such things as comfort, convenient access, and performance. It was proposed that the second-row buckle design met some vehicle manufacturers' specified resistance to opening when probed with varying diameter balls (e.g., General Motors® 40mm, Nissan® 40mm, Ford® 38mm, and Toyota® 35mm ball). Yet, the preponderance of evidence indicated the second-row left buckle was most likely inadvertently released during the collision.

Closer examination revealed curious artifacts to the plastic cover of the left buckle.

Furthermore, the lower corner of the adjacent center buckle has a smaller diameter than the balls used in resistance to opening testing. Several new exemplar components were obtained and tested. The elongation of the attachment webbing of the center buckle under reasonably anticipated tensile forces was demonstrated. Alignment of the buckle housing allowed for its lower corner to interact with the adjacent left buckle. Therefore, it was correctly concluded that interaction of the adjacent buckles in use at the time of collision caused inadvertent buckle release that resulted in the ejection and fatal injury of the second-row left-seated occupant.

### D40 Seat Belt Analysis: Sometimes Plastic Transfer to a Webbing Indicates the Restraint Was NOT in Use During a Crash

David J. Porta, PhD\*, Bellarmine University, Louisville, KY 40205

**Learning Overview:** After attending this presentation, attendees will understand the typical and atypical evidence of restraint system loading during a motor vehicle crash. The role of pretensioner deployment will be demonstrated in a moderate frontal collision.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing important information for any reconstructionist desiring to determine the relationship between restraint use and injury production.

In a collision described as very severe by police investigators, the front of a 2006 domestic sedan struck the left side of a 2013 tractor with trailer as they met at an intersection. Both second-generation front airbags in the sedan deployed (first stage only). The 5' 9" tall, 180lbs, 46-year-old female driver of the sedan was noted by police and Emergency Medical Services (EMS) as having been properly three-point restrained, as was her passenger. She was transported to the hospital with several complaints, including a closed head injury. The driver was released the next day and eventually filed suit claiming a traumatic brain injury. The passenger suffered a shoulder injury that required considerably more medical treatment, but she did not participate in the lawsuit. As part of a thorough accident reconstruction, the crash data recorder was downloaded, and it indicated the sedan experienced a change in velocity of 25mph at impact. This is well below the severity of impact in the United States Department Of Transportation (DOT) New Car Assessment Program frontal crash test for this model vehicle (New Car Assessment Program (NCAP) Test 4931). The NCAP test involved a 50 percentile male Anthropomorphic Test Dummy (ATD) of similar stature to the female driver in this case. The sedan earned a maximum five-star rating indicating the chances of serious injury at 10% or less in a 35mph frontal crash into a barrier. Test videos indicate the head and torso of the properly restrained ATD rotated into the deploying airbag and did not contact the headliner, dashboard, or windshield. The data recorder further indicated the sedan driver seatbelt was unbuckled, but the front seat passenger belt was buckled. An investigation of the vehicle was undertaken in order to rule out restraint system failure. Upon inspection, the passenger restraint system showed typical abrasions to the cabin-facing surface of the D-ring and concomitant plastic transfer to the seatbelt webbing—clear evidence of restraint use during the collision. The driver seatbelt webbing was found cut and exhibited similar plastic transfer from the D-ring. Without further examination, one might assume the driver had been properly restrained. However, the webbing was locked at a relatively unspooled length. A driver side retractor-mounted pretensioner clearly fired while the belt was in the stowed position. As the belt was quickly pulled into the spool, it produced abrasions to the inside of the plastic-coated D-ring (the side facing the B pillar). There was very clear evidence of plastic transfer to the belt at a location that would correspond to it being retracted at the time of firing. No evidence or testimony explained why the belt was cut, but it is not uncommon for tow truck operators to cut and use seatbelts to secure a door or the steering wheel.

The driver claimed to suffer a head injury, and, at inspection of the vehicle, it was noted that there were abrasions to the visor and a fracture to the windshield. Both were reasonable locations for head contact by an unrestrained driver—NOT one who was properly restrained, of a size similar to NCAP ATDs, and in an accident that was approximately 30% less severe than NCAP tests.

It is unknown how many vehicles have crash data systems programmed to trigger a pretensioner to fire on an unbuckled seatbelt, but this presentation clearly demonstrates one such case and attendees will now know of this possibility, and the evidence for it, when performing an analysis of a restraint system.

### D41 Void Analysis in the Inside of Arc Melting Using 3D X-Rays

*Young Jin Cho\**, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Dong Gyu Lee, MA*, National Forensic Service, Wonju-si 26460, SOUTH KOREA; *Sun Jae Kim, MA*, National Forensic Service, Wonju-si 26460, SOUTH KOREA; *Jong Teak Park, MA*, National Forensic Service, Wonju-si 26460, SOUTH KOREA; *Jae-mo Goh, PhD*, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Nam-Kyu Park, PhD*, National Forensic Service, Wonju, SOUTH KOREA

---

**Learning Overview:** After attending this presentation, attendees will better understand the feasibility of using 3D X-rays as a tool for the Void analysis of molten marks.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing an effective tool for the Void analysis of molten marks.

The arcing damage to electrical copper wires is often found at a post-fire scene where the electrical installation was energized during the early development of the fire. This damage can be useful to the investigation as it can provide reliable data to establish a fire's area of origin.

The primary arc melting refers to the arc melting acted as a cause of a fire, and the secondary arc melting refers to the arc melting formed while the insulated covering of electric wires is combusted after a fire breaks out. Since being able to distinguish the primary arc melting from the secondary arc melting means that it is possible to judge clearly whether it is acted as a cause of a fire or not, it could be very assistive in investigating causes of a fire. However, a definite method to discriminate this does not exist yet.

Researchers have studied diverse methods in order to distinguish the primary arc melting from the secondary arc melting for decades in the past, and one of those methods is to analyze the void inside the arc melting. It is said that the primary arc melting can be distinguished from the secondary arc melting by analyzing the number of voids, the size of voids, the location of voids at the cross section etc. but since the results of each researcher are different, it is also difficult to apply to actual situations.

The method analyzing voids can be used for researches to distinguish the arc melting from the fire melting apart from discrimination of the primary arc melting from the secondary arc melting.

To examine Void in the inside of molten marks, metallurgical analysis can be used. However, this method takes too much time due to many stages (cutting, molding, grinding, polishing, and etching), and it is only capable of observing one cross section.

This study, using Void analysis among the functions of software enabling 3D X-rays, determines that it is possible to easily and quickly interpret the proportion of Void in the volume of molten marks, the distribution of Void, and the diameter of Void. In addition, this study also shows that using the function of Void analysis should be much more precise and efficient than the method of physical cutting.

### D42 The Distinction Between Arc Melting and Fire Melting Using X-Rays

*Jae-mo Goh, PhD\*, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; Young Jin Cho, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; Dong Gyu Lee, MA, National Forensic Service, Wonju-si 26460, SOUTH KOREA; Sun Jae Kim, MA, National Forensic Service, Wonju-si 26460, SOUTH KOREA; Jong Teak Park, MA, National Forensic Service, Wonju-si 26460, SOUTH KOREA; Nam-Kyu Park, PhD, National Forensic Service, Wonju, SOUTH KOREA*

---

**Learning Overview:** After attending this presentation, attendees will better understand the feasibility of using X-rays as a tool for the distinction between arc melting and fire melting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing an effective tool for the distinction between arc melting and fire melting.

Molten marks found on copper wires at the scene of the fire can be largely divided into primary arc melting, secondary arc melting, and fire melting. For decades, many studies have been conducted to make a distinction between primary arc melting and secondary arc melting, but it is only possible to partially differentiate them under limited conditions.

The method of using Void in the inside of arc melting, among the methods proposed to differentiate between primary arc melting and secondary arc melting, mostly shows conflicting results. The results of preceding research and literature related to Void indicate that, although it is difficult to differentiate between primary arc melting and secondary arc melting, there are various types of Void in the inside of arc melting and that there are a much smaller number of Void in the inside of fire melting than that of arc melting.

Arc melting is characterized by the external visual indicators of the following: sharp demarcation between damaged and undamaged area, round shape of artifact, resolidification waves, etc. In contrast to melting caused by an arc, fire melting is characterized by the external visual indicators of the following: visible effects of gravity on the artifact, extended area of damage without a sharp demarcation from undamaged material, gradual necking of the conductor, etc.

The Void analysis method can be used to differentiate between arc melting and fire melting when external visual indicators are not sufficient or are disputed.

In this study, the distribution of Void in the inside of molten marks was examined using 2D and 3D X-rays as well as appearance tests to devise a method of differentiating between arc melting and fire melting, and, as a result, it was found in some cases that using X-rays to check the distribution of Void could lead to a clear distinction. Other than non-destructive inspection using X-rays, it is also possible to observe Void in the inside of molten marks with a microscope, but it takes time due to many stages (cutting, molding, grinding, polishing, and etching), and it allows an observation only on one cross section, which implies that using X-rays is much more precise and efficient in checking the presence of Void.

## E1 The First Cut Is the Deepest

Tyrish Y. Page, MA\*, *Sharing Hope SC, Charleston, SC 29405*; Jeff Thomas, MBA\*, *Sharing Hope SC, Charleston, SC 29405*; Angelina I. Phillips, MD\*, *MUSC, Charleston, SC 29425*

**Learning Overview:** After attending this presentation, attendees will understand that tissue procurement can preclude forensic autopsy without repercussions to the death investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the need to establish protocols between coroner/medical examiners and organ procurement organizations for pre- and post-autopsy tissue procurements.

Organ and Tissue Procurement Organizations' (O/TPOs) optimal goal is to maximize the "gift of life." The "gift of life" is offering hope and changing lives through organ, eye, and tissue donation. Tissue procurement must begin within 24 hours of the patient reaching asystole. This process may collide with the death investigation being conducted by the Medical Examiner and/or Coroner (ME/C), especially if an autopsy is necessary. The result has become a struggle about access to the body that pitted the transplant community's promise of "the gift of life" against the medical examiner's mandate to determine the cause of death in forensic case.<sup>1</sup> In 2017, 182 potential tissue cases were declined by coroners in South Carolina. These cases included donors who were eligible for either pre- or post-autopsy tissue procurement. Some ME/Cs deny procurement of organs and/or tissues for transplantation due to concerns of not being able to fulfill their legal mandate to determine the cause and manner of death, and to ensure that appropriate evidence is collected. With appropriate communication and cooperation between ME/Cs and O/TPOs, this should not be the case in the vast majority of situations.<sup>2</sup>

A referral for a 21-month-old female was called into Sharing Hope SC post-cardiac arrest from choking on a chewy candy, and the patient rapidly declined to death after admission. Organ procurement was unable to proceed due to the rapid decline, but the tissue procurement team immediately contacted the coroner for possible approval to procure. The coroner spoke with the family and medical examiner prior to giving authorization to procure heart valves. The coroner declined to have an autopsy but requested photos and a cardiac pathology report upon completion. During tissue procurement, the technician noted pulmonary edema and the heart was recovered for tissue processing. A detailed report provided by the processor's pathology laboratory examined the decedent's heart, myocardial thickness, coronary arteries, and valves and noted everything to be unremarkable. Several months later, the cause of death was amended due to the relaunching of the death investigation. The pre-autopsy photos and tissue procurement reports were momentous to the investigative team. The body was exhumed, an autopsy was completed, and the cause was changed to homicide.

Examining the heart during autopsy can be essential to the medical examiner when determining cause of death. Many O/TPOs and C/MEs have created and collaborated on methods to examine the heart while not disrupting the procurement of the allograft for transplantation. The result is that the medical examiner is able to determine and document the cause of sudden death, and heart valves that would previously have been denied are made available for transplantation.<sup>3</sup> Size-critical heart valves or tissue grafts are frequently requested by surgeons for patients that suffer from congenital defects of the pulmonary or aortic valve. Heart valves, especially pediatric heart valves, are in critical need. Nonetheless, the availability of homografts, especially in the smallest ranges, varies due to the limited donor pool.<sup>4</sup> This case study will highlight the need for pre-autopsy tissue, establish a protocol that MEs can visually examine the heart valve within a sterile environment and preserve evidence during pre-autopsy tissue procurements, and address ways the C/ME and O/TPO can work together to maximize the "gift of life" as well as be the voice for those who can no longer speak.

### E2 Which Came First, the Chicken or the Egg? A Key to Shed Light on a “Road Murder”

*Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Michela Ferrara, MD, Department of Forensic Pathology, Foggia 71122, ITALY; Lorenzo Spagnolo, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Giuseppe Davide Albano, MD, Foggia 71121, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Francesca Maglietta, MD, Department of Forensic Pathology, Foggia 71122, ITALY; Monica Salerno, MD, PhD, Department of Forensic Pathology, Foggia 71121, ITALY*

**Learning Overview:** The goal of this presentation is to underline the discrepancies between antemortem and postmortem instrumental diagnosis, confirming autoptic examination as the gold standard for forensic diagnosis. This is true even in cases of traumatic death, such as a traffic accident, in which radiology showed its indubitable function.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that a whiplash injury in an elderly patient with age-related vasculopathy can lead to the onset of an ischemic process, causing death. Even as a rare pathophysiological mechanism, this has to be considered when approaching cases as the one settled previously. Moreover, the forensic pathologist has to know the in-depth anatomy in order to adapt the dissection techniques to each specific case, even borrowing them from other surgical specialties. This need for continuous updating and a critical approach to the autopsy cannot help but be assisted by the new pre-autoptic technologies, always remembering that the macro- and microscopic studies remain irreplaceable.

Whiplash is a traumatic event affecting the cervical spine. In most cases, it arises following a sharp movement of the head that exceeds the physiological limits of joint excursion. Many studies document the presence of ischemic accidents following the compression of the vertebro-basal system arteries after whiplash in predisposed patients.

This case dealt with a 79-year-old man driving his own car who was involved in a frontal impact crash after he was hit by another car. He was transported to the emergency department, where the driver arrived comatose (GCS 3). Immediately, the patient underwent a brain Computed Tomography (CT) scan and angio-CT scan, directed, in particular, to study the epi-aortic vessels. The CT scan showed a wide ischemia of cortical and subcortical areas, particularly affecting the parietal and occipital encephalic lobes and cerebellum. The angio-CT scan revealed the complete occlusion of the lumen of both vertebral arteries at the level of the third cervical vertebra. The man died approximately four days after his admittance to the hospital.

The external examination of the body was not remarkable for any signs of trauma. The question was if the ischemia or the car accident came first.

Before performing the autopsy, a CT scan of the skull and neck was conducted. The autopsy was performed six days later, with a particular dissection protocol borrowed from the neurosurgery. The examination was focused on the vertebral artery segments between the third and fourth cervical vertebrae. During the dissection, an open-book cervical vertebral fracture was identified, leading to the complete obstruction of vertebral arteries, bilaterally. The histological examination of these vascular segments revealed the presence of a hemorrhagic infarction surrounding the adventitial layer, compatible with vitality at the time of its genesis.

Whiplash was the cause of death!

---

#### Whiplash, Traffic Accident, Vertebral Arteries

### E3 Bilateral Internal Carotid Arteries Dissection in Motorcycle Accidents: A Case Report and Review of the Literature

Caterina Petetta, MD\*, Department of Public Health and Pediatrics, Torino 10126, ITALY; Niccolò D. Melloni, MD\*, Department of Public Health and Pediatrics, Turin 10126, ITALY; Lucia Tattoli, PhD, Struttura Complessa di Medicina Legale, Torino, Turin 10126, ITALY; Davide Santovito, MD, Department of Public Health and Pediatric Sciences, Turin 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance of suspecting and evaluating cervical and intracranial vessel injuries in all patients involved in motorcycle accidents. Bilateral Internal Carotid Artery Dissection (ICAD) due to blunt head and neck trauma has an estimated incidence of 1%–1.7%.<sup>1</sup> It may also occur in motorcycle collisions, resulting in a life-threatening event if not promptly diagnosed and treated. Mortality rates for this injury are reported from 20% to 40%, while permanent neurologic deficits range from 40% to 80%.<sup>2</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that while bilateral ICAD in motorcycle accidents is very rare, timely diagnosis and treatment may prevent death or permanent neurological deficit. Early recognition is difficult and often delayed due to commonly associated severe multisystem injuries and the latent interval before the onset of clinical symptoms.

A case of a 44-year-old man involved in a high-speed motorcycle accident (frontal collision with a car) who sustained severe injuries, including bilateral ICAD, was reported. He was admitted to the emergency department unconscious, with severely altered vital sign parameters and bone and visceral injuries to the thorax and the pelvis. An initial brain Computerized Tomography (CT) scan was unremarkable. Because of his prolonged altered state of consciousness, a second cerebral CT scan and CT angiogram were performed. These studies revealed bilateral ICAD with thrombosis, treated non-operatively with fibrinolytic and anticoagulants, five days after the accident. The patient survived and regained consciousness. After multiple orthopedic and urological surgeries, he was discharged to initiate neuromotor rehabilitation and language therapy for the following two months. The bilateral ICAD has caused cerebral ischemic damage, resulting in upper and lower right limb hemiparesis and bradyphasia.

The literature review was conducted by the PubMed database with the goal of highlighting the importance of the traumatic mechanism of ICAD, risk factors, and its consequences for patient care and management. Papers regarding typical motorcycle accident injuries ( $n=24$  potentially relevant results), and bilateral ICAD due to blunt trauma ( $n=18$ ) were searched. The cross-search revealed motorcyclists are frequently exposed to direct traumatic injuries due to impact with: (1) rigid structures of the motorcycle (tank, handlebars, etc.); (2) collision vehicle; or (3) road pavement or other fixed obstacles on the scene at the time of projection to the ground. Typically, motorcyclists sustain abrasions, extremity fractures or avulsions, head and neck trauma frequently with skull base fractures, encephalic and spinal cord lesions, crushing thoraco-abdominal injuries, and perigenital and genital injuries. They may also suffer blunt force indirect injuries caused by rapid and sudden deceleration occurring at the moment of collision. This often causes traction and tearing of the organs held in place by vascular structures and/or ligaments. Among case reports of bilateral ICAD due to blunt trauma, none of these described this peculiar lesion in motorcycle victims, while the majority of cases occurred in horseback-riding, snowboard, or automotive vehicular collisions.

In the case reported, from a medical-legal standpoint, the man suffered both typical injuries due to direct trauma (such as abrasions, head, neck and thoraco-abdominal trauma, multiple pelvic fractures, and perigenital and genital injuries) and indirect trauma (such as bilateral ICAD).

Results from the literature review indicate that the early diagnosis of traumatic ICAD is important in order to prevent further complications. It should always be suspected in cases of motorcycle accidents as well as in blunt neck trauma with hyperextension or cervical spine fractures, especially in the presence of neurologic deficits not explained by head trauma.

## E4 Gone in 60 Seconds: A Fatal Case of Asphyxiation in a Confined Working Space

Giuseppe Davide Albano, MD, Foggia 71121, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY; Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Foggia 71100, ITALY; Francesca Maglietta, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY

**Learning Overview:** The goal of this presentation is to provide useful evidence regarding asphyxiation findings in confined space deaths in cases which, according to external inspection in a death scene, a Carbon Dioxide (CO<sub>2</sub>) poisoning could be expected.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing CO<sub>2</sub> poisoning cases when asphyxiation occurs in a confined space. When there are no specific CO<sub>2</sub> intoxication findings, the death scene and external investigation, gross anatomy, histology, and immunohistochemistry, as well as toxicological findings, are crucial to assessing asphyxiation features and to exclude other death causes.

CO<sub>2</sub>, a normal component of the atmosphere (0.02%-0.03%), a colorless and odorless gas, is physiologically produced by cellular metabolism and is widely used as an inert gas in fire extinguishers.<sup>1</sup> The toxicity of the CO<sub>2</sub> results from the effects to the respiratory center and from the replacement of oxygen. In low concentrations, it stimulates the respiratory center, and in high concentrations, it leads to respiratory depression and apnoea.<sup>2,3</sup> This data confirms how dealing with CO<sub>2</sub> is a great hazard. However, for forensic pathologists, the proof of CO<sub>2</sub> poisoning is still a great challenge.<sup>4</sup>

The presented case regards a 31-year-old man who was working as a fire extinguisher system maintenance person in the basement of a temporarily closed bank. There was only one main basement entrance. At that time, four other technicians were present. The anti-fire system was composed of several gas containers and many pipelines containing the inert CO<sub>2</sub> gas that was supposed to be released in case of fire and after the building evacuated. During maintenance activities, a massive gas leak from a container occurred. Four of the five men succeeded in escaping. The 31-year-old man was not able to get out and perished. Firefighters arrived and found his body without signs of life.

The forensic pathologist arrived and noted the position of the cadaver was a few meters from the gas container. The external examination revealed the presence of conjunctival petechiae, neck and face hypostasis localization, and no signs of injury. The autopsy, performed 24 hours after death, reported diffused brain and lungs edema, sub-pleural petechiae, and epicardial and myocardial petechiae. All vessels of the internal organs appeared to be congested. Histological investigation, with Hematoxylin and Eosin (H&E) stain, confirmed the gross anatomy findings. An increased number of alveolar macrophages were observed in the lungs as a consequence of protracted oxygen deficiency. Lung samples were processed for immunohistochemistry by using CD 68 and Hypoxia Induced Factor 1- $\alpha$  (HIF1- $\alpha$ ) antibodies. Positive reaction with macrophage marker CD 68 as well as HIF1- $\alpha$  was observed. Spectrophotometry analysis was performed in order to exclude high carboxyhemoglobin levels in periphery blood. Drug and alcohol concentrations in the periphery blood were not significant. Death scene information, and macroscopic, microscopic, and toxicological findings determined asphyxiation in a confined space as the cause of death.

Asphyxia in a confined space may be a consequence of oxygen exclusion because of depletion and replacement of another gas or as a result of chemical interference with its uptake and utilization.<sup>5</sup> In this case, a massive CO<sub>2</sub> leak from the fire extinguisher system occurred, and the basement was rapidly filled with CO<sub>2</sub>, which is denser than O<sub>2</sub> (1.98kg/m<sup>3</sup> vs 1.29kg/m<sup>3</sup>), leading to an oxygen exclusion. CO<sub>2</sub> intoxication is a diagnosis based on the scene investigation and circumstances surrounding a death with the exclusion of other causes of death.<sup>6</sup> There are no pathognomic autopsy findings and blood analysis for CO<sub>2</sub> content has no diagnostic significance, as CO<sub>2</sub> rapidly accumulates after death.<sup>7</sup>

In this case, the death scene investigation, autopsy, histological, immunohistochemical, and toxicological analysis were crucial to provide essential information in order to assess CO<sub>2</sub> intoxication. In such cases, CD 68 and HIF1- $\alpha$  antibodies use is essential in order to establish an oxygen deficiency and suggest asphyxiation death.

### Confined Space, Asphyxiation, CO<sub>2</sub> Intoxication

## E5 Fatal Alveolar Capillary Dysplasia (ACD) in Two Siblings: A Rare Heritable Form of Persistent Pulmonary Hypertension in Neonates

Caterina Petetta, MD\*, Department of Public Health and Pediatrics, Torino, Italy 10126, ITALY; Giovanni Botta, MD, Department of Pathology, OIRM Sant'anna, Torino 10126, ITALY; Andrea Zonta, MD, Medical Genetics, Molinette Hospital, Torino, Italy 10126, ITALY; Eleonora Di Gregorio, PhD, Medical Genet. Città della Salute e della Scienza, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the necessary elements for the diagnosis of ACD, a fatal lung disorder in premature or full-term infants. ACD is an uncommon interstitial lung disease causing Persistent Pulmonary Hypertension in Neonates (PPHN). Without responding to therapy, it is characterized with a mortality rate that approaches 100%.<sup>1</sup> The diagnosis of ACD is difficult because the etiopathogenesis of ACD and associated pulmonary hypertension remain to be fully explained.<sup>1</sup> Furthermore, an autopsy is not always performed after an infant's death, and ACD can be associated with other congenital system anomalies that are often considered to be the primary cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting that ACD must be suspected and immediately investigated in all infants with irreversible persistent fetal circulation. The literature review, conducted by the PubMed database, yielded 30 papers about ACD. It is described as a cyanogenic disorder characterized by failed postnatal decrease of the vascular pulmonary resistance, associated with the typical intrauterine right-to-left shunt. The disorder affects primarily the alveolar components leading to respiratory insufficiency early in life.<sup>2</sup>

Most ACD cases are *de novo* events but approximately 10% are heritable forms possibly involving siblings. 16q24.1 deletion and FOXF1 inactivating mutations have been identified as responsible in 40% of cases.<sup>1</sup> Currently, a definitive diagnosis depends on histological lung features found at autopsy or antemortem lung biopsy: (1) immature lobular development; (2) decreased number of pulmonary capillaries, dilated and located away from the alveolar epithelium; (3) thickened alveolar septa; (4) lymphangiectasis in interlobular septa; and (5) sometimes misalignment of pulmonary veins adjacent to pulmonary arteries.<sup>1</sup> In the case reported, two siblings born two years apart died after a severe and irreversible pulmonary hypertension with hypoxemia developed a few hours after their birth.

A 37-week gestational age (2,900g of weight, 9/9 Apgar score) male infant was born to a primipara via induced vaginal childbirth in view of polyhydramnios. The infant's respiratory status declined within the first 12 hours of life. Despite the immediate mechanical ventilation and inhaled nitric oxide, the neonate died 96 hours after birth because of irreversible respiratory failure. At autopsy, the histological examination of lung tissue showed immature and dilated alveolar capillaries distant from the alveoli through thickened septa, associated with lymphangiectasis. A 16p13.3 deletion was found through array Comparative Genomic Hybridization (CGH) analysis.

During the second pregnancy, the fetus shared the same 16p13.3 deletion through array CGH analysis on fetal DNA. Colon-sigma and rectum dilatation were detected by echocardiography at 17 weeks of gestation. A male infant was born by vaginal delivery at 38 weeks gestation (3,040g of weight, 6/9 Apgar score), but he developed serious pulmonary hypertension a few hours after birth. After detecting anorectal atresia, a right hemicolectomy was performed. Despite the regular clinical course, a respiratory failure occurred, not responding to any therapy until the infant's death 25 hours after birth. Autopsy and histological analysis showed underdeveloped acini and dysplastic and sparse capillaries within the thick interstitium in the lungs. In both cases, analysis of the lung tissues showed characteristic features of ACD as the cause of death. The recurrence of ACD and genetic tests (16p13.3 deletion) suggested an autosomal recessive or X-linked mode of inheritance.

Histological and genetic examinations have a key role in the diagnosis of ACD, especially in the prenatal period. An accurate assessment is fundamental for the management of PPHN because of the high rate of mortality. If death occurs, autopsy is recommended to verify system malformations. This approach may help to define the correct cause of death when related to ACD.

---

**Learning Overview:** After attending this presentation, attendees will be informed regarding a rare case of mummification that occurred in an unusual time interval.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that exceptions may exist in determining time since death in a complete mummified body.

A body in advanced stage decomposition is a challenge for forensic pathologists. Personal identification, as well as manner and time since death, require a specific skill, but sometimes they are not enough to explain all of the cadaveric phenomena.

It is known that mummification occurs in response to dryness of the environment, good ventilation, and high temperature. Due to the evaporation of water in the remains, the body becomes dehydrated or desiccated and shrivels. The natural appearances and features of the body are preserved indefinitely. Mummification is usually described after several weeks, and it is normally completed, on average, in a year.

In this case, a body in an advanced state of mummification was found during the summer season in an abandoned ground in southern Italy. The cranium was almost completely skeletonized, and the remaining part of the body was predominantly mummified. No signs of postmortem animal activity were found. No elements that allowed identification were found. The autopsy and the Computed Tomography (CT) scan excluded traumatic lesions, but the preservation of the organs' tissues, due to mummification, allowed histopathological analysis that concluded for a natural cause of death.

Police investigation revealed that 17 days before the discovery of the corpse, a missing Senegalese male was admitted to the emergency room after an accidental fall. During the admission, a CT scan was performed, but the subject left the hospital before completing all analysis, then he disappeared.

Odontological comparison was made between antemortem X-rays in the emergency room and skull X-rays performed at the Institute of Legal Medicine to compare the frontal sinus and odontological data. This provided a positive match between the mummified body and the missing Senegalese male.

Personal identification of the mummified body allowed the precise definition of the postmortem interval. The victim was in the emergency room 17 days before the discovery of the body, so one can conclude that the time of death was no longer than 17 days before the first inspection.

This case is interesting because of the atypical precocious mummification that occurred in a very short period of time (just two weeks) and for the procedure described by this study to obtain identification.

---

## E7 Mortality Among Hospitalized Injured Older Adults (HIOAs) for a Major Trauma: A Retrospective Autopsy Analysis (2000–2017)

Francesco Amico, MD, *Medicina Legale, Catania 95123, ITALY*; Giuseppe Davide Albano, MD, *Foggia 71121, ITALY*; Aldo Liberto, MD, *University of Catania, Catania 95123, ITALY*; Federico Patanè, MD, *Catania 95123, ITALY*; Dario Condorelli, *University of Catania, Catania 95100, ITALY*; Martina Fichera, MD, *University of Catania, Catania 95123, ITALY*; Diego Geraci, PhD, *Catania 95100, ITALY*; Monica Salerno, MD, PhD\*, *Department of Forensic Pathology, Foggia 71121, ITALY*

**Learning Overview:** Aging, injury, and hospitalization are a challenging triad for health care providers. In medical malpractice claims regarding HIOAs deaths, an Injury Severity Score (ISS) could be a very reliable evaluation parameter for forensic pathologists in order to establish health care workers' liability.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing useful and reliable data regarding HIOA deaths. Moreover, in such cases, when a malpractice claim occurs, death is a result of older adults' frailty, the trauma itself, as well as pre-existing medical conditions, leading to exclude health care workers' liability. This information needs to be taken into consideration in lawsuits regarding HIOA deaths.

Frailty is a leading feature in older adults and is characterized by physiological changes leading to an increased vulnerability to external stressors. A greater degree of frailty is associated with higher mortality risk and other adverse outcomes.<sup>1</sup> Trauma affects more than 9% of the United States population every year, and it is an important public health concern. In the United States in 2004, more than 2.9 million older adults were treated for traumatic injuries in hospital emergency departments.<sup>2</sup> Several studies suggested that older adults are at greater risk of fatal injury than their younger counterparts.<sup>3,4</sup> Furthermore, reliable data on fatal trauma is necessary for planning current and future trauma care in Europe.

This study reviewed all major trauma death autopsy databases regarding motor-vehicle crashes, cyclist investments, pedestrian casualties, falls from heights, accidental falls, aggressions, and accidents in the domestic and working place and was performed at the Department of Forensic Pathology of the University of Foggia from 2000 until 2017. Charts of all medical and forensic autopsies performed in the study were hand searched. Only cases with hospitalization previous to the death in patients older than 5 years of age were selected. The ISS is a method for numerically describing the overall severity of injury. It can be applied to those who have sustained injury to more than one area of the body as well as to those with isolated injuries. An individual's ISS is determined by rating each injury with the Abbreviated Injury Scale (AIS), then adding together the squares of the highest AIS rating for each of the three most severely injured areas. The ISS correlates substantially better with mortality than does the AIS rating for the most severe injury.<sup>5,6</sup> All cases with ISS greater than 15 were selected in this study. Demographic data, injury mechanism, pattern and severity, physiological signs, pre-existing medical conditions, and length of stay after trauma were obtained from pre-hospital trip charts, clinical charts, and forensic and medical autopsy records. In all malpractice claims, three different medical examiner offices, blinded to each other's opinions, evaluated the relationship between health care professionals' behavior and death.

Fifty-five autopsies were selected (35 M; 20 F; mean age 73, DS 5.4). Traumatic brain injury was the cause of death in 16 cases (29%), followed by pneumonia in 8 cases (15%), and Multiorgan Distress Syndrome, pulmonary embolism, and fat embolism (all in 6 cases, 12%). The median ISS was 21. The mean length of hospitalization was 27.78 days (median 15; I Q 6.5; III Q 29.5). In 43 cases (78%) pre-existing medical conditions were present. A negative correlation between time of survival after trauma and both number of pre-existing medical conditions and severity of trauma was observed.

In the case of HIOAs, undertriage remains a serious problem.<sup>7,8</sup> Treatment at a trauma center has been shown to be associated with a 25% lower mortality. In this study, in 32 of 55 cases (58%) hospitalization took place in a trauma center but in both the United States and Italy, there are no geriatric trauma centers.

In all cases, a correlation between health care professionals' behavior and death was excluded.

### E8 Funny Games: Homicide Among Neighbors

*Francesco Sessa, MS\**, Department of Forensic Pathology, University of FOGGIA, Foggia 71100, ITALY; *Michela Ferrara, MD*, Department of Forensic Pathology, Foggia 71122, ITALY; *Francesca Maglietta, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Irene Riezzo, MD, PhD*, University of Foggia, Osp D'Avanzo, Foggia 71100, ITALY; *Marcello Rendine, DBA*, Department of Forensic Pathology, Foggia 71100, ITALY; *Pietrantonio Ricci, MD, PhD*, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; *Natascha Pascale, MD*, Foggia 71100, ITALY

**Learning Overview:** The goal of this presentation is to show how a multidisciplinary approach to the crime scene is instrumental in the study of complicated inspections to detect all traces of the crimes and to direct investigations in the correct manner.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how a complete forensic team could provide important support to investigative activities by providing benefits to law enforcement regarding the performance of forensic K-9 units and their optimized combination with forensic operators, revealing their capability in detection, identification, and location of biological traces.

This case dealt with a 55-year-old man who was killed in front of a building near his unauthorized cottage. The forensic pathologist team was alerted by the local prosecutor to a case of gun homicide. At the crime scene, the man was found lying on the sidewalk, supine, with his thorax in a large pool of blood. In front of the entrance door to the building were two steps. Near these steps, at a distance approximately 370cm from the corpse, and on the sidewalk, was a cartridge case. On the other side of the steps, at a distance of approximately 390cm from the corpse, another casing was found. The access door of the house appeared open, with a broken lower panel. Along the wall of this door was a window that had one of the two glass panes broken.

The external examination revealed, in correspondence with the fourth left intercostal space, the presence of a linear wound with finely jagged margins and extroflexes (exit hole). At the left upper abdominal quadrant, immediately below the costal arch, was a round-shaped wound with jagged and introflected margins (entrance hole). The left forearm presented with two wounds: one in correspondence to the upper third of the dorsal face, which was round shaped with jagged and introflected margins (entrance hole); the other in correspondence to the upper third of the fly face that was oval shaped with jagged and extroflexed margins (exit hole). In the right dorsal region was a roundish wound, with jagged and introflected margins (entrance hole). At the autopsy, an ogive was found in correspondence with the adipose tissue of the right gluteal region. The death was attributed to a cardiac and vascular lesion with cardiac tamponade. Such a wound is produced by a single-munition gun. The autopsy also identified other internal injuries produced by a gun.

During the interrogation, the suspect declared he was attacked first by the victim, who had used a golf club to break the windows of the house and the car before striking the suspect. The golf club was not found near the houses of the suspect and victim, so the prosecutor asked for a new inspection of the surrounding land because witnesses saw the victim's family hide the body. This inspection was effectuated with the help of the Forensic K-9 Unit and dogs trained to detect and locate any biological trace, such as blood.

The golf club was found buried in a field in front of the victim's house and was compared to the suspect's lesions, which were compatible with the aforesaid blunt body. Comparative genetic tests were conducted, comparing the blood DNA profile found on the club with the suspect profile obtained by buccal swabs. After genetic analysis, the profile matched, confirming the history told to the judge. In light of these findings, the judge decided to close the case as a legitimate (self) defense.

At the end of the police investigation, the suspect was declared innocent and returned to his home, near the house of the victim. After a few days, his house was set on fire. The police arson investigation is in progress.

### E9 A Mafia Ritual of Hiding Murders: Sheep in Boots!

*Francesco Sessa, MS\*, Department of Forensic Pathology, University of FOGGIA, Foggia 71100, ITALY; Elena Varotto\*, Casa di Cura “Santa Lucia” Centro Polidiagnostico, Siracusa 96100, ITALY; Laura Landini, MS, Laboratory of Archeozoology, Department of Civiliz, Pisa, ITALY; Francesca Maglietta, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY; Santina Cantatore, Foggia 71100, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the modus operandi of an emerging Italian Mafia called Mafia of Gargano. A distinctive characteristic of the murders by this Mafia is the ritual of concealing the murder. Thanks to the karst conformation of this area, criminals frequently hide corpses in the natural ravines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing scientific data on the multidisciplinary forensic approach used to support investigations, increase the gathered information, and help in the identification process of unknown human skeletal remains.

The Mafia is a highly organized Italian criminal organization that began in Sicily at the beginning of the 19th century. There are four Italian Mafia organizations, namely “Cosa Nostra” (Our Thing or Our Affair) in Sicily, “Camorra” in Campania, “Sacra Corona Unita” (SCU, United Holy Crown) in Puglia, and “Ndrangheta” in Calabria. In the Apulian territory (a region of Italy) there are several subsidiary independent criminal groups that modeled their organizations on that of the Camorra.

One of these is named “Mafia of Gargano” (Gargano identifies an area located in northern Puglia, also known as “The Spur of Italy”). This criminal association began its illegal activities in the 1990s with a series of violent killings committed between 1990 to the present.

In the first years of activity, this outlaw movement was underestimated by the local judges. In fact, they believed that these crimes were committed among rural families for cattle thefts. This organization became very important in the Apulian criminal scenario, of significant interest for several outlaw activities, such as drugs and arms trafficking. To date, the “Mafia of Gargano” has been responsible for approximately 198 murders, 40 of which are classified as “Lupara Bianca” murders. “Lupara” is the Sicilian word for shotgun, a firearm traditionally associated with mafia-type organizations. The term “Bianca” (white) symbolizes the absence of blood because bodies and traces of murders are concealed; for example, burying the corpses in the countryside, in places they would be difficult to find. This Mafia ritual is highly facilitated by the natural conformation of the Gargano promontory. Indeed, the presence of numerous karst ravines gives this territory a unique conformation, useful for hiding drugs, weapons, and corpses. Hiding corpses in the isolated areas of grottoes, valleys, and ravines that are hundreds of meters underground and far from the urban area allows for the body to be hidden, and the criminals can evade prosecution.

During military operations in the ravines located in the Gargano area, a special team of “Carabinieri” (a police unit of the Italian armed forces) discovered numerous bones, some of them in farmer’s boots, similar to human phalanges. Subsequently, they collected these bones and isolated the area, interrupting all activities and alerting the prosecutor. In fact, in 2010, a vehicle of a missing person was found near the same ravine. A team of forensic multi-specialists (forensic pathologist, anthropologist, and geneticist) promptly supported all operations. The team went deep into the ravine where bone identification became very difficult because of the commingled animal remains and other materials. Moreover, a large amount of mud rendered the recovery and identification processes tedious and difficult. During the recovery operations, numerous Kalashnikov bullets were found. After three days of work, no human skeletal remains were located.

The bones previously collected were transferred to the Institute of Forensic Pathology of the University of Foggia for a complete multidisciplinary investigation. Forensic investigations consisted of radiological, histological, anthropological, and genetic studies; all data excluded the presence of human phalanges. It was a sheep in boots!

In conclusion, this study demonstrates the importance of the forensic sciences to support investigative activities. A multidisciplinary approach is very important because it helped gather a variety of information and excluded the presence of human skeletal remains in the analyzed ravine. In the future, the same approach could be very useful to recover the corpses of 40 missing people in the Gargano area.

#### **Italian Mafia of Gargano, Forensic Multidisciplinary Approach, Concealed Corpses**

## E10 Three Cases of Traumatic Death?

*Costanza Filomena\**, Pisa 56126, ITALY; *Francesca Iannaccone*, Pisa 56123, ITALY; *Federica Gori, MD*, University of Pisa, Pisa 56100, ITALY; *Luigi Papi*, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; *Angela Pucci, MD*, University of Pisa, Pisa 56100, ITALY

**Learning Overview:** The goal of this presentation is to emphasize the difficulty of differential diagnosis between natural and traumatic deaths, especially when the circumstantial data is misleading. In such cases, histology proves to be useful in the identification of the real cause of death.

**Impact on the Forensic Science Community:** This presentation will affect the forensic science community by showing that although in some cases the manner of death may appear evident from circumstantial data, an underlying cause could be hidden, and only a thorough scene investigation and complementary analysis such as histology can reveal the true manner of death.

The first case regards a 31-year-old male found dead in his car at the bottom of river at a depth of 10 meters. An initial investigation by local police suggested the man lost control of the car, hit the barrier of the bridge, was thrown 25 meters from the impact point, and fell into the water. Toxicological analyses showed a high blood alcohol level (2g/l).

The second case, a 22-year-old male who was swimming in a camping pool, suddenly collapsed and fell underwater. Cardiopulmonary Resuscitation (CPR) was attempted by the lifeguard and, upon arrival of the ambulance, defibrillation was performed, without results.

The third case deals with a 21-year-old girl found dead by her motorcycle at the road side, still wearing her helmet. In all cases, postmortem Computed Tomography (CT) and toxicologic examinations were performed. CT scans revealed no signs of trauma, and toxicologic analysis was positive only in Case 1 for alcohol.

In Case 1, external examination revealed no remarkable findings. At section, heavy, edematous and congested lungs, with foam inside the bronchial branches, and a heavy heart were discovered. In Cases 2 and 3, external examination showed frothy fungus at the nostrils and oral cavity, and bilateral subconjunctival petechiae (Case 2) and perioral and zygomatic superficial abrasions, an oily, blackish material on the left knee, and zygomatic abrasions on both hands (Case 3). At section, both cases revealed heavy, edematous, and congested lungs, with foam inside the bronchial branches.

In all cases, Hematoxylin-Eosin (H&E) and Masson's trichrome staining were performed. Histologic examination documented massive lymphocytic infiltration associated with some histiocytes in full thickness sections from both ventricles (including endocardium and pericardium), and acute emphysema in Case 1. In Case 2, myocytic hypertrophy with myocardial disarray and fibrosis, especially in the antero-lateral wall of left ventricle (>5% of total heart samples), and some areas of myocardial bridging were found. In Case 3, diffuse myocytic hypertrophy with myocardial disarray (>5% of total heart samples), endomyocardial clefts, contraction bands, fibrosis, and some areas of myocardial bridging were discovered.

In two of the cases, death was attributed to hypertrophic cardiomyopathy, not, as hypothesized, a traumatic cause. Case 1 is still doubtful as the man could have died by drowning (significant pulmonary findings, such as edema, acute emphysema) or by the accident due to the high alcohol level or by myocarditis.

Sudden and unexpected death in otherwise healthy individuals is probably the most difficult differential diagnosis in forensic pathology, especially with the presence of misleading circumstantial data.<sup>1</sup> In such cases, histology, along with complementary investigations, is fundamental to identify the real cause of death.

Myocarditis may cause sudden death. The reported incidence is higher than expected in younger age groups (less than 35 years of age), with 12% of sudden cardiac deaths attributed to myocarditis in young Australians and 34.7% in a Chinese autopsy case study.<sup>2,3</sup> Therefore, myocarditis should be suspected in cases of sudden unexpected death in otherwise healthy young people. Representative sections from anterior, lateral, and the posterior wall of the atria and ventricles, as well as sections from the ventricular septum, should be submitted for microscopic examination. Histological diagnosis is defined by Dallas criteria. The presence of an inflammatory infiltrate in the myocardium (>14 lymphocytes/mm<sup>2</sup>) with degenerative and/or necrotic changes of adjacent cardiomyocytes are not typical of ischemic damage.<sup>4</sup>

Another frequent cause of sudden death, especially in young subjects (12–35 years old) is hypertrophic cardiomyopathy, characterized by myocardial hypertrophy, usually asymmetrical, located in the septum and, less frequently, left ventricle; recent studies have also described an involvement of the right ventricle in cases with a worse prognosis.<sup>5,6</sup> At histology, the most specific finding is myocardial disarray (in >5% of histologic samples), with myocardial bridging and interstitial fibrosis. Physiopathological mechanism of death is usually arrhythmia, due to unstable electric conduction through disarrayed myocardial areas.

Circumstantial data could sometimes be misleading; thus, a careful autopsic and histological investigation are fundamental, as highlighted in these three cases.

## E11 Child Sexual Abuse of Boys: A Six-Year Retrospective Analysis

Serena Maria Curti, MD\*, Sezione Medicina Legale DSSPP, Torino 10121, ITALY; Caterina Bosco, MD\*, Department of Public Health and Pediatrics, Turin, Torino 10126, ITALY; Sara S. Racalbutto, PsyD, Dipartimento di Pediatria d'Emergenza, A.O.U. Ci, Turin, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, Turin, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the features of Child Sexual Abuse (CSA) perpetrated on male victims.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing tools to recognize a form of sexual abuse that is often difficult to identify.

The prevalence of CSA is dramatically high: in Europe it is estimated to be 13.4% for girls and 5.7% for boys.<sup>1</sup> However, the number of male victims is certainly underestimated for several reasons. Boys are usually abused by a caregiver, so they are not prone to disclose the abuse because of the strong affective bond between victim and perpetrator. Boys are also more reluctant to disclose the abuse for fear of reprisal or shame for being labeled as homosexual. Genital injuries are reported in less than 10% of the male victims, and few of them have been reported as highly suggestive of abuse.<sup>2-4</sup> The excellent healing capacity of children's tissues allows even serious genital lesions to go undetected even a few days after the trauma. Since the phenomenon is perceived as rare and few case series are available, literature about sexually abused boys is very limited and physicians have few tools to reach a correct diagnosis.<sup>5,6</sup>

In order to contribute to the knowledge of the topic, this study reports on the data collected from 2012 to 2017 in the multidisciplinary "Bambi" unit of the Pediatric Hospital "Regina Margherita" in Turin, Italy, composed by different health care providers trained in the assessment of child abuse. Among the 1,042 cases managed in this period, 494 were suspected cases of CSA. In 95 cases (19.2%), the victim of the suspected CSA was a boy. The cases highly suggestive of CSA were reported to the Judicial Authority (73 cases=77% of the suspected cases). For this group, the mean age of the boys was 6.9 years (range 2.5–15 years). Regarding the geographical origin of the victim's family, Italian children were predominant (51 cases), followed by Latin American (10 cases), African (7 cases), and eastern European (5 cases). In cases in which data was available, the family status analysis identified the same number of divorced and non-divorced parents (27 cases in both groups), while a small percentage of children resided in a community or with a foster family (7 cases). The most frequent suspected perpetrators were, with the same frequency, fathers and extra-familial people (both responsible for 33.8% of the cases), followed by other family members, such as victims' siblings (9.2%); 31.5% of the boys presented anogenital findings. These were mostly non-specific (erythema of the anal or genital tissues, 17 cases; anal fissures, 7 cases); only 2 cases revealed a finding highly suggestive of abuse (perianal laceration) and 87.7% of the boys did not present any skin injury. In the remaining cases, bruises and excoriations were observed in 6 cases, scars in 2 cases, and lacerated injuries in 1 case. In the suspicious cases managed by the "Bambi" unit in which, instead, the hypothesis of CSA was excluded after a careful multidisciplinary assessment (22 cases), the prevalence of negative anogenital inspection was slightly higher (77.2%). All the findings were non-specific (erythema, 1 case; anal fissures, 1 case; both, 2 cases; condyloma acuminatum transmitted by nonsexual contact, 1 case). There were no extra-genital skin lesions and the boys were older (mean age 7.9 years).

Despite the rarity of genital lesions in boys, health care providers must consider CSA as a possible differential diagnosis, especially when there is a disclosure or anomalous behavior of the child or the explanation of injuries by the caregivers is not consistent with the clinical findings. On the other hand, physicians who evaluate suspected cases of CSA must be familiar with pediatric diseases, pre-existing malformations, or "toilet trauma" that can resemble injuries caused by CSA in order to avoid over-reporting. For this reason, a multidisciplinary assessment conducted by a pediatrician, medical examiner, psychologist, and, eventually, urologist is recommended. This presentation provides attendees with better information concerning CSA perpetrated on male victims, which has not been extensively studied.

## E12 A Multiple Congenital Malformation in a Forensic Infant Autopsy

Francesco Lupariello, MD\*, University of Turin, Legal Medicine Section, Torino, ITALY; Serena Maria Curti, MD, Sezione Medicina Legale DSSPP, University of Torino, Torino 10121, ITALY; Janet B. Duval, MSN, Greensburg, IN 47240-8138; Giovanni Botta, MD, Department of Pathology, OIRM Sant'anna, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the pathophysiology and presentation of Congenital High Airway Obstruction Syndrome (CHAOS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the methods necessary for diagnosing CHAOS at autopsy for forensic purposes.

CHAOS is a rare anomaly that is characterized by a partial or complete obstruction of the fetal upper airways. Its exact incidence is not known. The most common cause of CHAOS is the laryngeal atresia.<sup>1,2</sup> Other causes are laryngeal webs and cysts and tracheal agenesis or atresia. At prenatal Ultrasonography (USG), the fetus may be characterized by enlarged echogenic lungs, inverted or flattened diaphragm, and fetal ascites.<sup>3</sup> In fact, “the non-clearance of fluid from the lungs, due to obstruction, results in a dilated trachea and lung parenchymal hyperplasia. This further leads to compression of the great veins and right atrium leading to ascites. The compression of the esophagus due to a dilated trachea may lead to polyhydramnios.”<sup>2</sup> In addition, the heart may be centrally placed because of the compression of the enlarged lungs.<sup>4</sup>

This presentation reports on a singular case of CHAOS in a female infant in which congenital agenesis of the trachea and atresia of the esophagus led to her death shortly after delivery, despite intubation attempts.

A 26-year-old pregnant woman was transported by ambulance to the hospital because of intense uterine contractions. The information about the woman’s pregnancy was limited because she lived in another country during the previous months of her pregnancy. The only information for clinicians included: 33 weeks + 2 days of gestational age, no known maternal pathologies, and amniocentesis had not been conducted. The maternal weight, stature, and Body Mass Index (BMI) were, respectively, 63kg, 170cm, and 19kg/m<sup>2</sup>. The woman gained approximately 8kg of weight during the pregnancy and did not receive regular USG or clinical medical evaluations during pregnancy. The only fetal USG available (conducted 13 days before delivery) showed polyhydramnios, suspected esophageal atresia, and arthrogyposis.

Immediately after admission of the woman to the hospital, the physicians decided to perform an emergency cesarean section because the fetal cardiotocography was highly pathologic. At delivery, the baby weighed 1.7kg, was non-reactive to stimuli, atonic and cyanotic, and the APGAR score was 1, 0, 0. The heart rate was 30bpm. The neonatologist attempted to aspirate the secretions from the upper respiratory airways, but to no avail. Therefore, he immediately tried to intubate the baby, inserting the tube as far as the vocal cords, but was unable to advance the tube beyond that point. Finally, despite multiple intubation and resuscitation attempts, the baby died. The case was referred to the forensic pathologist.

On the gross examination, the heart was centrally placed, and both lungs were enlarged and characterized by two lobes. The larynx was normally developed, but the probe did not manage to reach the trachea due to a cartilaginous septum that was located between the larynx and the trachea. The distal part of the trachea and the bronchi were present, and the trachea (in correspondence with the carina) showed a trachea-esophageal fistula. On the other end, the esophagus was atresic. Indeed, the probe did not manage to go beyond the upper part of the esophagus. In addition, the distal part of the esophagus was present and connected to the trachea through the fistula mentioned above. There was also peritoneal effusion, a small stomach, unicornuate uterus, and a recto-cloacal fistula. The microscopic examination only revealed an accumulation of mucus in the alveoli. The death was due to the congenital tracheal malformation that did permit intubation. The manner of death was natural. Reviewing the literature, the pathologists understood that the baby was affected by a peculiar form of CHAOS in which a type 2 of congenital tracheal agenesis (Floyd classification) was associated with a type C esophageal atresia (Gross classification).<sup>5,6</sup> The combination of these congenital anomalies has not yet been described in the literature. This may generate difficulties in the interpretation of anatomical findings at forensic autopsy. For these reasons, this presentation should serve as a stimulus to improve knowledge in the forensic community regarding these types of congenital malformations.

## E13 Penetration Injury From Child Sexual Abuse: A Systematic Literature Review

Patricia M. Speck, DNSc\*, Hoover, AL 35226; Caroline Concannon, BSN\*, University of Alabama at Birmingham School of Nursing, Birmingham, AL 35290-0001; Kimberly Peek, BSN\*, University of Alabama at Birmingham School of Nursing, Birmingham, AL 35242

**Learning Overview:** The goal of this presentation is to present a systematic literature review about full vaginal penetration of prepubertal children in published literature, exposing gaps in research. This presentation will impact the forensic science community by disentangling “it’s Normal to be Normal” (NtbN) categorization in Child Sexual Abuse (CSA) from “Full Penetration (FP).” At the end of this presentation, learners will: (1) identify two distinct care specialties for prepubertal children following sexual abuse—pediatric specialists and surgical specialists; (2) disentangle the legal and medical definitions of “penetration of the labia, however slight” from “full penetration,” respectively; and (3) distinguish disentanglement resulting in more questions about injury and long-term sequelae for prepubertal children experiencing full penetration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by an analytical literature review about prepubertal child sexual abuse that was 3-fold: (1) provide a platform for pre-licensure students to learn one aspect of the research process; (2) distinguish clinical skills necessary for providers in the evaluation of FP of a prepubertal child; and (3) create a foundation for future study about the unique population characteristics in different settings

Legislation, describing penetration as “separation of labia, however slight” guides definitions in CSA research and prosecution. Consequently, scholars using the legal definition argue it is Normal to be Normal (NtbN).<sup>1-3</sup> However, children experience significant injury with FP (defined medically as piercing into a cavity), challenging the NtbN notion.<sup>4-7</sup> Literature reports injury classifications as normal/non-specific (NtbN) to definitive injury (FP), mixing “separation of the labia, however slight” from those experiencing FP past the hymen into vagina cavity and elsewhere.<sup>8</sup> Stud-designed selection bias currently prevents injury incidence disentanglement, resulting in the NtbN notion.

A systematic literature review of CSA injury articles was conducted. PubMed, CINAHL®, Scopus®, and Google® Scholar discovered 35 articles responsive to CSA injury. Non-responsive to FP, a reference list search for articles sufficient to analyze rare FP injuries found 4 articles.<sup>3,4,6,9-13</sup> Analysis revealed that CSA, defined as “separation of the labia, however slight,” rarely results in injury detection (1%-6%), but FP injuries require surgical evaluation (11%-18%) and repair (4%-12%) with significant pelvic-floor outcomes.<sup>2,4,6,14</sup>

The systematic literature analysis disentangled two distinct populations and outcomes. The CSA specialty clinic studies seldom identify FP injury in prepubertal children. When compared, emergency pediatric hospitals and surgical specialty practices experienced significantly more FP injury cases. Therefore, this systematic review rejects the notion that it is NtbN with FP. Future studies distinguishing normal findings and non-penetrating vulvar trauma from vaginal FP are necessary to fully disentangle data and measure long-term physical impacts of prepubertal FP.

## E14 The Challenge of Diagnosing Child Abuse (CA): The Perks of a Multidisciplinary Approach

Francesco Lupariello, MD\*, University of Turin, Legal Medicine Section, Torino, ITALY; Sara S. Racalbutto, PsyD, Dipartimento di Pediatria d'Emergenza, A.O.U. Ci, Turin, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, Turin, ITALY; Greta Cena, MD\*, Dipartimento di Scienze della Sanità Pubblica e Pe, Turin 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will understand fracture patterns, which are highly suggestive of physical CA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the importance of a careful, multidisciplinary evaluation in cases of fractures from suspected CA.

CA represents a diagnostic challenge due to its complex presentation. Although the consequences of failing to diagnose CA may be life-threatening, a wrong diagnosis may have devastating sequelae too.<sup>1</sup> Imaging plays a major role since there are fracture patterns, which are highly suggestive of physical abuse.<sup>2,3</sup> According to Kleinman, injuries with high specificity for abuse include Classic Metaphyseal Lesions (CMLs), rib fractures, especially posteromedial, scapular fractures, spinous process fractures, and sternal fractures.<sup>4</sup>

However, no fracture in itself is pathognomonic for child abuse.<sup>5</sup> Therefore, it is important to take into consideration other factors that can increase the likelihood of abuse. The most significant are: the age and the developmental stage (ambulatory or not) of the child, the consistency of clinical history provided by caregivers, the presence of multiple fractures in different states of healing, coexistence of other injuries suspicious for abuse (bruises, contusions or internal injuries), and the characteristics of the family.<sup>4</sup>

The goal of this presentation is to report findings of a retrospective analysis of CA cases in which the abuse was associated with one or more bone-fractures. This study reviewed all cases managed from January 2012 to December 2017 by the multidisciplinary unit (“Bambi”) dedicated to the evaluation of suspected abused children at the Ospedale Regina Margherita of Turin, Italy. The operators of the “Bambi” unit examined 1,042 cases of suspected CA. In 39/1,042 cases, there were one or more fractures, and in 25/39 cases, suspected abuse was confirmed. Among these 25 children, 16 were male and 9 female, the mean age was 18 months, and 20/25 were non-ambulatory. In 6 cases, high-specificity fractures were diagnosed (2 CML, 3 rib-fractures, and 1 in which CML and rib-fractures coexisted). In all of these 6 cases, the children were non-ambulatory. Bruises, abrasions, lacerations, and findings of abusive head trauma were respectively described in 9, 4, 2, and 5 cases. In 10/25 cases, the child’s kin modified the initial version regarding how the fracture occurred. Among the cases with high-specificity fractures, 2 children suffered a fall from less than 1 meter high, and in 2 cases, from more than 1 meter high. In 2 other cases, these data were not available.

According to literature, physical abuse is more likely to be the cause of a fracture in children who are not yet walking. In compliance with that, this study revealed that 20/25 children were not yet ambulatory, with a mean age of 18 months. Moreover, all 6 children who were diagnosed with fracture highly specific for abuse were non-ambulatory.<sup>4</sup>

Other than the specificity of the fracture and the age and developmental stage of the child, the history provided by the caregivers can make a fracture suspicious for child abuse. In 10/25 cases, the caregivers changed the initial history provided or gave discordant explanations. Among the 6 cases with high specificity fractures, the history related to 4 of these was inconsistent with the energy needed to cause the fractures. The kin provided either no detail of the dynamic of the event in 2 cases, or in 2 other cases, related a history of a low-energy event (fall from less than 1 meter).<sup>4</sup> In the study sample, males were more likely to suffer from CA than females, but in literature, no significant gender differences were observed in terms of prevalence of CA.<sup>6</sup> The literature states that CA occurs in all socio-economic groups and across all racial and ethnic groups.<sup>4</sup> In the present report, 20/25 children came from families of low ( $n=16$ ) or average ( $n=4$ ) socio-economic status.

In the present review, only 6/25 cases of CA had highly specific fractures, but in the other cases, the “Bambi” staff diagnosed CA on the basis of other relevant findings. This presentation should serve as a stimulus to heighten the importance of the combination of radiological, clinical, investigative, and social findings in order to achieve a reliable CA diagnosis with a multidisciplinary approach.

### **Child Abuse, Fractures, Multidisciplinary Evaluation**

## E15 A Rare Case of Iatrogenic Skull Damage in a Newborn

Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Federica Gori, MD, University of Pisa, Pisa 56100, ITALY; Chiara Toni, MD, Pisa, ITALY; Sara Turco\*, University of Pisa, Pisa, Italy 56126, ITALY

**Learning Overview:** The goal of this presentation is to inform attendees concerning a very rare case of iatrogenic skull damage in a newborn due to cesarean section delivery without instrumentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making a differential diagnosis of lesions of the newborn, which is mandatory due to medical malpractice and refund implications.

Compared with adults, newborn skull fractures are very rare: the relatively malleable nature of a newborn's skull and bones separated by sutures allows greater deformation and reduces susceptibility to fractures. Skull fractures of the newborn could be linear, usually restricted to one skull bone, complex or depressed, when part of the bone surface is displaced inward (ping-pong fractures).<sup>1</sup> Head fractures of the newborn are usually associated with the use of instrumentation, both in vaginally or cesarean section delivery.<sup>2-5</sup> In literature, there are also cases of newborn skull fractures after complicated delivery due to obstetric maneuvers without instrumentation.<sup>4</sup> Furthermore, some authors reported cases of spontaneous skull fractures associated with the compression of the head of the newborn by the mother's bony pelvis, 5<sup>th</sup> lumbar vertebrae, ischial spines, sacral promontory, and symphysis pubis.<sup>3</sup> Non-depressed compound skull fractures usually have a good prognosis and watchful waiting could be the only treatment, while depressed skull fractures are more frequently associated with blood flow hypoperfusion, brain edema, and tears or ruptures of vessels, which can lead to severe cerebral injury and the creation of epileptic foci.<sup>4,6</sup>

A 32-year-old woman came to the local hospital during her 29<sup>th</sup> week of pregnancy. She had a history of abortion during the 1<sup>st</sup> trimester. The current pregnancy went normally until the 29<sup>th</sup> week, when she was admitted in the obstetric ward for a premature delivery threat. Clinical and instrumental exams were regular, as were laboratory analysis, so the clinicians decided to dismiss the woman. A month later, she had a premature membrane rupture with limpid amniotic fluid. The woman was admitted to the hospital. She was at the 34<sup>th</sup> week of pregnancy. The baby was in a cephalic position, but electronic fetal monitoring showed a non-reassuring fetal heart rate tracing, so the clinician decided to proceed with a cesarean section. The baby was delivered without instrumentation. The surgeon described several attempts at delivery before managing to effectively extract the baby, who had already been deeply engaged in the pelvis. No evident trauma was registered. At the time of delivery, the newborn had an Appearance, Pulse, Grimace, Activity, Respiration (APGAR) of 6 after five minutes and a cardiac pulse of 130/min. The baby didn't cry and breathe, so clinicians started non-invasive ventilation, and, after one minute, they proceeded with mechanical ventilation. The baby presented with a head tumor and hematoma of the head, neck, and upper thorax. Neurologic examination at birth was not performed, because of the clinical condition of the newborn. Sonography of the head revealed a subependymal hemorrhage. During the intensive care recovery, the baby had an epileptic crisis treated with phenobarbital. Electroencephalography revealed pathologic electric activity, without clinical signs and with progressive improvement during the hospital stay. Head Magnetic Resonance Imaging (MRI) performed 18 days after birth showed bilateral parieto-occipital subdural hematoma. A cranial Computed Tomography (CT) made one month after birth revealed a bilateral parietal fracture and a compound skull fracture of the lambdoid suture and of the right coronal suture. In all of these fractures, the theca surface was not displaced inward. At present, the child has spastic quadriplegia. He maintains the sitting position in autonomy, while he needs help to reach and maintain the upright position. Walking is uncoordinated. He presents a cognitive deficit, for which he is followed by specialists.

This case is unusual and deserves attention as the newborn suffered from severe brain damage and severe neurologic sequelae. The goal of this presentation is to explain that even during cesarean section delivery without the use of instrumentation, skull fractures associated with severe brain damage from inadequate obstetric procedures can occur. From a medicolegal point of view, a differential diagnosis of iatrogenic and non-iatrogenic-spontaneous lesions is mandatory due to medical malpractice and refund implications.

## E16 Causes of Death in Patients Under the Age of 65 at the Bari Polyclinic

*Gianni De Giorgio\**, Section of Legal Medicine, Bari, ITALY; *Fiorenza Zotti*, PhD, Bari 70124, ITALY; *Eloisa Maselli*, MD, Bari 70122, ITALY; *Valeria Bruno*, MD, D.I.M., Bari, Puglia 70124, ITALY; *Valentina Ronco*, MD, Section of Legal Medicine D.I.M., Bari 70124, ITALY; *Davide Ferorelli*, Bari, ITALY; *Francesca Donno*, MD, University of Bari, Bari 70121, ITALY; *Alessandro Dell'Erba*, PhD, Risk Management Unit, Bari 70124, ITALY

---

**Learning Overview:** The goal of this presentation is to identify the main causes of death in patients under the age of 65 years, demonstrating how some diseases are stratified by gender and age, probably in relation to specific risk factors, while others affect the study population almost transversely, placing legitimate doubt of environmental influences in the determining of events.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how some diseases are stratified by gender and age, while others affect the study population almost transversely. The stratification of mortality due to death is one of the most reliable epidemiological indicators aimed at monitoring the health status of a population.

According to the latest Italian National Institute of Statistics (ISTAT) report of 2012, beyond congenital pathologies and hematological malignancies that mainly concern childhood, in Italy, the main causes of death in subjects under the age of 65 years are cardiac diseases (16%) and tracheal, bronchial, and pulmonary neoplasms (12%). It is interesting to note that the heart diseases and the neoplastic pathologies—considered as a whole—are equivalent in the male sex, while cardiopathies are much less frequent in the female sex. Remaining in the field of oncological diseases, there is a clear preponderance of broncho-pulmonary and colon-rectal involvement in both sexes, with the addition of the high frequency of breast cancer in women.

The present analysis was conducted through a careful review of the ISTAT cards of patients who died in the Bari Polyclinic in 2017. The data were assessed in relation to the demographic characteristics of the patients (according to sex and age), the cause of death, and the department of hospitalization.

The patients who died in the Polyclinic in 2017, out of a total of 60,012 hospital discharge records, correspond to 1,200 units, of which 22% (268 units) were under 65 years of age. Analyzing the data regarding the sex of patients, among those under 65 years of age, there is a clear prevalence of mortality among male subjects compared to females (61% vs. 39%). The most reoccurrences, in relation to the intrinsic critical situations of patients at the time of admission, correspond to reanimation (33%) and internal medicine (11%). The stratification in relation to the causes of deaths emphasized the role of oncological pathologies in the determinism of deaths in the age group considered: in the Bari Polyclinic, 43% of the deaths in patients under 65 years of age are linked to neoplastic pathologies, followed by cardiovascular diseases (18%) and infections (18%).

Analyzing the neoplasms more specifically, the leading causes of death in the study population, leukemia and lymphomas, represent the most frequent neoplasms (20%), especially in the age group between 40 and 65 years of age; gastrointestinal and female genital-tract cancers are represented by 18% and 16%, respectively. Considering the different distribution of neoplasms in the two sexes, females have a higher mortality linked to tumors of the genital apparatus (41%) and colon-rectal and hematological (36% overall) tumors, while in the male sex it is interesting to note that, in addition to the prevalence of hematological tumors (20%), there is an exclusivity of pulmonary (14%) and hepatic tumors (12%).

Despite the small sample considered, the review conducted allows one to dwell on some peculiarities that partially differ from the national and international trend. First, there is an evident prevalence of neoplastic pathologies compared to heart disease, as well as a significant recurrence of causally related infections with deaths; moreover, in the field of neoplastic pathologies, the main role played by the diseases of the blood and of the blood and lymphatic organs is clear. A possible explanation for these particularities, in light of the risk factors of leukemia and lymphoma (solvents, ionizing radiation, in addition to drugs and congenital deficits), could result from further epidemiological studies related to environmental characteristics of the city and the province. Last, the pulmonary and hepatic neoplasms, exclusively in the case of the male sex, could be part of a still partially consolidated difference in lifestyle, relative to voluptuous habits.

### Mortality, Patients, Neoplasms

### E17 An Analysis of Death at Long-Term Care Health Facilities in Japan

Alissa M. Shida, BA\*, *Department of Legal Medicine, Osaka, Osaka 545-0052, JAPAN*

**Learning Overview:** After attending this presentation, attendees will understand the risk factors in nursing homes in Japan and how preventing these risks factors would help that society.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reviewing the records of autopsy cases of nursing homes and helping the investigation that occurs in these facilities.

Japan's declining birth rate and aging population are severe, even when compared to the demographic situation in other developed countries. With the related explosion in the number of long-term care health facilities established to cope with increasing numbers of community-dwelling elderly, Japan is facing social issues concerning the recognition of unnatural deaths. Based on forensic autopsy cases at the Department of Legal Medicine, Osaka City University Medical School, the present study analyzed deaths at long-term care facilities from the perspective of social medicine.

The records of 26 autopsies performed between 2005 and 2015 at the Department of Legal Medicine, Osaka City University Medical School, Osaka, Japan, of deaths at long-term care health facilities were investigated regarding characteristics such as age, sex, time of death, type of long-term care facility, number of nursing care staff, state of care, cause of death (internal and external causes), medical history, and autopsy findings.

A total of 26 (1.2%) of the 2,211 autopsies performed at the Department of Legal Medicine, Osaka City University Medical School between 2005 and 2015 were of deaths at nursing homes, ranging from approximately two to four cases per year. Women and individuals in their 80s represented 65% ( $n=17$ ) and 46% of cases, respectively. By facility type, most cases were from special nursing homes for the elderly (publicly operated facilities that provide nursing and custodial care services to elderly people requiring everyday care (65%;  $n=17$ ), followed by private residential care homes (privately operated homes for the elderly that provide nursing care services to relatively self-reliant elderly people;) (34%;  $n=9$ ). There was also one case each from an intermediate care facility (facilities aimed at helping residents  $\geq 65$  years old to return home) and a private nursing care home (privately operated residential facilities with 24-hour staffing for elderly people requiring nursing care).

For both internal and external causes, more deaths occurred at night (69%;  $n=18$ ) due to lack of staff compared to daytime (two staff). Causes of death were external in 15 cases and internal in 11 cases. After internal causes, the most common causes of death were blunt force trauma followed by drowning, asphyxia, and fire. The most common internal causes of death were cardiovascular disease (46%), pneumonia (18%), and malnutrition (18%). Known illnesses diagnosed before death included hypertension (34%;  $n=9$ ), dementia (30%;  $n=8$ ), cerebral infarction (23%;  $n=6$ ), and diabetes mellitus (11%;  $n=3$ ). Conversely, central nervous system diseases (46%;  $n=12$ ), circulatory conditions (42%;  $n=11$ ), and digestive system disorders (42%;  $n=11$ ) were only identified during autopsy. The predominant cause of blunt force trauma was falling, which is the most common external cause of death (60%;  $n=9$ ). Among these cases, 56% ( $n=5$ ) were to the head. Suspected negligence was involved in three cases of bathtub drowning, three cases of wheelchair falls, two accidents during assistance with activities such as changing clothes, and one case of aspiration and asphyxia while eating. Of these nine cases of suspected negligence, 78% ( $n=7$ ) occurred when staff was not in attendance. The present findings suggest that with the increasing establishment of long-term care facilities in response to the declining birth rate and aging population, systems of facility staffing and medical treatment by professionals such as doctors and nurses should be verified.

#### Legal, Health Care, Aging Population

### E18 The Faithless Nurse: A Strange Case of Hyperthermia

*Francesca Maglietta, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Lorenzo Spagnolo, MD*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Michela Ferrara, MD*, Department of Forensic Pathology, Foggia 71122, ITALY; *Dania De Carlo, MD*, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; *Giuseppe Davide Albano, MD*, Foggia 71121, ITALY; *Mauro A. Ciavarella, University of Foggia, Department of Forensic Pathology, Foggia 71121, ITALY*

**Learning Overview:** The goal of this presentation is to illustrate the risk of developing serotonin syndrome, particularly with cases involving administration of narcotics, such as methadone, in conjunction with other serotonergic agents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enhancing awareness regarding co-administration of serotonergic agents among heroin abusers who receive methadone maintenance therapy. This presentation will also stress the importance of developing the knowledge of mechanisms leading to hyperthermia and related to methadone consumption that have proven to be the culprit of serotonin syndrome.

Toxicological investigations are essential in identifying narcotics opioids overuse in suspected patients and should be performed routinely, but, unfortunately, the metabolism of methadone demonstrates extreme interindividual variation. This results in physicians not always performing a correct diagnosis in cases of serotonin syndrome. Clinical presentation includes a triad of autonomic instability (tachycardia, tachypnea, and hypertension), altered mental status (agitation and coma), and neuromuscular overactivity (increased tone). In life-threatening conditions, severe hyperthermia, hypertension, and tachycardia may lead to frank shock and coma. Typically, symptom onset occurs rapidly within hours of an increased dose of a serotonergic agent. Data from the Centers for Disease Control and Prevention (CDC) reveal that the United States opioid overdose epidemic continues to worsen, and guidelines on the prescription of opioids in chronic pain situations do not recommend the simultaneous administration of narcotics with other serotonergic agents.

In the hot summer of 2014 in Foggia, in the south of Italy, many inmates of the local prison experienced illness due to high temperatures. A 51-year-old man was found unconscious in the bed of his cell, wearing nine sweaters and three pairs of pants, covered with a wool blanket. The windows and the blind (type of door) of the cell were closed and the jail cell temperature was 29° Celsius. The man was rescued, transported to the hospital, and died shortly after his arrival at the emergency department from a malignant arrhythmia. The anamnestic data revealed that the man was a heroin addicted in daily treatment with methadone, paroxetine, and quietapine, and suffered from both Klinefelter Syndrome with hormone replacement treatment and from an anxious-depressive disorder. Approximately four hours after death, his rectal temperature was 41° Celsius. The external examination conducted on the cadaver was negative for signs of acupuncture or traumatic injury. Autopsy of the convict was performed after two days, with a complete biological sampling for toxicological purposes. Not surprisingly, all organs exhibited unspecific gross alterations and the immunohistochemical staining of kidney samples revealed some lumens and epithelial cells of proximal and distal renal tubules positive to anti-myoglobin antibody. Serum samples, collected at the time of hospitalization, detected positivity for paroxetine, quietapine, and methadone. However, the kidney and liver failure made it impossible to quantify the rate of recruitment due to a slowdown in the reduction in the elimination rate.

The results of criminal investigation by the police revealed that the nurse who took care of him had given him two doses of methadone, claiming that the first dose was inadvertently dropped while being taken in the cell. This scenario was reconstructed. Positivity in serum of paroxetine, a drug usually taken by the prisoner, justified its predisposition. By virtue of the inhibition that this SSRI has on cytochrome CYP2D6 and 3D4, it allowed a greater sensitivity to the double dose of methadone, favored the rapid development of a serotonin syndrome associated with coma and malignant hyperthermia, and allowed the settlement and orientation of the known inconclusive gross and histological findings for the syndrome.

#### **Methadone, Serotonin Syndrome, Hyperthermia**

### E19 A Tale of Two Sisters: A Case Review of a Suicide Pact Between Adult Siblings

Meryle A. Dotson, MA\*, Hillsborough County Medical Examiner's Office, Tampa, FL 33616; Mary Mainland, MD, Hillsborough County Medical Examiner's Office, Tampa, FL 33617

**Learning Overview:** After attending this presentation, attendees will be more familiar with a case of a successful suicide pact involving two adult siblings by ingestion of tramadol, doxylamine, diphenhydramine, and hydrocodone.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a unique scenario in which a thorough investigation of the death scene revealed evidence of premeditation and cooperation between two sisters who chose to enter into an agreement to end their lives together.

This information will assist law enforcement and medicolegal investigators by contributing to the understanding of the manner in which a scene investigation can reveal the sequence of events leading to the simultaneous deaths of two individuals. In this case, a multidisciplinary approach to death investigation was imperative. A detailed examination of the scene, thorough autopsy examination, and toxicological analysis permitted investigators to reasonably exclude the deaths to be results of a homicide-suicide.

A suicide pact is defined as a mutual agreement between two or more people to kill themselves, usually at the same time and location.<sup>1</sup> Suicide pacts are rare occurrences and represent less than four percent of all suicides. The frequency of successful suicide pacts is noted to be highest in Japan, where suicide pacts are more often reported among lovers.<sup>2</sup> In the United States, suicide pacts have been reported among aging, married couples as well as among siblings who face separation due to the ailing health of another sibling.<sup>1</sup> When investigating cases of reported suicide pacts involving two decedents, a thorough investigation of the death scene is imperative in determining whether the deaths of both individuals are a result of a successful suicide pact as opposed to a homicide-suicide. An essential component of a suicide pact that can be identified at the death scene is evidence of consent by both parties.<sup>3</sup> This presentation will present circumstances of the scene investigation and autopsy findings for an unusual case in which a successful suicide pact was carried out between two adult sisters who entered into an agreement to end their lives together, likely due to the failing health of the older sister.

The deceased in this case are a 61-year-old woman and her 52-year-old sister who resided together in an apartment in a residential Florida neighborhood. The older sister was previously diagnosed with multiple medical conditions, and her younger sister served as her primary caretaker. Neither sister had been seen during the week prior to being found deceased. Apartment complex staff noted a foul odor emanating from the residence and contacted law enforcement. Law enforcement forced entry into the residence and located the bodies of both siblings in states of decomposition on a bed in a rear bedroom. A table in the corner of the room contained two personalized memory boxes, urns, and pre-need contracts for cremation authorized by each sibling. A handwritten letter in the bedroom stated that the younger sister was not willing to continue life without her older sister and provided explicit instructions for final disposition of their bodies. The letter indicated that the sisters had no other surviving family members, and that they "choose euthanasia." The letter contained the signatures of both sisters. There was no apparent trauma to the bodies. Multiple empty juice bottles, empty pudding cups, and two empty vials bearing the initials of each sister were recovered from a plastic bin beside the bed. After subsequent investigation of the circumstances, foul play was not suspected.

When investigating a death scene of a potential suicide pact, investigators should keep in mind the possibility that the deaths may be the results of a homicide-suicide. Due to their rare occurrences, suicide pacts are infrequently reported in the literature. However, the cases that are published describe several hallmarks of a suicide pact that can be identified at the death scene.<sup>3</sup> Consent and understanding among all parties, detailed planning performed in secrecy, and execution of the pact in privacy are components of a suicide pact that cannot be identified by autopsy alone. This case study contributes to the documentation of suicide pacts between siblings in the United States and illustrates that a thorough, multidisciplinary investigation of the death scene is necessary in order to confidently determine the of manner of death as suicide by consensual means.

#### Double Suicide, Suicide Pact, Death Scene Investigation

### E20 A Case of Strangulation With a Cable Tie: Homicide or Suicide?

*Omar Bonato, MD\*, University of Ferrara, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Ferrara 44121, ITALY; Mauro Coppone, MD\*, University of Ferrara, Ferrara 44121, ITALY; Erica Bacchio, MD, University of Ferrara, Ferrara 44121, ITALY; Chiara Marini, MD, University of Ferrara, Ferrara 44121, ITALY; Letizia Alfieri, MD, University of Ferrara, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Lorenzo Marinelli, AOU Arcispedale Sant'Anna, Ferrara 44124, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY*

**Learning Overview:** The goal of this presentation is to expose a case of self-strangulation suicide in which plastic cable ties were used, analyzing and drawing attention to features that can be found in a forensic investigation in cases of suicidal and homicidal ligature strangulation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that, in a case of ligature strangulation, the differentiation between homicide and suicide can be difficult. This presentation can provide important support for the management of similar forensic cases.

Self-strangulation by ligature is an uncommon occurrence in forensic practice. In fact, strangulation cases are primarily homicides, with a few cases of sexual asphyxia or suicide.

A dead body of a 32-year-old male of Moldavian origin was found by the police at 1:40 a.m. along an isolated country road next to a truck. The victim was found in a supine position with a single plastic cable tie around the neck, with the knot (locking head) on the right posterolateral cervical region. Additionally, three cable ties around the ankles were documented. On the right side of the neck, a metal pincer was found, with the cutting edges that clamped a cutaneous fold immediately above the ligature. The subject had no history of psychiatric disorders, but financial problems were reported. Police officers initially suspected homicide.

A medicolegal autopsy was conducted the next day. At external examination, there was marked facial congestion with massive petechial hemorrhage in the face and in the conjunctivae. The ligature-produced furrow was evaluated after the ligature was removed; it was horizontally oriented, pale, deep, and encircled the neck completely. The pattern of the internal surface of the cable tie was reproduced in the furrow. The right cervical region, where the pincer was found, showed two small superficial injuries of the skin, with hemorrhagic infiltrates. No other external injuries were noted on the body.

Internal examination of the neck showed some hemorrhages of the left thyrohyoid muscle, thyroid cartilage, hyoid bone, base of the tongue, palatine tonsil, and to the cervical prevertebral fascia. No fractures to anatomical structures of the neck or elsewhere were found. All organs were congested, with petechiae on serosal surfaces of epicardium and visceral pleura. There were no other significant findings at autopsy. Histopathological examination of the skin on the furrow showed the vitality of the wound. No signs of struggle or other antemortem injuries were found. The ligature at the ankles were loosely bound and were easily released. The death was deemed a suicide by ligature strangulation.

There have been only a few previous reports in the literature regarding self-strangulation suicide in which cable ties were used. More often-described case reports involve the use of belts, ropes, and scarves. Furthermore, this study presents an unusual case of suicide in which plastic cable ties were used both for self-strangulation and for self-restraint of the ankles to prevent any possibility of getting free. However, the neck wounds made with the pincer to undo the ligatures appear unusual because, in similar cases, injuries indicating an attempt to relieve applied pressure are not seen, underscoring the rapid loss of consciousness.

In cases of ligature strangulation, forensic pathologists have to consider all the circumstances (crime scene investigation, historical data, autopsy, and histopathological examination) in order to differentiate between homicide and suicide, especially when the crime scene investigation is ambiguous.

#### **Strangulation, Suicide, Autopsy**

### E21 The Evolving Suicide Note

*Imron G. Ramos, BS\*, Clovis, CA 93619; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037*

---

**Learning Overview:** After attending this presentation, attendees will understand the importance of social media and electronic devices as an evolving entity for medicolegal death investigation compared to the age-old method of examining handwritten suicide notes, offering important legal implications regarding the manner of death of suicide vs. homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a detailed review of data collected over a ten-year period (2007–2016), reviewing all cases in which the manner of death was documented as a suicide. Case-related data was also obtained from the Community Regional Medical Center in Fresno, CA, and is the only Level 1 Trauma Center between Sacramento and Los Angeles, thus treating and serving surrounding counties in Central California.

Most research regarding suicide and the notes left behind by the deceased begin by reviewing the medicolegal death investigation file, coroner's inquest, and/or medical examiner's report. Medicolegal death investigators are responsible for recording and documenting suicide notes found during their investigation. In this study, suicide notes were divided into media and non-media types. Non-media suicide notes are handwritten. Media suicide notes are generated by a computer, cell phone, audio, video, social media platform (i.e., Facebook), or any other type of electronic communication device, and whether the suicide note, if left on a cellular phone, was a text message or an instant message.

This research project had four objectives to determine if there were notable difference between non-media and media suicide notes and how the notes were left. Objective 1 was to determine if people are leaving significantly less non-media suicide notes compared to media suicide notes. Objective 2 was to determine if younger people are leaving significantly more media suicide notes than older people. Objective 3 was to see if there is a significant increasing rate of media suicide notes over each year for the past ten years. Objective 4 was to determine if personal cell phones are the main source for leaving media suicide notes compared to all the other electronic devices

Of the 881 total suicide victims, 212 left a suicide note (24%). Out of the 212 suicide notes left, 162 (76%) were non-media notes and 54 (24%) were media suicide notes. Of the media suicide notes left, 87% were left by cell phone over the entire ten-year span of collected data. However, in 2007–2011, 17 media suicide notes were left, and from 2012–2016, 37 media suicide notes were left, reflecting an increase of 217%. Although the suicide note rate has remained relatively consistent over the ten-year span, the frequency of social media notes has increased when compared to non-media suicide notes over the most recent five-year time frame.

These results show that media suicide notes are being left in a higher frequency than non-media notes and that cell phones are the preferred mode of leaving these notes. This apparent change over the manner in which suicide victims convey their innermost thoughts to those left behind may be indicative of the population statistics that showed in 2016, 28.6% of the population were under 18 years of age and 11.8 % were 65 years and older, with 59.6% between these age groups. Thus, the use of social media for leaving behind suicide notes, by a younger population more familiar with the internet and those tools, would not be unusual. It also suggests that there may be suicide ideations on the social media links.

### E22 Determining the Accuracy and Suitability of Measurement Apps for Crime Scene Documentation

Victoria Zeger\*, West Melbourne, FL 32904; Christina A. Malone, MSFS, Defense Forensic Science Center, Forest Park, GA 30305

**Learning Overview:** After attending this presentation, attendees will better understand the current capabilities of several mobile device measuring software applications (apps) that have the potential for obtaining measurements when documenting a crime scene.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the benefits and limitations of the forensic use of mobile device measuring apps and the potential for such apps to be a low-cost, user-friendly, and efficient method of collecting measurements at a crime scene.

The spatial location of evidence drives crime scene documentation, requiring the measurement of numerous distances during the course of a criminal investigation. One major advantage of crime scene documentation involves placing the judge and jury into the scene through reconstruction techniques. Traditional reconstruction techniques are laborious and time consuming, while automated methods for capturing distance measurements (e.g., total stations and 3D laser scanners) may be cost restrictive. An efficient, portable, cost-effective device that can match the accuracy of a tape measure is ideal for crime scene documentation.

With the prevalence of mobile devices, the development of apps has flourished. The advancements in technology have resulted in the inclusion of augmented reality into these applications, allowing real and virtual worlds to interact in real time. Measurement apps can generate distance measurements either through augmented reality or point-and-shoot methods. However, both methods involve a set of algorithms that utilize data from sensors to output measurements. Image sensors and display sensors are major contributors of input data and offer technical limitations to the application and variability among devices. The sensitivity of the technology in the mobile devices and the precision of the data type used in the application are critical for accurate outputs.

Three mobile phones (Apple® iPhone® 7 Plus, Samsung™ Galaxy Note® 3, and Amazon® Fire®) were selected for use in this study due to their availability. Pertinent information on each phone was documented due to the potential impact of the operating system and sensor size/type when collecting distance measurements through each phone's camera. A series of known distances was established through hand measurement with a tape measure. Repeated distance measurements were then collected using each of three apps (AirMeasure, Smart Measure, and 3D Measure) specific to the phones operating systems (iOS®, Android®, and Fire® OS, respectively). Factors that were presumed to affect the accuracy of the measurements, such as distance from which the measurement was taken, lighting, angle, and shape/size of objects, were assessed. Statistical analyses were conducted to determine which apps produced the most consistent and accurate results compared to the hand-measured distances. The data collected, combined with an assessment of the ease of use for each app, demonstrates the benefits, limitations, and overall suitability for using mobile measuring apps for crime scene documentation.

### E23 Observation, Explanation, and Testing in Forensic Science Using a Death Investigation Active Learning Assignment

*Trevor I. Stamper, PhD\*, Purdue University, West Lafayette, IN 47907; Krystal R. Hans, PhD, Delaware State University, Dover, DE 19901*

---

**Learning Overview:** After attending this presentation, attendees will understand some principles for instructing students in teaching scientific observation, explanation, and testing in an undergraduate education setting using forensic examples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an understanding on how framing the scientific method in the proper context can allow students to better understand how the forensic process is itself scientific, from the collection of the trace to the use of that trace in trial.

Traditional forensic science textbooks offer little guidance on how to approach teaching the salient features of the scientific method—observation, explanation, and testing—as an inherently *forensic* endeavor. However, without an appreciation of the scientific method, teaching forensic subdisciplines is more science appreciation than science application. Over four iterations of Purdue’s Entomology (ENTM) 22810: Forensic Investigation course, students were provided detailed scientific method active learning assignments, but failed to connect these assignments to the scientific method and forensic science subdisciplines. It was realized that this was the result of using non-forensic examples or forensic examples lacking a trackable process with a discernable beginning, middle, and end. To resolve these disconnects, an active learning assignment was created from a real *New York Times* article series of a 1922 double death investigation. The current assignment has been used in four iterations of ENTM 22810: Forensic Investigation.

This case study demonstrates the importance of observation, explanation, and testing in a forensic science context, and also allows students an approachable way to grasp the concepts of relevance and anomalous phenomena. Further, students are trained to differentiate facts, conjectures, and assumptions from each other. Students assess how these different elements impact the possible explanations for the deaths of Mr. and Mrs. Jackson as the case matures. This is accomplished because students organize the various explanations using a supported argument format. The assignment further provides students with an inquiry-based structure to objectively evaluate observation events not previously presented in the forensic context.

This case highlights the actions of the first forensic toxicologist in the United States, Alexander Gettler, while at the same time exploring the impact that historical events, such as prohibition, have on cases. Teaching methods are highlighted and physical examples of the *New York Times* articles and active learning assignments are presented for attendees to review. Students enrolled in this course completed surveys prior to this assignment to serve as a baseline measurement of knowledge regarding crucial concepts: anomalous phenomenon, relevance, observation, explanation, testing, and understanding the difference between facts, conjectures, and assumptions. At the end of the semester, after completing the active learning assignment, students are provided with a post-assignment survey. Student learning was assessed by comparing the students’ abilities to decipher these concepts from the beginning to the end of the semester.

---

#### Undergraduate Education, Scientific Methods, Case Analysis

## E24 The Development of a Flexible Algorithm for Substance Identification Using Mass Spectrometry

*Samantha A. Mehnert\**, West Virginia University, Morgantown, WV 26506; *Brandon D. Lowe*, St. Vincent College, Latrobe, PA 15650; *J. Tyler Davidson*, MS, West Virginia University, Morgantown, WV 26505; *Glen P. Jackson, PhD*, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will better understand the value of ion correlations in mass spectrometric analyses through the demonstration of a dynamic algorithm that provides higher discriminatory power and increased confidence in mass spectrometric compound identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a mathematical model for compound identification from mass spectrometric data that is more accurate and more precise than current static/discrete methods. The application of a more selective algorithm will decrease the incidence of false positives and further assist with the identification of unknown compounds.

It is hypothesized that a mathematical model that employs the covariance between ion abundances will provide a more discriminatory algorithm with improved compound identification rates relative to a model that does not take into account the covariance between ion abundances.

Current mass spectrometric methods of substance identification use a static algorithm to determine the identity of a substance. Existing algorithms compare the relative abundance of each peak within a given spectrum to those of discrete reference spectra in a library. However, the variance in ion abundances for this type of comparison is generally around  $\pm 20\%$ , which can result in false positives for substance identification. An algorithm that can adapt to varying relative ion abundances using a continuously variable model will provide a more selective and more accurate identification algorithm than the current discrete methods.

Replicate measurements of various chemical standards show that ion abundances within replicate mass spectra of the same compound are not independently variable, but correlated or anti-correlated with coefficients of correlation as strong as an  $R^2 \geq 0.8$ . Two databases were developed to assess the accuracy and selectivity of this dynamic model. The first database consists of five illicit drugs, and the second database was comprising eight n-alkanes. The ion abundances were normalized to the base peak and the 15–16 most abundant ions were selected to be the dependent variables within the general linear models. The general linear models were constructed within SPSS statistical software using 90% of the spectra in each database. The remaining 10% of the spectra were used to assess the accuracy of the model. The model essentially predicts ion abundances at each  $m/z$  value, and these predicted abundances are then compared to the measured spectra using Pearson product-Moment Correlations (PPMCs). The significance of different PPMC's were compared through z-tests on Fisher transformations of the PPMC's.

The dynamic/continuous model was able to distinguish between the five illicit drugs with ease. The model provided significantly better ion abundance predictions for true positives than for true negatives, which is a requirement of a successful model. Consecutive n-alkanes (e.g., C16 vs. C17) were difficult to discriminate using comparisons of the PPMC's, so additional statistical analyses were performed to provide meaningful assessments for spectral identifications.

### Dynamic Algorithm, Mass Spectrometry, Ion Correlations

### **E25 A Qualitative Analysis of Human Growth Hormone (HGH) by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) and Complementary Techniques**

*Breanne Hamlett\*, Defense Forensic Science Center, Forest Park, GA 30297; Natalie Howard, BS, Defense Forensic Science Center, Forest Park, GA 30297; Anna L. Deakin, MS, Defense Forensic Science Center, Forest Park, GA 30297; Brent M. Allred, PhD, Defense Forensic Science Center, Forest Park, GA 30297*

**Learning Overview:** The goal of this presentation is to introduce attendees to the analysis and identification of protein-based molecules used in conjunction with controlled steroids, such as HGH. Liquid Chromatography/Mass Spectrometry (LC/MS) and LC/MS/MS methods on intact and digested proteins will be discussed, as well as the theory and protocol for commercial Enzyme-Linked Immuno-Sorbent Assay (ELISA) kits specific to the protein of interest.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a new series of techniques for highly specific identification of a protein-based hormone, such as HGH.

The United States Food and Drug Administration states that HGH and other related proteins are only approved as a prescription for a limited number of conditions and are prohibited for use as an anti-aging product, body-building supplement, or for muscle enhancement. Independently, United States Army Regulation 600-85 prohibits the use of prescription medications for anything other than their intended purpose or possessing a medication without a prescription. Military investigating agents often submit for analysis HGH and related proteins along with other controlled steroids. When submitted substances are suspected to be testosterone-related steroids, there are routine small molecule assays suitable for their identification. However, due to their complexity and size, proteins such as HGH must be analyzed using alternative methodologies.

In this study, HGH was analyzed using two LC/MS/MS-based methods, as well as sandwich ELISAs. The intact HGH protein was analyzed via LC/MS using a reverse phase, highly porous column. The intact protein demonstrated a repeatable retention time and characteristic multiply-charged ions from which the whole molecular weight of intact HGH was calculable. The ELISA-based assay successfully bound the folded HGH protein as indicated by the colorimetric response, with no observed cross-reactivity. Last, the trypsin digested peptide sequencing assay provided the greatest specificity. Predictable peptide fragments, unique to HGH, were obtained via a classic trypsin digestion of the protein, then were sequenced using LC/MS/MS fragmentation. An average of 85% coverage of the protein's expected peptides was observed. The ten specific HGH peptides that were further fragmented to acquire amino acid sequencing data resulted in the unique identification of HGH when compared to more than 139 million sequences in the National Center for Biotechnology Information (NCBI) protein database. Each of the three experimental methods resulted in complementary and orthogonal proteomic data, thereby making the identification of HGH highly specific.

Once an identification protocol was developed, the stability of HGH was investigated, since submitted samples can be in various states of degradation, potentially resulting in the misidentification of the protein. Numerous storage conditions were probed, including as a lyophilized powder or in assorted diluents, at different temperature ranges (up to 37°C), and over various time scales (up to three months).

For up to one month, no samples, regardless of storage conditions, showed degradation in the whole molecule LC/MS method, the trypsin digested LC/MS/MS method, or the ELISA method.

While the pros and cons of each method should be considered when creating an overall method for protein identification, the complementary information gained from each technique creates an overall highly specific method for the identification of HGH. The introduction of probabilistic language into forensic chemistry chemical identification reports will be discussed.

**E26 WITHDRAWN**

## E27 Flubromazepam: Synthesis and Characterization of Positional Isomers for Forensic Analysis

*Evelyn S. Ligon\**, Atlanta, GA 30318; *Jason R. Nawyn, MSFS*, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297; *Lonnie V. Jones II, BS*, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297; *Stefan A. France, PhD*, Georgia Institute of Technology, Atlanta, GA 30332; *Brent M. Allred, PhD*, Defense Forensic Science Center, Forest Park, GA 30297; *Daniel V. Reinhardt, PhD*, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297

**Learning Overview:** The goal of this presentation is to demonstrate a complementary application of organic and analytical chemistry for the forensic analysis of Novel Psychoactive Substances (NPS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing: (1) useful reference data for flubromazepam, a designer benzodiazepine of interest, and its 11 positional isomers; (2) a synthetic scheme to prepare pure standards of additional benzodiazepine positional isomers; and (3) a baseline analytical protocol to facilitate future forensic analysis, whether through new reference spectra or through predictions derived from spectral pattern recognition.

Benzodiazepines constitute a class of sedative, depressant, and relaxant compounds, many of which are controlled under Schedule IV of the United States Code Controlled Substances Act. Positional isomers of benzodiazepines are nearly identical structurally and are expected to exhibit similar bioactivity as a result. But due to the technically legal status of various benzodiazepine isomers, as the definition of “analog” in the Code of Federal Regulations does not apply to Schedule IV benzodiazepines, they represent potentially attractive substitutes for drug abuse. Few of these positional isomers are represented in scientific literature and, consequently, the reference analytical data or commercial reference standards necessary for accurate identification are not available to forensic chemists. Therefore, if a positional isomer of a scheduled benzodiazepine were ever presented as a legal alternative by a distributor, positive identification would prove challenging due to the lack of characteristic reference data.

In this study, flubromazepam, a recognized designer benzodiazepine since 2012, was targeted for synthesis and characterization due to its potential for federal scheduling. Currently, flubromazepam is not federally scheduled within the United States, but the strict laws imposed on military personnel to ensure operational readiness still make this a compound of active interest to the United States Department of Defense. Additionally, flubromazepam has appeared as evidence submitted in forensic casework with regard to investigations concerning drug-related civilian crimes and military operational readiness violations.

This project was divided into two phases: synthesis and characterization. First, a uniform synthetic method was developed to prepare purified reference materials of each positional isomer of flubromazepam for which the positions of aromatically bound bromine and fluorine were varied. Traditional methods are not optimal for these positional isomers, as they are low-yielding and non-regioselective, leading either to amounts of precursor so small as to prevent completion of the synthesis or to mixtures of isomers that are difficult to separate. Though the chemistry employed in this study would likely not be used by typical drug distributors, sufficient pure quantities of each isomer were successfully obtained for analysis.

Second, the corresponding analytical reference spectra for each positional isomer of flubromazepam were collected. The structural identification of synthesized flubromazepam isomers were validated primarily using High Resolution Accurate Mass Spectrometry (HRAMS) and both Proton and Carbon Nuclear Magnetic Resonance ( $^1\text{H}$ -/ $^{13}\text{C}$ -NMR). Isomers were then characterized using traditional forensic analytical techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Mass Spectrometry (LC/MS), and Gas Chromatography/solid phase Infrared Spectroscopy (GC/IR). From this data, an analytical scheme was developed to accurately identify and differentiate each positional isomer of flubromazepam. Additionally, pattern recognition by NMR and IR was established to enable predictive analysis of unknown positional isomers that may appear in future forensic cases.

### **Flubromazepam, Positional Isomer, Novel Psychoactive Substance (NPS)**

### E28 Sudden Infant Death in a Newborn From Drug-Dependent Parents: The Utility of Hair Analysis

Costanza Filomena\*, Pisa 56126, ITALY; Silvio Chericoni, University of Pisa, Pisa, ITALY; Fabio Stefanelli, University of Pisa, Pisa, ITALY; Chiara Toni, MD, Pisa, ITALY

**Learning Overview:** The goal of this presentation is to emphasize the usefulness of hair analysis to identify chronic exposure and life-threatening situations for children of drug-dependent parents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing specific neonatal data that are lacking and that the interpretation of hair results with respect to systemic or only external exposure is particularly important for an accurate assessment of the toxic health risk.

Drugs abuse is on the rise in our society and with the growing use of methadone in adults, the number of poison exposure cases in infants is increasing. Drug-related deaths in infants is more difficult to identify due to the different pharmacological parameters and the lack of specific data. Moreover, it is difficult to distinguish between systemic incorporation into hair after ingestion and external contamination. However, the difference is crucial to assess particularly dangerous situations and evaluate the health risk. Therefore, the parameter of hair concentrations should not be used alone since it could be difficult to interpret. As a consequence, forensic experts should take into consideration this datum together with a thorough investigative history and laboratory and autopsy findings.

Pediatric exposure to drugs is relatively rare but concerning, with potentially serious complications, such as seizures, dysrhythmias, and death. The variations in pediatric metabolism and the lack of neonatal data make a precise diagnosis difficult. This may contribute to these cases being labeled as “undetermined” by the forensic community. Hair has been suggested to be a suitable matrix to document repetitive exposure to drugs.

Reported here is the case of a sudden and unexpected death of a 5-month-old girl born to drug-addicted parents. The infant was delivered by cesarean section after a full-term pregnancy. Newborn urine was positive for methadone, as her mother had a known history of methadone intake during pregnancy. The baby had a withdrawal syndrome treated by phenobarbital. The infant was discharged from the hospital healthy. At home, she was both breast- and bottle-fed. Four months after birth, the baby had a seizure, spontaneously solved, and Electrocardiogram (ECG) and Electroencephalograph (EEG) were unremarkable. The day the child died, she had fever for which she had been given acetaminophen. In the evening, she had her meal and fell asleep, but soon after she started to vomit. Emergency services were called, and cardiopulmonary resuscitative maneuvers were initiated by the parents. The infant arrived at the emergency room in asystolic arrest and could not be resuscitated. Blood tests showed anemia and leukocytosis. An autopsy was disposed by the local prosecutor.

At the external examination, traumatic injury was not observed; postmortem Computed Tomography (CT), autopsy, and microbiological and histopathological examination revealed no significant findings. Also, the toxicological analyses, Liquid Chromatography/High Resolution Mass Spectrometry (LC/HRMS), performed on the peripheral blood and organ specimens were negative. Instead, hair analysis showed a strong positivity for methadone (2.3ng/mg) and its metabolite EDDP (0.1ng/mg), cocaine (2.6ng/mg) and its metabolite benzoylecgonine (0.75ng/mg), 6-monoacetylmorphine (a direct metabolite of heroin, (0.2ng/mg), and morphine (1.0ng/mg), suggesting chronic exposure to cocaine, methadone, and heroin. Literature reveals the association between sudden death (due to arrhythmias, seizures, or respiratory failure) and chronic exposure to such substances; accordingly, the infant’s death can be reasonably attributable to the combined effect of all these drugs.

In young children, the major problem in testing hair for drugs is the interpretation of the findings. Hair is thinner and more porous than in adults and therefore the risk of contamination by sweat is higher, the growing is asynchronous, and it is difficult to detect. Transfer through sweat can be the result of contact with pillows, bedding, parental kisses, and skin contact, and it is the first reason to have positive hair tests in children. Considering that metabolites could also be present in large amounts in sweat, their presence cannot be discriminative for drug administration or accidental intake. Moreover, drugs positivity in children’s hair could be the result of *in utero* exposure.

#### Drug Intoxication, Sudden Infant Deaths, Hair Analysis

### E29 A Novel Vapor Delivery Device for Homemade Explosive Analysis

*Laurn DeGreeff, PhD\*, U.S. Naval Research Laboratory, Washington, DC 20002; Christopher J. Katilie, Nova Research, Inc., Alexandria, VA 22308; Susan Rose-Pehrsson, PhD, U.S. Naval Research Laboratory, Washington, DC; Michael Malito, Nova Research, Inc, Alexandria, VA*

**Learning Overview:** After attending this presentation, attendees will have learned about binary explosive mixtures used in Homemade Explosives (HMEs) and will understand safety concerns that limit work, be it research, vapor generation, or canine training, with such materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a method of HME vapor delivery and generation using two novel odor delivery devices and how such devices can be used to overcome the challenge of working with binary explosive materials.

HMEs are commonly found in Improvised Explosive Devices (IEDs) that have become increasingly commonplace in Middle East conflicts and also pose a threat at home. HMEs are often composed of simple, binary mixtures of an oxidizer and a fuel. The individual components often have common, innocuous uses, independent when separated, but form an explosive mixture when combined. Common examples of oxidizers are Ammonium Nitrate (AN) or Potassium Chlorate ( $\text{KClO}_4$ ), and examples of fuels include, but are not limited to, aluminum powder and fuel oil.

Mixed explosives are often difficult and expensive to safely obtain, store, and transport. Safety measures may limit use to same-day production with strict mass limits and disposal protocols. These regulations often restrict or preclude training, analytical research, and other testing using the mixtures themselves. For this reason, detection protocols often focus on the detection or sensing of the oxidizer alone. Canines, for example, are often trained on solely AN and not AN-fuel mixtures, though recent canine evaluations have shown that the canines perform better when trained to the mixed components.

A novel Mixed Odor Delivery Device (MODD) was designed to safely contain the solid or liquid components of HMEs and deliver the HME vapor signature for passive or active sampling. Within the device, vapors from the separately housed components mix as they move through the device toward the outlet. The resulting mixed vapor is representative of that which would be achieved from the actual mixed explosive material. For active sampling, air flows from an external source, through the device, carrying the mixed analyte vapor toward the instrument of choice. For passive sampling, component vapor diffuses from the bulk material through a Teflon<sup>®</sup> neck, where vapors mix before exiting the device at a bowl-shaped outlet. Both active and passive transport devices have been tested with surrogate components as well as actual explosive components. The MODD offers transportability and ruggedness for field use with minimal sample size requirement and is easily adaptable for the varied components one might encounter in the field.

Initial characterization of the active MODD was conducted using single compounds characteristic of HME components. The equilibration time for each compound in the device and the stability of the equilibrium concentration over time was measured with a focus on flow rate and temperature dependence. Run-to-run and day-to-day reproducibility in vapor generation using the MODD was illustrated by the generation of octane and 2-phenylethyl alcohol (separately) from the MODD. The equilibrium vapor concentrations for both compounds were shown to be stable for more than four hours and were reproducible over several days, respectively.

A computational model was used to predict the transport of analyte vapor by diffusion within the passive MODD. The focus of the analysis was the symmetry of the analyte vapor concentration across the MODD outlet. Assuming a symmetric concentration field at the outlet, the vapor profile would be equal whether approached from the left or from the right, and the components in the MODD would not be recognizable as separated, but instead only as a mixed vapor. The models demonstrated that the concentration field becomes symmetric due to the small central channel separating the upper and lower chambers. Laboratory evaluations were completed to ensure the model was satisfactory and that the MODD delivers a uniform mixture of vapor at a detectable level. Based on this data, it can be shown that the MODD accurately portrays the mixed vapor of these separated compounds.

#### Vapor Detection, Homemade Explosives, Vapor Delivery

### E30 The Current State of Homemade Explosive Detection by Canines—Research and Knowledge Gaps

Lauryl DeGreeff, PhD\*, U.S. Naval Research Laboratory, Washington, DC 20002; Kimberly Peranich, BS, NSWC IHEODTD, Indian Head, MD 20640; Alison G. Simon, PhD, Washington, DC 20375

**Learning Overview:** After attending this presentation, attendees will have learned of the changing trends in explosive threats and how this pertains to canine detection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with an understanding of where there are knowledge gaps in regard to canine detection of explosives, why these gaps exist, and how they may be filled.

The gold standard of non-contact explosives detection in real-time is canine detection. Canines are sensitive and selective detectors that can easily be trained to locate novel materials. However, there is often little research to support canine training and deployment. Per this study's research, the most recent review of the scientific foundation for canine research was published in May 2001, prior to the September 11, 2001, attacks and the Boston Marathon bombings of 2013.<sup>1</sup> Both of these events broadly altered law enforcement, affecting every aspect of training and deployment, including the canine sector.<sup>2,3</sup> Compounding the issue, Homemade Explosives (HMEs) have emerged over the last two decades as the predominate weapon used against the United States, but there are still significant gaps in the literature and research on this topic. HMEs are easily constructed or synthesized using commercial ingredients and equipment that are more difficult for traditional methods to detect. Even with the diversity and power of the canine detector, there are minimal resources available for canine research, financial and otherwise. This leads to a dearth of understanding of this detector, which ultimately has a negative impact on canine detection proficiency.

A thorough survey was conducted to assess current and past research in the field of canine detection. This evaluation included research on the detection of explosives, as well as other targets relevant to military and law enforcement. This includes narcotics, human remains, and human tracking, as well as associated research in the fields of veterinary, neuro, and behavioral sciences as they relate to canine detection. Information was collected in the form of surveys provided to researchers in the field of canine detection across many disciplines, as well as to operational users, including canine handlers and trainers. In addition, an extensive review of both peer-reviewed literature and government reports was conducted and a searchable database of canine detection-related literature was compiled. Data from both the surveys and the literature review were used to identify critical knowledge gaps and user needs. Suggestions for appropriate topics for future funding to best serve the canine detection community, with the goal of improving the canine as a versatile field-detector, have been made. Areas of recommended future research include the following: (1) odor delivery, diffusion, and availability; (2) training aids, including storage and shelf life; (3) HMEs; and (4) veterinary health and canine ability/proficiency. It was also suggested that a repository for canine research be created for users and future researchers and maintained on a regular basis. While the body of canine research continues to grow, there remains a need to conduct further research to ensure the ability of these detectors to meet the changing nature of warfare.

### E31 The Detection of Risk Factors of Elder Abuse in Domestic Settings

Maria Carla Mazzotti, MD\*, Department of Medical and Surgical Sciences, Unit, Bologna, ITALY; Alberto Amadasi, MD, Università di Bologna, Bologna 40126, ITALY; Anna Maria Govi, MD, Department of Medical and Surgical Sciences, Bologna 40126, ITALY; Giancarlo Salsi, PhD, Department of Medical and Surgical Sciences, Bologna 40216, ITALY; Susi Pelotti, MD, University of Bologna, Bologna 40100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand: (1) some principles of elder abuse, (2) the different practice settings and various forms in which it may present, (3) the current prevalence, and (4) that available data still represents an underestimation of the phenomenon, as the abuse is frequently unreported.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a key aspect in the detection of risk factors of elder abuse in domestic settings, increase awareness of the existence of this particular form of abuse, and guide the training of health care providers for primary and secondary prevention. Indeed, the results of this study provide a framework for forensic researchers and practitioners on a phenomenon that is still submerged, unlike other forms of domestic abuse.

In Italy, limited research has been conducted on indicators of individuals who may be more susceptible both to perpetrate violence or to be susceptible to abuse. The purpose of this study was to investigate the presence of potential forms of elder abuse in domestic settings by analyzing risk factors related to both the caregiver and the elderly person in order to assess individuals who may be at risk for, or victims of, abuse.<sup>1</sup>

Data was collected on a sample of 88 volunteers of an Italian Association named “Auser,” each of whom was in charge of an elderly person assisted by a caregiver in a domestic setting. A previously designed and validated questionnaire (Indicator of Abuse (IOA)–Screen) was used to collect data from participants.<sup>2</sup> The questionnaire consisted of 13 questions for the caregiver and 24 questions for the elderly person. Multiple logistic regression models were used for data analysis in Stata/SE 10.1 for Microsoft® Windows.

A situation of possible or suspected abuse was detected in 59% of the cases, of which 69% identified the caregiver as a family member. The average age of the caregiver was 55.5±16.3 years, while the average age of the elder was 80.4±8.2 years. The most frequent risk factor for elders to be exposed to higher rates of abuse were dementia, followed by financial dependence. Concerning the caregiver, alcoholism was the most common risk factor. Logistic regression did not show a difference in gender (both in caregivers or elderly people) as statistically significant.

In view of the rapidly aging population, the detection of elder mistreatment is emerging as a public health priority.<sup>3</sup> Indeed, as the population ages, the percentage of older adults experiencing abuse, neglect, or exploitation is expected to grow. In such scenarios, interventions to prevent or reduce elder abuse are crucial. This study has found potential risk factors of caregivers and elderly people that may be preventable, to an extent. It is therefore recommended that medicolegal experts become familiar with elder abuse and its potential risk factors.

## E32 Forensic Evidence and Investigation Implications in Domestic Violence Incidents Involving Non-Fatal Strangulation

Katherine M. Brown, PhD\*, Tarleton State University, Bryan, TX 77807; Tara O. Shelley, PhD, Tarleton State University, Fort Worth, TX 76116; Lacy Hensley, MA, One Safe Place, Fort Worth, TX 76104

**Learning Overview:** After attending this presentation, attendees will: (1) understand the nature and extent of domestic violence incidents involving Non-Fatal Strangulation (NFS); (2) be able to recognize the physical symptoms and injuries associated with NFS; (3) be aware of the forensic evidence and investigative implications of these incidents; and (4) be able to identify additional correlates and risks associated with NFS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing competence in response to NFS domestic violence incidents. This presentation will increase recognition of physical signs and symptoms and other important forensic evidence and will investigate implications in these incidents. Specifically, this presentation will allow attendees to identify evidence and additional correlates and risks associated with NFS in domestic violence incidents and will also give first responders and investigators information about an underresearched area.

It is estimated that the number of women who experience NFS is at least 10% and could be as high as 68% for female victims of Domestic Violence (DV).<sup>1-4</sup> It is also estimated that between 22%-35% of women who visit the emergency room are there for medical problems related to DV, and one out of every three female trauma patients is a DV victim.<sup>5</sup> Unfortunately, most victims of NFS will not seek medical treatment and law enforcement frequently misses, or fails to properly document, the external evidence, signs, and symptoms of strangulation.<sup>2-6-9</sup> While some research indicates that 40% of DV victims were strangled, only about 10% actually reported to law enforcement and emergency personnel that they had been strangled and were experiencing physical symptoms.<sup>10,11</sup> Increasing their risk, victims of DV who experience NFS are *seven times more likely* to be victims of attempted homicide and *eight times more likely* to subsequently become victims of a homicide.<sup>1,6,7,12-14</sup> The children of victims are also at risk. The presence of children to NFS in DV incidents also places them at risk of adverse health effects, and estimates show that between one and ten children are at risk because of exposure to DV.<sup>15</sup> In addition to adverse impacts on the child, the presence of a child in a DV incident may increase the strangulation risk to the victim. In approximately half of strangulation cases, children were present at the time the victim was strangled.<sup>8</sup>

This presentation examines NFS DV incidents involving victims seeking services from One Safe Place Family Justice Center (OSP) in Fort Worth, TX, from January 1, 2016, to June 30, 2017 ( $n=1862$ ). Researchers collected and analyzed OSP client records from numerous sources: (1) intake and incident forms (e.g., previous victimization, children, relationship characteristics, nature of abuse); (2) a danger assessment instrument (e.g., risk factors associated with homicide in violent relationships); and (3) a strangulation questionnaire administered to clients reporting strangulation in the danger assessment instrument (e.g., frequency of strangulation, symptoms, and injuries).

The findings include descriptive data regarding the nature and extent of strangulation physical symptoms and other factors that provide important forensic and investigative implications. Researchers also utilized logistic regression to determine correlates of NFS. Preliminary results indicate that 56% of the sampler had been strangled ( $n = 663$ ), 73% of these victims reported they had a child under the age of 18, and 48% indicated they had children in the household who were not the offender's biological child. Victims also reported an array of physical strangulation symptoms: difficulty in breathing (68%); lightheaded or dizziness (54%); vision or hearing issues (27%); loss of consciousness (53%); and some reported the loss of bodily functions (12 reported urination and 2 reported defecation). Post-strangulation incident, victims reported: bruising (56%); difficulty swallowing (42%); difficulty breathing (33%); and changes in their voice (35%). Only 5.5% of strangulation cases had no law enforcement involvement, and 74% of victims did not seek medical treatment for their injuries.

When cross-referencing danger assessment scores with the occurrence of strangulation, it was discovered that 72% of victims in the extreme danger range had been strangled (versus 28% that had not been strangled). The difference between the two groups was statistically significant. Logistic regression results indicate that victims are also *significantly more likely to experience strangulation* if: their abuser has previously threatened to kill them; if the abuser has previously avoided arrest; if children present were not related to the abuser; if verbal and physical abuse had previously occurred in front of children; and if the offender had beaten the victim while she was pregnant. In addition, the practical implications for evidence collection and investigation in NFS incidents will be presented.

### E34 Forensic Investigation and Criminal Profiling of Very Unusual Infanticide in Italy

*Luciano Garofano, PhD\*, President of Accademia Italiana di Scienze Forensi, Parma 43100, ITALY; Laura Volpini, PhD\*, Rome 00174, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the dynamics of a very specific infanticide that took place in Italy in 2002, in which a mother killed her baby. There will be discussion of the analysis done of Bloodstain Pattern Analysis (BPA), the crime scene analysis used to solve the murder, and the method adopted for the analysis of this crime.

**Impact on the Forensic Science Community:** This presentation will impact the forensic scientific community by discussing the importance of a multidisciplinary approach and how it could be effective in the resolution of complex forensic cases.

The case concerns an infanticide which occurred in Cogne, a small mountain village in northern Italy in January 2002. The case had a great media echo that lasted for years due to the duration of the investigation and the trial, both on television and in the press.

The body of a 3-year-old baby was found in the parents' bedroom, completely smeared with blood. Many technical activities were conducted by the specialists of the forensic science lab of the Carabinieri-Parma. A thorough examination of the crime scene and further analyses of hundreds of pieces of forensic evidence were subsequently conducted at the urging of the defense experts. The total lack of fingerprints or DNA other than the victim's family, as well as the particular distribution of bloodstains, progressively focused suspicion on the mother, even though she proclaimed herself innocent.

Great attention was dedicated to the physical characteristics and distribution of bloodstains, which were analyzed through a rigorous application of BPA. To do this, the murder room was reconstructed in order to test two main hypotheses: (1) an attack carried out by an aggressor positioning himself exclusively next to the bed; (2) an attack carried out by an aggressor who—wearing the mother's pajamas—initially hit the victim beside the bed and then moved on the bed, hitting the victim frontally and inflicting wounds only on his head.

A forensic psychiatric assessment on the woman was also performed, as well as a second psychiatric assessment ordered by the Court during the second-degree trial. The psychiatric examination conducted during the appeal trial used an innovative methodology in the forensic field. The various tasks were distributed among a team of experts, then the results of the work were reassembled to outline the psychological framework and the criminodynamics of aggression in an integrated manner. After a close confrontation between all the experts, including the results achieved by the psychiatric examination, the only sustainable hypothesis was the criminal responsibility of the mother. After three degrees of judgment, she was sentenced to 16 years imprisonment.

The oral presentation of this case will reconstruct with great detail the criminal dynamics, the psychological motivations at the origin of the crime, and the psychological profile of the mother. Salient data referable to infanticide in Italy will also be discussed.

### E35 Crime Scene Reconstruction in an Organization of Scientific Area Committees (OSAC) World

*Peter R. Valentin, MSFS\*, University of New Haven, West Haven, CT 06516*

---

**Learning Overview:** After attending this presentation, attendees will understand the important role crime scene reconstruction has in the understanding and interpreting of forensic evidence in both criminal and civil cases. The conspicuous absence of a separate crime scene reconstruction subcommittee as part of the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) tacitly suggests that the interpretation of the physical evidence is best handled in a courtroom or otherwise as part of the legal process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by starting a conversation about what happens to the evidence we analyze. Specifically, should we develop and apply scientific standards to how we interpret evidence in much the same way we apply standards to how we examine evidence?

With the creation of the OSAC under NIST, considerable progress has been made to strengthen the scientific foundations and processes in many forensic disciplines. What is lacking is the development of a similar process for crime scene reconstruction. When the significance or interpretation of forensic evidence is disputed, and in particular when that information needs to be integrated into the body of investigative information, a crime scene reconstructionist can help evaluate possible scenarios. With so much emphasis on solidifying forensic science, why has the interpretation of that information been left to be decided in a courtroom? Shouldn't the interpretation of forensic science (in the context of a case) be subject to the same types of guidance we seek to codify as part of the OSAC standards development process?

The absence of a reconstruction committee suggests that either the forensic science community does not concern itself with the interpretation of its work product or that we believe that this is adequately handled as part of the adversarial court system. Neither is (or should be) true. While an OSAC crime scene investigation subcommittee already exists, the sheer amount of work before them in addition to reconstruction makes this too large a task for a single subcommittee to handle. Additionally, with all the potential disciplines reconstruction can draw their information from, a dedicated committee with representation from many disciplines should be developed.

At the root of many legal cautionary tales on the use of forensic science are issues of interpretation and presentation of forensic evidence. If we fail to act decisively, we run the risk of having this critical function curtailed. Shouldn't we provide guidance for the reasonable interpretation of forensic evidence just as we do for understanding the results in a specific discipline?

### E36 Dermoscopy in Forensic Medicine

*Benjamin Mokdad\**, Rouen, Normandie 76000, FRANCE; *Anne-Claire Lhoumeau, MD, CHU Charles Nicolle, Institut Médico-Légal, Rouen 76031, FRANCE; Pauline Jorda, Rouen, Seine Maritime, FRANCE; Paul Young, MD, Chu Rouen, Rouen 76000, FRANCE; Gilles P. Tournel, Rouen, Seine Maritime 76000, FRANCE*

**Learning Overview:** The goal of this presentation is to demonstrate that dermoscopy is a simple, fast, and cheap technique useful in legal medicine that can substitute for DNA identification techniques in many situations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a new technique for the identification and examination of stab wounds and gunshot wounds.

Dermoscopy is a technique initially used for the early detection and diagnosis of melanomas. As a useful tool, it was further developed to diagnosis other skin lesions that include skin cancers and inflammatory and infectious diseases. Per research, this work reports on the first use of dermoscopy in forensic medicine. For one year, the Forensic Medicine Department at the University Hospital of Rouen in France has been equipped with an immersion dermoscope (Heine® 20). It has been used systematically in many medicolegal situations. Three cases utilizing dermoscopy in forensic medicine will be discussed.

**Fingerprints:** The formal identification of bodies by the fingerprint method is an empirical method that has lost its beauty since the discovery and use of DNA. However, fingerprint analysis by dermoscopy coupled with photography allows a clear image of dermatoglyphs, even when there is no longer an epidermis or in cases of mummified skin. On very damaged bodies for which the traditional method of fingerprints (powders) is no longer possible, the dermoscope provides images of sufficient quality for identification. In addition, it is possible to observe the sweat pores, which are not currently a point of comparison, despite a recent study of interest in identification. Considering sweat pores, a square millimeter fingerprint fragment has tens to several hundreds of points for comparison. This is enough to certify an identity and to propose a new fingerprint analysis method. Dermoscopy allows high-quality fingerprints that are directly scanned and therefore easily comparable to a national fingerprint database.

**Gun wounds:** Dermoscopy directly visualizes the soot and grease traces at wound sites and makes it possible to quickly distinguish between the inlet and the outlet wounds without having to resort to a pathological examination. This is accomplished by using the dermoscope to identify grains of powder and other trace residues at the wound.

**Stab wounds:** Dermoscopy allows for a fast and precise analysis of stab wounds. It allows a more rigorous analysis of the ends and edges of wounds than is possible solely with a visual examination. This makes it possible to discern if the knife used possessed a single or double edge. The edges of the wound can adopt a bifid or unique wound characteristic that is easily analyzed by dermoscopy and can guide both the type of blade and the possible blade movements.

Several techniques are recognized and validated to obtain formal recognition of deceased subjects. In the case of very damaged bodies, the examination of the dentition is often not very conclusive. The realization of fingerprints is a well-established technique, but difficult or impossible to use in cases of hand alteration (drowning, mummification). In these cases, performing a DNA search is a destructive technique because it requires the removal of sufficient muscle (often psoas, as it is better preserved) or bone marrow (whole femur). In addition, it is a more complicated and expensive technique, requiring extra steps (lysis, elimination of proteins and acids, concentration of DNA, etc.). Dermoscopy allows visualization of the sweat pore. Thus, it makes it possible to obtain a much greater number of comparison points than with a conventional technique. Sweat pores have already been identified as a reliable element for identification. This technique allows a considerable reduction of the risk of misidentification because a multiple fold number of comparison points are available on a small surface (1cm<sup>2</sup>). The comparison of the sweat pores is not currently used in France but is already in use by some foreign police departments.

### E37 Diligence, Dedication, and Devotion: Reaching Back Into History for the Image of a Victim

*Sandra R. Enslow, BA\*, Los Angeles County Sheriff's Department, Monterey Park, CA 91755*

---

**Learning Overview:** After attending this presentation, attendees will understand some of the difficulties that forensic artists often encounter with facial reconstructions. Facial reconstructions are developed from the skull or, in this case, photographs of the skull in order to get a better understanding of what a victim looks like. This information may possibly identify a victim, even if the case is 28 years old.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the work that forensic artists do for their detectives and investigators. The majority of this work goes beyond drawing a composite of a suspect. In this presentation, an outstanding cold case criminal investigation that requested a facial reconstruction will be presented. The female victim's skeletal remains were discovered in 1980 in a dry riverbed in a suburb of Los Angeles County. The skull had a bullet hole in it. This informative presentation will highlight original photographs, step phases, and finalized images of the victim's face.

The skeletal remains were cremated at some point, which sometimes happens. This does not deter a forensic artist, but rather sends them down other avenues for the information they seek. Vital information and clues about the face can be found in the anthropologist's final report. This turned out to be the case here. The Los Angeles County Coroner's Office anthropologist in 1980 noted descriptive features about the victim's palate and orbital sockets. This information was extremely helpful and gave the forensic artist specific direction in producing those parts of the image.

There were two challenges in this case. First, without the actual skeletal remains, the photographs of those remains became the crucial source for reference. The photo of the skull, while somewhat clear, was taken for general documentation purposes only. This photo was not to the standard used for a facial reconstruction. The care and specificity that a forensic artist would have applied to the angle and presentation of the skull for photography purposes was not there. Approximating the Horizontal Frankfort position was not possible. There were no lateral views of the skull.

The second challenge was the missing mandible. Many skulls are discovered without this important part of the skull. For forensic artists, this just goes with the territory and is often the rule rather than the exception. In Photoshop®, a new mandible is generated and applied in the photographic phase. This allows the continuation of the facial reconstruction, although it is not ideal.

The skull needed to be reconstructed before the facial reconstruction could even begin. The skull's right side was intact, but the zygomatic bone on the left side had been broken off. This had to be approximated and accepted as similar to the right side.

This case was considered to have possible connections to another serial murder series in the Southern California region. Whether this individual had been a victim of the serial murderer remains to be seen, although the location and time frame position her as a candidate. Creating the image, then obtaining an identification of the victim were the first two steps in the process of finding a possible connection. Much of that casework is still ongoing.

Forensic art is a rapidly expanding discipline that requires specialized training, above and beyond advanced drawing skills. The forensic artist is called upon for many different skill sets that assist in the identification process. Applications relate closely with those of other disciplines of the forensic sciences, especially forensic anthropology, forensic odontology, and forensic psychology.

### **E39 Forensic Validity and Usefulness of the Apache Tracking Method: A Multifaceted Research and Development Protocol**

*Joseph L. Lewis III, MFS\*, National University, Forensic Sciences Program, La Jolla, CA 92037; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037*

**Learning Overview:** After attending this presentation, attendees will develop an understanding of the Apache Tracking Method and its forensic relevance and validity regarding how speed of human travel can be determined from shoe impression details left in substrates affected by the kinetic energy transference associated with forward movement. Average speeds of travel can be determined from the track details denoting forward motion of subjects.

**Impact on the Forensic Science Community:** This presentation will impact attendees by adding another novel level of scientific knowledge for biometric identification and investigation. This is noteworthy since there has not been adequate empirical data collected about tracking methods. This would offer useful information about suspect identification, crime scene reconstruction, pursuit of criminals, and apprehension of fugitives.

The key objective of this study was to determine if travel speeds can be approximated (mph) by interpreting the kinetic energy transfer details left in the shoe print impressions in a given substrate. If correct, then there should be no differences observed in the speed assessment of three subjects traveling at similar speeds. The speed assessments would be criteria dependent based on the shoe impressions, not subject dependent, assuming roughly similar weights. For this study, three male volunteers (average weight: 173.2 lbs, +/-19.4lbs SD) were recruited to travel through a tracking box (3.5 ft. wide, 12 ft. long, and 4 in. deep) filled with damp sand (Zero Earth) and with travel speed ranges of 6–8mph, 9–11mph, and 12–14mph measured by Doppler radar. This experimental “field” model was done to determine what correlation (if any) the subjects and travel speeds may have relative to pressure release scales (The Wave, The Double Wave, The Disk, The Disk-Fissure, The Disk-Crumble, The Dish, The Dish-Fissure, The Dish-Crumble, and The Explode-Off). The shoe prints left in the Zero Earth substrate were photographed and analyzed using the forward motion pressure release analysis and categorization method.<sup>1</sup> Any statistical difference across the test subjects at the travel speed ranges and pressure release categorizations were analyzed by chi-squared ( $\chi^2$ ) test (p value <0.05).

There was no significant difference between the three subjects at the three travel speed ranges. The three speed ranges can be differentiated by pressure response in the Zero Earth substrate, across nine different pressure response scales. The same classes of kinetic energy transfer details were detected at the same speed ranges. This allowed for a reliable estimate of subject speeds by shoe print analysis. The chi-squared test indicated there was no difference in the likelihood of making the same class of substrate pressure details (pressure releases) for the respective travel speed ranges.

The conclusion of this presentation is that specific travel speeds can be approximated by reading the forward motion details (pressure releases) in the shoeprint substrate. It was determined that The Disk pressure release class was found in all three subjects’ shoe print series at the 6–8mph travel speed range, The Disk-Crumble pressure release class was found in all three subjects’ shoe print series at the 9–11mph travel speed range, and The Explode-Off pressure release class was found in all three subjects’ shoe print series at the 12–14mph travel speed range.

### **E41 A Forensic Criminological Approach to Oil Spill Investigation**

*Edidiong Mendie\*, Houston, TX 77007; Ashraf Mozayani, PharmD, PhD, Texas Southern University, Houston, TX 77004*

---

**Learning Overview:** After attending this presentation, attendees will better understand the correlation between forensic science procedures and their impact on oil spill identification. This awareness will help attendees be more familiar with the role forensic science plays in oil spill cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of why the evidence management procedures should be given equal relevance in oil spill retrieval to avoid contamination. This presentation will also provide recommendations as to the need for adopting a benchmark that will be employed by forensic analysts that use forensic techniques in identifying oil spills.

Oil spill disasters have become a global problem that adversely affects people and the environment. When there is an oil spill, forensic experts are involved because the evidence retrieved from the crime scenes are sent to the forensic laboratory for analysis. Flowing from this, environmental forensics has emerged as a tool for regulating environmental contamination, especially those arising from oil spills. This has been achieved through different oil spill identification mechanisms. Oil spill identification involves techniques employed to discern causes of oil spills. Thus, forensic techniques such as Gas Chromatography/Mass Spectrometry (GC/MS), and Polycyclic Aromatic Hydrocarbons (PAHs) play a significant role in determining the source of spilled oil so that we are better able to deduce their occurrences.

Earlier studies have researched various forensic methods used in oil spill identification. This was achieved by retrieving data from oil spill locations, comparing the chemical components from such investigation sites with substances from other locations, and analyzing the results to determine whether or not a match exists. However, questions as to whether these forensic studies were conducted following laid-down standards have been left unanswered.

In understanding the oil spill identification process, this report employed a case study approach. It divided the analysis into three stages, namely the pre-analytical, analytical, and post-analytical phases. The pre-analytical stage assessed the retrieval of evidence from oil spill sites. It examined whether evidence retrieved from select oil spill sites were conducted using forensic techniques. The analytical phase focused on evidence collection and its perceived impact on the oil spill process to avoid contamination. It emphasized the compliance steps required for the purpose of evidence handling. The post-analytical phase studied the overall effect on the criminal justice system, such as the courts, that relies on such evidence and the testimonies of expert analysts.

This exhibition highlighted the need to properly collect and preserve evidence from the oil spill site that will be sent to the laboratory for testing. The oil spill investigation scene ought to be treated as a crime scene investigation to prevent the loss of important evidence. Thus, retrieval of evidence from oil spill sites must be performed by following all relevant evidence management procedures.

Being the first of its kind, the purpose of this analysis is to offer the recommendation that a universal framework be adopted in forensic testing of oil spill cases. By doing so, this report seeks to assure the public of the credibility in the forensic science discipline and its procedures.

### E42 Validation of a Dry Vacuum Swabbing Method for the Recovery of Epithelial Cells From Handled Porous Substrates

*Yih Ling Saw, MSFS\*, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Kevin J. Piccirilli, MSFS, Utah Bureau of Forensic Services, Taylorsville, UT 84129; Sara G. Goodman, MSFS, Columbia, SC 29210; Heather E. McKiernan, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will understand the value of employing an efficient collection technique for the analysis of touch-based samples and be able to evaluate the application of dry vacuum swabbing on commonly handled porous evidentiary materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing validation data supporting the use of an alternative collection technique, a dry vacuum swabbing method, for handled porous items of evidence for genetic analysis. Evaluation of the efficiency, reliability, and potential limitations of this collection methodology will help analysts decide under what conditions it could successfully be applied to forensic casework.

Analysis of low template touch DNA samples has always been a challenge for forensic analysts. Over the years, the field of forensic science has seen numerous improvements in technology in terms of analytical approaches and reaction chemistries that have been made commercially available to improve the quantitative and qualitative recovery of such samples. However, in order to increase the initial yield of recovered DNA, optimization of the collection technique applied is just as crucial to the DNA workflow.

Several collection techniques have traditionally been employed in the collection of touch-based samples in crime laboratories. More recently, a commercially available wet vacuum collection application has also been applied to casework samples. Each of these techniques have their own benefits and challenges, some working better on more non-porous substrates, others working better over larger surface areas, and some showing poor recovery of epithelial cells.

Several mock items of evidence were handled, then samples were collected using several collection techniques: double swabbing, scraping, tape lifting, and the in-house dry vacuum swabbing technique. Substrates evaluated in this study included an array of commonly encountered porous substrates submitted for touch DNA analysis, such as articles of clothing and rope. In one scenario, individuals wearing long-sleeved cotton shirts were dragged across the floor by their arms. Each of the collection techniques were applied in an attempt to target the “suspect” versus the “victim” DNA. Statistically significant increases in the amount of recovered quantifiable DNA were observed when using the dry vacuum swabbing technique ( $F_s=8.270$ ;  $df=3,28$ ;  $p=0.0004$ ) when compared to the other collection techniques evaluated. This subsequently resulted in the generation of robust, high-quality Short Tandem Repeat (STR) profiles in which 100% of the “suspect’s” alleles were detected. In contrast, traditional collection techniques produced lower quality STR profiles with a high degree of allelic dropout. In another scenario, “victim’s” hands were tied together by the “suspect’s” using natural fiber rope. Once again, all collection techniques were utilized and evaluated. Samples from the middle of the rope (the portion in contact with the “victims”) were collected separately from the ends of the rope (those in greater contact with the “suspects”). Once again, downstream genetic analysis showed that the dry vacuum swabbing collection technique recovered the highest quantity of DNA from the rope ends when compared to all other collection techniques assessed, recovering 80+% of victim and perpetrator profiles from both the center and ends of the rope, respectively. Recovery of low-level touch DNA from simulated sexual assault scenarios in which “suspects” forcibly removed “victim’s” denim jeans and bra also showed drastic differences between the performance of the assessed techniques, with the dry vacuum swabbing collection technique recovering an average of 3.81% more male DNA attributable to the “suspect” than the other collection techniques.

As the number of touch type DNA samples being submitted for casework analysis continues to rise, it is imperative that front-end optimization is achieved to bolster the success of downstream analyses. While recovery of touch DNA has historically been challenging for forensic analysts, this research has proved that the dry vacuum swabbing collection technique may be an ideal workflow solution for the efficient recovery of epithelial cells from porous substrates, especially in instances in which targeted collection is needed to avoid wearer or “victim” DNA. Additionally, this technique is easy and cheap to assemble in a forensic laboratory and does not require the purchase of dedicated and expensive commercial products.

## E44 Validation of the PrepFiler® Express BTA™ Forensic DNA Extraction Kit

*Jessica Slater\**, Huntington, WV; *Dorothy M. Catella*, MSFS, Oakland County Sheriff's Office, Pontiac, MI 48341; *Megan Connolly*, MPS, Oakland County Sheriff's Office, Pontiac, MI 48341; *Kelly Beatty*, MSFS, Marshall University Forensic Science Center, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will have information concerning the use of PrepFiler® Express BTA™ and the possible substrates for extraction with PrepFiler® Express BTA™, as well as the advantages and disadvantages of using PrepFiler® Express BTA™.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, especially those in the DNA biology analysis field, by describing a method of obtaining a DNA Short Tandem Repeat (STR) profile from substrates with a limited quantity of DNA by using the PrepFiler® Express BTA™ extraction kit.

Currently, methods to extract DNA from bone, teeth, and adhesive substrates, such as cigarette butts, chewing gum, envelope flaps, and Fastape, are growing in popularity. However, there are multiple methods that give varying results when trying to extract DNA from these substrates. A possible reason for these variabilities could be the high rate of degradation/inhibition that occurs with bone, teeth, and adhesive substrates. PrepFiler® Express BTA™ DNA extraction kit was designed for those types of substrates because it is able to remove Polymerase Chain Reaction (PCR) inhibitors and helps extract more DNA from these substrates than previously used reagents when accompanied by an AutoMate Express™.

The validation for PrepFiler® Express BTA™ DNA extraction kit was conducted by the Oakland County Sheriff's Office Biology DNA Laboratory. During this validation, four different studies were performed to help determine if this extraction kit would be beneficial to implement for casework when working with these substrates. These included: (1) assess the optimal amount of sample from various types of bone/teeth, as well as determine the optimal incubation time for extraction; (2) confirm that all four of the AutoMate Express™ instruments in use in the lab give comparable results; (3) determine if PrepFiler® Express BTA™ is able to produce STR profiles from non-probative samples that are typical for case work and are suitable for comparison to known samples; and (4) determine if PrepFiler® Express BTA™ was better at removing inhibitors and extracting DNA from these challenging substrates when compared to PrepFiler® Express™. Along with these validation studies, a case study was performed on bone chips discovered in Italy that were believed to be from the 1800s. All samples were extracted on an AutoMate Express™ instrument using PrepFiler® Express BTA™, except for the samples that were extracted with PrepFiler® Express™. They were quantified using Quantifiler® Trio Quantification Kit on an Applied Biosystems® 7500 Real-Time PCR System and amplified using GlobalFiler™ PCR Amplification kit using an Applied Biosystems® 9700 GeneAmp® PCR System. Capillary electrophoresis was performed on Applied Biosystems® 3500 Genetic Analyzer.

It was determined during this validation that when using PrepFiler® Express BTA™, a complete STR profile was obtained for both femur and tooth powders from 10mg to 50mg, while rib powder was best extracted from 40mg to 50mg. However, using 50mg of powder obtained from the bone chips did not produce full profiles and produced only a partial STR profile for one of the ten samples. It was observed during this validation that when extracting DNA from multiple replicates of bone powder samples, all four of the AutoMate Express™ instruments did in fact produce similar profiles. Also, the validation illustrated that PrepFiler® Express BTA™ is able to produce profiles for non-probative evidence samples that can be used for comparison to known profiles. When comparing PrepFiler® Express BTA™ to PrepFiler® Express™, it was determined that PrepFiler® Express BTA™ gave overall better profiles with less degradation/inhibition when extracting DNA from adhesive substrate samples. However, when extracting DNA from Fastape, better quality profiles were obtained with extraction following the bone and tooth protocol instead of the adhesive substrate protocol.

Based on the results from the validation of PrepFiler® Express BTA™, it was concluded that this DNA extraction kit was able to extract DNA from bones, teeth, and adhesive substrates in a way that prevents PCR inhibition and increases the quantity of DNA extracted compared to PrepFiler® Express™. PrepFiler® Express BTA™ was able to extract DNA in a manner that produces STR profiles that can be used on forensic samples commonly processed in this laboratory.

### E45 An Evaluation of the Effects of Various Digest Times on the DNA Yield for Differential Separations at the West Virginia State Police Forensic Laboratory

Allegra N. Forwith, BA\*, Marshall University Forensic Science Center, Huntington, WV 25703; Bailey E. Hill, MS, West Virginia State Police Forensic Laboratory, S Charleston, WV 25309; Kelly Beatty, MSFS, Marshall University Forensic Science Center, Huntington, WV 25701

**Learning Overview:** The goal of this presentation is to communicate the findings that 60 minutes is the ideal digest time for epithelial cell lysis in differential samples containing sperm from sexual assault cases. Attendees will learn that heating differential samples at 56°C for 60 minutes yields the best male DNA yield while maintaining the integrity of the DNA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the method for processing sexual assault samples in order to obtain higher male DNA yields and better forensic male DNA profiles.

Every year, thousands of sexual assaults occur in the United States.<sup>1</sup> Sexual assaults make up a large percentage of the cases handled by forensic DNA laboratories and adopting an optimized procedure for processing these cases is of the utmost importance.

Differential extraction is the process used to separate epithelial cells (e-cell) and sperm cells during DNA extraction in sexual assault cases.<sup>2</sup> Samples are heated while suspended in digest reagents, with the goal of separating the sperm cells from the e-cells.<sup>3</sup> This isolated sperm can then be used to develop a male DNA profile.

The current procedure for differential extraction at the West Virginia State Police Forensic Laboratory requires sample digestion at 56°C for 30 minutes to two hours.<sup>2</sup> The purpose of this study was to determine the ideal incubation time within this range in order to optimize the DNA yield in the e-cell and sperm fractions of differential samples. Five digest times were evaluated in this study: 30 minutes, 45 minutes, 60 minutes, 90 minutes, and 120 minutes.

To prepare for this study, a three-fold serial semen dilution was prepared for a series of six semen dilutions (A-F). Female saliva was obtained and diluted (1:2) with nuclease-free water. Six sets of samples (A-F) were prepared by adding 25µL of a respective semen dilution and 25µL of saliva dilution to sterile cotton swabs and dried. Swabs were nutated in 1,000µL of nuclease-free water for one hour, transferred to spin baskets, and centrifuged at 13,000 RPMs for five minutes. The resulting liquid was added back to the sample tube and re-centrifuged for an additional five minutes to concentrate the cellular material into a pellet. Approximately 920µL of water was removed and discarded, and 500µL of digest mix (475µL Sarkosyl buffer + 25µL Proteinase K) was added to the remaining pellet for each sample.

Samples were digested on the 56°C heat block for each of the incubation times and transferred to the QIAGEN® QIAcube® for separation, using Protocol 12A/12B. A sperm-lysis solution was prepared for a pipet volume of 145µL per sample (7.25µL ProK + 7.25µL DTT + 130.5µL Sarkosyl buffer) and loaded into the QIAcube® in position A to be added to the sperm fraction after the wash steps. Samples were extracted on the QIAGEN® EZ1® using Large Volume protocol for the e-cell fraction and Trace protocol for the sperm fraction; samples were eluted in 40µL of TE buffer.

All samples were quantitated using Quantifiler® Trio on the Applied Biosystems® 7500 Real-Time PCR System and amplified using GlobalFiler™. Capillary electrophoresis was performed on the Applied Biosystems® 3500 Genetic Analyzer, and analysis was performed using GeneMapper® IDX.

Results for each semen dilution (A-F) indicate that a 60-minute digest time yields the highest male DNA quantitation values. The second highest male DNA yields were seen at 90 minutes or 45 minutes. The data for each semen dilution graphically follows a normal distribution pattern, with the ideal digest time being 60 minutes. Both the human and male DNA quantitation values for the 120-minute samples had the lowest quantitation values for all semen dilutions. The data suggests that 30 or 45 minutes is not enough time for the digest mix to lyse the e-cells.

The results generated from this study support the conclusion that 60 minutes is the ideal digest time. The DNA profiles from the 60-minute digest time samples had the purest and most robust sperm cell fractions, as they produced single-source profiles with alleles above the analytical threshold. The sperm fraction of samples digested at 30 and 45 minutes contained female DNA, likely due to undigested epithelial cells. The sperm fraction samples subjected to 90- and 120-minute digest times had good separation but showed evidence of degraded DNA due to lower allele peak heights.

While male DNA profiles can be generated from samples heated for 45–90 minutes, the ideal digest time for differential samples is 60 minutes. Implementing a strict 60-minute digest time into the differential separation protocol could lead to better separation of epithelial and sperm cells, while maintaining the integrity of the male DNA.

### E46 The Effect of Crime Scene Investigation (CSI) on Forensic DNA Database Recognition: A Public Survey of South Koreans

Jihyun Lee, Seoul, SOUTH KOREA; Sung Kyum Cho, PhD, Chungnam National University, Daejeon 34134, SOUTH KOREA; Sohee Cho, PhD, Seoul National University College of Medicine, Seoul 110-799, SOUTH KOREA; Moon-Young Kim, Seoul National University College of Medicine, Seoul 03080, SOUTH KOREA; Soong Deok Lee, PhD, Seoul 110-799, SOUTH KOREA; Kun Won Jung, MD, PhD\*, Hanyang University, Seoul, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will understand the impact of forensic television programs such as *CSI* on overall forensic awareness, including forensic investigation and the DNA database, through a survey of South Koreans.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how people are affected by media, including forensic science television programs, and how people's perceptions change. A survey of South Koreans' attitudes affected by media demonstrates a change in opinion regarding forensic science overall, especially the criminal DNA database.

Data was collected as a part of the Korean Academic Multimode Open Survey for Social Sciences (KAMOS), which provides scientific survey data for social scientists. KAMOS is a member of the international Open Probability-Based Panel Alliance (OPPA). KAMOS is a representative survey of Korean adults. The panel was created using stratified cluster random sampling of home addresses. Of 2,000 randomly selected panel members, 1,000 respondents participated in this survey.<sup>1,2</sup>

The survey on which we asked our questions also saw a rise in the popularity of crime procedural dramas in Korea, such as *CSI* and *Law and Order*. These dramas portray forensic teams and detectives in a positive light and demonstrate how having a database of information available in criminal situations and persons may help solve crimes. Of the respondents, 57.8% (more than 50% of all ages, except 60 or older) responded that they have seen forensic-related media contents. In addition, a majority of these respondents had higher education than a high school diploma. It is believed that there are barriers, such as linguistic or scientific education, in encountering foreign media or in understanding forensic science and scientific facts. The 578 people who had seen forensic dramas or movies were asked how their perception of forensic investigation methods changed after watching the video; 70.5% of respondents thought they were more positive than before. Only 4.7% of respondents thought they were more negative than before.

Between similar surveys conducted in 2003 and this survey, there have been many series about crime scene investigation in Korea. This study may provide a comparative analysis of the results of two surveys over time and the opinions of those exposed to these media have changed. We may also be seeing some version of the "CSI Effect" in Korea as well; that is, there may have been an increase in positive attitudes toward the use of a database thanks partially to these programs. While a survey from the United States found that watching crime shows such as *CSI* was positively correlated with a belief in the reliability of DNA testing, it was not related to support of a DNA bank. Nonetheless, the "CSI Effect" may be slightly different in Korea and may provide a partial explanation for the increase in positive attitudes toward a criminal DNA database.

This survey will help enlighten policymakers about what to consider when linking forensic science and legal systems. Public opinion is also an important consideration when enacting or amending the law, and it is necessary to prevent public opinion from being distorted by media exposure.

### E47 An Evaluation of the Efficacy of Whole Genome Amplification (WGA) for Degraded DNA

Mitsuyo Machida\*, Tokyo Women's Medical University, Tokyo 162-8666, JAPAN; Kazuhiko Kibayashi, MD, Tokyo Women's Medical University, Tokyo 162-8666, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the need for Whole Genome Amplification (WGA) prior to Short Tandem Repeat (STR) analysis using degraded DNA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that WGA is a potential preamplification method for STR analysis of challenging DNA samples.

DNA in biological samples is often vulnerable to environmental factors, such as Ultraviolet (UV) irradiation, high temperature, high humidity levels, and microorganism degradation. STR profiling, the most commonly used method for forensic DNA identification, is difficult to analyze highly degraded DNA samples, since structural modification or fragmented DNA templates can affect downstream analyses. An increase in the number of starting templates may improve the success of STR profiling. One approach to increase the number of DNA templates is WGA. Although WGA has mainly been demonstrated in clinical applications, few studies have shown the ability to evaluate the availability of WGA for degraded DNA samples in forensics.

Therefore, a PCR-based WGA called modified Improved Primer Extension Preamplification (mIPEP) was performed prior to STR analysis using degraded DNA, since the PCR-based WGA method is less affected by DNA quantity and quality. The mIPEP method uses a 15-mer random-sequenced primer and low stringency annealing conditions to amplify larger templates of the genome. To assess the efficacy of the mIPEP method for degraded DNA, this study artificially degraded DNA using UV light for different durations and analyzed the STR profiling.

Saliva from four volunteers was previously dried onto filter papers. These samples were exposed to UV light (365nm) for 3, 7, and 14 days, and 1 month in duplicate. The DNA were extracted from UV-irradiated saliva samples. The mIPEP method was initiated using 5ng and 0.5ng of DNA. Following the mIPEP, STR analysis was performed using the AmpF $\ell$ STR<sup>®</sup> Identifiler PCR Amplification Kit. This study was approved by the ethics committee at Tokyo Women's Medical University.

The average peak height of 16 STRs drastically decreased until seven days of irradiation, then gradually decreased until one month of irradiation without mIPEP. After performing mIPEP using 5ng of input DNA, the peak height was higher than that without and with mIPEP using 0.5ng of input DNA after seven days of irradiation. Successful STR profiling decreased with increasing duration, and 12% of the STR loci were shown after one month of irradiation without mIPEP. The number of detectable STRs with mIPEP using 0.5ng of DNA was similar to that without mIPEP after UVA irradiation. However, the number of detectable STRs with mIPEP using 5ng of DNA was greater than that without and with mIPEP using 0.5ng of input DNA after 14 days of irradiation. In addition, longer STR loci, such as D21S11, D7S820, CSF1PO, D2S1338, D18S51, and FGA, were difficult to recover despite performing mIPEP.

Hence, 5ng of input DNA is necessary for mIPEP to improve the success of STR profiling using highly degraded samples. Moreover, the difficult recovery of STR loci by mIPEP should be considered when analyzing STRs using degraded DNA.

### E49 The Development of Two Forensically Important Blow Flies Collected From Human Remains in Western Colorado

Brandon V. Everhart, BS\*, Cornell University, Department of Entomology, Ithaca, NY 14853; Alexander J. Smith, BA, Grand Junction, CO 81502; Melissa A. Connor, PhD, Colorado Mesa University, Grand Junction, CO 81501-3122; Elson Shields, PhD, Cornell University, Entomology Department, Ithaca, NY 14853

**Learning Overview:** The goal of this presentation is to provide attendees with information regarding the necrophagous flies that colonize human remains in western Colorado, with an emphasis on the development of two species poorly represented in the literature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the two dominant species of blow flies found during the late fall to early spring months at the Forensic Investigation Research Station (FIRS) located in Mesa County, CO. Data on the two fly species, *Calliphora latifrons* and *Calliphora coloradensis*, are either poorly represented or absent in the literature, and this research will help fill an important information gap. This developmental data will also be useful throughout the multi-state range for these two species.

Necrophagous insects provide a wealth of information during death investigations. This information includes time since death, whether neglect or abuse took place antemortem, and if remains were moved.<sup>1</sup> In particular, flies in the family Calliphoridae are generally the first insects to visit remains and are usually the most forensically informative. They are often used to estimate the Time Of Colonization (TOC) and, thus, the Postmortem Interval (PMI). However, to properly use insects for this purpose, it is important to know which necrophagous insects are present in a given area and the rate at which they develop.

FIRS is a facility dedicated to researching human decomposition. FIRS represents the only such facility in the semi-arid region of the southwestern United States, providing a unique opportunity to study human decomposition under these conditions. The presence of donated human remains placed in the facility throughout the year allows for a continuous survey of blow fly species active during the different seasons of the year.

Cadavers were inspected daily at FIRS and maggots were collected when seen on cadavers. To identify the blow flies that colonized human remains in the area, maggots were collected and reared out using methods identified in the FIRS protocols.<sup>2</sup> Pupae and deceased adult flies were sent to Cornell University, where they were identified to species. Two species, *Calliphora latifrons* and *Calliphora coloradensis*, were found to be the dominant colonizers of human remains during the late fall to early spring (November–March). The lack, or minimal amount, of developmental data in the literature for these two species suggested that a basic study on temperature-related development would be useful to the forensic community, so this project developed a study.

Development trials were completed at Cornell University's Shields Laboratory using reach-in environmental chambers set at different temperatures as replicates. Initially, development was documented across a broad range of temperatures (15°C, 20°C, 25°C, and 30°C). This was followed by more focused trials looking at development at a low range of temperatures (4°C, 8°C, 11°C, and 13°C). These lower temperatures were chosen to reflect the common ambient temperatures at the FIRS facility during the seasons when *C. latifrons* and *C. coloradensis* are most common. Three replicates were run at each temperature with each replicate consisting of four enclosures where maggots were allowed to develop from egg to adult with sampling conducted at regular intervals to measure maggot length and determine life stage. The resultant data was used to make isomegalen and isomorphen diagrams as well as a thermal summation model. Validation trials are planned to test the lab-collected temperature data in a field environment at the FIRS facility.

Findings generated from this work provide important baseline information regarding insect activity at the FIRS facility. This information will allow FIRS to more fully assist law enforcement in the area and pave the way for future experiments exploring the human necrobiome and the development of other insects that colonize human remains at the FIRS facility. It has ramifications for estimation of the PMI throughout the semi-arid areas of the western United States.

#### Forensic Entomology, Blow Flies, Development

### E50 The Effects of Ketamine and Xylazine on Larval Development in the Blow Fly (*Phormia Regina*)

Stephanie A. Olson\*, Arcadia University, Glenside, PA 10938; Tobias Landberg, PhD, Arcadia University, Glenside, PA 19038; Brandon Strauss, MS, University of Nebraska-Lincoln, Lincoln, NE 68588; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038

**Learning Overview:** After attending this presentation, attendees will better understand how the presence of ketamine and xylazine in the diet of black blow fly (*Phormia regina*) maggots affects their growth and development throughout the larval stages.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing entomological data to increase the accuracy of Postmortem Interval (PMI) determinations.

Entomotoxicology is an expanding field of forensic entomology that focuses on the effects of drugs and other toxins on insects. This project spans both main branches of entomotoxicology, growth/development studies and extraction/qualitative studies. This study focuses on development and will report the extraction results elsewhere. Insect larvae also produce a unique opportunity for toxicological samples when all other body tissues and fluids have degraded in late stages of decomposition. Previous studies have shown that there are various effects of drugs on the growth and development of insects. For example, ketamine and xylazine are sedatives that are commonly used in veterinary medicine. Ketamine is a common party drug that is known on the street as Special K. It is also associated with drug-facilitated crimes. Xylazine is not commonly abused on its own, but it has been found in street heroin samples. Since these two drugs are both found on the street, they are of forensic importance. Asian blow fly, (*Chrysomya megacephala*) development may be affected when reared on rat meat dosed with ketamine and xylazine compared to those reared on drug-free meat.<sup>1</sup> These differences can lead to errors in PMI estimation. However, development may speed up or slow down depending on drug dose and the stage of larval development.

Preliminary research conducted on flesh-eating beetles (*Dermestes maculatus*) indicated there was no development change when the beetle larvae were exposed to ketamine in their rat meat diet. The purpose of this experiment is to evaluate temporal dynamics of larval instar-related developmental changes when exposed to ketamine and/or xylazine in a North American blow fly, *P. regina* (as overall developmental rate may not be affected).

*P. regina* is a cosmopolitan species that is commonly encountered and utilized in forensic entomology. The present study describes the effects of ketamine and xylazine on the development of *P. regina* from first to third instar. Twenty Sprague Dawley rats were dosed with ketamine and/or xylazine in saline via intraperitoneal injection as follows: K1 at 100mg/kg of ketamine, X1 at 10mg/kg of xylazine, K2X2 at 300mg/kg ketamine and 30mg/kg of xylazine, and K3X2 at 450mg/kg of ketamine and 30mg/kg of xylazine. The first two doses are therapeutic levels and the last two are lethal doses. A control group was injected with saline. All rats were then euthanized and dissected; the brain, liver, and heart were removed. Ten maggots were then placed onto each organ, and larval stage was recorded twice per day. Temperature was monitored to determine Accumulated Degree Hours (ADH) to provide a more accurate measure of PMI.

The results indicate that there is an effect on early instar developmental rate (instars 1 and 2) which is drug- and dose-dependent; however, larval development (to instar 3) is similar to controls. This highlights the importance of determining drug presence in tissues and understanding instar-dependent variation of PMI estimations utilizing *P. regina*.

#### Entomotoxicology, Ketamine, Xylazine

## E51 Profiling the Odorant Chemicals Present in *Cimex Lectularius*

Katelynn A. Perrault, PhD\*, Chaminade University of Honolulu, Honolulu, HI 96816

**Learning Overview:** After attending this presentation, attendees will better understand the Volatile Organic Compounds (VOCs) emitted from *Cimex lectularius* (bed bugs), a well-known human parasite that is commonly detected by scent detection canines in the United States.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by studying the scientific foundation for the use of pest/insect detection canines, which is important due to the current development of guidelines surrounding their use by the Organization of Scientific Area Committees (OSAC).

In 2017, the Dogs and Sensors Subcommittee within the Crime Scene/Death Investigation Committee of OSAC began to establish guidelines on the training and certification of pest/insect detection canines. The goal of these guidelines is to improve the performance, reliability, and courtroom defensibility of detection dog teams in the field. Current best practices dictate that training shall be performed on actual live *C. lectularius* adults. There is currently a major knowledge gap in the VOCs produced by *C. lectularius*, and limited current research being conducted in this topic area. Surrogate training aids are available for *C. lectularius*; however, these are not recommended by current practices. In addition, very little is known about the difference in odor profile between live and dead *C. lectularius* adults, as well as the various life stages of this species. The overall aim of this work is to provide chemical data that can improve detector canine operational performance and provide a scientific foundation for training, certification, and use guidelines. The objective of the current study was to establish a VOC profiling method for *C. lectularius* that can be used in future work and to provide a preliminary comparison of living and dead *C. lectularius* adults.

Adult *C. lectularius* were profiled in sealed headspace vials using Solid-Phase Microextraction (SPME) Arrow. This is a technique that permits non-contact sampling of the insects, while allowing a high capacity of VOC loading onto the Arrow fiber. The samples were then analyzed by Gas Chromatography/Mass Spectrometry (GC/MS). A VOC signature could be detected from two adults in a single vial; however, a 10min exposure time was recommended to increase the intensity of the signal for GC/MS analysis. This preliminary work identified that some compounds were specific to live *C. lectularius* (e.g., phenol, 6-methyl-5-hepten-2-one) and some were specific to dead *C. lectularius* (e.g., 2-octenal). In addition, some compounds were found to be in common between the live and dead insects but were found either in higher concentrations in the live individuals (e.g., decanal, caprolactam) or dead individuals (e.g., 2,4-ditertbutylphenol). A single compound, nonanal, was found to be in both live and dead bed bugs at approximately equal concentrations. Additional work is needed to validate the identity of these specific compounds and whether these trends can be consistently seen across insects that may have been bought from different sources or have been stored for different lengths of time. Improving this chemical foundation for the use of live *C. lectularius* insects during detection dog training may assist in developing improved or more convenient training procedures. It may also permit the development of suitable surrogate training aids.

This research is significant because it is the first primary study that provides a chemical foundation for the use of live *C. lectularius* for training bed bug detection canines. This can assist in improving standards for training, certification, use, documentation, and management of detection canines as a valuable forensic tool. It will also serve to improve the reliability and courtroom defensibility of pest/insect detection canines.

### Scent Detection Canines, Volatile Organic Compounds (VOCs), Bed Bugs

## E52 Can Body Cooling Animal Models Help Solve the Jeju Island Cold Case?

*Dae-Kyoon Park, MD, PhD\**, Soonchunhyang University, Cheonan-si, Seoul 31151, SOUTH KOREA; *Duk-Soo Kim, PhD*, Soonchunhyang University, Cheonan-si, YT Seoul 331946 Korea, SOUTH KOREA; *Cheolho Hyun*, Jeonju, Jeonbuk, SOUTH KOREA; *Taehwa Song*, Korean Police Investigation Academy, Asan, SOUTH KOREA; *Kyeongyang Sim*, Suweon, Gyeonggido, SOUTH KOREA; *Na Jin Kim*, Busan, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will understand the application of body cooling animal models to solving cold cases in that the rectal temperature could be influenced by the ambient temperature and the surface temperature where the body was laid.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating more reliable time-since-death estimation in the early stages of decomposition by employing animal models.

When a body is found at the early stages of decomposition, crime scene investigators estimate time since death using the Henssge nomogram that requires rectal and ambient temperature. However, the application of the Henssge nomogram is problematic in Korea because there may be interferences with body heat radiation during algor mortis. A previous study suggested that the temperature of the substrate has a greater effect on the postmortem cooling of the body than the ambient temperature.<sup>1</sup> For this experiment, key words in cold case files such as “rectal temperature” or “time since death” were reviewed. The Jeju Island homicide case involves a body that was found in a drainage area at 1:30 p.m., on February 8, 2009, seven days after the victim was reported missing. Six hours later, the body was moved to the road beside the scene, and the rectal and ambient temperatures were 13°C, and 9.2°C, respectively. According to the autopsy report, internal organs were fresh, and stomach contents were present. Based on these observations, the postmortem interval was estimated as within 24 hours from the time the body was found. The prime suspect was released from the police investigation as the man had an alibi during that postmortem interval. The purpose of this study is to reconstruct the Jeju Island crime scene and to reevaluate the postmortem interval by employing animal models.

The study was approved by the Korean Police Investigation Academy Institutional Animal Care and Use Committee (KPIA-18—01). Four pig (*Sus scrofa* L.) and three beagle (*Canis familiaris* L.) carcasses were placed at the scene where the body was found and monitored for eight days by Closed-Circuit Television (CCTV), from January 29 to March 2. Six temperature probes were placed: inside the rectum; on the body surface (skin); inside the clothing; on the surface of the clothing; in between the body surface and the surface of the drainage; and inside the drainage. Temperatures were recorded every ten minutes with a data logger system, and the WatchDog® 2000 mini station was placed next to the carcasses to record ambient temperature.

The mean temperature inside the drainage area was higher (0.93°C to 3.13°C) than the mean ambient temperature during the daytime. Because the drainage was exposed to sunlight from 9:00 a.m. to 4:00 p.m., the temperature inside the drainage might be affected by solar radiation. The rectal temperature reached that of the ambient temperature in at least 50 hours in pigs and 28 hours in beagles. The rectal temperature fluctuated thereafter; as the temperature inside the drainage rose, the rectal temperature rose four to six hours after, and when the temperature inside the drainage fell, the rectal temperature fell six to eight hours after. Therefore, the Henssge nomogram may have been an unreliable method for estimating postmortem interval in the Jeju Island homicide case.

The present study demonstrates that the postmortem interval in the Jeju Island case is greater than 24 hours because the victim’s rectal temperature was possibly affected by the temperature inside the drainage. Furthermore, the victim was found seven days after being reported missing. After reviewing the original autopsy report and applying the results of this study, it was estimated that the postmortem interval is 28 to 50 hours from the day the victim was reported missing and not from time when the body was found. It could also be suggested that the Jeju Island case needs to be reinvestigated. The results of this study on postmortem cooling of animal models has a potential application in unsolved cold cases in Korea.

### E53 Climate's Influence on Diptera Present on a Carcass

*Timothy Juedes, MS\**, Platteville, WI 53818; *Ismail M. Sebetan, MD, PhD\**, National University, La Jolla, CA 92037-1011; *Paul Stein, PhD\**, National University, La Jolla, CA 92037

---

**Learning Overview:** After attending this presentation, attendees will better understand the role of climate on the presence of flies (Order: Diptera) that would be expected to colonize human remains in southwest Wisconsin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing the relationship between climate and the presence of flies on remains located in southwest Wisconsin. Entomological information is provided from other studies conducted that have similar climates to southwest Wisconsin for data analysis. Relationships between data collected from the adult and larval flies recovered from pig and rabbit carcasses and the Postmortem Interval (PMI) will be presented.

This study hypothesized that the local climate would affect the Diptera present on a decomposing carcass. A key objective was to identify the taxonomic relationships of flies (Order: Diptera) that colonized the pig and rabbit carcasses. The locations of these flies were documented relative to the proximity to areas of trauma. Postmortem indicators of death (algor, livor, and rigor mortis) were also observed and recorded. A scale was developed to determine the level of fixation for each of the PMI indicators observed.

Animal carcasses were exposed to the local climate conditions recorded between September 2016 and December 2017 (16 months) at the field study station located in Platteville, WI. The animal was placed on a soil-filled wooden box that was placed on top of a cement slab isolated by a chain link kennel fence. This simulated a body dump site on top of soil but was protected from scavenging animals. Temperatures were measured at selected intervals up to 72 hours after death. Fly samples were collected at these intervals and at any time the site was inspected. A chi-square test for independence was used to analyze the various data collected and significant differences indicated by p values <0.05

Results of the study indicated that the climate impacted the presence and species of flies colonizing the animal carcasses at the field station. Two families of Diptera were present, these were identified as Calliphoridae and Muscidae. Data also agreed with the observations that flies appear on deceased bodies prior to any other indicators of death. The data indicated that flies did not have a preference to colonize an area of trauma or a natural orifice. Temperature and rainfall impacted the quantity of flies and number of species present in the warmer months (June–September) compared to the colder months (October–December) when flies were noticeably reduced.

Entomological information on the presence and species of flies colonizing remains found in southwest Wisconsin was reported for the first time by these research findings. This information may be extrapolated to human remains and would be a basis for interpreting medicolegal findings during possible homicide investigations.

### E54 The Mystery Behind the Composition of Black Fingerprint Powders

*Grayce Behnke, BS\*, Export, PA 15632; Andrea Kardohely\*, Canton, OH 44718; Catherine G. Rushton, EdD, Marshall University Forensic Science Program, Huntington, WV 25701; Rosalynn Quinones, PhD, Marshall University, Huntington, WV 25755*

**Learning Overview:** After attending this presentation, attendees will understand the characterization of black fingerprint powders using a variety of different analytical instrumental techniques in order to determine the particle size, homogeneity, elemental composition, and surface functionalized groups.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by classifying black fingerprint powders in order to assist in the selection of a fingerprint powder that is most appropriate for the desired use. The objective of this research was to characterize black fingerprint powders in order to assist latent print examiners in the selection process of a black powder for fingerprint development.

Fingerprint development has been used to visualize latent prints since the 19<sup>th</sup> century, and several modern companies produce a variety of different commercially available black fingerprint powders. While the method to develop fingerprints has been refined over the years, the composition of the fingerprint powders that are used in this print development has not been studied extensively.

Black fingerprint powders were analyzed using Dynamic Light Scattering (DLS), zeta potential, Inductively Coupled Plasma/Optical Emission Spectroscopy (ICP/OES), Attenuated Total Reflectance/Infrared (ATR/IR) spectroscopy, and Scanning Electron Microscopy (SEM) with Energy Dispersive X-ray Spectroscopy (EDS). DLS can be used to determine the size distribution of small particles in suspension or solution. Zeta potential can be used to evaluate the stability of particles in solution. ICP/OES is an analytical technique that is used in the detection of chemical elements. ATR/IR can be used to identify the functional groups present in a sample with little to no sample preparation. SEM is used to produce images of a sample by scanning the surface with a focused beam of electrons. EDS is used to determine the elemental composition of a sample.

DLS was used to obtain the particle sizes of the black fingerprint powders in an aqueous suspension and SEM was used to obtain the particle sizes of the black fingerprint powders in their native form. DLS and SEM in conjunction were used to assess the homogeneity of the fingerprint powders. ATR/IR assisted in determining the surface functional groups present in the variety of black fingerprint powders studied. ICP/OES was used to quantify the elements present and, in conjunction with EDS, was used to determine the elemental composition of the components present in black fingerprint powders.

Preliminary DLS data indicates that black fingerprint powders from several different manufacturers are not homogenous and that the dispersion of particle sizes in the samples varies between different manufacturers. It should be noted that the average particle size remains fairly consistent between manufacturers. While the particle size dispersion varies between manufacturers, the zeta potential, which is the surface charge of the particles, is consistently negative and ranges from -26.31mV to -37.31mV. This indicates that the surfaces of the particles are stable in an aqueous solution. The methods of characterization described above will be applied to colored fingerprint powders, in addition to white and bichromatic fingerprint powders, in the future.

Black fingerprint powders from different manufacturers can be characterized using DLS, zeta potential, ICP/OES, ATR/IR, and SEM with EDS. This characterization can be used to assess the performance of black fingerprint powders in the development of latent prints.

---

#### Fingerprint Powder, Characterization, Particle Size

### E55 A Comprehensive Schematic for Postmortem Fingerprint Stations at Mass Fatality Incidents

*Marzena H. Mulawka, MFS\*, San Diego County Medical Examiner's Office, San Diego, CA 92123; Michael A. Mosco, MS\*, San Diego Police Department Crime Lab, San Diego, CA 92101; David Martinez, BS, San Diego, CA 92117*

**Learning Overview:** After attending this presentation, attendees will better understand how to set up a comprehensive disaster morgue fingerprint station for Postmortem (PM) fingerprint recovery during Mass Fatality Incidents (MFIs). A schematic of the fingerprint station will be displayed, along with various types of supplies and equipment that may be used for obtaining examination-quality fingerprint records from Unidentified Human Remains (UHR). Incorporating the highlighted equipment and supplies into disaster morgue operations may help identify many of the UHR that are processed during MFIs. Not only will identification of UHR yield valuable investigative information, but it will also allow for the notification of next-of-kin regarding the fate of their family member.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping further the ability of forensic and emergency management professionals to enhance disaster morgue operations by utilizing the comprehensive PM fingerprint station to efficiently and effectively handle fingerprint identification matters during disasters, especially for agencies exhibiting a high caseload during MFIs, when time and resources are significantly limited. This presentation will provide the specific resources needed to set up the presented PM fingerprint station during MFIs.

The use of fingerprints for forensic identification is a rapid, reliable, and cost-effective means to identify UHR. The use of friction ridge impressions for forensic identification during MFIs is well established in forensic science. However, the most efficient workflow for PM fingerprint recovery in a disaster morgue setting can be complex, often requiring the need for a more comprehensive and complete PM fingerprint station containing various specialized equipment and supplies. Factors such as the scale and nature of the incident, condition of the various remains, and condition of the friction ridge skin on each decedent are rarely uniform and often unexpected. These factors will dictate which methods must be used to successfully enhance and record any valuable friction ridge information. As a result, multiple techniques exhibiting varying complexities may be used with each set of remains. The wide range of techniques include, but are not limited to, the reconditioning of skin using tissue injection, soaking/rehydration, boiling, manipulation of degloved epidermal skin, as well as recording techniques, such as ink/card, fingerprint powder/adhesive lifter/acetate sheet, fingerprint powder/castings, photography, and digital scanning. As such, the appropriate supplies and equipment for each of the various techniques should be readily available in the disaster morgue. This can be accomplished by following the schematic and creating a comprehensive inventory of PM fingerprint recovery supplies and equipment that can be rapidly deployed during MFI disaster morgue operations.

#### Postmortem Fingerprint Recovery, Mass Fatality Incidents, Forensic Identification

### E56 Forensic Podiatric Science and Practice in Crime Scene Investigation

*Kewal Krishan, PhD\*, Panjab University, Chandigarh 160 014, INDIA; John A. DiMaggio, DPM, Bandon, OR 97411-8816*

**Learning Overview:** After attending this presentation, attendees will understand the value of an important and emerging subdiscipline of forensic science, forensic podiatry, which deals with the examination, interpretation, and evaluation of pedal evidence encountered at crime scenes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the utility of a comparatively new subsection of forensic science that is concerned with the inspection of pedal evidence at crime scenes. This may motivate young forensic scientists to take up this discipline for research and practice.

Forensic podiatry is comparatively a new scientific subdiscipline of forensic science that deals with the examination of pedal evidence generally encountered at crime scenes. It is defined as the application of sound and researched podiatric knowledge and experience in forensic investigations to show the association of an individual with a scene of crime or to answer any other legal question concerned with the foot or footwear that requires knowledge of the functioning foot.<sup>1</sup> Forensic podiatrists contribute to the personal identification in crime scene investigations whenever foot-related evidence is recovered from the crime scene. The need to establish the identity of dismembered remains may arise in cases of mass fatality incidents such as terrorist attacks, mass murders, transport accidents, tsunamis, floods, and earthquakes. Dismembered and mutilated remains are usually encountered in these mass fatality incidents. There is an increased likelihood of the recovery of feet (often enclosed in shoes), separated from the body in mass disasters such as high-power explosions and bomb blasts, airplane crashes, and other high-impact transportation accidents. In this regard, forensic podiatrists can collect the evidence related to feet and help in the identification of the individuals from the foot and its parts. Furthermore, forensic podiatrists conduct the examination of footprints generally recovered at the crime scene. Footprints are commonly recovered at every crime scene in the form of bare footprints, socked footprints, or shoe prints.

There are many ways in which footprints can be used to establish personal identification in forensic podiatry. The analysis of bare footprints involves identification based upon class, intermediate class, and individual characteristics of the footprints. For example, features such as corns, pits, ridges, humps, creases, hammertoe deformity, an extra toe, missing toe in the foot impression, and flat footedness are characteristics of the footprints that can be utilized as forensic evidence in establishing personal identification. This type of physical evidence can positively link a suspect to a crime, or it can prove one's innocence. By using different anthropometric methods, the stature, sex, and body weight can also be estimated from the footprints recovered at the crime scene. As stature and body weight can provide an idea about the size of the individual, so can they provide useful clues to a forensic scientist in a criminal investigation. Apart from this evidence in forensic podiatry, gait analysis and step/stride length analysis can also furnish some indication about the criminals involved in a particular case.

This presentation will discuss various methods of personal identification related to the pedal evidence which is usually recovered from the crime scene or scene of occurrence in the form of mutilated/dismembered remains, footprints, or questioned footwear.

### **E57 A Reference Collection of Footwear Randomly Acquired Characteristics (RACs) for Frequency and Spatial Distribution Analysis**

*Kim Dang, BS, ORISE/FBI, Manassas Park, VA 20111; Colbey Ryman\*, Woodbridge, VA 22191; Thomas G. Kopczynski, BS\*, Mokena, IL 60448; Katherine Ky, ORISE/FBI, Oak Ridge, TN*

**Learning Overview:** After attending this presentation, attendees will understand how RACs can be used to determine frequency and spatial distributions for probability assessments in forensic footwear analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a dataset to be used for statistical analyses and determining RAC probability assessments.

Footwear impressions are often deposited on a surface when a shoe worn by an individual makes contact with a surface. If detected and recovered, this evidentiary item can provide valuable investigative linkage to a suspect. RACs are frequently used to make comparisons between a questioned impression and known footwear. Recently, there have been courtroom challenges regarding the discrimination potential of footwear evidence, particularly when there are mass productions of similarly modeled and sized shoes. To address these challenges, the Federal Bureau of Investigation (FBI) is currently compiling data on the frequency and spatial distribution of RACs detected on the outsoles, then marked using Adobe® Photoshop® for more than 1,500 boots with a similar outsole pattern and class characteristics. A visualization of common and rare RAC locations and frequencies are represented in heat maps, providing a visual approach into the role RACs play in the differentiation of impressions and outsoles.

The purpose of this study was to assign and characterize, in a quantitative fashion, the frequency and positional descriptions of RACs on boot outsoles acquired by FBI agents in training as they performed similar tasks while wearing the same type of Eastern Mountain Sports® Day Hiker boots.

To prepare boots for analysis, the outsoles were initially cleaned and scanned. Test impressions of the outsoles were created with the use of black powder and adhesive sheets. The scanned boot impression and corresponding test impression were then aligned with each other. After background subtraction, a comparable boot shape was obtained.

Preliminary visual interrogations using only oblique lighting of each physical boot outsole were conducted after test impressions were created. Documentation of any discernible RACs were recorded on a paper template without magnification. Observations of the outsoles of the boots were made in conjunction with the corresponding scanned test impressions to assess that all of the lugs were impressed properly. When the impression was verified, Quality Assurance/Quality Control (QA/QC) checks for both intra- and inter-evaluator RAC assessments were completed.

Throughout the project, questions were raised about RAC frequency and placement. While there was no correlation between RAC counts and boot size, greater percentages of RACs were found in the toe and on the edges than in other areas of the boot. Results also indicate there is no correlation between RAC frequency and gender. Since weight, height, and gait were all unknown variables, they were not considered.

The FBI boot outsole reference collection dataset consists of more than 150,000 RACs and provides valuable information for quantifying the discrimination potential of footwear evidence, specifically in regard to the use of RAC location in outsole identifications. Shape similarity metrics will be applied in Phase II of this project to quantitatively compare the closeness of features across known non-match boots to evaluate the probability of two different boots sharing the same shaped feature or feature set.

#### **Footwear Analysis, Randomly Acquired Characteristics, Database**

### E58 A Longitudinal Database of Athletic Shoe Outsole Wear

*Susan VanderPlas\*, Ames, IA 50011; Guillermo Basulto-Elias, PhD, Iowa State University, Ames, IA 50011; James E. Kruse, CSAFE, Iowa State University, Ames, IA 50010; Stacy Renfro, MS, Iowa State University, Ames, IA 50011; Alicia L. Carriquiry, PhD, Center for Statistics and Applications in Forensic, Ames, IA 50011*

---

**Learning Overview:** After attending this presentation, attendees will be familiar with the features of a new longitudinal database of athletic shoe outsoles. Attendees will be able to query the database for data from different collection methods, shoe styles and sizes, and wear levels.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on a new resource for understanding the development of individualized wear patterns on athletic shoes. This presentation will also discuss the development of individual characteristic wear patterns over the course of the study for each of the two athletic shoes examined in this experiment.

In order to ground forensic science in data-driven methodology, it is necessary to assemble reference databases that can be used to benchmark new methods. The longitudinal shoe outsole database hosted on the Center for Statistical Applications in Forensic Evidence (CSAFE) data portal contains images of 160 pairs of athletic shoes, in two styles and four sizes. Participants wore the shoes for at least 10,000 steps per week, and images of the shoes were taken at five-week intervals, producing five observation points for each pair of shoes. At each time point, shoes were imaged using pressure-mat scans, high-resolution photography, 2D digital scanning, 3D scanning, film/dust prints, paper/dust prints, and vinyl/dust prints intended to simulate crime scene prints. For a subset of the shoes, randomly acquired characteristics have been marked and identified by the Israeli Police.

This database, which is freely available to the public, provides a curated data set for examination of Randomly Acquired Characteristic (RAC) development, individual wear pattern characterization, and benchmarking of statistical methods for matching outsole prints. As there are many replicates of each size/style combination in the data set, it is possible to assess within-style individual characteristics and examine how those characteristics develop over time. In addition, as shoes have been imaged using multiple methods, with replicates of each method at each timepoint, it is possible to examine the variability of each collection method and establish the strengths and weaknesses of each method. The database is structured to allow for the download of query-filtered subsets of the images and accompanying metadata. Users can also preview images and 3D surface files using the graphical database interface. Bulk downloads of the full dataset, which is approximately 1.4 TB, will also be available.

This presentation will include a live demonstration of the database and an example of the development of wear over time for one pair of shoes, as shown using several 2D data collection methods.

---

#### Database, Outsole, Wear

### E59 Paternity Testing and Next Generation Sequencing: New Approaches to Detecting Illegal Bird Trading

Ana Luiza Queiroz, BA\*, Federal University of Minas Gerais, BELO HORIZONTE, Minas Gerais 31270-901, BRAZIL; Wander U. Mesquita, BSc, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL; Adriana H. Pereira, MSc, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL; Susanne Facchin, PhD, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais 31270-901, BRAZIL; Sandra Ludwig, PhD, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL; Nazaré L. Abreu, MSc, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL; Isabella Pena, PhD, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL; Evanguedes Kalapothakis, PhD, Federal University of Minas Gerais, Belo Horizonte 31270-901, BRAZIL

**Learning Overview:** After attending this presentation, attendees will understand important aspects about wildlife trafficking in one of the most biodiverse countries, including its regulation, problems with the current form of identification of legal specimens, and new approaches using DNA to detect illegal bird trade.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing modern techniques applicable to wildlife forensics, especially in regard to illegal bird trafficking.

Birds born in captivity are identified by a small, individually numbered metal tag attached to the leg. However, despite many regulatory standards set for this identification, frauds are frequent and often hard to detect by conventional forensic methods. Paternity tests using microsatellites (Short Tandem Repeats in the DNA) presents an alternative for these cases.

Researchers from the Laboratory of Biotechnology and Molecular Markers developed a standardized paternity test for the blue-fronted Amazon (*Amazona aestiva*) using traditional methodology (Polymerase Chain Reactions (PCRs) followed by analysis of amplified fragments on a 3130 Genetic Analyzer with an estimated cost per sample of approximately USD \$25.00) based on eight loci. This methodology, later employed in a joint inspection with the Brazilian environmental agency, successfully identified fraudulent bird trade, resulting in the shutdown of the breeding sites.

Building on the success of this approach, the same research group then focused on the development of a paternity test for *Saltator similis* (Green-winged Saltator) and *Sporophila maximiliani* (Great-billed Seed-finch), both listed as among the most trafficked species in Brazil.<sup>1</sup> This time, in order to develop a more cost-, time-, and labor-effective methodology, Next-Generation Sequencing (NGS) was utilized, which allowed the manipulation of 384 samples in a single run, representing a cost per sample of approximately USD \$8.00. With this technique, microsatellites on contigs were found using msatcommander and the selected ones had their primers synthesized, PCR reactions standardized, and tested for their degree of polymorphism.<sup>2</sup>

For *Sporophila maximiliani*, ten selected loci were already tested in different populations and proved to be efficient in successfully detecting paternity. For *Saltator similis*, experiments are in the final stages and show promising results.

In summary, paternity testing is a promising technique to help enforcement agencies fight illegal bird trade. The use of NGS considerably facilitates this process, saving time and reducing costs.

### E60 Death Due to Unintentional Dichloromethane Inhalation: A Case Report and Cautionary Tale

Anita Roman Hasert, BS\*, Charleston County Coroner's Office, North Charleston, SC 29405; Demi B. Garvin, PharmD, Forensic Science Network, Columbia, SC 29201; Angelina I. Phillips, MD, MUSC, Charleston, SC 29425

**Learning Overview:** After attending this presentation, attendees will understand the safe and thorough medicolegal death investigation practices needed to: (1) interview those in contact with the victim prior to death; (2) review the victim's social circumstances and medical records; and (3) ensure effective coordination and collaboration with emergency medical services, fire, law enforcement, and Hazardous Materials (HAZMAT). Attendees will also understand specific challenges associated with the scene evaluation, evidence collection, body transport, autopsy protocol, and toxicology testing in a case of fatal hydrocarbon intoxication.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing fatal Dichloromethane (DCM, methylene chloride) exposure and the vital medicolegal death investigation procedures needed to ensure a safe and accurate evaluation of these fatalities.

The true epidemiology of hydrocarbon exposure, morbidity, and death is difficult to determine from available data sources. DCM is a halogenated hydrocarbon commonly found in paint removers, cleansers, degreasers, and aerosol propellants. Reported intoxications from DCM have occurred from inhalation, dermal, ocular, and/or oral exposure. Deaths resulting from unintentional methylene chloride inhalation appear to be relatively uncommon. A colorless, non-flammable liquid with sweet, chloroform-like odor, DCM can rapidly induce general anesthesia when inhaled.

Acute toxic effects may begin immediately upon inhalation with the development of confusion, dizziness, shortness of breath, numbness, nausea, vomiting, and fatigue. Prolonged exposure may lead to lethargy, unconsciousness, and death. The organs primarily affected by DCM are the liver and brain, although an association with cardiovascular disease has also been reported. Unlike other hydrocarbon compounds, DCM is metabolized by liver P450 mixed-function oxidase to carbon monoxide. As a result, significant, delayed, and prolonged carboxyhemoglobinemia has been described.<sup>1-3</sup>

The decedent was a 31-year-old Caucasian male found unresponsive on the floor inside the walk-in refrigerator of his cold brew coffee business. Emergency Medical Services (EMS) were notified and the victim was pronounced dead at the scene. It was determined that he had collapsed while applying a liquid, sprayable paint stripper product containing dichloromethane and methanol. On scene, EMS personnel described the presence of existing and pungent chemical fumes. A HAZMAT team responded to detect, contain, and remove the material, monitor scene safety, and decontaminate the decedent prior to transport and autopsy.

This presentation will include discussion of the history, scene, practices, and personal protective equipment used by the victim, as well as the challenges associated with safe and effective evidence collection in presumed toxic exposures. Pathology and toxicology findings specific to this case will be presented in the context of DCM fatalities previously published in the peer-reviewed literature. Education of the forensic community and the consumer regarding the proper use of hydrocarbon products and their potential hazards is critical to the prevention of toxic and perhaps fatal exposures. Coordination and collaboration with multiple agencies will be necessary for the safety of those involved as well as the accurate determination of cause and manner of death.

## E61 Artificial Intelligence for Homicide Investigations

Jiaqi M. Lu, MS\*, University of New Haven, West Haven, CT 06516; Xuanfeng Fang, MSc, University of New Haven, West Haven, CT 06516; Elaine M. Pagliaro, JD, University of New Haven, West Haven, CT 06516; Henry C. Lee, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to introduce a different approach to performing a forensic investigation that could be assisted by data technology and Artificial Intelligence (AI) and to demonstrate the capacity of these emerging technologies and how they may benefit our daily work.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by utilizing and developing the necessary data technologies to increase the accuracy and efficiency in forensic investigation.

AI is the simulation of human intelligence performed by the computer system.<sup>1</sup> AI research is becoming more and more popular in many professional fields around the world, including finance, health care, industry, education, transportation, smart city management, and many other fields. Research has indicated that the primary feature of AI, learning and problem solving, could also assist in the criminal investigation as well.<sup>2</sup> Although there are many data models and prototype AI systems already developed and employed by the law enforcement community, AI is still an emerging technology for forensic investigation fields. This study attempts to evaluate the potential of AI in forensic investigation and to develop an approach that facilitates an effective investigation through the application of AI.

The proposed approach is built on data and algorithms, and this study concentrated on developing the forensic investigation application through available multidimensional data and efficient algorithms. As a part of computer technology, AI has many unique features in addition to characteristics of the contemporary computer system, including high-performance and accuracy in processing, high capacity in data storage, and high scalability and distribution in network.<sup>3</sup> This research specifically identified the features of AI technology that may assist in the forensic investigation by its particular advantages, especially machine learning, as the most important aspect of AI technology would provide investigators with the data-driven predictions and decisions learning from previous cases. The different analytical models of AI to increase the certainty and efficiency in forensic investigation will be introduced. The models simulate a human's perception to enhance the data process, which image recognition and natural language process would help homicide investigators retrieve the critical information from large-scale of data within minimal time. The analytical models also provide the investigators with crucial patterns by pattern recognition, anomaly detection, clustering, classification, and regression. The linkage with individual, evidence, time, location, pattern, and fact in a case will be developed; associate related or serial cases; eliminate the irrelevant individual and evidence; present the case information with graphical depiction; identify and profile the possible suspect; and develop many other investigative leads from data mining by examining correlations, associations, and factors.<sup>4</sup> Two serial homicide cases will be utilized to demonstrate the process of data collection, data integration, the unstructured data transformation, analysis and reasoning, evaluation and verification, and reconstruction through the application of AI. Details of each logic reasoning and specific data model will be explained as well.

### E62 Complex Suicides and Where to Find Them: Disclosing the Mystery

*Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Francesca Maglietta, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Mauro A. Ciavarella*, University of Foggia, Forensic Department, Foggia 71121, ITALY; *Carmela Fiore, MD*, Ospedale “G. Tatarella,” Cerignola, Foggia 71100, ITALY; *Irene Riezzo, MD, PhD*, University of Foggia, Osp D’Avanzo, Foggia 71100, ITALY; *Pietrantonio Ricci, MD, PhD*, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; *Francesco Sessa, MS*, Department of Forensic Pathology, University of Foggia, Foggia 71100, ITALY

**Learning Overview:** The goal of this presentation is to discuss the wide spectrum of methods employed to commit suicide, including complex suicides, and how a methodological, multidisciplinary approach is mandatory to define the cause of death and serve justice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping pathologists with the management of particular cases, such as complex suicides, and also to show the importance of a methodological multidisciplinary approach to support investigations and find the solution.

Suicide is a serious widespread health problem; according to the World Health Organization data, suicide completion accounts for one death every 40 seconds. Complex suicides deal with more than one method employed to commit suicide, accounting for only 1.5%–5% of all completed suicides. These cases represent a significant challenge for the forensic team, particularly in the definition of the cause of death and the reconstruction of the event. Four cases between 2010–2017 were analyzed by the Department of Forensic Sciences of the University of Foggia. To solve these cases, a multidisciplinary approach was needed and included: a careful crime scene investigation, a complete victim medical history analysis, a meticulous autopsy, with histological and immunohistochemical examinations, and both toxicological and genetic support.

The first case dealt with a 38-year-old man who was found lifeless in the woods with multiple adhesive band loops, obstructing his nostrils and mouth, and two gunshot wounds at the right temporal region and left thoracic side. A gun was located a few meters from the car.

The second case concerned a 32-year-old man found dying in his own car at a highway rest area. He had a deep neck wound, which exposed the underlying hemorrhagic muscular tissues and the laryngeal cartilages. This wound was inscribed in a complex of superficial slashed wounds. The left wrist was also slashed.

Another case dealt with a 76-year-old woman found lifeless in her house, hanging from a scarf wrapped around her neck, in the storage room with multiple superficial and parallel slashed wounds to the flexor surface of both forearms. In her bedroom, a white cotton sheet was found, severely blood stained with a kitchen knife on it.

Last, at a beach resort, a 46-year-old male body was found hanged. A hangman’s noose was made of his car safety belts tied together and was attached to the air conditioning fan. On this fan, a blood-stained knife was also found. His van had a tube connected from the muffler to the right-side window.

In all of these cases, only the mindful integration of all evidence can provide the most reliable reconstruction of the lethal chain of events leading to suicidal choices: all were complex suicides.

To complete the analysis of these cases, given the recent interest in the relationship between polymorphisms in the promoter region of the serotonin transporter gene (SLC6A4 gene) and psychiatric disturbances, this region was tested. In particular, the presence of one or two short alleles of 5-HTTLPR was associated with anxiety-related personality traits and psychiatric disturbances, such as depression. Genetic tests identified the hidden line that linked each case to the others: all subjects were homozygote for short variant.

#### Complex Suicides, Multidisciplinary Approach, 5-HTTLPR Short Allele

### E63 An Eight-Year Retrospective Study on Suicides in Washington, DC

*Breanna M. Cuchara, MFS\*, Manassas, VA 20110; Francisco J. Diaz, MD, Office of the Medical Examiner, Washington, DC 20024*

**Learning Overview:** After attending this presentation, attendees will understand how beneficial it is to perform toxicological analyses on every suicide and monitor the drug trends in suicides, given the current opioid crisis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing evidence that supports a need for states to increase the funding for medical examiners' and coroners' offices. With this increase in aid, the trends in drugs among suicides can be analyzed and new prevention programs can be created by other health agencies.

Suicide is the tenth-leading cause of death in the United States and it is steadily increasing.<sup>1</sup> More than 44,000 people commit suicide every year.<sup>1</sup> When a suspected suicide occurs, the medical examiner, per statute, has jurisdiction over the decedent. A forensic pathologist must consider many factors when ruling the death a suicide, including if the decedent has had suicidal ideations or attempts before, diagnosis of a mental illness, and the amount of drug(s) present in the toxicology report, all of which must be considered before he or she can rule the death a suicide.<sup>2</sup> It is also important to understand the drug quantity and if it had been taken recently or chronically before a suicide. Each of these factors were examined and analyzed during this review.

This study analyzed toxicology, autopsy, and investigative reports for trends within this population. Between 2009 and 2016, the mortality rate for suicides in Washington, DC, had decreased from 8.8 to 6.5 per 100,000 people. Interestingly, the mortality rate was at its highest in 2014 with 10.5 per 100,000 people. When compared to different states, the population size of Washington, DC, was taken into account.

It was found that 394 decedents committed suicide, most commonly by hanging (31.2%), firearms (20.3%), and drug intoxication (15.7%). The majority of decedents were Caucasian males that resided in Washington, DC, between the ages of 20–29 years old. Interestingly, the toxicology trend showed either no drugs (33.7%), ethanol (26.4%), or opioids (14.9%) most frequently detected. Using the test of two proportions, data showed that decedents between the age of 30–39 years old were significantly more likely to have ethanol recognized in their system versus the rest of the population (P value=0.0251). Also, opioids were most commonly found in decedents ages 70–79 years old (P value=0.00398). This study analyzed the method of suicides compared to the month in which this event occurred, presence or absence of suicide note(s), suicide by firearms, the anatomic location of the injury, and more.

This research provides statistical data for public health officials when confronting the issue of suicide. It will help officials move forward with creating outreach programs to specific areas of the community that are at risk for suicide attempts or ideations. The hope is to encourage other offices to perform toxicological analysis on every suicide because drugs play a significant role in behavior. Understanding the significances of prescription or illicit drug use and the effects on behavior will bring health agencies one step closer to decreasing suicide.

### E64 Drowning in the District: A Ten-Year Retrospective Review of Cases in the Nation's Capital

*Daniel J. Morgan, MS\*, Washington, DC 20024*

---

**Learning Overview:** The goals of this presentation are to discuss: (1) the epidemiological profile of District of Columbia drowning cases, (2) common pre-drowning activities, (3) challenges in determining the manner of death when a body is found in water, and (4) recommended investigative protocols.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to the body of knowledge of medicolegal investigation of drownings in natural and man-made waterways.

The District of Columbia has a resident population approaching 700,000 and a daily surge in population of workers and tourists. The District of Columbia also has natural and man-made waterways that are highly accessible, yet drowning is a rare phenomenon. For this study, the Office of the Chief Medical Examiner's case management system was searched for the keyword "drowning" in the cause-of-death statements for all accepted cases from 2007-2016. Of the approximately 12,000 accepted cases in this ten-year period, only 100 deaths were attributed to drowning. The results were further filtered by "injury address" to identify deaths occurring in waterways, and 49 cases were identified. Finally, case files were reviewed in order to identify the epidemiological profiles of the decedents and to obtain descriptions of their pre-drowning activities.

In this study, all decedents were identified. The vast majority of decedents were male, which is consistent with published literature. The racial breakdown was as follows: 49% Black, 33% White, 12% Asian, 4% Hispanic, and 2% Other. The percentage of Asian decedents was overrepresented in drowning cases as compared to all other types of medical examiner cases. The age range for decedents was 11 to 76 years with a mean of 45 years old.

Drownings occurred in rivers in 78% of cases, man-made waterways in 16%, and creeks in 6%. The manner of death was Undetermined in 43%, Accident in 31%, and Suicide in 26%. This study may have a higher percentage of Undetermined drownings since the pre-drowning activities were often difficult to identify as the decedents' entry into the water was unwitnessed in 76% of the cases. In the witnessed cases, decedents were involved in recreational activity, lived on/near the water, or intentionally entered the water to commit suicide.

In addition to the challenges of identifying a decomposed "floater," this presentation will discuss two equivocal cases that illustrate the challenges of determining the manner of death. This presentation will conclude with a list of recommended protocols for the medicolegal investigation of bodies found in water.

---

#### Investigation, Drowning, Natural Waterways

### E65 A Killer in the Hospital Wards: Murders Committed by the Criminal Administration of Heparin

*Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Federica Gori, MD, University of Pisa, Pisa 56100, ITALY; Chiara Toni, MD, Pisa, ITALY; Sara Turco\*, Istituto di Medicina Legale, Pisa 56126, ITALY*

**Learning Overview:** The goal of this presentation is to highlight the importance of a multidisciplinary approach in the police investigation of a complex case of murders in a hospital due to criminal heparin administration. Autoptic examination, histopathological, immunohistochemical, and toxicological analysis together with a meticulous analysis of the clinical reports and Postmortem Computed Tomography (PMCT) revealed 12 cases of “natural death” to be murders due to the voluntary administration of heparin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the great importance of a multidisciplinary investigation in a nearly unique case of multiple murders due to the criminal administration of heparin by a health care worker.

In May 2015, investigations began from a confidential report to the police, related to the suspicious death of two patients admitted to the intensive care unit of a small-town public hospital. Both cases presented with sudden and unexplained hemorrhagic episodes associated with the evidence of very high levels of heparinemia.

Following this report, a police investigation began. At first, police identified ten cases of similar sudden deaths, all occurring between 2014 and 2015. In all of these cases, sudden death followed hemorrhagic events and was associated with a complete alteration of the coagulation parameters. All the hemorrhagic events were not related to pathologies, either of the therapy administered at home or during the hospital stay.

After May 2015, two further deaths occurred. The last, similar to the other deaths, was characterized by hemorrhagic events and very high levels of heparin in the blood immediately after a surgical procedure for femoral fracture and occurred in September 2015. Inspection of the hospital room revealed an empty bottle of heparin in the garbage bin. Then, another case was discovered: a patient who was in the same room as the first patient of the series. He survived but showed an unexplained alteration of coagulation values. Investigations revealed 13 suspicious cases, 12 deaths, and 1 survivor.

In March 2016, a nurse who worked in that hospital was implicated for heparin administration. The forensic investigation began in March 2016, with a team comprised of a forensic medicine expert, a hematologist, and an anesthetist. Autopsies were performed on eight exhumed cadavers; the other six patients had been cremated. Analyses included a total body-computed tomography and toxicological and histological examinations. The latter was performed using traditional staining with trichrome. The samples of major interest were further examined with an immunohistochemistry analysis based on a glycophorin-test, which is recognized as a reliable test to reveal erythrocytes and the precursors in decomposed tissues.

Despite the advanced state of decomposition, autoptic examination confirmed macroscopic findings of hemorrhagic events described in medical records, while immunohistochemical analysis confirmed the presence of blood in the tissues. The forensic analysis of the case was also based on the thorough examination of the clinical reports, in order to assess the coagulation parameters and therapies.

Further investigation regarding all the patients deceased in that unit from 2014 to 2017 pointed to ten other suspected cases; among these, two were strongly suggestive of voluntary heparin administration and, in one case, the death was related to the combination of heparin and insulin administration.

Worldwide, there is only one other known case of multiple murders due to voluntary administration of heparin, which occurred in the Czech Republic with seven deaths, while in this case, forensic analysis performed with the accurate examination of clinical reports, PMCT, autoptic examination, and histopathological and toxicological evaluation helped reveal the violent death of 12 patients and the death threat of another. The nurse is now on trial, charged with first degree murder. The scientific proof will be fundamental in court.

#### **Heparin, Coagulation, Homicide**

### **E66 Down the Rabbit Hole: The Functional Paralysis of a Medical Examiner Facility by Contaminated Palo Mayombe Artifacts**

*Brett E. Harding, MBA\*, District 5 Medical Examiner's Office, Leesburg, FL 34748; Kyle Shaw, MBBS, District 5 Medical Examiner's Office, Leesburg, FL 34748; Barbara C. Wolf, MD, District 5 Medical Examiner's Office, Leesburg, FL 34748*

---

**Learning Overview:** After attending this presentation, attendees will understand: (1) the dangers of elemental mercury facility contamination, (2) the potential danger of Palo Mayombe artifacts and the potential risks to facility and staff, and (3) the multidisciplinary methods utilized to return facilities to functional operations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the dangers associated with Palo Mayombe artifacts and elemental mercury.

The efficient daily operation of a medical examiner/coroner facility is an integral part of the criminal justice system and is essential for the timely service of the citizens who are served. The operations are usually dependent on predictable factors, such as employee staffing, case load, equipment operations, etc. These institutions are expected to maintain a functional operational status through all types of adversary. Protocols address the possible interruption of utility services to help assure the continued operation. However, unforeseen factors or situations arise that may paralyze the successful daily operations of the usually "smooth running" institution.

Contamination hazards within a medical examiner/coroner facility are usually confined to bloodborne pathogens associated with decedents' bodies. These pathogens are generally well understood, and safety procedures have been universally instituted. These biological hazards do not routinely affect the general operation of a medical examiner's office.

Chemical contamination can also be encountered when removing decedents from hazardous environments. Liquids, such as diesel fuel, gasoline, and non-petroleum-related chemicals, can be neutralized or semi-neutralized after the body is removed from the hazardous environment but before transport to the institutional facility for examination.

Gases such as carbon monoxide, cyanide, and methane are usually contained within the environment itself and do not routinely present a threat from "off gassing" once brought into a medical examiner/coroner facility. Potassium and sodium cyanide, often used in jewelry cleaning, may be of particular concern because of the rapidity with which it kills. These effects can be limited to the scene of death and may not pose a risk to operational effectiveness.

Bio-terrorism utilizing bacterial agents, such as anthrax, can also shut down the functional effectiveness of a facility. Unfortunately, in the short term, a false bacterial agent can be as effective as the real bacteria until its authenticity can be verified.

Radiation exposure is a potential hazard but is often limited to the medical therapies within the body itself. These radioactive dangers are limited to the staff performing the internal examination of the body and not to the functional operation of the facility.

Elemental mercury is one of the most common and hazardous contaminants in health care and biomedical research facilities. Its neurological effects are a known danger to individuals who suffer a significant exposure to this toxic "liquid metal." The inadvertent spilling of elemental mercury is the most common method for human exposure. The "Mad as a Hatter" neurologic effects are often a result of chronic exposure from unrecognized spilled mercury and may result in significant medical treatment.

Elemental mercury contamination of human remains, and other objects associated with Palo Mayombe religious practices is an infrequent but real danger encountered by medical examiner's facilities in Florida. The mishandling of such remains may result in not only the interruption of medical examiner services, but substantial monetary costs associated with decontamination and medical evaluation and treatment of exposed staff.

This presentation details the case of an acute elemental mercury contamination within a medical examiner facility. The multidisciplinary methods that are used to continue daily operations, the restoration of functional facility operations, the medical evaluation of staff, and the potential for the establishment of a universal contamination control plan will be highlighted.

### E67 Look in the Freezer—The Story of a Murder: A Case Report From Portugal

*João Manata, MSc\*, Instituto Nacional de Medicina Legal CF, IP, Coimbra, PORTUGAL; Diogo J. Calçada, MSc, Instituto Nacional de Medicina Legal CF, Coimbra 3000, PORTUGAL; Claudia Marques, MD, Largo Se Nova, Coimbra 3000, PORTUGAL*

**Learning Overview:** After attending this presentation, attendees will understand a case of a homicide in Portugal in which a corpse was found inside a freezer, requiring an extensive forensic investigation until it was resolved, and the murderer arrested.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that postmortem freezing of a corpse is a rare method of concealing a homicide, leaving behind both macroscopic and histological findings related to the mechanics of freezing and thawing, helping to establish the precise cause and manner of death and to distinguish between postmortem artifacts and death by hypothermia.

This study presents a case of an elderly woman, missing for two days, who was found inside a freezer in her kitchen, which was being searched by authorities and friends. Over the freezer, there were no signs of disorder. The corpse was completely frozen, in a supine position, semi-flexed, with her head on a step inside the household appliance. She presented several bruises on the head and upper limbs and abrasions on both lips, on the right upper limb and on the lower left limb. The victim's head and mouth were wrapped in transparent tape and, next to the head, was a lady's handkerchief with "supposedly blood-stained patches." The crime scene investigation did not find signs of a break-in, although there were signs of robbery. According to neighbors, the victim was a belligerent person.

Before the necropsy examination, even though the corpse had been thawed for about two days, it was still partially frozen. The forensic autopsy confirmed the presence of multiple bruises scattered on the body surface, mainly on the scalp and face (translated at external and internal habits), and also on the dorsal aspects of the forearms and the right hand. These findings were compatible with a physical confrontation between the victim and the offender, as the lesions located on the forearms and the hand were suggestive of defensive lesions. From the facial lesions, the blunt wounds and the bruises located at the level of the perioral region and oral cavity were emphasized, with bloody infiltration of the perioral muscular plane and intrinsic muscles of the tongue. Such findings were consistent with a mechanism of smothering. The examination of cervical structures identified a fracture of the base of the right lower horn of the thyroid cartilage, with underlying blood infiltration, that may represent a sign of an extrinsic neck compression. Although the organs, soft tissues, and some biological fluids were still partially frozen, the smothering mechanism was reinforced by the presence of non-specific signs of asphyxial nature, namely pulmonary edema, exuberant visceral congestion, and prominent and diffuse alveolar distention. Diptera eggs were found inside the oral cavity, suggesting that the corpse remained for some time outside the freezer before being placed inside the household appliance. The genital exam performed in the autopsy room showed findings consistent with recent vaginal sexual practices. It should be noted that no macro or microscopic signs consistent with a hypothermic death were observed. In turn, the toxicological tests did not detect the presence of acetone, a compound that, when at high levels, represents a toxicological finding highly indicative of hypothermia. There were no histological findings consistent with artifacts from freezing.

This case report highlights the importance of a thorough forensic investigation, including police investigation and a complete autopsy, in order to determine the manner of death and to define the real cause of death.

#### Smothering, Hypothermia, Homicide

### E68 A Practical Classification for Spree Killers

Mark E. Safarik, MS\*, *Forensic Behavioral Services International, Fredericksburg, VA 22408*; Katherine Ramsland, PhD\*, *DeSales University, Center Valley, PA 18034*

**Learning Overview:** After attending this presentation, attendees will be familiar with a classification system for spree killers that includes subtypes for which it is possible to develop a strategy of identification and capture.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating to the legal and investigative community the need to restore and hone the concept of a spree killer toward the development of tactics for apprehending them and protecting their potential targets.

Multicides have traditionally been categorized as double, triple, mass, serial and spree.<sup>1</sup> Mass and serial have been further divided into subcategories.<sup>2</sup> However, spree killing, which involves the killing of at least three persons at two or more locations in a close timeframe, due to a precipitating incident that fuels the urge to kill, remains a unified but poorly defined concept.<sup>3</sup> The Federal Bureau of Investigation (FBI) eliminated this term from its discussions of multicide in 2005, citing its lack of utility for law enforcement.<sup>4</sup> However, an examination of 112 incidents involving 134 spree killers from 26 countries reveals that not only is there enough diversity among spree killers to form classifications similar to those devised for mass and serial, but also that two spree subtypes offer distinct utility for identification, tracking, and warning potential targets.

This makes the designation of spree killer unique, in that law enforcement personnel who are trained in what to look for can respond efficiently to identify and stop certain types. The behaviors and motives for spree killers align in six categories, at least three of which can be divided into subcategories. Some sprees are random, and some occur in a timeframe or set of locations too tight for an effective response. However, many have identifiable targets, due to grudges or a mission, and some incidents last long enough for law enforcement to mobilize and predict where the killer will likely go. Examples are Christopher Dorner and Dwight Lamon Jones, who left behavioral tracks that served as guides for future targets.<sup>5,6</sup> The killers' agendas were clear and required several days to achieve.

Forty-six of the 112 incidents (41%) are in one of two categories for which law enforcement can form a viable strategy. This percentage supports the need to research spree killers as a distinct type of multicide, standardize the definition, identify categories and subcategories, and provide tools for response strategy. Since the law enforcement response to a spree killer is different than for a mass murderer or serial killer, for those cases for which there is sufficient time to identify potential targets, the data from research on spree killers can be used toward honing an effective response. In addition, spree killer subcategories will inspire more research in criminology for improved comprehension of these killers' diverse triggers and for improved intervention.

### **E69 Pozzetto: Inside Behavioral Mazes**

*Edwin O. Olaya Molina, BA\*, Bogotá 111321, COLOMBIA*

---

**Learning Overview:** After attending this presentation, attendees will be familiar with one of the most violent episodes in the history of Colombia, the characteristics of the case, and some of the results that emerged from the discussion with the current knowledge of the criminal investigation and forensic sciences.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the status of a criminal investigation in the 1980s in Colombia and how the research activities in this specific case searched for an explanation for what happened and focused on other aspects.

In Colombia, there have been thousands of massacres. Innocent people have suffered directly or indirectly from guerrillas, paramilitaries, drug traffic, politics, and extreme brutality. But after many years, an atypical case in Colombia remains in the memory of many.

The first week of December 1986, one man, Campo Elias Delgado Morales, committed one of the worst crimes that has been registered in Colombia. In a 24-hour period in three different places, armed with a knife and a gun, Morales killed 28 people. He stabbed and burned his mother, her neighbors were shot, he bound and stabbed his English student and her mother, and, finally, after dinner, he shot at several customers in a restaurant named Pozzetto. After an exchange of gunfire with the police, the murderer died. The case was called the Massacre at Pozzetto.

Today, after reviewing photographs, plans, autopsy reports, and statements pertaining to the case more than 30 years later, some of the circumstances of the event are further explained. Forensic ballistics and bloodstain pattern analysis “spoke” about the circumstances surrounding the death of a murderer; the crime scene analysis and behavioral analysis allowed a glimpse of the strong personal feelings of a murderer and a sexual motivation in some of the crimes. Finally, this work attempts to explain what type of killer Campo Elias Delgado Morales was and the particulars of his actions.

This is a case of mistakes and successes, pointing out the importance of comprehensive investigation to seek answers in the criminal investigation, especially the “Why,” which quite often is overlooked in legal proceedings in Colombia. Also discussed will be the contribution of criminal behavior analysis in this and other cases.

---

### **Behavioral Evidence, Criminal Behavior, Murder**

### E70 Gargano Mafia: The Fifth Italian Mafia With an Analysis of 129 Murders

Francesca Maglietta, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY; Giuseppe Bertozzi, MD, Department of Forensic Pathology, Foggia 71121, ITALY; Giuseppe Davide Albano, MD, Foggia 71121, ITALY; Angelo Montana, MD, University of Catania, Catania, ITALY; Anna Cornacchio, Department of Forensic Pathology, Foggia 71121, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Monica Salerno, MD, PhD\*, Department of Forensic Pathology, Foggia 71121, ITALY

**Learning Overview:** The goal of this presentation is to examine the fifth Italian mafia, the “Mafia of Gargano,” the youngest of the famous criminal organizations in Italy, its homicidal mode, type of weapons used in murders, and the typology of action.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the distinctive features of a criminal association in Puglia through the analysis of several murders committed there.

Four principal criminal organizations are known to exist in Italy: “Cosa Nostra” in Sicily, “Camorra” in Campania, “Sacra Corona Unita” (SCU, United Holy Crown) in Puglia, and “Ndrangheta” in Calabria. It is also well known to the Italian authorities that there are several subsidiary independent criminal groups that modeled their organizations after the Mafia. In the Apulian Region the SCU developed: The “Foggia Society” and the “Garganic Mafia.” The Mafia’s historians traced back the origins of “Foggia Society” to January 1979, when the main criminal leader of the area was in a meeting at the Hotel Florio, on the road from Foggia to San Severo. The Godfather of the occasion was Raffaele Cutolo, Neapolitan Mafioso of the “New Organized Camorra.” The Godfather arrived in Foggia and explained the dynamics of organized crime and affiliated the local gangsters. He also explained the Mafia method and created the “Foggia Society.” The “Mafia of Gargano” began their criminal activities in the 1990s with a series of violent murders committed between 1990 and 2002.

This group was initially classified by both the district attorney and local authorities as a group of “familial thugs” of rural origin, but it is now known as a large, notorious organization, recognized in 2009 as a “mafia-like criminal association.” In the last decade, the “Mafia of Gargano” established its power and control in both national and international laundering, human smuggling, illegal distribution of drugs and tobacco, and trafficking in weapons from the east countries by way of the Balkans. Some “Mafia of Gargano” murders are intended to portray the power of a group and its ability to control a territory. On the other hand, murders have the goal of eliminating individuals that may represent an obstacle to the criminal organization’s business. This statistical study analyzed 129 cases of homicides committed by firearms between 2000 and 2015 in the Foggia countryside. In all, 69 incidents occurred in the “Gargano area,” all planned to follow the pattern of attack, and the other 60 incidents happened in suburban areas and around Foggia. These murders were categorized in regard to the type of weaponry and homicidal modality, with particular care taken of the description and classification of the target body regions.

Subsequently, the type of weapon used for the various murders was taken into consideration; this is another significant variable characterizing the classic *modus operandi* of the Gargano Mafia. In 42 out of 69 homicides, the weapon typically used is the rifle, while in the remaining 26 homicides, the weapon used is handgun, whereas in the murders in the Foggia area, the weapon typically used is a handgun, characterizing as many as 47 homicides out of 60. In the Gargano Mafia murders, it is possible to underline that 26 murders exhibited the presence of the *coup de grace*, but all followed the pattern of an ambush. The complete analysis of these homicides sheds some light on a specific “way to kill” that binds and defines the “Gargano Mafia murders, establishing the existence of a canonical procedure of preparation and execution of the criminal events with the primary intent of avoiding an open casket funeral. Predominant is the will to express the strength of the group and its affiliates, the total disregard of rules among members, the recourse to deception to lure the victim, and the involvement of innocent unrelated people—all elements that characterize the “Mafia of Gargano.”

#### Italian Mafia, Criminal Organization, Mafia Murder

### E71 A Closer Look Into Latino Youth Gang Violence: From MS13 to the Latin Kings

*Cliff Akiyama, MPH, MA\*, Akiyama and Associates, LLC, Philadelphia, PA 19143*

**Learning Overview:** The goal of this presentation is to educate attendees about Latino youth gangs and the violence that is seen on a daily basis throughout the United States, in order to keep themselves safe out on the streets.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making attendees more aware of the “signs and symptoms” of Latino youth gang violence, so that they may keep themselves safe while investigating the deaths of these individuals.

One cannot open the newspaper or watch the local news without hearing of another casualty of gang violence. Throughout the country in urban, suburban, and rural communities, gang violence has reached epidemic proportions, according to the Department of Justice, Office of Juvenile Justice and Delinquency Prevention. Furthermore, gangs have been identified in every state, meaning that gangs are no longer just a California problem. Nationwide there are 24,500 gangs with a gang membership of more than 750,000, with the ethnic composition of these gangs including 47% Latino, 31% African American, 13% Caucasian, 7% Asian, and 2% Mixed. In particular, youth gang violence in the Latino community has had a dramatic increase in the past two years. In Los Angeles County, CA, alone, there are currently 750 documented Latino gangs with a gang membership of more than 93,000. Demographics report a gang member average age of 15 years old with a range of 8–22 years of age. Other counties in California and nationwide have seen increases in Latino gangs, especially in rural communities such as York, PA. The Mara Salvatrucha (MS 13), an El Salvadorian gang originating in the Pico-Union area of Los Angeles, CA, since 1983, has seen the largest increase in membership nationwide, with more than 67% in some states. More than 600 gang members were interviewed for this study out in the streets, jails, and juvenile halls in California and Pennsylvania. This study identified eight distinct manifestations of gang violence and nine ethnic differences and similarities among Latino gangs (i.e., definite cultural differences between Latino gangs and various other ethnic gangs, drugs, weaponry, killing over turf/territory, extortion, defacing property/graffiti, and women in gangs).

This study found that Latino gangs are motivated by a state of mind driven by “La Raza,” which translated means “for the race.” It is important to note that La Raza is more of a cultural ideology than a gang-related motto. Latino gangs are extremely territorial and unlike African American gangs where the individual is important, for Latino gangs, it is the gang as a whole that is important and not the individual. To illustrate this point, when Latino gang members go to prison, one of two prison gangs run and controlled the environment depending on the geographic location of the prison: La Eme or Nuestra Familia. La Eme, otherwise known as the Mexican Mafia, is a prison gang originating in California and is considered the leadership arm of all Latino gangs in Southern California. The letter “M” in Spanish is pronounced “eme” and is the 13<sup>th</sup> letter of the alphabet. Consequently, throughout Southern California, Latino gangs will often call themselves by the city or area that they represent, followed by the number “13” to indicate “La Eme” or “Southern” by giving respect to the Mexican Mafia. In Northern California, the Nuestra Familia, which translated means “our family,” is the prison gang that controls every Latino gang north of Fresno, CA, and is often indicated by the number “14,” representing the letter “N” for Nuestra and Northern. It is important to remember that Latino gangs are not just a California problem, although California is where these gangs originated. Rural, suburban, and urban communities across the nation are now seeing an increase in Latino gangs that mimic the California-based Latino gangs, such as the MS 13.

In direct response to the increase in gangs, the state of California, North Carolina, Virginia, and Idaho have passed gang enhancement laws, which increase the penalty if an individual is found to have committed a felony for the benefit, association, or direction of a criminal street gang. Other states, including California, have also filed a civil injunction or “gang injunction” against specific gangs, whereby removing the leadership of the gang and disbanding its members.

The purpose of this presentation is to present timely data on Latino gangs and offer strategies on how to recognize and interpret various tattoos and graffiti associated with these gangs, which could assist the medical examiner/coroner and death investigator in the positive identification of the decedent out in the field and/or in the autopsy room. This presentation will also discuss some of the recent gang-enhancement laws that California, North Carolina, Virginia, and Idaho have in place to help tackle this deadly problem.

#### **Latino Gangs, Gang Enhancement Laws, Youth Violence**

### E72 The Cruel Deaths by Suffocation of 71 Migrants Smuggled From Hungary to Austria: A Tragic Case Study

*Armin A. Farid, DMD\*, Budapest 1067, HUNGARY; Christoph Reisinger, MD, Medizinische Universität Wien, Vienna 1090, AUSTRIA*

---

**Learning Overview:** The goal of this presentation is to discuss forensic methods of identification and legal procedures, as well as humanitarian aspects of human smuggling.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by detailing the dangerous, cruel, and inhumane consequences of human smuggling, so common in different parts of the world.

In 2015, Europe became the scene of mass immigration, especially over the so called “Balkan Route” from Turkey to Greece, and from Macedonia, Serbia, and Hungary to Austria and Germany. During this time, smugglers made huge fortunes transporting desperate refugees from the east to the west of Europe. The unscrupulous actions of such smuggling rings not only exploit the immigrants but puts lives in grave danger due to the lack of sufficient means of safe transportation from one location to another.

In August of 2015, a truck was discovered on the roadside of an Austrian motorway, containing the bodies of 71 immigrant men, women, and children who began the journey in Hungary. Only 30 minutes after the truck left its place of origin, the passengers were struggling to breathe due to the crowded conditions and lack of sufficient oxygen. Three hours later, all had died. The cause of death was determined to be suffocation.

Hungarian and Austrian authorities immediately began an investigation that resulted in the arrest of four smugglers. They determined the time of death to have taken place in Hungary where the journey first began. Austrian officials took on the task of identifying the victims, primarily using DNA analysis, while Hungarian law enforcement handled the legal proceedings resulting with the criminal conviction of the smugglers in June of 2018. Considering most immigrant deaths in Europe occur at sea while crossing the Mediterranean from North Africa to Italy and Malta, this large death toll occurring on land could have been avoided and was due to the extreme inhumane conditions, crowding 71 people in the back of a truck with no oxygen.

Despite the call of the prosecution for a life sentence, the four smugglers, one from Afghanistan and three from Bulgarian descent, were convicted and sentenced to only 25 years imprisonment in a court in Central Hungary, with no prospect of earlier release. Altogether, 14 people were involved in this smuggling ring, and the involvement ranged from planning and organization of vehicles for smuggling people to hiring drivers. The four main leaders who held key positions in the ring who were convicted for 25 years consisted of the ring leader, the deputy ring leader, the truck driver, and the driver of the car that followed the truck during this “journey to death.” The other ten people involved were also convicted and sentenced to somewhere between 3 to 12 years imprisonment, depending on their degree of the involvement in this unimaginable tragedy. The international character of this case, involving the two neighboring countries of Austria and Hungary, demonstrates on a small scale how all of Europe is affected by this crisis.

---

#### Identification, Smuggling, Suffocation

### E73 A Crucifixion Experiment to Assess Wrist and Forearm Blood Flows as Observed on the Shroud of Turin

*John P. Jackson, PhD\**, Turin Shroud Center of Colorado, Colorado Springs, CO 80922; *Keith E. Propp, PhD\**, Colorado Springs, CO 80936; *Kim M. Look, DDS\**, Colorado Springs, CO 80916; *Rebecca S. Jackson, MBA\**, Colorado Springs, CO 80936

**Learning Overview:** The goal of this presentation is to test the blood flow patterns on the Shroud of Turin with actual crucifixion configurations of a human body.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by utilizing medical forensics, physics, and historical data to probe and provide insight into the practice of crucifixion, using the Shroud of Turin as a possible example of that ancient practice, and by possibly providing help with other forensic problems or having forensic applications to archaeology.

A recent paper reported by Borrini and Garlaschelli concluded from blood flow experiments that the observed wrist/forearm blood flow patterns on the Shroud of Turin are sufficiently inconsistent with the studies so that the Shroud of Turin should be considered to be a probable forgery.<sup>1</sup> However, the conclusion of the scientific experiments and analyses of the same blood flows have reached the opposite conclusion.

In this presentation, the forensic analysis is based on live suspensions on a cross with volunteer subjects, a methodology that was not used by Borrini and Garlaschelli to reach the conclusions.<sup>1</sup> After reviewing and discussing important pertinent historical data and archaeological artifacts related to the practice of crucifixion in the ancient Roman world, this study designed an experimental protocol by which special wrist and foot attachment mechanisms safely and realistically suspend the male subjects on a full-size cross. Professional medical personnel were invited to not only contribute to the experimental protocol and analyses, but also to ensure the medical safety of the subjects. The male subjects were carefully chosen to correspond, as closely as possible, to the physiology depicted by the frontal and dorsal imprints visible on the Shroud of Turin. A comprehensive evaluation was performed of the totality of blood flows found on the Shroud to determine which flows occurred during the alleged crucifixion process and which were of a postmortem nature. The specific crucifixion nailing characteristics and locations represented by the Shroud image were also determined. The subjects were then suspended on the cross according to those determinations. The cross and suspension system were designed to accommodate various positional adjustments of the body as appropriate.

Once the study team and supporting review team were satisfied with the validity of the crucifixion positions of the subjects, blood was deposited externally on the body at the previously determined nail sites. The resulting flow patterns over the simulated, crucified subjects were documented and analyzed. The crucifixion positions of the subjects were likewise documented.

These experiments represent an important utilization of medical forensics, physics, and historical data to probe and provide insight into the practice of crucifixion, using the Shroud of Turin as a possible archaeological depiction of that ancient practice, the details of which are virtually unknown in modern times. Moreover, the techniques that were specifically developed for this study conceivably may be helpful in analyzing certain other forensic problems, as well as in forensic applications to archaeology.

The presentation, using the perspectives from the above disciplines, will discuss how conclusions were obtained that appear to support the hypothesis of Shroud authenticity in some new and unexpected ways.

### E74 Testing Sexual Assault Kits Supports the Principle of “Justice For All”

*Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Suzanne Miles, BS\*, Utah Bureau of Forensic Services, Taylorsville, UT 84129; Leslie Miles, DNP, Brigham Young University, Provo, UT 84602; Linda Mabey, DNP, Brigham Young University, Provo, UT 84602*

---

**Learning Overview:** After attending this presentation, attendees will understand research data on Sexual Assault Kit (SAK) submission rates and DNA analysis findings that supports the testing of all SAKs to establish justice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by strengthening the justification to test all SAKs with research data from a large, retrospective study.

In most areas of the United States, law enforcement agencies have been the decision-makers regarding the submission of SAKs to crime laboratories for analysis. SAKs not submitted have either been maintained in law enforcement storage or destroyed. Recently, law enforcement agencies have been encouraged to submit previously unsubmitted SAKs for DNA analysis. Victim advocacy groups have encouraged the submission and testing of all SAKs to ensure justice for victims.

This presentation provides research findings from a large, retrospective study on the submission rates of 4,038 SAKs (collected from 2010 to 2016) and subsequent DNA analysis findings. Predictors of SAK submission rates through Generalized Estimating Equation (GEE) logistic regression modeling will be shared. Research data on the apparent subjectivity in the decision-making process to submit SAKs for testing will be discussed. Short Tandem Repeat (STR) and STRs found on the male-specific Y-chromosome (Y-STR) DNA analysis findings of SAKs submitted within 1 month, 1–12 months, and 1 year or more from the date of assault and evidence collection will be provided. No significant differences were found between DNA analysis findings on SAKs submitted within 1 month, 1-12 months, and 1 year or more from the date of assault and evidence collection. This finding supports the submission and testing of all SAKs as those SAKs submitted soon after the crime had similar DNA analysis findings as those kits previously in law enforcement storage. Although DNA analysis findings from SAKs were similar between jurisdictions, the determination of DNA profiles as Combined DNA Index system (CODIS) -eligible profiles was found to have increased variability.

This retrospective study also explored the identification of sexual assault cases in which the DNA analysis findings excluded the identified suspect. It was found that approximately 2% of tested SAKs had DNA analysis findings that excluded the suspect, therefore also establishing justice for the accused. Testing SAKs is often touted as establishing justice for victims, but findings from this study also indicate testing SAKs is necessary to establish justice for both victims and the accused.

At the conclusion of this presentation, attendees will understand research data which supports the submission and testing of all sexual assault kits to support the principle of “Justice For All.”

### E75 Forensic Doctors and Clinical Forensic Medicine: Should or Could?

*Pierre-Antoine Peyron, MD, Département de Médecine Légale, Montpellier 34295, FRANCE; Elodie Michel, Department of Forensic Medicine, Montpellier 34295; Eric Baccino, MD\*, Hopital Lapeyronie, Montpellier, Cedex 5 34295, FRANCE*

---

**Learning Overview:** The goals of this presentation are: (1) to question whether or not forensic doctors have an interest in being involved in Clinical Forensic Medicine (CFM), (2) to evaluate if the appropriate training is obtained, and (3) to assess where forensic nurses fit in this field.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing how the French medicolegal system allows CFM to be integrated into the daily practice of forensic doctors thanks to close collaboration with forensic nurses.

Even if statistics are lacking, there are two reasons to support the general feeling that the number of “traditional” forensic doctors is not increasing: (1) a decline in the autopsy rate due to the rapid development of imaging techniques (so called “virtopsy”) and also to “ethical,” legal, and political opposition, (2) the attractiveness of a much more lucrative private practice for highly trained forensic doctors (i.e., forensic pathologists).

In countries with no Anglo-Saxon forensic tradition, the examination of living victims of violence (mainly “ordinary” violence but also torture) by forensic doctors who are not always specialized in histopathology (but rather in performing autopsies) is developing rapidly, sometimes in association with the examination of people in custody and bodily damage evaluation.

Forensic doctors have an interest in being involved in CFM as the activity related to living victims has a huge potential for development and, consequently, will result in an increasing number of forensic doctors. To be able to practice CFM, forensic doctors should have a basic General Practice (GP) training as well as special training in drug addiction, gynecological examination, child abuse evaluation, basic psychiatric knowledge, etc. Those who specialize only in histopathology would need additional specialized training in CFM.

In some countries facing a lack of availability of forensic doctors and a much higher cost of medical intervention in emergencies, trained and dedicated forensic nurses can provide adequate service in the narrow field of CFM. Since 2011, France has benefited from a new state-funded national medicolegal system, encompassing all aspects of forensic medicine (autopsy, histopathology, CFM).

In this presentation, the French organization in which forensic doctors and forensic nurses collaborate in the best interest of justice, patients, and our professional bodies will be presented and analyzed. The literature data on the organization of CFM worldwide from a medical and nursing point of view will also be discussed.

---

#### Clinical Forensic Medicine, Forensic Doctors, Forensic Nurses

### E76 DNA Evidence Collection and Analysis in Groping Sexual Assault Cases

*Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Suzanne Miles, BS\*, Utah Bureau of Forensic Services, Taylorsville, UT 84129*

---

**Learning Overview:** After attending this presentation, attendees will have better understand the importance of DNA evidence collection in stranger groping assault cases and best practice guidelines for evidence collection in groping sexual assault cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing best practice guidelines in DNA evidence collection in stranger groping sexual assault cases.

Within a state database of 4,038 sexual assault kits linking information from evidence collection to DNA analysis findings, 66 groping cases were identified in Utah. Approximately 250 legal or extralegal variables were coded on each case to explore victim and assault characteristics in stranger groping cases. A summary of key variables on the stranger groping cases will be briefly discussed. Information regarding sexual assault kit submission rates in the groping cases will be provided. The DNA analysis findings on groping cases submitted for testing will be shared and compared to DNA analysis findings on sexual assault kits in which victims had contact with body fluids from assailants.

An interesting case report will be reviewed on the successful identification of a serial groper on a university campus from touch DNA analysis findings. An overview of the Short Tandem Repeat (STR) and Y-chromosomal Short Tandem Repeat (Y-STR) DNA results found in this case will be shared to explore the practice implications on evidence collection and analysis in sexual assault groping cases.

The 66 groping cases found in the Utah database represent a mere 1.6% of collected sexual assault kits from 2010 to 2016. The findings from this study and case report support increasing evidence collection in sexual assault groping cases. To address the need to increase evidence collection in stranger groping cases in Utah, an educational program by medical/nursing forensic examiners and forensic scientists has been developed and presented to multiple law enforcement agencies. Information on the educational program and the statewide Touch DNA Evidence Collection Form will be shared with attendees. Key points from a literature review on touch DNA analysis findings in sexual assault cases will be reviewed. Best practice guidelines based upon study findings and literature review in collecting evidence for DNA analysis in stranger groping cases will be presented.

Additionally, this presentation focuses on exploring the benefits of a strong working relationship between medical/nursing forensic examiners with those processing the biological evidence, forensic scientists, to achieve optimal results in DNA findings in sexual assault and stranger groping cases. Collaboration between medical/nursing forensic examiners and forensic scientists is necessary to establish and achieve best practice guidelines for evidence collection in sexual assault cases.

#### Groping Cases, DNA, Evidence Collection

### E77 Forensic Nurses in Institutes of Forensic Medicine: An Evaluation of the Zurich Integration Model

*Valeria Hofer\**, University of Zurich, Zuerich CH-8057, SWITZERLAND; *Michael Thali, MD*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; *Rosa M. Martinez, MD*, Universitat Zurich, Zurich CH-8057, SWITZERLAND

**Learning Overview:** After attending this presentation, attendees will have a deeper understanding of a specific role of forensic nurses in the institutes of forensic medicine. It is proposed that a similar model may be worth implementing at other forensic medicine institutes globally.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the added value a forensic nurse brings to the table in terms of documentation and sampling. Forensic investigation, both in the dead and living, is an ever-evolving and growing field, requiring expertise at many levels.

Since the autumn of 2016, the Institute of Forensic Medicine at the University of Zurich, Switzerland, has employed a nurse (Advanced Federal Diploma of Higher Education), who is also a university graduate in Certificate of Advanced Studies (CAS) forensic nursing.

An increased demand for qualified personnel in forensic health care has existed over the past years. As a result, the implementation and application of forensic nursing science is in the pioneering stages at institutes of forensic medicine in Switzerland, and this development has been very exciting thus far. The Institute of Forensic Medicine in Zurich was the first institution in German-speaking parts of Europe to employ and integrate a forensic nurse in daily forensic medicine practice. Accordingly, other institutes of forensic medicine in Switzerland followed this trend and are developing specific training and educational programs for nurses.

After the first year of having a forensic nurse on-site at the Institute of Forensic Medicine in Zürich, the outcomes were evaluated in order to examine: (1) the current situation in terms of service delivery, and (2) the status of practical integration of the forensic nurse employed at the Institute of Forensic Medicine in Zurich. A questionnaire was designed to rate the value of forensic nursing in terms of clinical and postmortem forensic work in the opinion of doctors working in the field. The forensic nurse played an active role in assisting doctors with documentation, photography, obtaining and securing blood, urine, and hair samples of suspects or victims, and negotiation with clinical personnel at medical facilities. The forensic nurse was also utilized at large-scale police checkpoints, where motor vehicle drivers were screened for their fitness and ability to drive, among other forensic tasks. The results conformed to a double hump curve, with two peaks: one with a high and one with a low rating. These findings correlated strongly with the level of exposure to forensic nursing assistance, in the sense that the doctors who regularly attended cases with the forensic nurse were generally more positive about the experience, whereas some forensic medical practitioners who rated forensic nursing negatively had not ventured to conduct case work alongside the forensic nurse in order to directly observe and experience the possibilities of this new inter-professional cooperation. One interpretation has been that the doctors who did not wish to utilize the support of a forensic nurse had been overly influenced to be entirely self-sufficient. The doctors who actively integrated with the forensic nursing service also reported an increase in acquiring practical forensic skills, resulting in a win-win situation.

In conclusion, evaluation of the contribution of forensic nursing to service delivery at an institute of forensic medicine in Switzerland one year after implementation of the service revealed that integration of a forensic nurse into the field of forensic medicine, albeit a complex task, holds great promise.

#### Forensic Nursing, Institutes of Forensic Medicine, Evaluation

### **E78 When the Confirmation Sample Doesn't Match the Profile Entered Into the Combined DNA Index System (CODIS): Troubleshooting the High-Throughput Database Process**

*Devon Hall, MFS, Maryland State Police, Pikesville, MD 21208; Bruce J. Heidebrecht, Maryland State Police, Forensic Sciences Division, Pikesville, MD 21208; Michelle Groves, MS\*, Maryland State Police Forensic Sciences Division, Pikesville, MD 21208; Argiro G. Magers, MS, Pikesville, MD 21208*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the need to verify the accuracy of profiles obtained from database samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by alerting scientists to the possibility of a DNA profile being incorrectly associated with a specific database sample and of a strategy created by the Maryland State Police-Forensic Sciences Division (MSP-FSD) to efficiently troubleshoot this issue and correct any identified errors.

A CODIS hit occurred at Maryland's State DNA Index System (SDIS) level between a database sample and a forensic profile from one of the Local DNA Index System (LDIS) laboratories. The LDIS laboratory requested the match be processed for the offender's information. Prior to releasing the offender's information to the requesting agency, MSP-FSD procedure requires any database sample involved in a hit to be tested a second time to confirm that the original profile entered into CODIS was correct. The confirmation testing of this specific sample produced a different profile when compared to the original profile entered into CODIS. This discrepancy led to an immediate investigation and the samples involved were re-tested to obtain the correct DNA profiles. Upon completion, the CODIS hit was re-generated to the correct database sample and the offender's information could then be released to the requesting agency in relation to the CODIS hit.

During the troubleshooting of the original incident, scientists determined the error may have occurred during the initial testing of the database samples and may have been due to a sample punch landing in a different well than expected during the automated processing. It was also determined that this error may be more widespread than initially believed. Scientists determined the troubleshooting would require the investigation of all database samples with duplicate profiles in CODIS. Nearly 23,000 duplicate matches, involving more than 45,000 samples, were researched to verify their accuracy. MSP-FSD scientists developed a method to automate a majority of the research into each of these, therefore reducing the number of samples that needed to be manually researched.

During the troubleshooting process, scientists found that, in addition to the original error detected during the hit confirmation, there were other types of errors occurring in the system that needed to be researched and addressed. These errors were occurring prior to receiving the sample at the laboratory, during the collection process, and while being processed in the laboratory. Procedures were put in place at MSP-FSD to identify and correct all types of past issues that were identified. Procedures also needed to be created and implemented to detect and address any newly identified errors in a timely manner moving forward. Thankfully, none of the identified errors resulted in MSP-FSD missing a CODIS hit; however, this incident did bring to light potential threats that could impact other CODIS laboratories.

---

### E79 Rapid DNA Implementation—Experiences From an Accredited Laboratory

*Kristen Naughton, BS, Bode Technology, Lorton, VA 22079; Stephanie R. Sivak, MS\*, Bode Cellmark Forensics, Lorton, VA 22079; Jamia J. Mealy, MS, Bode Technology, Lorton, VA 22079*

**Learning Overview:** After attending this presentation, attendees will: (1) be introduced to Rapid DNA technology and data, (2) be provided with an overview of the standards governing the use of Rapid DNA, (3) learn the challenges of implementing Rapid DNA testing in an accredited DNA laboratory, and (4) learn the importance of setting recommendations for partnered law enforcement agencies to follow to maintain courtroom confidence in DNA testing technology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a blueprint as to how an International Organization for Standardization (ISO) 17025 accredited laboratory can adopt and assist law enforcement agencies to successfully implement rapid DNA technology. This presentation will focus on the importance of implementation recommendations that meet and/or exceed current Quality Assurance Standards to ensure the integrity of DNA testing, even in the hands of non-DNA experts.

Rapid DNA describes the fully automated hands-free process of developing a Combined DNA Index System (CODIS) Core Loci Short Tandem Repeat (STR) profile from a reference sample. Rapid DNA instruments are designed specifically for use by law enforcement in non-laboratory environments, such as booking stations. This “swab in—profile out” technique generates results in just 90 minutes, providing both DNA laboratories and law enforcement with immediate information to aid in investigative leads.

This presentation will delve into the changes that Bode Cellmark, as an ISO 17025 certified laboratory, made to accommodate rapid DNA into current casework workflows. This included the training of DNA analysts in both Rapid DNA instrumentation and modified Rapid DNA analysis methods. A brief overview of the internal validation will show attendees an example validation plan that meets both ISO/International Electrotechnical Commission (IEC) 17025 and the Federal Bureau of Investigation Quality Assurance Standards, including discussion of the new standards expected to be released in early 2019. This presentation will also demonstrate the hurdles of bringing a newly released technology on-line, sample type compatibility with the current Rapid DNA instruments, and a review of challenging type samples that will encompass discussion on the current limitations of Rapid DNA.

With the recent passage of the Rapid DNA Act in August 2017, a move toward expanding the ability of law enforcement to implement Rapid DNA analysis technology and profile upload into the federal database has begun. Commercially available Rapid DNA instruments have been targeted toward law enforcement agencies; however, policies for this new technology have yet to be instituted. Establishing best practices within the forensic community is crucial. State and local crime laboratories inevitably will face similar inquiries about Rapid DNA from the local law enforcement agencies. This presentation provides implementation recommendations for both DNA laboratories and law enforcement agencies regarding appropriate documentation of validation, training, and maintenance of instruments to meet accreditation standards.

Rapid DNA technology is a great advancement for the field of forensics, but the implementation must be a cooperative effort between law enforcement and crime laboratories to ensure that accurate, reliable, and reproducible data is produced and presented in a court of law.

---

#### Rapid DNA, Quality Assurance, Law Enforcement

### E80 The Smell of DNA: How Genetics and Fear Influence the Human Scent

*Francesco Sessa, MS\*, Department of Forensic Pathology, University of Foggia, Foggia 71100, ITALY; Marcello Rendine, DBA\*, Department of Forensic Pathology, Foggia 71100, ITALY; Carmela Fiore, MD, Ospedale "G. Tatarella," Cerignola, Foggia 71100, ITALY; Stefania De Simone, MD, Department of Forensic Pathology, Foggia 71122, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Irene Riezzo, MD, PhD, University of Foggia, Osp D'Avanzo, Foggia 71100, ITALY*

**Learning Overview:** After attending this presentation, attendees will better understand how genetics and fear can modify the human scent.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an explanation of how genetic characteristics and fear-stressor situations could influence the human scent, creating great difficulties for detection dogs.

Human scent identification is based on a matching-to-sample task in which trained dogs are required to compare a scent sample collected from an object found at a crime scene to that of a suspect. Based on dogs' greater olfactory ability to detect and process odors, this method has been used in forensic investigations to identify the odor of a suspect at a crime scene. These dogs are also used to search for missing persons.

Many studies have shown that human scent can persist and maintain its main chemical features for a significant period of time in a particular place or/and on an object that was manipulated by a subject. For this reason, search and rescue dogs are trained to follow the scent of each person to be located and finally rescued. The results are very surprising; in previous studies, perfect responses were obtained. But, unfortunately, real cases frequently report non-positive results, especially in the recovery of missing people. One of the causes of the failed findings of the missing persons is the so-named "smell of the fear" that could confound the dog, covering the original scent of the missing person.

In specific situations, the stress management represents an important aspect to releasing the confounding scent. Moreover, several studies have provided strong evidence for an association between a polymorphism in the promoter region of the serotonin transporter gene (SLC6A4 gene) and neuroticism, defined as proneness to negative emotionality, including depression and anxiety.

The goal of this experimental study is to define how genetics influences the release of the confounding scent in the particular stressor events that occur in real forensic cases, such as a homicide or missing person. Several volunteers were tested for the 5-HTTLPR polymorphism. Two groups will be defined: ten in the group's homozygotes for the long variant (good management of the stress) and ten in the group's homozygotes for short variant will be enrolled.

A t-shirt was worn for ten minutes under normal circumstances, without a stressor event ( $T_0$ ). Then another t-shirt was worn after a stressor event ( $T_1$ ). All t-shirts were concealed in different places. Subsequently, a trained dog was used to find the t-shirts, with the aim of verifying if the stressor event in the subject with the short variant had changed the released scent. Finally, a mass spectrometry analysis was performed to analyze if the characteristics of the released scent were modified between the two tests ( $T_0$ - $T_1$ ).

After attending this presentation, attendees will have a better comprehension on a direct implication of the stressor events on the forensic investigation. Moreover, it will be illustrated that genetic characteristics could influence the human scent.

#### DNA, Smell of Fear, Detection Dogs

### E81 A Raman Spectroscopic Method for Semen Identification: Azoospermia

Marisia A. Fikiel, MS\*, State University of New York at Albany, Albany, NY 12222; Igor K. Lednev, PhD, State University of New York at Albany, Albany, NY 12222

**Learning Overview:** After attending this presentation, attendees will understand: (1) the need for a non-destructive and more specific test for human semen, (2) the advantages of using Raman spectroscopy and chemometrics to identify semen, and (3) how sperm contribute to the Raman spectra of semen.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing alternative methods for body fluid identification that are improvements over current methods.

This presentation will focus on semen, a body fluid that is especially important in sexual assault cases, and the validation of an alternative method for its identification. Semen is a special body fluid because it is made of two distinct parts, seminal fluid and sperm. Sperm are the most unique part of semen and, therefore, the presence of sperm is the most reliable method of positive semen identification. However, current semen tests rely on the detection of proteins that are not unique to semen in the seminal fluid because some semen contains no sperm, a condition called azoospermia. The laboratory has been developing a Raman spectroscopic test for the identification of dry traces of body fluids, including semen, for forensic purposes. An automatic software has already been built for differentiating all main body fluids.<sup>1</sup>

The main objective of this study was to evaluate the ability of Raman spectroscopy to identify semen traces in the absence of sperm. This will ensure that the method is compatible, even with semen in disease states. For this purpose, a comparative analysis of Raman spectra of semen, seminal fluid, and sperm samples obtained from several donors was conducted. The spectra of seminal fluid were very similar to that of whole semen. Both of these spectra were dominated by contributions from the amino acids, tyrosine and phenylalanine, and the insoluble crystal spermine phosphate hexahydrate. The spectra of semen and seminal fluid were also very different from the spectra of sperm. It was determined that the contribution of seminal fluid dominates the Raman spectra of semen. This was further confirmed by analyzing Raman spectra of semen obtained from a donor who had had a vasectomy (azoospermia). These spectra very closely resembled those of semen and seminal fluid. The individual spectra from seminal fluid and azoospermic semen were correctly identified with a previously made chemometric model as semen. It was concluded that the presence of sperm is not necessary for the correct identification of semen using Raman spectroscopy and chemometrics. This further demonstrates a great potential of Raman spectroscopy as a universal tool for confirmatory identification of all main body fluids for forensic purposes.

### E82 Phenotype Profiling Based on Raman Spectroscopy of Biological Stains: A Blood Test for the Donor Age

Igor K. Lednev, PhD\*, State University of New York at Albany, Albany, NY 12222; Kyle C. Doty, PhD, Silver Spring, MD 20904

**Learning Overview:** After attending this presentation, attendees will better understand the potential forensic application of Raman spectroscopy. The implementation of advanced statistics for the analysis of spectroscopic data and the evaluation of the accuracy and reliability of the conclusions made will be discussed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the accuracy and effectiveness of biological stain analysis for forensic purposes.

This presentation will report on the development of a universal, non-destructive, and confirmatory method for characterizing biological stains. The all-in-one method has a capability to identify the body fluid, determine human or animal origin, time since deposition and phenotype profile, race, sex, and chronological age, specifically.

Traces of body fluids discovered at a crime scene are a potential source of DNA, which is a major individual evidence in the modern forensic investigation. The application of Raman spectroscopy for non-destructive, confirmatory identification of biological stains at a crime scene, including dry traces of sweat, vaginal fluid, semen, saliva, and blood, has recently been reported.<sup>1</sup> The method allowed for differentiating animal and human blood as well as menstrual and peripheral blood.<sup>2,3</sup> In addition, the method was further developed for determining the time since deposition for bloodstains for up to two years.<sup>3</sup>

It would be of great help for criminal investigation to develop a phenotype profile immediately at a crime scene based on a rapid analysis of biological stains. With this goal in mind, the possibility of race and sex differentiation based on Raman spectroscopy of body fluid traces has been investigated.<sup>3</sup> Specifically, advanced statistical analysis of spectroscopic data was used to discriminate between Caucasian and African American donors based on dry peripheral blood traces. In addition, the differentiation of the donor's sex based on bloodstains and saliva traces, as well as race differentiation based on traces of semen, has been demonstrated.

The theory behind Raman spectroscopy is based on the inelastic scattering of low-intensity, non-destructive laser light by a solid, liquid, or gas sample. Very little or no sample preparation is needed, and the required amount of material tested with a Raman microscope can be as low as several picograms or femtoliters. A typical Raman spectrum consists of several narrow bands and provides a unique vibrational signature of the material. Typically, non-resonance Raman spectroscopy is not destructive for the sample. A portable Raman spectrometer is a reality now that should allow the identification at the crime scene.

In this proof-of-concept study, Raman spectroscopy and chemometrics have been used to analyze blood from human donors and differentiate between samples based on Chronological Age (CA).<sup>4</sup> Three groups of donors were selected including newborns (CA of <1 year), adolescents (CA of 11–13 years), and adults (CA of 43–68 years). A Support Vector Machines Discriminant Analysis (SVM) model was constructed, which demonstrated high accuracy in correctly predicting blood donors' age groups by showing the cross-validated sensitivity and specificity over 0.96. Overall, this preliminary study demonstrates the high selectivity of Raman spectroscopy for differentiating between blood donors based on the CA. The demonstrated capability completes this suite of phenotype profiling methodologies, including the determination of sex and race. CA determination has particular importance since this characteristic cannot be determined through DNA profiling, unlike sex and race. When completed, the developed methodology should allow for phenotype profiling based on dry traces of body fluids immediately at the scene of crime. The availability of this information within the first few hours since the crime discovery could be invaluable for the investigation.

*This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.*

## E83 Discovery Index Metabolites for the Estimation Age of Bloodstain

*You-Rim Lee, BS\**, Gyeonggi-do, Korea, SOUTH KOREA; *Ae Eun Seok, BS*, Eulji University, Gyeonggi-do 13135, SOUTH KOREA; *Jiyeong Lee, PhD*, Eulji University, Seongnam-si 13135, SOUTH KOREA; *Yoo-Jin Lee, MT*, Eulji University, Gyeonggi-do 13135, SOUTH KOREA; *Hyo-Jin Kim, MT*, Eulji University, Gyeonggi-do 13135, SOUTH KOREA; *Sora Mun, MT*, Eulji University, Gyeonggi-do 13135, SOUTH KOREA; *Hee-Gyoo Kang, PhD*, Eulji University, Gyeonggi-do 13135, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will understand that bloodstain metabolites can be used to reliably index material for an estimation of a bloodstain age. Attendees will also learn that the age of a bloodstain can be distinguished weekly using candidate metabolites.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting candidate metabolites for estimating bloodstain age. This study is the first report to identify index materials used to analyze the age of bloodstains through metabolomics analysis.

In this study, index material for determining the age of bloodstains was discovered by analyzing changed patterns of bloodstain metabolites using High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS). Bloodstains were prepared on filter paper and confirmed at weekly intervals until day 21. Using Venn diagrams and multivariate analysis, 62 candidate molecular features were selected.

Partial Least Squares Discriminant Analysis (PLSDA) was used to confirm that the group could be classified with an accuracy of 75.0%, and R2 and Q2 were 0.7513 and 0.6998, respectively. Among the 62 candidates, five metabolites were successfully identified. Metabolite A decreased as time passed. In the cases of metabolite B, metabolite C, and metabolite D, they increased at day 7 after day 0, and gradually decreased after day 7. In the simple regression analysis, all five candidates were statistically significant at day 21 versus day 0, and metabolite B and metabolite C at day 21 versus day 7 were also significant. The *p*-value of metabolite A was significant in all date combinations, so it is possible to distinguish time by week. Metabolite B and metabolite C were also statistically significant in all combinations, except day 14 versus day 7. Metabolite D showed significant results in all combinations, except day 7 compared to day 0, and metabolite D was significant at day 0 versus day 21, day 7 versus day 21, and day 14 versus day 21. Therefore, it is possible to measure the age of the bloodstain according to the distinguishing characteristics of candidate by date.

These novel metabolic approaches will help in the estimation of the age of bloodstains in forensic analysis. Currently, the time of the incident is specified through the estimated time of death by autopsy and forensic entomology. However, a metabolic approach can be used as the main basis for screening suspects by estimating the time of occurrence of the crime through the measurement of the age of bloodstains using the metabolites.

### E84 Veterinary Forensics: Animal Death Investigations and Veterinary Diagnostic Laboratory Personnel

*Megan Romano, DVM\*, University of Kentucky Veterinary Diagnostic Labor, Lexington, KY 40511; Michael S. Filigenzi, PhD, California Animal Health and Food Safety Laboratory, Davis, CA 95616; Robert H. Poppenga, DVM, PhD, California Animal Health and Food Safety Laboratory, Davis, CA 95616; Cynthia L. Gaskill, DVM, PhD, University of Kentucky Veterinary Diagnostic Labor, Lexington, KY 40511*

**Learning Overview:** After attending this presentation, attendees will understand the need for early communication and cooperation between law enforcement officials and veterinary diagnostic laboratory personnel in criminal animal death investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the important role of the veterinary diagnostic laboratory in a criminal animal death investigation. A 2018 case involving the death of a police dog will be presented.

In the spring of 2018, a 2-year-old intact male German Shepherd police dog was inside a 20'x20'x8' run in the center of a fenced yard while the dog's handler was away for several hours. The handler returned home and found the dog deceased. Several piles of vomit containing hot dog pieces were on the kennel floor. The handler had not given the dog any hot dogs in the past 48 hours. The handler rushed the dog to a veterinarian, who pronounced the dog dead. Malicious poisoning was strongly suspected due to the sudden death of a young, healthy dog, and the vomited hot dog pieces. The scene was photographed, and evidence was collected and taken to the state crime laboratory.

The veterinarian performed a gross postmortem examination. Tissue samples were collected, and formalin fixed. Fresh liver, heart blood, and urine were also collected. Samples and the dog's remains were submitted to a veterinary diagnostic laboratory for histological examination and toxicological analysis. The investigating detective requested analysis for drugs of abuse. The laboratory did not have the instrumentation to perform all requested analyses. The University of Kentucky Veterinary Diagnostic Laboratory (UKVDL) Toxicology section was consulted and received samples from the initial veterinary diagnostic laboratory as well as the state crime laboratory. Urine and hot dog pieces were analyzed via Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), and high-resolution LC/MS. Very high concentrations of caffeine were detected in both the urine and the hot dog pieces. Lower concentrations of theobromine and theophylline were also detected in the hot dog. No illicit or prescription drugs, pesticides, herbicides, or other compounds detectable by these methods were present. Caffeine can cause agitation, tachycardia, vomiting, diarrhea, muscle tremors, and seizures in dogs. Caffeine can be lethal to dogs at high concentrations (minimum lethal dose in dogs is estimated at 110mg/kg body weight), and in this case was considered the likely cause of death. However, remains were not grossly examined by a board-certified veterinary pathologist, and histological examination was limited to samples collected by the veterinarian. Potentially valuable samples were stored inappropriately, misidentified, or not collected. Only one sample—the hot dog pieces from the state crime laboratory—arrived with a chain of custody. In animal cruelty cases, animals and excretions are important evidence. Following proper evidence handling protocol ensures the best chance of a successful prosecution.

Early consultation with veterinary diagnostic laboratory personnel in criminal animal death investigations is critical to ensure appropriate sample collection, storage, and analysis. A thorough postmortem examination by a qualified veterinary professional (ideally a board-certified veterinary pathologist) is vital to determining cause and manner of death. A complete, accurate history is essential to interpret postmortem examination findings and to direct additional testing. Communication and collaboration between police and veterinary diagnostic laboratory personnel from the outset ensures the best results in criminal animal death investigations.

## E85 A Validation Study on Automated Groove Detection Methods in 3D Bullet Land Scans

Kiegan Rice, MS\*, Center for Statistics and Applications in Forensics, Iowa State University, Ames, IA 50011; Heike Hofmann, PhD, Center for Statistics and Applications in Forensic, Iowa State University, Ames, IA 50011; Ulrike Genschel, Center for Statistics and Applications in Forensics, Iowa State University, Ames, IA 50011

**Learning Overview:** After attending this presentation, attendees will understand the proposed pre-processing approach, as well as be aware of outcomes from automated comparison methods from a variety of validation tests on different bullet types.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a new groove detection and removal process which leads to higher accuracy than currently implemented methods and reduces error rates in the automated comparison process on a variety of bullet types.

The prevalence of research on the automated comparison of bullet marks has increased in the past several years, particularly following the 2016 President's Council of Advisors on Science and Technology (PCAST) report on the validity of feature-comparison methods in forensic science. The main avenue being pursued in this research area is the use of statistical models applied to high-resolution 3D scans of Land Engraved Areas (LEAs). An important step in introducing these new automated methods is ensuring accurate data pre-processing techniques.

Being able to correctly identify between data from LEAs and Groove Engraved Areas (GEAs) turns out to be the single, most important step in data pre-processing. Dealing with these areas separately is crucial to ensure good model fits in subsequent processing steps. Removal of data from GEAs significantly reduces the amount of noise in the characteristics used in automated comparisons. Failure to correctly identify and remove data from GEAs can lead to misidentification of these characteristics.

Distinguishing between LEAs and GEAs is a problem at which human vision excels, but it is quite challenging for automatic procedures due to the nature of the data collected: the bullet curvature presents the main structure in the data, but the abrupt change between LEAs and GEAs introduces a competing structure. This overwhelms standard modeling techniques. This study employed pre-processing techniques based on robust statistical methods to distinguish between LEAs and GEAs. Techniques from robust statistical methods allow the algorithm to focus on the main structure and separate out elements from the secondary structure of the GEA.

Results from these techniques showed early promise when applied to the closed-set study of the Hamby Set 44 bullets.<sup>1</sup> The pre-processing methods are evaluated at different levels. In the first step, predicted results from the techniques were compared to manually identified groove locations. The second, and perhaps more important step, was to assess the performance of a method in regard to the prediction accuracy of the automated matching algorithm as described in Hare, Hofmann, and Carriquiry.<sup>2</sup>

This study is using closed-set and open-set studies to evaluate the effectiveness and accuracy of the proposed techniques. Results are based on publicly available data from the National Institute of Standards and Technology (NIST) Ballistics Research Database as well as studies from collaborating forensic laboratories and departments across the United States. This additional validation step tests the proposed method's ability to transfer to different types of bullets and rifling methods and highlights limitations.

This litany of validation steps ensures a safe use of the proposed technique in fully automating the process and removing the need for human intervention in the data pre-processing.

### E86 Discrimination Between Aerial and Targeted Shooting by the Analysis of Trace Evidence: A Case Study

*Khalid S. Feras, MPhil\**, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; *Mohammad A. Tahir, PhD\**, Punjab Forensic Science Agency, Lahore, Punjab 54500, PAKISTAN; *Mudassar Baig, MSc\**, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; *Abdul Razaq, MPhil\**, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; *Muhammad Irfan Ashiq, PhD\**, Punjab Forensic Science Agency, Lahore, Punjab 54500, PAKISTAN; *Zumrad Usman Bhutta, MS\**, Sargodha, Punjab 40100, PAKISTAN

**Learning Overview:** After attending this presentation, attendees will understand the use of trace evidence analysis to establish trajectory of the bullet and to discriminate between aerial and targeted shooting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the use of Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDX) for the analysis of trace evidence trailing on the bullet and to reach a definite conclusion regarding aerial or targeted shooting.

A suspected shooting took place in the area around the residence of a famous personality from the Pakistani judiciary. The matter was highlighted in the media and led to chaos. It was suspected to be a targeted shooting. However, no loss of life or injury to the residents took place. The matter was taken up by the provincial government and the crime lab was requested to unveil the facts behind the incident. The task was to determine that either the incident was some terrorism activity (targeted firing) or the bullets could have been the result of some aerial shooting (i.e., stray bullets).

The crime scene investigation team found two bullets, one (30-bore pistol) bullet found in the garage and the second (9mm pistol) found in the backyard area shaded by a fiberglass shed. The team noticed a suspect hole in the fiberglass just above the area where the 9mm bullet had landed. Both bullets and a portion of the fiberglass that had the suspected piercing damage in it were submitted to the trace chemistry department to determine whether these were the result of targeted shooting or were stray bullets.

Keeping in mind the case scenario, an analysis strategy was devised to establish the trajectory/path that both the bullets could have followed to approach the target. The bullets were initially examined through low power magnification light microscopy followed by SEM/EDX to observe the surface of the bullets for the severity of impact and for the detection and identification of any traces of building material, vegetation, paint, or something else adhering to the bullets. No significant damage (deformation) was observed on either bullet tip, which could have come about as the result of targeted firing impacting the hard targets. However, the SEM/EDX examination revealed that the 9mm pistol bullet had some greenish material impinged into the damage site of the bullet, which was identified as the fiberglass through SEM/EDX. A relatively minor bullet defect is an indication of possible aerial shooting because the velocity of the bullet may have been slowed due to air drag, and the speed was further reduced by striking and passing through the fiberglass shed. Whereas, the second 30-bore pistol bullet was found to have only traces of silicate (i.e., soil material) adhering to the side of the tip along a soft depression due to the free-fall parabolic path impact on the ground.

The SEM/EDX analysis of aluminum stubs coated with pure carbon adhesive prepared by a single perpendicular dab just on and around the defect hole in the fiberglass revealed the presence of copper and consistent Gunshot Residue (GSR) particles. The presence of GSR particles around the hole in the fiberglass sheet of the shed indicates that the hole had been sourced from the bullet during its entry through the fiberglass sheet.

The bullet-intermediate target interaction, path of the travelled bullets, origins of trace evidentially valued deposits on bullet, traces of the bullet jackets and the gunshot residues due to the bullet wipe on the fiberglass shed, and, finally, the extent of bullet's surface deformation demonstrates that the incident was an aerial shooting as opposed to a targeted shooting.

#### Forensic Investigation, Trace Evidence, Aerial/Targeted Shooting

### E87 The Forensically Relevant Applications of Laser Ablation Direct Analysis in Real Time Imaging-Mass Spectrometry (LADI-MS)

Kristen L. Fowble, BS\*, State University of New York at Albany, Albany, NY 12222; Rabi A. Musah, PhD, State University of New York at Albany, Albany, NY 12222

**Learning Overview:** The goals of this presentation are to introduce attendees to: (1) the basics of the new imaging mass spectrometry technique known as LADI-MS; (2) its wide applicability to small molecule spatial distribution mapping in forensic sample types, including psychoactive compounds in latent fingerprints and inks on paper; and (3) its non-imaging capabilities, including derivatization of the psychoactive component of psilocybin mushrooms (i.e., psilocybin).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a new technique that is being developed for potential integration into crime laboratories and research institutions. The wide applicability of the technique means that a single instrument could tackle a number of forensic sample analyses, thus reducing the cost and training that would be required for multiple instruments.

Imaging mass spectrometry provides a means to obtain chemical composition information while retaining the spatial distribution of the detected analytes in the sample of interest, thus providing two types of information that would typically require multiple instruments. Most current imaging techniques require the use of solvent, high vacuum, and/or the application of a matrix. However, these steps can complicate the ability to routinely detect and map the spatial distribution of small molecules and can also be time-consuming and contribute to casework backlogs. It is demonstrated that using an approach that integrates a Direct Analysis In Real Time (DART<sup>®</sup>) ionization source, an ultraviolet neodymium-doped yttrium aluminum garnet (Nd:YAG) laser ablation system and a Time-Of-Flight (TOF) mass spectrometer, small-molecule spatial distribution maps can be acquired for a broad range of sample types, with no sample pretreatment requirements.

The ability of the technique to detect small molecules within latent fingerprints was demonstrated using prints that were deposited after exposure of hands to psychoactive plant material (*Piper methysticum*), cocaine, or pseudoephedrine. LADI-MS revealed spatial distributions of endogenous cholesterol, localized to fingerprint ridges, while providing confirmation of exposure to the psychoactive small-molecule cocaine, kavain (derived from *P. methysticum*), and pseudoephedrine. The spatial distribution mapping of cholesterol in a lifted print on the non-conductive adhesive side of tape was also accomplished. The ion images obtained of the endogenous compounds revealed the fingerprint ridge pattern necessary for identification of an individual.

The approach was also applied to the detection of differently sourced inks on paper. A peace sign image was drawn using two different brands of black markers (one used to draw the outer circle and the other, the inner lines). LADI-MS small-molecule spatial distribution maps allowed the two inks to be distinguished based on the chemical composition. This technique was also applied to numbers that were subsequently altered with a second pen to form a different number (i.e., number 1 changed to 7). This technique would be useful in determining alterations made to a document using differently formulated inks.

The robust LADI-MS system can also be utilized for non-imaging experiments. Typically, the psychoactive compound psilocybin undergoes dephosphorylation to psilocin during traditional chromatographic-mass spectrometric analysis. To confirm its presence in a sample, derivatization is required, thus prohibiting the ability to detect the intact molecule in imaging experiments of psychoactive mushrooms. Here, the laser was used for the instantaneous derivatization of psilocybin directly on the sample by firing at a drop of psilocybin solution and the derivatizing agent (*N*-methyl-*N*-(trimethylsilyl)trifluoroacetamide) on the surface of a piece of cloth. Both psilocybin+2TMS and psilocybin+3TMS were detected by LADI-MS. This could lead to the potential imaging of psilocybin spatial distributions in intact mushroom material by spraying the derivatizing agent on the surface of mushroom samples prior to imaging experiments.

The newly developed LADI-MS technique can be applied to a number of forensic sample types, including latent fingerprints, inks on paper, and derivatization of psilocybin. It is shown to be a powerful tool for the detection and mapping of a range of small molecules in a variety of sample types with no sample preparation steps.

#### Imaging Mass Spectrometry, Latent Fingerprints, Inks on Paper

### E88 How Do Latent Print Examiners Perceive Proficiency Testing? An Analysis of Examiner Perceptions, Performance, and Print Quality

Sharon Kelley, PhD\*, Institute of Law, Psychiatry, and Public Policy, Charlottesville, VA 22903; Daniel C. Murrie, PhD, Institute of Law, Psychiatry, & Public Policy, Charlottesville, VA 22908; Brett O. Gardner, PhD, University of Virginia, Charlottesville, VA; Karen D.H. Pan, Department of Statistics Halsey Hall, Charlottesville, VA 22904; Karen Kafadar, PhD, University of Virginia, Charlottesville, VA 22904; Kellyn Blaisdell, BA, University of Virginia, Charlottesville, VA 22902

**Learning Overview:** The goal of this presentation is to educate attendees on how latent print examiners view current proficiency testing items and how such views relate to more objective measures of proficiency tests, such as print quality metrics and examiner test performance.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by shedding light on the current state of latent print proficiency testing as viewed by its primary consumers (i.e., latent print examiners). This presentation will investigate the connection between these views and the results of objective evaluative measures (i.e., print quality metrics). Both these views and the objective measures ultimately will inform efforts to craft more rigorous, or better operationalized, materials for training and assessing proficiency.

Accrediting agencies generally require that forensic science laboratories administer proficiency tests, or practice tests designed to resemble real forensic casework, at regular intervals to assess analysts' competence. Moreover, latent print examiners sometimes cite results on proficiency tests as evidence that the work in an actual case is accurate.<sup>1</sup>

Importantly though, commercial test materials may differ in important ways from "real world" evidence.<sup>2,3</sup> If proficiency tests are simpler than actual casework, the value may be diminished. On the most recent latent print examination proficiency test administered by Collaborative Testing Services, Inc. (CTS), 91% of respondents received a score of 100%.<sup>4</sup> This study may reveal important ways in which proficiency tests do not provide true metrics of competence or proficiency in the field. Without such metrics, both internal (e.g., by laboratory managers) and external oversight (e.g., by accrediting bodies) become less meaningful.

For the present study, CTS added a series of questions to its latent print examination proficiency test shipped in August 2017. Three hundred twenty-two latent print examiners submitted completed tests and answered attached survey questions during the testing period. The survey asked respondents to separately rate the level of challenge and similarity to casework of each latent print on the test using an 11-point scale ranging from 0=*Extremely easy/Nothing like casework*, to 10=*Extremely challenging/Exactly like casework*. Additionally, examiners identified the *least* and *most* challenging latent print and rated their confidence in the accuracy of their decisions. For the latent print that examiners identified as most challenging, examiners identified the characteristic(s) that caused the print to be challenging. Finally, to provide a more objective measure against which to evaluate the proficiency test and examiners' perceptions of the test, all prints used in the test were examined using a global-quality metric algorithm (i.e., LQM).<sup>5</sup>

In brief, the mean level of perceived difficulty across all items was 4.27, indicating that, in general, participants found the questions to be relatively easy. Examiners also typically perceived latent prints in the test to be similar to their casework ( $M=6.97$ ). Interestingly, items perceived as more similar to casework were also perceived as more difficult to complete ( $r[308]=0.30, p<.001$ ). Examiners expressed significant confidence in conclusions regarding both the least and most challenging items on the test.

In general, all included prints scored highly on a metric examining level of image quality. Indeed, no latent print scored below a 60 out of 100 and the estimated probabilities that an examiner would find each print of value for identification and comparison were 95% or greater for all prints included in the test. The quality metric scores for each latent print and its source print were averaged to compute an overall quality score for each test item. This quality score was not significantly correlated with examiners' perceptions of item difficulty ( $r[7]=-0.68, p=0.09$ ) but was significantly correlated with perceptions of item similarity to casework ( $r[7]=-0.79, p=0.04$ ). Additional analyses exploring examiner perceptions and related associations with objective print quality and test performance will be discussed.

In conclusion, the current findings reveal that examiners viewed proficiency test items as generally easier than casework, were highly confident in the conclusions, and achieved very high accuracy in the conclusions. Quality metric scores corroborated examiners' perceptions in that included prints were consistently rated as very high quality. Given that examiners viewed more challenging prints as more similar to typical casework, the results have important implications for meaningful proficiency testing moving forward.

## E89 How Does Training and Certification Affect the Perception of Accuracy During Fingerprint Examinations?

Crystal L. Wagoner, MFS\*, Clarksville, TN 37043

**Learning Overview:** After attending this presentation, attendees will understand the different training and certification requirements of latent print examiners at local, state, federal, and private agencies, and how that training and/or certification impacts the individual fingerprint examiner's perception of accuracy during fingerprint examinations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the decision-making process for standardization of training and certification for latent print examiners and providing recommendations for future research in this area. This study could potentially be expanded to include the training and certification requirements for other fields in forensic science.

For more than 100 years, fingerprints have been used as a means of human identification.<sup>1</sup> Fingerprint technology is one of the oldest disciplines in forensic science and has been accepted in the court system for more than a century.<sup>1-4</sup> However, several high-profile cases have highlighted the potential for human error during the identification process, and the reliability of latent print identifications and other forensic sciences are now being challenged.<sup>5-8</sup> However, very little research exists to determine if differences in training or certification have any effect on the accuracy of fingerprint examinations.

A quantitative correlational study was conducted to examine the training and certification process for fingerprint examiners at various levels of law enforcement (local, state, federal, and private) and to determine what effect, if any, these differences had on the accuracy of conclusions drawn during fingerprint identifications. A total of 404 fingerprint examiners from the American Academy of Forensic Sciences (AAFS) or the International Association for Identification (IAI) participated in an online questionnaire. The data obtained from that questionnaire was analyzed using the latest SPSS software and a Pearson's Chi-square.<sup>9</sup>

The results of the study indicated a significant correlation between the level of agency and the type of training a fingerprint examiner was required to complete. There was also a significant correlation between the level of the agency and a requirement for certification. No significant correlation was found between differences in training and the accuracy of fingerprint examinations. However, logistic regression analysis suggested that fingerprint examiners who received Outside Training, and a combination of Outside Training with On the Job training were significant predictors of a perception of accuracy by fingerprint examiners. Finally, there was a significant correlation between the requirement for certification and the perception of accuracy during fingerprint examinations.<sup>9</sup>

Identifying the training and certification procedures that result in the greatest accuracy and reliability of fingerprint examinations will reinforce the credibility of fingerprint examinations as a means of identification and pave the way for recommendations of standardized training and certification. This presentation will demonstrate the inconsistencies that exist in the training and certification of fingerprint examiners and the areas that need more research.

### E90 What Do Latent Print Examiners Want in a Statistical Model?

*Anthony Koertner, MS\*, Forest Park, GA 30297*

---

**Learning Overview:** After attending this presentation, attendees will have gained knowledge on the various statistical models currently in existence in the latent print community. This presentation will discuss scores derived from various statistical and probabilistic models and how they fit in the many available Bayesian Verbal Equivalent Scales utilized not only in the forensic sciences but other industries as well. Attendees will also be more familiar with recently published research surrounding how potential jurors interpret scores derived from a particular latent print statistical model.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing current progress and inherent limitations of proposed statistical approaches to quantify fingerprint evidence with the intent to elicit candid discussion on what can realistically be achieved at this time and whether these limitations are “true” issues or merely byproducts of any acceptable scientific method. Shedding light on these perceived limitations may assist latent print examiners in their understanding of these statistical models and the imperfections and may be somewhat suitable in an attempt to satisfy some of the demands set forth by the National Research Council (NRC) and the President’s Council of Advisors on Science and Technology (PCAST).

The search for a suitable latent print statistical model to assist in expressing the weight of friction ridge evidence has intensified since the 2009 NRC Report on Forensic Science, *Strengthening Forensic Science in the United States: A Path Forward*. The NRC report, along with the 2016 PCAST report, *Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods*, challenged the friction ridge community to become more objective and develop tools to express the strength of evidence that is communicated to stakeholder communities. As practitioners, there is a tendency to be concerned with how evidence can best be presented in a trial format in a manner that accurately conveys the strength of the evidence and is understandable by a jury.

From a practitioner perspective, there should be a model that: (1) supports an expert’s opinion of source attribution, (2) does not over- or understate the strength of the evidence, (3) shields from *any* potential error, (4) provides the exact same results every time, and (5) is entirely objective. While all these criteria may be desired, can or will these requirements be met? Barring these achievements, are any statistical models “useless” or do practitioners need to curb expectations of what can be realistically achieved within the acceptable limits of science?

### E91 Plato: Unaware Narrator of a Death by Hemlock Poisoning—From Socrates' Death to the Present

*Isabella Aquila, MD\**, Institute of Legal Medicine, Catanzaro 88100, ITALY; *Matteo A. Sacco, MD\**, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; *Roberto Raffaele, BE\**, University Magna Graecia of Catanzaro, Crotona, ITALY; *Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; *Pietrantonio Ricci, MD, PhD*, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand poisoning by hemlock with the analysis of an emblematic historic case—the death of Socrates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the uniqueness of the Platonic writing in the tale of a rare case of poisoning by hemlock.

Poisonings are classified according to the manner in which they occur. The forensic sciences deal with the deaths that occur with violent modality, such as suicides or homicides. Poisoning by hemlock has special toxicological characteristics. Hemlock (*Conium maculatum* L. *Umbelliferae*) has long been known as a poisonous plant, belonging to the Apiaceae family.<sup>1</sup> The toxicity of hemlock is due to the 5-piperidine-type coniine alkaloids, including coniine and  $\gamma$ -coniceine. The dried plant contains the highest concentration of coniine, while the fresh plant material tends to contain the most  $\gamma$ -coniceine. The action of coniine alkaloids is intended to stimulate and then paralyze the nicotinic receptors. The  $\gamma$ -coniceine is among the most toxic alkaloids biosynthetically formed. The poisoning in humans can be caused by ingestion of the plant. No forensic cases of poisoning by hemlock have been reported. For this reason, this study reports on a historic and emblematic case of this type of poisoning through the historical-scientific analysis of the death of Socrates.

A review of literature was performed on the search engine PubMed NCBI inserting the keywords “Socrates” and “Hemlock & *Conium maculatum* death.” Socrates (Athens, 469-399 BC), son of a sculptor and a midwife, dedicated himself from an early age to philosophy. After the fall of the Thirties, in 399 BC, he was subjected to a political process with the charge of impiety (not believing in the gods of the state) and moral corruption of the young disciples. It is probable that the accusers intended only to exile him, but Socrates refused the compromises and renounced the opportunity of escape. Plato, in *Phaedo*, describes in detail, through the eyes of Critone, the death of Socrates. In the conclusive lines, it reads that a servant entered the room with the prepared drug, pounded into a cup. Socrates, after drinking it, began to feel heavy legged and began to lie on his back. Meanwhile, the Executioner was examining his feet and legs through the application of painful stimuli in order to see if the pain was perceived. By now, cold had come to his belly and, a little later, the widened eyes of Socrates remained open and fixed. This description, quite detailed even considering the era in which it was written, currently remains the only report in the literature.

It would appear that the poisoning of Socrates represents to date, after more than 2,000 years, the first case with forensic aspects regarding the manner of death in history, primarily because it was a capital punishment. The scientific articles published to date have focused in particular on chronic hemlock poisoning in cattle, on chemical characteristics of the alkaloids, or on cases of accidental poisonings. General symptoms of poisoning by hemlock are represented by effects on the central and peripheral nervous system and the autonomic nervous system ganglia with vomiting, tremor, rhabdomyolysis, ataxia, headache, acute renal failure, rapid breathing, ipsalivation, nausea, convulsions, and coma until the fatal outcome. The alkaloids are volatile and produce a characteristically unpleasant odor that can be observed in the breath and urine of poisoned individuals. The progressive centripetal paralysis is characteristic of poisoning by hemlock.<sup>2,3</sup> This data makes it doubtful hemlock was used in the death of Socrates, according to some authors, especially noting the absence of the description of unpleasant odor and the common gastrointestinal effects of the poison. However, it is believed that Plato gave a modified side of the story about the death of Socrates for political, apologetic, and philosophical reasons, describing a more “noble” death. Through looking at the past, the case of Socrates is unique for its characteristics, but, above all, because it represents to date the only example of poisoning by hemlock of historical and forensic interest present in ancient literature.

---

**Learning Overview:** After attending this presentation, attendees will understand how common inhaled anesthetics for general hospital anesthesia interact with routinely encountered volatile compounds.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the issues that can arise with the presence of an inhaled anesthetic when analyzing a sample for ethanol concentration under HS/GC.

Blood alcohol analysis plays an important part in the legal realm. Alcohol analysis in a crime laboratory is performed to determine the concentration of ethanol present in a biological sample for criminal and death investigations. In driving under the influence cases, the ethanol concentrations are the basis for filing criminal charges. In a blood sample tested by the Canton-Stark County Crime Laboratory (CSCCL) for criminal investigation, an unknown compound coeluted with ethanol under HS/GC.

Based on the information provided by the investigating officer, the individual from whom the sample was collected was being prepared for surgery while the sample was drawn; therefore, the unknown compound was thought to be an inhaled anesthetic. Inhaled anesthetics administered during preparation for surgery are very volatile. Desflurane, isoflurane, and sevoflurane are commonly available inhaled anesthetics. These anesthetics were analyzed following the CSCCL ethanol analysis protocol used to determine Blood Alcohol Content (BAC), and it was discovered that sevoflurane had an almost identical retention time as ethanol. Sevoflurane was observed as a shoulder on the ethanol peak using the BAC1 column. Sevoflurane and ethanol completely coeluted on the BAC2 column, which was comparable to the casework sample analyzed by the CSCCL.

In addition, the three anesthetics were evaluated against other common volatile substances (methanol, isopropanol, and acetone) included with ethanol in the laboratory's volatile mixture standard. While sevoflurane coeluted with ethanol, the other two inhaled anesthetics coeluted with two other volatile compounds. Desflurane partially coeluted with methanol on the BAC1 column, but separation was achieved with the BAC2 column. Isoflurane appeared as a shoulder on the isopropanol peak, partially coeluting on both BAC1 and BAC2 columns.

By decreasing the temperature of the GC oven from 40°C to 26°C, separation was achieved between the sevoflurane and ethanol peaks. At this time, the method for the separation of the compounds was not able to be validated due to problems with the bias for the ethanol quantitation results. Future research would include improving the bias, performing a full-method validation, and separating the two compounds on different columns and instrumentation in order to observe any variation.

#### Ethanol Analysis, Inhaled Anesthetics, Coelution

### E94 Illicit Drug Deaths in Older Adults: The Need for Comprehensive Scene Investigation

*Stanislaw T.J. Bielous, BS\**, Syracuse, NY 13210; *Dennis J. Chute, MD*, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601; *Veronica Salvas, MPH*, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601; *Robert J. Bready, MS*, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601; *Kia K. Newman, MD\**, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601

**Learning Overview:** After attending this presentation, attendees will: (1) have an increased awareness of the often-overlooked area of older adult illicit drug use, (2) understand the importance of approaching every death scene with a reasonable amount of suspicion, and (3) understand the need for comprehensive scene investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by shining a light on the growing trend of illicit drug use in older adults and will present case studies demonstrating how a thorough scene investigation can prevent the misclassification of substance abuse-related deaths.

Drug use in older adults is a growing issue within both the legal and medical communities. Studies conducted in the early 2000s predicted that the number of adults over 50 years of age with substance abuse issues would almost triple from 1.7 million in 1995 to an estimated 4.4 million in 2020.<sup>1,4</sup> This dramatic rise is attributed to both a 50% increase in the over-50 population and a 70% increase in the rate of substance abuse.<sup>1</sup> It is thought that due to pharmacokinetic changes associated with age, older individuals are more sensitive to adverse side effects of drug use, such as reduced physical functions and an increased risks of falls.<sup>2,3</sup> In a review of all substance abuse-related deaths in Dutchess County, NY, between 2010 and 2017 ( $n=436$ ), it was found that adults over 50 years of age accounted for 29% of all accidental drug overdose deaths; the oldest illicit drug case was 75 years old.

Death scene investigations are an integral step in establishing the circumstances and causes of sudden and unexpected deaths investigated by medical examiner and coroner offices. Many times, death of individuals over 50 years old appear natural due to concurrent health conditions. However, it is critical that each scene be approached with an appropriate level of suspicion. In such cases, the possibility of illicit drug abuse may seem unlikely at first, and paraphernalia may have been removed or hidden from view by family or friends. Presented here are three cases that may have been released at the scene and attributed to natural causes. However, a comprehensive scene investigation revealed evidence of drug use and an autopsy was performed.

**Case 1:** A 67-year-old female was found naked on the toilet. She had a history of chronic obstructive pulmonary disease and recent complaints of body aches. Without proper scene investigation, this decedent's cause of death may have been erroneously attributed to her natural disease. A meticulous scene investigation revealed white powder in a covered, decorative bowl, marijuana, juice box straws with white residue, and other paraphernalia. An autopsy showed pulmonary emphysema, bronchiolitis, and atherosclerotic cardiovascular disease. However, toxicology revealed THC, cocaine, and codeine in her blood; her death was certified as due to acute cocaine intoxication.

**Case 2:** A 66-year-old male was found on his knees in his apartment. A careful review of the decedent's medications revealed a white plastic straw, white residue, and several glassine envelopes hidden within a prescription bottle. Autopsy revealed hypertensive and atherosclerotic cardiovascular disease and obesity. Toxicology results showed numerous substances and his death was certified due to acute fentanyl, heroin, and alprazolam intoxication.

**Case 3:** A 61-year-old male with a history of diabetes and mental health issues was found dead, lying supine on the floor of his bedroom. A careful investigation of the scene revealed a white powder that appeared to be either crushed medication or cocaine and signs of oxycodone abuse. An autopsy showed coronary artery atherosclerosis. However, toxicology revealed alprazolam, cocaine, morphine, oxycodone, and fentanyl, and his death was certified due to acute opioid, alprazolam, and cocaine intoxication.

Illicit drug use in older adults is an issue that will continue to grow and subsequently be reflected in the caseloads seen by medical examiners. These case studies highlight examples of how comprehensive scene investigation helped identify illicit drug use in atypical scenarios and thus averted the incorrect assumption of an older adult death as being natural. These circumstances present just one reason well-trained medicolegal death investigators are needed to perform comprehensive scene investigations. It is vital that investigators understand the growing prevalence of drug use in older adults and become proficient in recognizing the signs of drug use within this population.

#### Illicit Drug Deaths, Older Adults, Death Scene Investigation

### E95 I Smell a Rat: Optimizing a Method for Detecting the Rat Poison Brodifacoum With Gas Chromatography

Abigail L. Meyer, BS\*, Medina, OH 44256; Morgan M. Clothier, MFS, DC Department of Forensic Sciences, Washington, DC 20024; Brandon P. Jones, MS, DC Department of Forensic Sciences, Washington, DC 20024; Luke C. Short, PhD, DC Department of Forensic Sciences, Washington, DC; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand how to detect brodifacoum, a type of rat poison that has recently gained notoriety as an emergent adulterant to illicitly purchased controlled substances, using Gas Chromatography/Mass Spectrometry (GC/MS) and Gas Chromatography with Flame Ionization Detection (GC/FID). It is imperative that both GC/MS and GC/FID, two gold standards within the field of forensic chemistry, are capable of detecting this lethal compound. A method for detecting brodifacoum will be discussed by varying several instrument parameters (e.g., column length and inlet temperature). As proof of principle, the optimized method will then be applied to mock case samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a validated method to target this emergent adulterant. Forensic methods often trade run time by sacrificing detection of these later-eluting compounds. Such rapid schemes run at odds of assessing the potential presence of brodifacoum. Further, there is a paucity of modern literature to detail the analytical detection of this compound, or even related compounds, via GC. Thus, available methods discussed in literature are not germane to current analytical instrumentation.

Brodifacoum is currently a common rodenticide belonging to the class of pesticides known as “superwarfarins.” These compounds were developed from toxicants of warfarin, a response to the increase in warfarin-resistant rats and mice. Brodifacoum is a coumarin anticoagulant, causing hemorrhaging and severe vitamin K deficiency after prolonged exposure. It has the potential to be lethal both to rodents and to humans due to its long half-life and, thus, residency within the body.<sup>1</sup>

In early 2018, Illinois health care providers reported multiple cases of patients with unexplained bleeding who had also self-reported as using illicit substances, specifically synthetic cannabinoids. Further clinical testing detected the presence of brodifacoum as a likely causative factor in hemorrhaging, which was later found to be present in tested synthetic cannabinoid samples.<sup>2</sup> Over the following months, more than 200 clinical cases of brodifacoum poisoning resulting from synthetic cannabinoid use were reported in nine states.<sup>3</sup> While exposure to brodifacoum is only seldom lethal, the treatment is prolonged and requires hospitalization.<sup>4</sup>

In Washington, DC, the use of synthetic cannabinoids has significantly escalated since 2015. For example, over a two-week peak period in July 2018, DC Fire and Emergency Medical Services (EMS) reported more than 450 calls for suspected synthetic cannabinoid overdoses, including some resulting in fatalities.<sup>5</sup> It is imperative that forensic science laboratories in the region and other cities across the country are equipped with optimal methods for detecting brodifacoum. Such detection techniques will better equip local public health officials with the tools to detect this toxic compound, as well as other poisons, as these emerge in the local illicit controlled substances.

This research is directed at solving not just a validation scheme, but also to provide the forensic chemist a method to be used on real-world samples. Initial analyses were performed using a sample of brodifacoum in various solvents. Different methods and different column lengths were tested using both GC/MS and GC/FID. Additionally, the inlet temperature was adjusted to account for any possible thermal decomposition of brodifacoum. Once optimal parameters were established, non-controlled plant material was adulterated with brodifacoum, synthetic cannabinoids, and various combinations of both in order to mimic real-world scenarios. Further analyses will seek to establish the optimal method for detecting brodifacoum and other similar rodenticides in combination with common spices and controlled substances.

The initial screen for brodifacoum in acetone using GC/MS produced two late eluting peaks; these results were consistent for all methods and column lengths tested. The results were also repeatable when analyses were conducted in a variety of solvents. An observed decrease in peak area indicated that inlet temperatures greater than 260°C resulted in the breakdown of brodifacoum. When analyzed with GC/FID, two late eluting peaks were also present. The results of both GC/MS and GC/FID will be compared to determine which approach is optimal for detecting trace amounts of brodifacoum, but additionally, both instruments will be demonstrated to function to successfully presumptively detect and confirm the presence of brodifacoum in samples, a requirement for confirmation under the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) guidelines.

## E96 Method Validation for the Detection of 22 Benzodiazepines, Including Clonazolam, Etizolam, and Flubromazolam, Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Rachel Lane\*, Huntington, WV 25701; Dustin Smith, BS, South Carolina Law Enforcement Division, Columbia, SC 29212; Jared Castellani, MS, South Carolina Law Enforcement Division, Columbia, SC 29212; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand the analytical method for the determination of benzodiazepines, including clonazolam, etizolam, and flubromazolam, in human whole blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a reliable method for quantifying the target compounds by incorporating the analysis of emerging designer benzodiazepines into a previously accepted method for the analysis of classic benzodiazepines and their metabolites.

Benzodiazepines are a heterocyclic class of drugs used to treat a range of conditions, including anxiety, insomnia, and alcohol withdrawal.<sup>1</sup> In the United States between 1996 and 2013, the number of adults who filled a benzodiazepine prescription increased from 8.1 million to 13.5 million.<sup>2</sup> Benzodiazepine dosage also increased by more than triple during this period.<sup>2</sup> From 2002 to 2015, there was a 4.3-fold increase in the total number of deaths involving benzodiazepines.<sup>2</sup> The adverse effects of benzodiazepine abuse and addiction continue to be overlooked, most likely because 75% of deaths involving benzodiazepines also involve an opioid.<sup>2</sup> Designer benzodiazepines are structural analogs of controlled benzodiazepines that have been synthesized to mimic the pharmacological effects.<sup>3</sup> Clonazolam, etizolam, and flubromazolam are three designer benzodiazepines that have recently been observed in South Carolina casework. These drugs are marketed online as “research chemicals” and “not for human consumption.” Given the increase of designer benzodiazepines being shipped to the United States with very similar molecular formulas and structures to already scheduled benzodiazepines, there is a pressing need for confirmatory methods that can differentiate between analogous compounds.

Samples (1.0mL) were prepared for analysis using Solid Phase Extraction (SPE) with an elution solvent of ethyl acetate containing 3% ammonium hydroxide on Clean Screen<sup>®</sup> 10mL DAU columns. Chromatographic separation was achieved on a Liquid Chromatograph Tandem Mass Spectrometer (LC-MS/MS) system (Agilent<sup>®</sup> Technologies<sup>®</sup> 1290 LC coupled with an Agilent<sup>®</sup> Technologies<sup>®</sup> 6430 triple quad mass spectrometer) using positive electrospray ionization and dynamic multiple reaction monitoring mode with a UCT Selectra<sup>®</sup> DA column (50mm x 2.1mm, 3 $\mu$ m). Solvent A was 0.1% formic acid in Dionized (DI) water and solvent B was 0.1% formic acid in methanol. Mobile phase was introduced in a gradient programmed with 35% B, isocratic for one minute that was increased to 70% B over 7.5 minutes, increased again to 95% B for 1.6 minutes before the gradient was returned to the initial conditions and held for the remaining 1.8 minutes. The flow was set to 0.4mL/min with a total run time of 11 minutes.

The method was developed to be a sensitive assay with optimal run time. The following studies were all conducted in concurrence with the Scientific Working Group in Toxicology (SWGTOX) guidelines: bias, precision, calibration, dilution integrity, carryover, limit of detection, limit of quantification, and stability. Interference and ionization suppression/enhancement studies are currently in progress. The designer benzodiazepines had a defined limit of quantitation at 10ng/mL and limit of detection at 5ng/mL. The method was stable up to 72 hours and free from carryover at 7.5 times the highest calibrator. For the three designer benzodiazepines, within-run precision ranged from 3.6% to 8.2% for the Lower Limit Of Quantification (LLOQ) at 10ng/mL and 1.4% to 3.0% for the high control at 600ng/mL. For the low and high controls respectively, the between run precision ranged from 4.8% to 8.2%, and 2.7% to 4.7%, and the accuracy ranged from -5.7% to -0.56% and -2.2% to -0.6%.

### E97 A Paper Analytical Device to Evaluate Illicit Drug Supply Chains

*Tracy-Lynn E. Lockwood, BS\*, South Bend, IN 46615; Marya Lieberman, PhD, University of Notre Dame, Notre Dame, IN 46556*

---

**Learning Overview:** The goal of this presentation is to clearly demonstrate the different levels of the supply chain that illicit drugs take to make it to market. This includes the various hands passed through from cook to dealers to end user. It is believed that different drugs spend a different amount of time in the supply chain as they are diluted with fillers and other drugs such as fentanyl; this is believed to be how fentanyl came to be so prevalent in the market today. By using a paper-based analytical device designed to identify illicit drugs and various cutting agents to assess a simulated supply chain, we can evaluate how well this field device can track supply chains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new paper-based analytical device (idPAD) that can field test illicit drugs and identify various cutting agents and be used as a potential tool for law enforcement and first responders. The presumptive drug tests currently used by law enforcement officers in the field are often critiqued by the public due to high false positive rates and subjective interpretation. This paper analytical device uses less solid sample than current presumptive tests, costs less than the test pouches, and can be used in fewer than five minutes. Additionally, a portable light box ensures consistent lighting on the idPAD so the colors can be read accurately, regardless of the environment, which lowers user error. Current testing on the idPAD includes evaluating its ability to track various supply chains to better understand how and where these drugs are entering the market. Further understanding of the illicit drug supply line will provide law enforcement with information to hopefully lower the spread of drugs.

By combining 12 chemical color tests that target specific functional groups in illicit drugs as well as various cutting agents, a unique color-bar code is generated for each substance. When illicit drugs are being brought to market, there are dilutions with different cutting agents as they are passed through the hands of dealers, which can reveal useful information about the supply chain. The idPAD has been used to evaluate a simulated supply chain. The idPAD's ability to identify the illicit substances and the cutting agents used, and to evaluate how many people are creating distinguishable batches of products, will be discussed.

## E98 Anabolic Androgenic Steroids Abuse: New Molecular Biomarkers

*Francesco Sessa, MS\*, Department of Forensic Pathology, University of Foggia, Foggia 71100, ITALY; Monica Salerno, MD, PhD, Department of Forensic Pathology, Foggia 71121, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Cristoforo Pomara, MD, PhD, Catania, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of Anabolic Androgenic Steroids (AASs) assumptions, side effects, organ damages, and MicroRNAs (miRNAs) dysregulation. The first results obtained on this research hypothesis will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a systematic review and meta-analysis on the miRNA dysregulation linked to the adverse effects of AASs use/abuse. This review also aims to suggest a new study hypothesis on the role of miRNAs as new molecular biomarkers of AASs use/abuse.

Currently, even if AASs abuse is clearly associated with a wide spectrum of side effects, frequently adolescents and athletes use a large group of synthetic derivatives of testosterone, both for aesthetic uses and for improving performances.

Nandrolone, testosterone, stanozolol, methandienone, and methenolone are the most frequently abused androgens and account for a major fraction of androgen abuse. One common factor between detecting each of these performance-enhancing drugs is that the traditional methods of drug testing were taken at a single point in time. An enhanced method of detection has been required to counter the increasingly sophisticated doping regimens and the ongoing development of new substances. For these reasons, the identification of new molecular biomarkers remains an ambitious target for the scientific community.

In the past few years, the development of microRNA (miRNA) technologies has become an essential part of research projects. Their role as potential molecular biomarkers is frequently investigated by the scientific community. The principal application of miRNA dosage is the characterization of cancer; moreover, miRNAs are frequently investigated as prognostic biomarkers, evaluating the disease evolution. More evidence suggests that miRNAs are deregulated in viral infections, nervous system disorders, cardiovascular disorders, muscular disorders, diabetes, and other diseases.

The research hypothesis of this presentation is a direct implication among drugs assumption, side effects, organ damages, and miRNAs dysregulation, with the goal of finding a direct link between AASs use/abuse and miRNA dysregulation. Moreover, with this proposal, the results obtained with the experimental model used will be presented.

Databases from 2000 to June 2017, including Medline®, Cochrane Central, Scopus®, Web of Science, Science Direct®, EMBASE, and Google® Scholar, were searched using the following keywords: miRNA, anabolic androgenic steroid, side/adverse effects, organs and systems (Cardiovascular system, reproductive system, central nervous system, liver, kidney, and skin). The main keywords were individually searched in association to each of the others.

Due to reviewing and analyzing each adverse effect caused by AASs use/abuse, a selection of miRNA signatures was performed. For example, a pivotal role on the activity of the cardiovascular system was played by myo-miRNAs; the up/under-expression could be important to generate adverse effects after AASs assumption. Following the research proposal, the dysregulation of the expression profiles of these miRNAs could suggest a direct action on tissues. Moreover, the same miRNAs could become the signatures of AASs abuse. Due to Real-Time Polymerase Chain Reaction (RT-PCR) technique, the miRNAs expression levels were evaluated on autopsy samples of young male deaths with toxicological positive tests for anabolic agents.

In conclusion, the identification of new tools for AASs use/abuse represents an important challenge for the scientific community. In the past few years, several studies highlighted the role of miRNAs as a highly accurate diagnostic tool. Moreover, miRNAs in serum are stable at room temperature and are resistant to freeze-thaw cycles; these characteristics highlight the important role of miRNAs in the future as new tools for the anti-doping war.

Knowledge regarding miRNA in human diseases related to AASs use/abuse may eventually lead to serum or tissue biomarkers with anti-doping utility. In this regard, there are major challenges, such as the need for careful validation of diagnostic miRNA candidates in well-annotated toxicological studies. The rapid progress in anti-doping technologies using miRNA-based strategies for discovered the drugs of abuse, such as AASs use/abuse, allow optimism for new approach definitions based on existing and emerging knowledge.

### **E99 The Comparison of Entry Bullet Holes in Glass, Metal, and Wood With a Variance in Caliber, Distance, and Grain Weight**

*Mark A. Waldo, MFS\*, Santa Ana Police Department, Santa Ana, CA 92702; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the differences in entry bullet holes in glass, metal, and wood substrates created by variables often encountered in shooting incidents: (1) different caliber ammunitions, (2) different grain weights, and (3) shooting distances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the understanding of entry bullet holes and validating expert testimony regarding the origin and relationships of these in the reconstruction of shooting incidents.

This study hypothesized that a larger caliber bullet with a heavier grain weight would make a larger entry bullet hole, compared to a smaller caliber bullet with a lighter grain weight. It also hypothesized that a bullet fired at a closer distance would make a larger entry bullet hole than being fired at a further distance and one could expect significant differences in entry bullet holes depending on the nature of the target substrate. These possibilities were tested at an outdoor shooting range.

The following studies were conducted on three different surfaces (laminated glass, sheet metal, and plywood). The first study was conducted using a laminated glass as the target to simulate a vehicle windshield (24"x24" and 7mm thick). The second study was conducted using sheet metal as the target to simulate a metal vehicle quarter panel (24"x24" and 20 gauge). The third study was conducted using a plywood target (24"x24" and 1/2") to simulate a covering of an outdoor structure. There were three different shooting distances: near (4"), intermediate (24"), and distant range (48"). The shooting distances were measured from the muzzle of the handgun to the target surface. Six shots were fired for each caliber and grain weight: six shots for the distances of the metal and wood targets and only four shots for the glass target, due to the fragility of the glass. The entry holes were photographed with a Canon® EOS 70D camera and an American Board of Forensic Odontology (ABFO) metric scale. Camera settings were set manually according to the lighting at the time of shooting. The diameters of the entry holes were measured with a digital caliper and the data analyzed for statistical significance using the One-Way Analysis of Variance (ANOVA) statistical test and a p value of <0.05 to indicate significance.

The findings indicated that there was no statistical significance difference in the diameter of the entry hole in the targets, handgun caliber, grain weight, and firing distances used in this investigation. This research may dispel the often-held myths related to the tested variables and will provide crucial information for establishing the truth by supporting or refuting eyewitness or suspect testimony in the courtroom.

## E100 An Investigation Into the Discriminating Potential of Different Techniques for the Analysis of Cosmetic Foundations

Jessica McFarland\*, North Wales, PA 19454; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104; Megan Zellner, MSFS, L'Oreal Cosmetics, Clark, NJ 07066; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how cosmetic foundations can be discriminated using Raman microspectrophotometry, Attenuated Total Reflectance (ATR) infrared spectroscopy, and Scanning Electron Microscopy/Energy Dispersive X-Ray Spectroscopy (SEM/EDX).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a basis for the use of multiple techniques to distinguish between cosmetic foundation samples. All three techniques can be used without any sample preparation, which makes them quick and easy and allows for a minimal risk of contaminating or diluting the sample.

Cosmetics, such as foundations, are easily transferrable personal care products that can leave evidence at a crime scene. A smear could be left behind on anything that comes into contact with a victim or assailant wearing a cosmetic. This transferred smear could then be used to corroborate accounts of events, if the evidence can be compared with a known sample. Little research has been done in the way of analyzing foundation samples in a forensic context, although it is unclear as to why.<sup>1</sup> There is a large variety of components in cosmetic foundations, and these vary between manufacturers, foundation types, and foundation colors.<sup>2</sup> If a technique, or combination of techniques, could determine the differences, then it could be used to differentiate between foundations.

In this study, 34 cosmetic foundation samples from a variety of manufacturers and types were analyzed. For all techniques, the samples were analyzed with little sample preparation. For Raman analysis, each sample was placed directly onto a glass slide for analysis. Three different locations on the sample were scanned 16 times. The spectra for each sample were determined to be reproducible. Each sample spectrum was then compared to every other sample spectrum in pairs. Of the 561 pairs, 90.55% could be discriminated.

Using ATR, each sample was analyzed in triplicate. Each spectrum was obtained using 32 scans at a resolution of  $4\text{cm}^{-1}$ , with a background taken prior to each collection. The spectra for each sample were determined to be reproducible. Each sample spectrum was then compared to every other sample spectrum in pairs. Of the 210 pairs, 95.23% could be discriminated.

An SEM fitted with an iXRF<sup>®</sup> EDX unit was used to collect elemental information about each of the samples. Each sample was placed onto a piece of carbon tape before being analyzed. Every sample was analyzed at 200 times magnification in three different areas. A 20-kV beam with a 4.4 spot size was used. The concentration of elements in each sample was then analyzed with Principal Component Analysis (PCA) using BioVinci (version 1.1.3). Principal components 1, 2, and 3 were found to account for 40.60%, 22.55%, and 14.76% of the variance, respectively. Visual examination of 3D plots showed that replicates of each sample clustered together and could be distinguished from others.

In conclusion, using a combination of Raman microspectrophotometry, ATR infrared spectroscopy, and SEM/EDX shows the potential to differentiate between 34 cosmetic foundation samples. The use of non-destructive techniques with little to no sample preparation allows for the preservation of samples. The combination of the three techniques provides the forensic scientist a method for comparison of cosmetic foundation samples that are complimentary, easy to use, and sensitive.

## E102 Preparation of Molecularly Imprinted Polymers for the Extraction of Azo and Anthraquinone Dyes From Diesel Fuel

*Antonija Glavac, BSc, Zagreb, CROATIA; Hrvoje Sarajlija, PhD\*, Zagreb, Croatia, CROATIA; Ivana Bacic, PhD, Forensic Science Centre "Ivan Vucetic," Zagreb 10000, CROATIA; Dragana Mutavdic Pavlovic, PhD, Zagreb, CROATIA; Gordana Matijašić, PhD, Zagreb, CROATIA*

---

**Learning Overview:** The goal of this presentation is to demonstrate preparation, characterization, and efficiency of Molecularly Imprinted Polymers (MIPs) designed to extract azo and anthraquinone dyes from complex matrices such as diesel fuel. MIPs are prepared for the Solid Phase Extraction (SPE) to be a faster, simpler, and more accurate way for the determination of the presence of these dyes in "laundered" fuel, even when they are present at very low concentrations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into how novel polymeric materials, prepared in a laboratory in an economical and fast way, and used as a sample pretreatment can improve detection of the desired analytes and thus provide valuable forensic evidence.

Fuel consumption is steadily rising, which generates substantial profits for the oil industry, but also causes fuel prices to rise. Except, the economic factors, local laws, and regulations also determine the level of fuel tax, which differs from country to country and depends on its use. In Croatia, fuels are distinguished by use for transport vehicles, heating fuel, and fuel for propulsion of agricultural machines. Blue diesel, intended for use in agriculture, fishing, and aquaculture, has a taxable amount of 0.0 and is classified as a tax-reduced energy source, unlike tax-fueled diesel, for which the price is higher for even 0.4 €L. In order to distinguish fuels depending on use and to prevent misuse, fuels are marked with a dye and a marker. The most commonly used marker in the European Union is Solvent Yellow 124 (SY124), the application of which is legally prescribed in Croatia. This marker is not visible to the naked eye, but only by extraction with hydrochloric or sulfuric acid, and the fuel is also labeled with visible colorants. Colorant used for labeling blue diesel in Croatia is Solvent Blue 35 (SB35), and Solvent Red 19 (SR19) is used for labeling heating oil. The fuel quantity is not legally prescribed, as opposed to the SY124 marker, which is added to the fuel in the amount of 6.0mg/L to 9.0mg/L. A big difference in the tax on such fuels, unlike fuel for transportation and its ever-increasing cost, leads to misuse. The illegal practice of removing fuel differentiation components and reselling it at a higher price is called fuel "laundering." Fuel "laundering" occurs by adsorption of markers and colorants from fuel with widely available materials and chemicals. Losses for the state are measured in the millions. Except for the state, users of such fuel are also damaged, and the substantial damage is made to the environment because of the waste, which is disposed without proper care.

As marker SY124 is not noticeable in fuel to the naked eye, intense work is conducted on the development of analytical procedures for its detection, especially in "laundered" fuel where its concentrations are extremely low. In addition to the SY124 marker, it is also important to prove the presence of blue and red dyes such as SB35 and SR19. For this purpose, MIP syntheses were performed using 4-vinylpyridine, methacrylic acid, or hydroxyethyl methacrylate as functional monomers, ethylene glycol dimethacrylate as a crosslinker, 2,2'-Azobis(2-methylpropionitrile) (AIBN) as an initiator, and acetonitrile as a porogen. Template molecules were dyes SY124, SR19, and SB35 or combinations thereof. Various methods such as Fourier Transform Infrared (FTIR) spectroscopy, Scanning Electron Microscopy (SEM), the Brunauer-Emmett-Teller surface analysis method, and Evolved Gas Analysis-Mass Spectrometry (EGA-MS) have been used to characterize the MIPs. The efficiency of the prepared printing polymers was monitored by Liquid Chromatography/Tandem Mass Spectrometry (LC-MS/MS) and compared to commercially available SPE columns. The obtained results indicate that MIPs have a possible application in the daily problem of fuel "laundering."

### E103 Self-Organizing Maps to Analyze the Relationship of Ignitable Liquids and Substrates

Nicholas A. Thurn\*, University of Central Florida, Orlando, FL 32826; Mary R. Williams, MS, National Center for Forensic Science, Orlando, FL 32816-2367; Michael E. Sigman, PhD, University of Central Florida, Orlando, FL 32816

**Learning Overview:** After attending this presentation, attendees will understand how the components of substrate backgrounds relate to components of the American Society of Testing Materials Standard Test Method for Ignitable Liquid Residues in Extracts from Fire Debris Samples by Gas Chromatography/Mass Spectrometry (ASTM E1618-14) ignitable liquid classes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an easy-to-visualize graphical representation of the relationship between two reference databases to better inform the analyst of where problematic class overlap can occur and types of substrate background that may interfere with the interpretation of casework samples.

Fire debris samples are currently analyzed according to ASTM E1618-14, which makes use of the total ion chromatogram, extracted ion chromatogram, and target compounds. Ignitable Liquid (IL) residues are classified as one of the following seven classes given by ASTM E1618-14: gasoline, petroleum distillate, isoparaffinic, aromatic, naphthenic-paraffinic, normal alkane, and oxygenate. The chromatographic profiles and the relative presence of the major compound types are used to determine which classes the IL residue falls into. Any ignitable liquids that do not fall into these classes are designated as miscellaneous and have characteristics of multiple classes. Even with the guidelines provided by ASTM E1618-14, determining the presence of IL residues is still a time-consuming manual pattern recognition process for the analyst and is highly subjective in nature. To counteract this, automated chemometric methods that use the Total Ion Spectrum (TIS) are being developed. The TIS is the time-averaged mass spectrum across the total chromatographic profile and allows for comparison within or between labs due to the absence of the retention time variation. This work makes use of the Extracted Ion Spectrum (EIS), a subset of the TIS, which is generated using the ions in Table 2 of ASTM E1618-14. These ions are representative of the major compound types present in each of the ASTM classes and include: normal alkanes, branched alkanes, cycloalkanes, aromatics, polynuclear aromatics, ketones, and oxygenates.

Self-Organizing Maps (SOM) are a type of artificial neural network used for the visualization of large datasets and can be easier to visually interpret than principal component analysis for complex data. In a previous study, it has been shown that IL group according to their ASTM class designations using the EIS of ASTM ions and the SOM. This work expands on previous work and uses SOM to examine the relationship of substrates and IL from the National Center for Forensic Science (NCFS) Substrate and Ignitable Liquid Reference Collection (ILRC) databases. Substrates grouped in the center of the map with the ASTM classes surrounding them. However, significant overlap was observed between substrates and the oxygenate class. Substrates were labeled according to their major polymer type and whether they are derived from wood or non-wood materials. Ground truth samples were also projected onto the map to examine the potential of the trained map to classify fire debris samples. There was a reasonable trend observed for the position of the ground truth samples on the map with respect to the ratios of the individual components used to create them. This study demonstrates the power of unsupervised machine learning methods to be used as a quick screening tool in forensic science and allows the analyst to qualitatively assess the class or components of a casework sample.

### E104 An Application for Forensic Analysis: The Discrimination of Fibers Using a Trace Organic Additive and Pyrolyzate Marker

Chikako Takei, BioChromato Inc, Fujisawa-shi, Kanagawa-ken 251-0053, JAPAN; Kenichi Yoshizawa, MPharm\*, BioChromato, Inc, Fujisawa 251-0043, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the value of a Thermal Desorption and Pyrolysis device combined with Direct Analysis in Real Time Mass Spectrometry (TDP/DART®-MS) for the rapid discrimination of polymer material products, such as cloths, fibers, and containers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how TDP/DART®-MS can be effectively applied as an identification and screening technique for tracing evidence.

Scientific examination of miscellaneous evidence collected at the crime scene is required to extract information during a criminal investigation. There are two methods of approaching physical evidence, namely, identification and comparison.<sup>1</sup> The former involves surveying and recording the substances that make up the evidence. In the latter, the same inspection is applied to a specimen of unknown origin (suspected sample) found at the scene of the crime and an apparent specimen (controlled sample) derived from or near the suspect. Subsequently, an analysis is performed using test results to ascertain whether the two are from the same source. The comparison process uses a combination of numerous methods, including observing features and appearance, measuring physical properties, and analyzing chemical compounds. For chemical analysis, comparison of trace compounds is sometimes more effective than the main compound.<sup>2</sup>

The DART® ion source is one of the ambient ionization methods reported by Robert B. Cody et al. in 2005.<sup>3</sup> It is excellent in versatility and speed, as ionization occurs easily by holding the sample over an ion source. However, when a product consisting of a polymer material, such as cloth or plastic, is to be analyzed, it is difficult to observe the peak of the target compounds. Therefore, a TDP process was developed for DART®-MS, which consists of a device capable of directly heating the sample from room temperature to 600°C. It has also been established as being usable for the identification of additives and polymer matrices in polymer material products. In this presentation, it is shown that the TDP/DART®-MS method can be used for both identification and comparison of polymer material products by using the analysis results of various polymer materials.<sup>4</sup>

In this study, several types of cloth fibers were used as samples. Mass spectra were obtained by a quadrupole Time-Of-Flight (qTOF) mass spectrometer equipped with a DART® ion source and a TDP unit. The TDP unit was mounted between the DART® ion source and the mass spectrometer. Mass spectra were measured in the positive-ion mode as the samples were heated from room temperature to 600°C. Analysis results of fibers using TDP/DART®-MS, namely, organic additives contained in fibers and pyrolysis products of polymer matrix, were detected at the thermal desorption region and pyrolysis region, respectively. It was confirmed that this analysis method is useful for the identification of polymer materials by using the pyrolysis products of polymer matrices as a marker. Additionally, this study established that this analysis can be used for comparison by using both organic additives and pyrolysis products of these samples as a marker. Thus, the combination of conventional methods and TDP/DART®-MS could contribute to the differentiating of evidence in criminal investigations.

### E105 Validation of New Test Media for Gunshot Residue Visualization in Distance Determination Methods

Steven J. Little, BS\*, Marshall University, Huntington, WV 25701; Jessica Coudriet, BS, North Carolina State Crime Laboratory, Raleigh, NC 27603; Jessica Pappas, MS, North Carolina State Crime Laboratory, Raleigh, NC 27603; Catherine G. Rushton, EdD, Marshall University Forensic Science Program, Huntington, WV 25701; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will better understand the advancements in, as well as limitations of, contemporary substrates used to perform chemical analyses in gunshot distance determinations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by validating the capabilities of modern test media to replace the dwindling supply of conventional resources, as well as demonstrating the efficacy, or lack thereof, of the new materials when integrated into proven laboratory methodology.

Considering the staggering number of violent crimes committed using firearms in the United States, it is crucial for analysts to have a reliable means of evaluating and reconstructing a gunshot incident.<sup>1</sup> The estimation of muzzle-to-target distances is commonly inferred by measuring the diameter of the nitrite residue pattern transferred from the victim's clothing onto desensitized photographic paper via the Modified Griess Test (MGT), then comparing that measurement to a range of laboratory-generated standards. However, with the proliferation of digital photography, inkjet photo papers have been examined as a replacement to their increasingly costly and scarce predecessor with remarkable success.<sup>2,3</sup>

The goal of this study was twofold: (1) validate an inkjet photo paper to be incorporated into the Standard Operating Procedure (SOP) for the North Carolina State Crime Laboratory, and (2) evaluate the potential of the paper to retain adequate lead residues following Modified Griess processing to be revealed using an application of Sodium Rhodizonate.<sup>4</sup> The goal of the latter parameter was to identify a means of reinforcing the results obtained through the traditionally accepted methodology.

During the MGT, a hot clothing iron is pressed onto an assembly comprised of a piece of gauze saturated with a 15% acetic acid solution and the sample material placed face down on the emulsion side of photo paper. The paper was previously treated with a sulfanilic acid and alpha-naphthol solution. The acetic acid is vaporized and penetrates the sample material, inducing a chromophoric reaction on the photo paper indicating the presence of nitrite residues. It was the secondary intention of this study to confirm the incidental transfer of lead residues to the photo paper during MGT processing. The Sodium Rhodizonate test could then be performed on the photo paper to reveal the presence of lead residues that may have been displaced by the MGT. The fundamental mechanism driving the movement of lead residues is similar to that of the Bashinski Transfer method, a previously verified procedure among firearms examiners.<sup>4</sup> Filter paper saturated with acetic acid is placed over a bullet hole on the victim's clothing, ironed until dry to attract the lead, and subsequently treated with Sodium Rhodizonate. If lead residues adhered to the photo paper in a similar manner during the MGT, the paper could be treated with Sodium Rhodizonate alongside the other materials, and the results used to supplement any findings using the Bashinski method.

The inkjet paper performed comparably to the desensitized paper without any alterations to the established Modified Griess procedure, noting that the papers with a glossy or semi-gloss finish were substantially better suited for this analysis. It was not possible, though, to observe lead residues on the photo paper to a degree that would satisfy evidentiary standards or outperform the recognized methodology.

### E106 A Comparison of Gunshot Residue (GSR) Visualization With Alternate Light Sources (ALS) and Infrared (IR)

*Mark Vecellio, MFS\*, Methodist University, Fayetteville, NC 28311; Alycia M. Smentkiewicz\*, Methodist University, Garner, NC 27529; Sarah V. Morello\*, Raeford, NC 28376; Patrick M. Wright\*, Saint Pauls, NC 28384*

---

**Learning Overview:** After attending this presentation, attendees will understand how ALS and IR light is used to locate GSR on dark-colored substrates and recognize the need for additional research concerning the detection of GSR on painted surfaces.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting a better understanding of the capabilities of ALS and IR in visualizing GSR on dark-colored surfaces and will also help attendees understand the need for additional research on how paint may affect visualization of GSR.

Initial detection of GSR at a crime scene, even if presumptive in nature, may aid investigators in better understanding shooting scenes and can be very valuable during a variety of investigative tasks, particularly interviews and evidence collection. GSR can be observed on many surfaces; however, dark-colored surfaces often obscure it. This study examines two methods of presumptively detecting the presence of GSR on dark-colored surfaces, both ALS and IR.

Four types of ammunition (.22, .223, 9mm, and .45) were fired five times each from a distance of six inches into two substrates: (1) black, cotton tee-shirt samples, and (2) drywall samples painted with Valspar® Black Gloss Latex Enamel paint. The samples were later observed using Sirchie TMX (395nm and 450nm) and Sirchie Megamax (530nm) ALS light sources with appropriate orange and red barrier filters, and a Fuji XT1 IR camera with IR 695 and IR 830 filters was utilized, in conjunction with 100-watt incandescent light sources, to observe the samples with IR. All samples were viewed with the same ALS and IR equipment prior to shooting for control purposes. No particles were detected on any of the samples prior to shooting.

GSR was visualized on all 20 cotton tee-shirt fabric samples using both IR (both filters) and ALS 450nm. ALS 530nm allowed visualization of GSR on 14 of the 20 samples, while ALS 395nm allowed visualization of GSR on seven of the 20 samples. GSR was not identified on any of the painted drywall samples using any of the light sources.

The GSR observed with IR on cotton fabric was located in close proximity to the bullet defects, while the particles observed with ALS (all wavelengths) were scattered and found up to four inches away from the bullet defects. Though these methods should only be applied as search tools, the GSR identified with IR could be easily interpreted due to its contiguous presence around the circumference of the bullet holes. However, the scattered particles detected with ALS could cause interpretation difficulties when other trace particles are present, thus potentially minimizing some of the immediate interpretative value of the evidence.

The inability to visualize GSR on the painted drywall using either method is significant. Additional research could analyze how other paints may affect visualization and seek alternative visualization methods.

---

#### GSR, Infrared, ALS

### E108 Laser-Induced Breakdown Spectroscopy (LIBS) as a Rapid Detection Technique for Gunshot Residue (GSR)

Korina Menking-Hoggatt, MSc\*, Morgantown, WV 26501

**Learning Overview:** The goal of this presentation is to inform attendees of a rapid technique for the detection of Gunshot Residue (GSR) using LIBS and the performance measures associated with the method.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that LIBS can decrease turnaround time by providing practitioners with a rapid, reliable screening test for GSR detection on hands.

The detection of GSR is crucial during the investigation of firearm-related crimes, and is, therefore, a commonly submitted form of evidence to forensic laboratories. The United States National Crime Victimization Survey (NCVS) most recent data reported 480,000 firearm-related crimes in 2016, and a report by Project FORESIGHT for the 2015-2016 fiscal year found the average turnaround time for GSR to be between 19 and 89 days and cost between \$800 to \$3,500 per forensic report.<sup>1,2</sup> The current American Society for Testing and Materials (ASTM) standard requires the identification of characteristic elements (typically lead, barium, and antimony) using Scanning Electron Microscopy/Energy Dispersive X-ray Spectroscopy (SEM/EDS).<sup>3</sup> Although the SEM/EDS method is reliable, it is also costly and time consuming. The goal of this study is to develop a reliable screening method capable of detecting GSR in just a few minutes with minimal destruction of the sample, high specificity, and sensitivity. LIBS is proposed for GSR detection using a universal sampling method compatible with current practice (SEM/EDS). The advantages of this method are the simultaneous multi-element capability, selectivity, sensitivity, versatility, and portability.

A validation set of 296 samples originating from 60 non-shooters and 56 shooters was used to evaluate the accuracy of the method. The non-shooter specimens were collected from at least one of the hands of each individual using the standard carbon adhesive tabs. The sample set from known shooters was collected using four GSR separate stubs from the hands of each individual after firing a pistol or a revolver (right back, right palm, left back, and left palm).

The research presented here developed two different LIBS acquisition methods, one ablating a line of 7mm by 100 $\mu$ m at the GSR stub surface, and another shooting the laser in a 5 by 5 grid of 100 $\mu$ m diameter spots. The grid method allowed for the addition of chemical mapping and spatial information to determine the location of the GSR species on the stub. Both methods left more than 99.9% of the carbon stub intact for further confirmatory testing. Data pre-processing included background subtraction, peak identification, and peak integration. Box plots and principal component analysis were used for exploratory analysis of the data. A positive threshold/result was established when the signal of the analyte was above the limit of detection and exceeded the non-shooter background signal by at least three standard deviations. Alternatively, discriminant analysis was used as a classification tool to group unknowns into shooter or non-shooters categories. The line scanning method showed a true positive rate (sensitivity) of 73%–86%, a true negative rate (specificity) of 97%–100%, and an overall accuracy of 87%–90%, depending on the statistical classification method. The grid method showed a true positive rate (sensitivity) of 73%–100%, a true negative rate (specificity) of 96%–100%, and an overall accuracy of 82%–100%.

The results demonstrated that LIBS is as a rapid, reliable technique with high sensitivity and specificity for GSR detection. The incorporation of a rapid screening method into the current protocol of GSR examination could minimize unnecessary confirmatory analysis of negative samples, reducing costs and offering a more streamlined and efficient management of casework. Moreover, LIBS will provide complementary information to SEM/EDS and increase confidence in the interpretation of the evidence.

### E110 Violence Against Health Workers in Turkey

*Inci Y. Tezbasan, BSc\*, Uskudar University, Istanbul 34662, TURKEY; Ümit Ertem, MSc, Üsküdar University, Istanbul 34662, TURKEY; Sevil Atasoy, PhD, Uskudar Üniversitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY*

**Learning Overview:** The goals of this presentation are: (1) to present some featured cases that appeared widely in the national media, (2) to present statistical results regarding violent attacks by patient or relatives during medical service, and (3) to discuss possible intervention techniques in Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing some nationally featured cases, statistical results regarding violent attacks during medical service, and possible intervention techniques in Turkey.

Violence is defined by the World Health Organization as “the intentional use of physical force or power, threatened or actual, against oneself, another person, or against a group or community, which either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment, or deprivation,” although the group acknowledges that the inclusion of “the use of power” phrase in its definition expands on the conventional understanding of the word.

In health institutions, violence is defined as “the case consisting of the threatening behavior, oral threat, economical misuse, physical assault and sexual assault risky for the health care workers, caused by the patient, the patient’s relatives, or any individual.” The health care workers are in communication with the patient and his/her relatives, having socio-cultural characteristics that are different from each other due to their professions. It affects the treatment’s process, the patient’s satisfaction of the health care worker at his/her service, and the hospital’s reputation.

Working at a health care institution is riskier than working in other places in regard to violence. It is particularly observed that the frequency of oral violence is higher than physical violence in health care institutions. There are also various risks in the fields in which health care services are offered as there are in all fields in which the human life continues. It is quite important to solve these risks previously, to determine what should be done, and how risk management should be ensured when it is performed. Therefore, various means were needed in order to manage immediate cases, a number of the stimulating systems, and the interference codes aimed at them. Color codes are one of the methods that are most commonly used worldwide. These codes announce/notify hospital workers in cases of risk when communication is allowed, providing a short, clear message that provides time for the right interference, prevents the occurrence of panic, assists in enabling emergency preparedness, and provides security for patients and workers in the institution.

The “white code,” used to provide security for patients and workers, is the emergency management method aimed at preventing violence to workers in hospitals. For the code system to work well, it is extremely important to provide training for the health care workers regarding the system and to have regular practices focused on these codes.

The rise in violence in recent years and gynecologists being the primary target will be interpreted and the proper use of the “white code” and the follow-up procedures will be discussed.

#### Health Workers, White Code, Violence Prevention

### **E111 The Role of Human Rights as a Reason for Refugee Status and Immigration Requests: A Retrospective Analysis of Southern Italy**

*Isabella Aquila, MD\*, Institute of Legal Medicine, Catanzaro 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Elena Sacco, Luca & Partners, Crotona, ITALY; Piero Lucà, Lucà & Partners, Crotona, ITALY; Fabio Lucà, Lucà & Partners, Crotona, ITALY; Santo Gratteri, MD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the more common reasons why migrants leave their countries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the need to promote the defense of human rights.

Immigration is a phenomenon of great social impact. In recent years, there was an increase in disembarkations in the Mediterranean Sea. In 2017, according to United Nations High Commissioner for Refugees (UNHCR) data, approximately 110,000 migrants landed in Italy. In recent years, forensic sciences have also been interested in this phenomenon. In 2017, more than 2,300 immigrants died.<sup>1</sup> This was related to the risk of drowning, dehydration, and dangers associated with travel. Despite the spread of the phenomenon, the reasons for escape from their native countries are not always known. The goal of this study is to assess the reasons for legal requests of refugee status.

The study was carried out with the collaboration of a law firm in southern Italy that analyzed the rights of approximately 1,500 immigrants. A retrospective analysis of the testimonies of 500 immigrants disembarked in southern Italy was performed. The data were collected from interviews carried out and performed with a native speaker. The interviewees were asked to explain the reasons why they had left their own country. The data were then classified according to sex, country, and reason for requesting a residence permit for every immigrant. Data was compared and analyzed.

The retrospective study revealed that 98% of the questioned people were male and all came from Asia or Africa. Regarding geographical origin, 289 (57.8%) came from Pakistan, 42 from Bangladesh (8.4%), 42 from Nigeria (8.4%), 37 from the Gambia (7.4%), 37 from Senegal (7.4%), 16 from Ghana (3.2%), 12 from Mali (2.4%), 8 from the Ivory Coast (1.6%), 6 from Guinea (1.2%), 3 from Guinea Bissau (0.6%), 2 from Niger and Afghanistan (0.08%), and 1 from Sierra Leone, Liberia, Burkina Faso, Togo (0.08%). Approximately 40% provided evidence or documents regarding their origins.

The main reason for escape was terrorism (30.6%), followed by religious (14.2%) and political persecutions (13.6%). Among the remaining reasons were unjust judicial persecutions (11%), personal persecutions (9%), homosexuality (6.8%), family persecutions (6%), and poverty (3.8%). The remaining 5% of cases of escape were due to female circumcision, mistreatment, sexual violence, ethnic discrimination, war, or illness.

From this investigation, terrorism was the reason for escape, especially from Pakistan, and the victims named specific organizations. The migrants describe many attacks, forced disappearances, systematic homicides involving family members, witnessed by photos, threat letters, newspaper articles, and images about autopsies or funerals of family members.

Regarding religious persecutions, most reported attacks on religious minorities, such as Ahmad, Shiite, Hindu, Christians, or violence committed by members of religious sects. Religious persecutions were the first reason for leaving from Nigeria and Senegal but were also present in Gambia and Ghana.

With regard to political attacks, migrants described many episodes of violence by police or opponents belonging to terrorist groups during demonstrations. Political persecution was the first reason for escape from Bangladesh.

Unfair justice persecutions, due to episodes of repression of the judiciary or fear of unjust detention, torture, or death sentences, were the first reasons for escaping from Gambia and Ghana.

Homosexuality was considered a crime in nearly all countries examined, and nearly all of the homosexual interviewees said that they suffered threats, personal injuries, torture, and the death penalty.

Female circumcision was a relevant reason for escaping, especially from Africa, particularly in Senegal, Nigeria, and the Gambia. In fact, not only women but also men who opposed this practice were forced to escape, as they were condemned by their communities.

This study revealed that less than 4% reported poverty as a reason for escaping. Therefore, the serious violation of human rights in these countries would be the main cause of request for a residence permit. Although only 40% of interviewees provided evidence, their statements were significant for understanding the need to promote the defense of human rights in these countries. This study offers evidence of the importance of epidemiological data regarding the phenomenon of immigration in order to find new solutions for migratory flows and to improve assistance to refugees.

## E112 Perceptions of Task Relevance in Forensic Science: A Survey of Forensic Analysts

Brett O. Gardner, PhD\*, University of Virginia, Charlottesville, VA; Sharon Kelley, PhD, Institute of Law, Psychiatry, and Public Policy, Charlottesville, VA 22903; Daniel C. Murrie, PhD, Institute of Law, Psychiatry, and Public Policy, Charlottesville, VA 22908; Kellyn Blaisdell, BA, University of Virginia, Charlottesville, VA 22902

**Learning Overview:** The goal of this presentation is to educate attendees about predominant beliefs among forensic analysts regarding the relevance of information types when conducting forensic analyses and to demonstrate how such beliefs are integral to managing contextual bias.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reviewing the literature on contextual effects in forensic analyses and providing results of the first empirical attempt to discover what forensic analysts from wide-ranging disciplines believe to be task-relevant to their scientific analyses. This presentation will also discuss how results can shape future research, policy, and professional practice.

Forensic analysts are often exposed to wide-ranging contextual information (e.g., suspect criminal history) regarding cases as they complete analyses. At the same time, research across forensic science disciplines has shown that irrelevant contextual information can bias analyses, even though analysts are generally unaware that such information is influencing their decisions.<sup>1-3</sup> Based on this body of research, the National Commission on Forensic Science reported that “forensic science service providers should rely solely on *task-relevant* information when performing forensic analyses.”<sup>4</sup>

Scholars, government agencies, and national authorities increasingly caution courts about the effects of contextual bias on experts and have called for laboratories to implement context management procedures.<sup>5</sup> However, no research has examined what types of information forensic analysts consider to be task-relevant and task-irrelevant. This distinction is necessary to help implement recommended procedures that limit exposure to task-irrelevant information.

The present study surveyed forensic analysts regarding their opinions of what types of information commonly contained in evidence submission forms are “essential” versus “irrelevant” to the analysis of forensic evidence. Understanding what information forensic analysts consider to be essential versus irrelevant, and whether there is consensus among examiners, may play an important role in informing efforts to minimize contextual bias.

In total, 183 practicing forensic analysts from wide-ranging disciplines completed a three-part survey at the outset of five training programs in the United States. In brief, the survey presented analysts with a list detailing 16 different types of information regarding case details (e.g., offense type, description of evidence), suspect details (e.g., suspect name, suspect criminal history), and victim details (e.g., victim race, victim name), most of which are commonly found on evidence submission forms.<sup>6</sup> Participants then described the importance of each type of information when performing their specific duties as a forensic analyst (i.e., “analyzing evidence in your discipline”) by indicating whether they believed such information was “Essential,” “Irrelevant,” or “Not essential, but you would review this if available.”

This presentation will provide detailed charts and statistics summarizing analysts’ perceptions according to their primary discipline. In certain disciplines, there was a lack of consensus regarding the relevance of some pieces of information. For example, analysts within forensic chemistry were equally divided (i.e., ≈33% endorsed each relevance category) regarding the relevance of knowing offense type when conducting analyses. Across all disciplines, some patterns emerged regarding the types of information that analysts most frequently agreed upon. Analysts were more likely to agree on the task relevance of information relating to a suspect or victim than they were to agree on the relevance of case information (e.g., method of evidence collection). Further, analysts were most likely to agree that information, particularly information regarding a suspect or victim, was *irrelevant* to their analyses rather than *essential*. Analysts within crime scene investigation appeared unique from other disciplines as such analysts were much more likely to describe wide-ranging types of information as *essential*.

Taken together, the current findings reveal a lack of consensus regarding the relevance of some types of information (e.g., offense type) to forensic analyses and a majority opinion that other types of information are irrelevant (e.g., victim ethnicity). Given human vulnerability to contextual bias, it is critical to determine which information is essential to forensic analyses and to limit exposure to extraneous information. The present study consequently reveals a need for further work to understand what information is thought to be task-relevant versus task-irrelevant. Such information is critical to informing future methods (e.g., context management procedures) to limit bias.

### E113 National Institute of Justice (NIJ) Initiatives and Partnerships to Advance the Forensic Sciences

*Jonathan G. McGrath, PhD\*, National Institute of Justice, Washington, DC 20531*

---

**Learning Overview:** After attending this presentation, attendees will better understand the initiatives developed by the Department Of Justice (DOJ) and the NIJ to advance the forensic sciences at the federal, state, local, and tribal levels. Attendees will learn how coordinated efforts and new partnerships are providing resources to meet the needs identified by the forensic science stakeholder community. Attendees will also learn how to access these resources, including reports, webinars, and learning opportunities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying resources developed through the work of several forensic working groups and will provide important information relevant to forensic science practitioners, medical examiners and coroners, forensic science stakeholders, and students.

The DOJ recently conducted a needs-based assessment of forensic laboratories that included public crime laboratories with medical examiner and coroner offices as an overview of academic forensic science resources. The NIJ supported this effort to learn from state, local, and tribal stakeholders about forensic services provided across the United States. Along the way, the NIJ learned critical information that is serving to enhance existing programs and foster new initiatives and partnerships. This presentation will discuss the NIJ's activities to identify key priorities and to develop practical solutions to support the forensic science community.

This presentation will discuss the NIJ activities to support the work of several working groups, including for the recently established Forensic Laboratory Needs-Technology Working Group (FLN-TWG), to help focus resources to achieve actionable results and the Office of Justice Programs/Department of Health and Human Services Federal Medicolegal Death Investigation (MDI) working group. This presentation will discuss recent developments from partnerships with the Bureau of Justice Assistance (BJA), the Bureau of Justice Statistics (BJS), and the Office of Victims of Crime (OVC), including training and technical assistance opportunities. This presentation will highlight the NIJ's coordination with the DOJ Office of Justice Programs (OJP) partner agencies to coordinate activities that involve forensic science and the criminal justice system stakeholder community. The BJA is advancing public safety and public responses to the opioid crisis through the BJA Comprehensive Opioid Abuse Program. The BJS is developing survey tools to implement the Census of Publicly Funded Forensic Laboratories and the Census of Medical Examiner and Coroner Offices. The OVC has developed a Vicarious Trauma Toolkit and a Mass Violence Toolkit. This presentation will also impact the forensic science community by identifying resources developed through these working groups and that are available through the NIJ Forensic Technology Center of Excellence that is supporting the forensic science community to advance technology, share knowledge, and address challenges.

The NIJ is the research, development, and evaluation agency of the DOJ and is dedicated to improving knowledge and understanding of crime and justice issues through science. The NIJ provides objective and independent knowledge and tools to reduce crime and promote justice. The NIJ supports the DOJ's priorities on forensic science to improve capacities, increase coordination and collaboration at the Department, among Federal agencies, and with state, local, and tribal entities, and advance the reliability and sensitivity of forensic science testing. The OJP's mission is to increase public safety and improve the fair administration of justice across America through innovative leadership and programs.

### E114 Addressing the Challenge of Conducting Undergraduate Research in Forensic Science Academic Programs Using a Course-Based Undergraduate Research Experience (CURE)

Kimberly S. Koboжек, MS\*, Arizona State University New College, Phoenix, AZ 85069-7100; Pamela A. Marshall, PhD, Arizona State University West, Phoenix, AZ 85069-7100; Ken G. Sweat, PhD, Arizona State University West, Phoenix, AZ 85069-7100; Jennifer Broatch, PhD, Arizona State University, Glendale, AZ 85306-4908; Jennifer Foltz-Sweat, PhD, Arizona State University West, Phoenix, AZ 85069-7100; Anthony B. Falsetti, PhD, George Mason University, Fairfax, VA 22030

**Learning Overview:** After attending this presentation, attendees will understand how to develop and execute a course-based method to integrate research into undergraduate forensic science academic programs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating a modality for integrating research into an undergraduate forensic science academic program, as well as creating a potential pipeline for mutually beneficial collaborations between crime labs and forensic science academic programs.

There are inherent challenges when conducting any type of Science, Technology, Engineering, and Mathematics (STEM) research. Money, personnel, and time are just a few of the overarching issues that researchers face. Forensic science is both more interdisciplinary and applied than many other “traditional” STEM fields, so the task of implementing a robust research experience for undergraduate students to the field of forensic science research may face additional challenges. Traditionally, research at the university level has been the purview of graduate students and academic faculty; thus, research monies are awarded to these groups and research positions for undergraduates can be difficult to obtain. While many undergraduate STEM programs have encouraged participation in research, tenure track, or other research, faculty may not be performing research of interest to the undergraduate forensic science student. Thus, students typically participate in existing faculty members’ research programs, which are often not specifically focused on the forensic sciences.

Both the 2004 Technical Working Group for Education and Training in Forensic Science (TWGED) report and the 2009 National Academy of Sciences Report made it clear to the forensic science community that research is essential for the support and advancement of the forensic sciences.<sup>1,2</sup> If crime laboratories are increasingly placing a premium on applicants who have research experience in addition to an appropriate science degree, then graduate students would be more sought after versus an applicant with “only” a four-year science degree. However, many students choose not to continue in a graduate program. This deficiency of participation in graduate programs coupled with the reality that there are not as many specific forensic science graduate programs as there are other traditional STEM graduate programs in the United States leads to a dearth of research-trained forensic scientists. This situation creates a demand that is difficult to meet and places students, educators, and crime laboratories in a bind.

Employing a CURE is a method for both new and established undergraduate forensic science programs to incorporate research into their undergraduate curriculum. By using a CURE modality, undergraduate students can participate in authentic research and carry that experience with them as a unique skill set that crime laboratories and other forensic-based employers are seeking.

The development of a core CURE curriculum designed to be used by multiple disciplines was created by an interdisciplinary collaboration at Arizona State University funded by the National Science Foundation. This model curriculum was applied to the forensic sciences by investigating the persistence of latent forensic evidence. The core curriculum included document templates and teaching module outlines for instructors and students to use throughout the course. These materials covered the importance of research; what “good” research looks like; experimental design, execution, and analysis; and presentation of research via different manners—scientific poster, oral presentation, and/or publishable research paper.

Research is no longer the province of just graduate programs and tenure-track academics. The CURE can serve as a single-semester research experience or a year-long capstone project. Whatever the format, the CURE model is an innovative and unique opportunity for undergraduate students to perform research at the university level, gain valuable experience while still an undergraduate student, and potentially collaborate with practicing forensic scientists on current research and/or validation projects.

*This material is based upon work supported by the National Science Foundation. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.*

### E115 The Use of Large-Scale Faux Crime Scenes and Cold Case Coursework to Teach Forensic Science in Social Science-Based Coursework

*Michelle Rippy\*, California State University-East Bay, Hayward, CA 94542*

---

**Learning Overview:** After attending this session, attendees will be able to identify common issues with teaching science-based courses in a social science major. Attendees will be able to discuss assignment options for non-scientists and employ new tactics for expanding learning. Attendees will be able to outline coursework options using assignment examples provided and relate assignments to student feedback.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering background and ideas on how to teach complicated forensic science topics to non-science majors. Examples of coursework and student evaluations of the assignments are provided to allow educators to expand knowledge and assist in assessing projects to enhance student learning and application of knowledge.

Educating undergraduate students in a social science major on forensic science topics is especially challenging, as many have not taken a science course since high school. Teaching basic science is required for understanding of forensic science techniques and processes, which consumes valuable class time and can lead to student frustration. Complex forensic science topics can be successfully broken down using case studies and by showing the intersection of forensic science with social science-related criminal justice topics. The high-impact practice of incorporating collaborative assignments assists in increasing student involvement and learning to work in a team. The use of large-scale faux crime scenes incorporates collaborative assignments and gives students groundwork of basic science relating to different types of evidence. The students are responsible for recognizing evidence, photographing, collecting, processing, and recognizing the proper type of scientific forensic testing to request—showing application of the material. The crime scene also incorporates interviewing witnesses at the scene to employ knowledge and skills gained during the foundation portion of the course. Cold cases from local agencies are presented by detectives, and students are provided with the case files to review and “work” in a tabletop format. Using foundational knowledge gained from the beginning of the class, student groups review the evidence, assess the evidence and information available, and complete assignments based on other work or theories that can be followed. Student evaluations of forensic science-based activities in social science coursework show support of the assignments in analyzing cases, employing the basic science concepts learned, and interpreting evidence found during the faux crime scenes.

**Forensic, Education, Non-Scientists**

### E116 The Educational Outreach Program at the Defense Forensic Science Center (DFSC)

*Rachel L. Creager, Defense Forensic Science Center, Forest Park, GA; Thomas A. Meyer, MS, Atlanta, GA 30311; Henry P. Maynard III, MSFS\*, Stockbridge, GA 30281*

**Learning Overview:** After attending this presentation, attendees will understand the DFSC's Educational Outreach Program (EOP) and the opportunities available to participate in cutting-edge research at DFSC.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing future forensic scientists and their academic mentors about available research options at DFSC that can advance their careers while furthering forensic science capabilities.

The Office of the Chief Scientist at DFSC performs one of the essential elements of the organization's mission by providing forensic research capabilities that support the Department of Defense (DoD). It is the mission of the Office of the Chief Scientist to increase the Army's readiness by executing an innovative Research, Development, Test, and Evaluation (RDT&E) program that strengthens current and develops future forensic science capabilities. For that reason, the DFSC EOP was established in 2011 to provide qualified university students an opportunity to conduct meaningful short-term research in a world-class forensic laboratory. The EOP introduces students to careers in the DoD, while building partnerships between DFSC and academia. Students receive a wealth of experience in experimental design, test and evaluation efforts, validations, and analysis of complex data. The Office of the Chief Scientist participates in various programs that allow students to work at DFSC, including the DoD Science, Mathematics, and Research for Transformation (SMART) program and the Army Educational Outreach Program College Qualified Leaders (referred to throughout as Research Associate) program. This presentation will benefit prospective students by highlighting these career-developing opportunities (a brief summary of each is provided below).

The Office of the Chief Scientist coordinates DFSC's participation in the SMART program. The goal of the SMART program is to increase the number of civilian scientists and engineers that are employed by the DoD laboratories. To do this, students at any level within their academic career (Bachelor's, Master's, or PhD) can apply to the SMART program to receive a full academic scholarship and future employment at a DoD laboratory upon degree completion.

Through the Research Associate program, undergraduate students come to DFSC to work on research projects for a summer, a semester, or a year. While in the Research Associate program, students receive a generous stipend. Our Research Associate program differs from traditional internship programs in that the students participate directly on a research project under the guidance of a DFSC research scientist. The Research Associate program allows students to gain valuable knowledge, skills, and abilities in experimental design, testing, and analysis from dedicated forensic mentors.

Since 2011, DFSC has had 169 EOP participants from 65 universities provide more than 75,000 hours on more than 100 DFSC-led research projects. The DFSC's Educational Outreach Program has been growing annually and these numbers will continue to rise. Come learn more about the opportunities at DFSC and join the research team!

### E117 Improving Forensic Science Information Seeking

Laura Sare\*, Texas A&M University, College Station, TX 77843; Sarah Bankston, MS\*, Medical Sciences Library, College Station, TX 77843; Jeffery K. Tomberlin, PhD\*, Department of Entomology, College Station, TX 77843-2475; Samantha J. Sawyer, BS\*, Department of Entomology, Texas A&M University, College Station, TX 77842

---

**Learning Overview:** The goal of this presentation is to describe the findings from a survey of forensic science professionals from a variety of disciplines on how they search for information related to their occupation. The researchers aim to discover how libraries can serve as gateways to provide assistance when seeking information, such as scholarly materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting strategies to potentially enhance the ability to locate scholarly materials applicable to their profession. Such skills could lead to efficient skills for also assessing these materials.

In order to provide the forensic science community with effective and useful educational materials, this survey was the first stage of an investigation on forensic science professionals' information search strategies. The researchers wanted to uncover how forensic scientists think about finding information in their specific fields, tease out strengths that could be shared throughout the forensic science community as a whole, and identify knowledge gaps in search strategies that could be improved upon and brought to the community through learning modules.

A survey created in Qualtrics®, comprised of 13 questions, was sent out on August 19, 2017, via the American Academy of Forensic Sciences (AAFS) listserv. The survey was open for responses until November 8, 2017. There was a total of 547 responses, and the dataset consists of the 333 completed surveys. Multiple choice response analysis was provided by Qualtrics®, while open response questions were coded using central themes for each question independently and analyzed.

While most forensic science professionals surveyed do not search for research material daily, many need to find information on a monthly or weekly basis. For those positions and disciplines that need to conduct research, a majority said they often could not access articles they located and would like to use due to paywalls. Those that did not have problems accessing articles were usually affiliated with a university.

Results of the survey indicate some forensic science professionals are in need of training for effectively locating scholarly research material. Three themes developed from this research. The first is that libraries and researchers have different definitions for information seeking terminology that need to be bridged. The second theme was a need for guidance on where to find quality materials and how to find open access (freely available research) materials for those who do not subscribe to journals. The last theme that emerged was the need for direction on how to create an effective search strategy using keywords and Boolean operators.

This project will determine how forensic scientists locate and evaluate information to allow the researchers to develop educational materials aimed at improving these skills and their efficiency with locating quality literature. Attendees will learn strategies potentially enhancing their ability to locate scholarly materials applicable to their profession.

*This research was funded by National Institutes of Justice grant 2016-R2-CX-0054. Opinions, points of view expressed in this research, and products discussed represent a consensus of the authors and do not necessarily represent the official position, policies, or endorsement of the United States Department of Justice, Office of Justice Programs, or the National Institute of Justice.*

### E118 A Journal of Our Own: *The Journal of Forensic Science Education*—The Official Publication of the Council of Forensic Science Educators

Lawrence Quarino, PhD\*, Cedar Crest College, Allentown, PA 18104; Kelly M. Elkins, PhD, Towson University, Towson, MD 21252; Adrienne L. Brundage, PhD, Bryan, TX 77807

---

**Learning Overview:** After attending this presentation, attendees will be aware of a newly developed open-access journal titled *The Journal of Forensic Science Education* that is intended to be a resource to help forensic science educators: (1) develop pedagogy and curriculum appropriate to the forensic science discipline, (2) promote scholarship in forensic science education, and (3) serve as a communication resource between forensic science educators.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how *The Journal of Forensic Science Education* can further the goal of quality forensic science education by serving as a vital resource for educators that can help develop scientific competency in students at multiple levels.

An assessment of the forensic sciences, published in 1999 by the National Institute of Justice, described the educational and training needs of the forensic science community as “immense.”<sup>1</sup> This immense need has developed over the past three decades by the unprecedented demand of the criminal justice system for crime laboratory services due in large part to the development of technologies that can provide scientific information that previously could not be obtained. As a result of this demand, local, state, and federal government resources have been allocated to expand laboratory services, although the availability of individuals with the requisite skills and education to fill new positions is severely limited. To try and meet this need, undergraduate and graduate forensic science programs have developed at an unparalleled rate over the past two decades in the United States and abroad. An examination of the American Academy of Forensic Sciences website reveals more than 120 forensic science programs leading to a bachelor’s or master’s degree. This number is probably the proverbial “tip of the iceberg,” particularly considering that few international programs are listed. Considering that the vast majority of these programs did not exist 20 years ago is cause for optimism about the future of forensic science. However, at the same time, this rapid growth is cause for concern about the quality of many of these programs. In addition, the forensic science educational landscape is even bigger considering the number of high school science teachers who now teach forensic science courses, usually as popular science electives.

The Council of Forensic Science Educators (COFSE) was created more than 20 years ago with this goal in mind. COFSE objectives include the exchange of ideas and discussion of problems of common interest between forensic science educators and for educators to work collectively to upgrade the quality of forensic science education. COFSE is composed of individuals involved in forensic science education from the high school through graduate level. It has helped give rise to the “forensic science educator,” a concept distinct from educators of other scientific disciplines. COFSE is also the parent organization of Delta Delta Epsilon, an international honor society designed to recognize high-achieving forensic science students at the undergraduate and graduate level, furthering the idea of forensic science as more than simply an applied scientific discipline. At the annual meeting of the American Academy of Forensic Sciences in 2018, COFSE presented a full-day workshop on active learning in forensic science.

It makes sense, then, for COFSE to take the next step and establish an official publication. *The Journal of Forensic Science Education* will commence in 2019 and will be an international, peer-reviewed journal devoted to improving forensic science education pedagogy, laboratory and classroom activities, and promoting the scholarship of forensic science education. In many ways, it will be modeled after the *Journal of Chemical Education* offered through the American Chemical Society that has been in publication since 1924. Currently, the planning committee for the *Journal* is creating an editorial board and an on-line platform. The *Journal* will be open access and housed through the Texas Digital Library. Articles will be indexed through Google® Scholar and other databases. The *Journal* will welcome editorials, commentaries, letters, pedagogical articles, laboratory experiments, demonstrations, technology reviews, and books reviews. The *Journal* will serve to enhance communication among forensic science educators from high school to university and people interested in the teaching and learning of forensic science from forensic laboratories and government.

### **E119 Is the Decentralization of Forensic Capabilities Providing an Opportunity for Forensic Science to Reach the End of the Crossroads?**

*Claude Roux, PhD\**, University of Technology Sydney, Broadway, NSW 2007, AUSTRALIA; *Eoghan Casey, PhD*, University of Lausanne, Lausanne, Vaud, SWITZERLAND; *Frank Crispino, PhD*, Université du Québec à Trois-Rivières, Trois-Rivières, PQ G9A 5H7, CANADA; *Olivier Delémont, PhD*, School of Criminal Justice, University of Lausanne, Lausanne, Vaud CH-1015, SWITZERLAND; *Olivier Ribaux, PhD*, Ecole Des Sciences Criminelles, Lausanne 1015, SWITZERLAND

**Learning Overview:** The goal of this presentation is to provide an outlook of forensic science and its future by considering the rapid and ongoing technology changes in modern society, especially regarding the decentralization of forensic capabilities and digital traces.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing guiding principles to be better equipped to face current and future challenges in forensic science. This presentation will encourage managers, educators, researchers, and policymakers to look beyond the usefulness of forensic results for solving individual investigations and to realize the value of combined forensic knowledge and intelligence for developing broader strategies to deal with crime in a globalized, digitalized society.

Forensic science has been at the crossroads, not to say in crisis, for more than a decade. The robustness of the scientific foundations of essentially all of the forensic science disciplines is being questioned on a regular basis. Further, the usefulness of forensic science continues to be questioned by evaluative studies focusing on the judicial contribution. In this debate, it is apparent that very few discussions considered the very nature of forensic science, overlooking essential contributions to investigation and security, beyond the single production of evidence in court. Further, some rapid changes in society and organizations are bringing additional challenges for forensic science laboratories. One such critical change is the expanding decentralization of forensic capabilities, particularly for digital traces, which exposes and catalyzes a rupture with the traditional central forensic science laboratory model. In this presentation, it is argued that this situation generates not only challenges but also opportunities for forensic science to move forward.

To assist this unavoidable decentralization, it is recommended that laboratories undertake digital transformations to capitalize on the decentralization movement, develop a more comprehensive understanding of crime and security-relevant problems, and play a more central role in problem solving collaboratively with law enforcement organizations and other stakeholders. A model for bilateral transfer of information and knowledge is proposed to magnify the impact of forensic science laboratories on abating crime, strengthening security, and reinforcing the criminal justice system. To accomplish digital transformations, laboratories require personnel with different expertise, including investigative reasoning, knowledge codification, data analytics, and forensic intelligence.

A policy window is open. Forensic science laboratories have the potential to achieve the broader legitimacy that is required for redefining their position through transformed processes. However, this requires some courage and conviction from the forensic science community and reciprocal commitment, including the creation of processes within law enforcement organizations and government that ensure the new knowledge generated by laboratories will be utilized effectively.

At that stage, one may have reached the end of the crossroads.

#### **Forensic Intelligence, Problem-Oriented Policing, Knowledge Management**

## E120 Perceptions and Estimates of Error Rates in Forensic Science: A Survey of Forensic Analysts

Daniel C. Murrie, PhD\*, *Institute of Law, Psychiatry, and Public Policy, Charlottesville, VA 22908*; Brett O. Gardner, PhD, *University of Virginia, Charlottesville, VA*; Sharon Kelley, PhD, *Institute of Law, Psychiatry, and Public Policy, Charlottesville, VA 22903*; Kellyn Blaisdell, BA, *University of Virginia, Charlottesville, VA 22902*

**Learning Overview:** The goal of this presentation is to educate attendees about commonly held beliefs of forensic analysts across multiple disciplines regarding the prevalence and acceptability of different types of errors (i.e., false positive and false negative errors) in their field.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results of the first study to empirically assess forensic analysts' opinions and attitudes regarding the prevalence and acceptability of errors within their discipline, as well as to show common misperceptions relating to error rates among forensic analysts.

Historically, many forensic scientists have adamantly denied the presence of error in their field.<sup>1,2</sup> Critical reviews have noted that such statements are not scientifically defensible and have called for research to appropriately quantify error in all valid forensic science disciplines.<sup>3,4</sup> However, because such research is relatively recent and controversial, error rates in many forensic science disciplines remain unknown and even the best estimates are unreliable.<sup>3,5</sup>

The present study sought to evaluate how forensic analysts think about error in their disciplines and how demographic characteristics might influence such perceptions. In total, 183 practicing forensic analysts from wide-ranging disciplines completed a three-part survey at the outset of five training programs in the United States. For the current study, results are presented from the first two parts of the survey addressing: (1) attitudes regarding the acceptability of error types, and (2) estimates of error rates within forensic science.

Before asking questions about perceptions or estimates, participants were educated on false positive and false negative errors. Analysts then indicated how they "weigh and prioritize the risk of each type of error" on an 11-point scale ranging from 0=*I minimize the risk of false positives*, to 10=*I minimize the risk of false negatives*. Participants also completed similar questions indicating how they believed their laboratory, and discipline as a whole, weigh and prioritize the risk of each error type. In part two of the survey, participants estimated the false positive and false negative error rates in their discipline using a scale of 14 possible error rates ranging from "approximately 1 time in 2," to "such an error is impossible." After estimating error rates, participants either identified a specific source for their estimates or indicated that they did not know of any source documenting known error rates in their discipline.

Analysts generally perceived false positive errors to be less frequent than false negatives, although both error types were considered to be infrequent. Across disciplines, 38% of analysts indicated that the rate of *false positive errors* was equal to or less than one in one billion, with 10% stating that such errors were not possible. Likewise, 22% of analysts indicated that the rate of *false negative errors* was equal to or less than one in one billion, with 6% stating that such errors were not possible. Notably though, estimated error rates differed according to discipline, with forensic biology analysts typically estimating that errors were less common than did pattern evidence analysts. When asked to identify a source for their estimated error rates, the vast majority of analysts (78.7%) did not provide a source.

In general, analysts reported that they, their workplace, and their discipline prefer to minimize the risk of false positives and thus tolerate a greater risk of false negatives. Crime scene investigation analysts were the lone exception in that they held a more balanced view regarding minimizing false positive and negative errors. Additional detailed results and moderating variables (e.g., work experience) will be addressed at the conference.

In conclusion, this presentation will discuss how forensic analysts view error rates in their field and discuss implications for future practice and research. For example, although most forensic science disciplines do not have established error rates, the fact that more than one in five analysts estimated the risk of each error type to be impossible or very low (i.e., less than one in one billion) is concerning in light of: (1) the inevitability of errors, and (2) human vulnerability to cognitive bias.<sup>3</sup> Results highlight the need for further work investigating and disseminating error rates as a step toward informing policy and practice.

### E122 Forensic Archaeology and Search Strategies for Clandestine Burials: Geographic Profiling in Reverse and “Winthroping”

*Sharon K. Moses, PhD\*, Northern Arizona University, Flagstaff, AZ 86011-5200*

---

**Learning Overview:** After attending this presentation, attendees will better understand how geographic profiling and “winthroping” may be useful tools for clandestine burial searches. This presentation will familiarize attendees with the basic principles of geographic profiling commonly used by law enforcement to locate an offender’s likely home base according to mapped patterns of their crime scenes. However, searches for clandestine burials need to be based upon geographic profiling patterns in reverse: the offenders’ home base (known or suspected), the victims’ home base, other related crime scenes as applicable, and the offenders’ habits to determine likely areas for a clandestine burial. Attendees will also be introduced to the concept of “winthroping,” which was originally developed by the military for the purpose of locating hidden munitions caches. Most clandestine burial searches are based upon tips, tracking offenders’ activities close to the disappearance date of a suspected victim, and general speculation combined with a hit-or-miss approach of volunteer groups who typically canvass areas around a victim’s last known whereabouts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing involvement of forensic archaeologists’ skills in conjunction with adapted geographic profiling strategies that can aid in identifying possible burial locations. Forensic archaeologists have been taught as part of their academic training to recognize and understand spatial dynamics of built and natural environments and human and animal movement across those landscapes. It cannot be overstated that these skills can offer important insights that an untrained eye may miss in an outdoor crime scene. This presentation promotes the involvement of forensic archaeologists to participate before the actual excavation of a clandestine burial and encourages law enforcement to utilize their skills in the search phase. Many times, a homicide is suspected but a body has not been found. Locating a body is problematic without a confession, and oftentimes cases are severely disadvantaged when the victim is not found.

This presentation will demonstrate that geographic profiling, originally conceived of as a means to locate offenders, is a tool that may also be adapted to focus on patterns and choices to find burials. This presentation will explore how an offender’s environment and relationship (or lack thereof) to a victim also influences choices for clandestine burial sites.

There is unique value in combining forensic archaeological skills with understanding multivariate landscapes in criminal activities, human connection to those landscapes, and consideration of unconscious and habitual behavior patterns toward identifying likely burial locations. Research on profiling in this context is currently very limited and this presentation is aimed at stimulating more exploration into, and development of, adapting and incorporating geographic profiles in conjunction with forensic archaeologists’ involvement in burial search strategies.

### **E123 Interagency Cooperation in the Recovery of Human Cremains and Human Remains**

*Rebecca Wood, MFS\*, Washington, DC 20024; Francisco J. Diaz, MD\*, Washington DC Office of the Medical Examiner, Washington, DC 20024*

---

**Learning Overview:** After attending this presentation, attendees will understand what encompasses an incident action plan, how decedents are most commonly identified at the Washington, DC, Office of the Chief Medical Examiner (OCME), and the challenges faced when a funeral home is closed indefinitely.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by shedding light on a seldom-discussed topic: the closing of a funeral home and the role of the medical examiner therein. This presentation will also provide an overview of the way the DC OCME notified and interacted with next of kin as well as assisted with the reunification of families.

The Washington, DC, Office of the Chief Medical Examiner partnered with the DC Office of the Attorney General (OAG) and the United States Marshals Service in a small-scale operation involving the recovery of more than 100 cremains and several non-cremated human remains from a funeral home that was closing in Washington, DC. The operation was conducted over the course of two days, one day in November and one day in December of the 2017 calendar year. There was intensive preparation prior to the recovery, and this presentation will highlight the preparation, logistics, and field cataloging process.

This presentation will include an overview of the method the DC OCME used to identify cremains and the limitations this process exposed. This presentation will highlight challenges faced in an effort to assist other medical examiner/coroner offices who may encounter similar situations. Attendees will be provided with the methodology behind creating a field cataloging process, as well as an overview of the comprehensive Microsoft® Excel® spreadsheet created by the DC OCME to properly document, triage, and analyze the cremains and non-cremated human remains recovered during this small-scale operation. Additionally, a time-line will be provided to further assist in visualizing the long-standing effects such an operation can have on a medical examiner/coroner office, the other agencies involved, and the community as a whole (to include the next of kin).

This presentation will also impact the forensic science community by discussing interagency cooperation among organizations within three regions: the District of Columbia, the Commonwealth of Virginia, and the state of Maryland. Finally, this presentation will impact the forensic science community by encouraging other agencies to become aware of the possibility that they too may be called upon to assist in such a recovery mission.

#### **Interagency Cooperation, Human Cremains, Family Reunification**

### E124 The Identification of Necrophagous Insect Species by Ambient Ionization Mass Spectrometry and Chemometrics for Postmortem Interval Estimations

Rabi A. Musah, PhD\*, State University of New York at Albany, Albany, NY 12222; Samira Beyramysoltan, PhD, State University of New York at Albany, Chemistry Department, Albany, NY 12222; Justine E. Giffen, BS, State University of New York at Albany, Albany, NY 12222; Jennifer Rosati, PhD, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the principles of ambient ionization mass spectrometry and its applications to forensic entomology. Additionally, attendees will learn about artificial neural networks and Self-Organizing Maps (SOMs) and how they can be generated from mass spectral data and utilized to determine the species identity of sample unknowns.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of ambient ionization mass spectrometry techniques in forensic entomology. The ability to rapidly analyze and identify necrophagous insects discovered on a corpse, or in animal or elder care abuse cases, will reduce some of the challenges and shortcomings of traditional species identification methods and enable more rapid analysis and species identification.

Conventional methods of species identification of necrophagous insects for determination of the postmortem interval in medicolegal investigations are often time- and resource-consuming. Furthermore, the results can easily be influenced by a number of factors, including the manner in which death occurred, the environment and temperature in the area of the body, and the climate and time of year. Presented here is an alternative mass spectrometric and chemometric approach to species identification of blow flies at each of their life stages (eggs, larvae, pupae, and adults). Application of this approach has revealed: (1) information regarding the biomarkers responsible for the differentiation between species at each life stage, (2) that even closely related species can be differentiated, and (3) that SOMs derived from mass spectral data provide a highly accurate means of identifying insect species.

Egg, larva, pupa, and adult stage samples of blow flies belonging to six species within the order Diptera were collected and suspended in 70% aqueous ethanol storage solutions, which is the conventional practice for storage of entomological evidence discovered on or near a corpse. These solutions were then rapidly analyzed by Direct Analysis in Real Time-High-Resolution Mass Spectrometry (DART<sup>®</sup>-HRMS) to determine the unique chemical fingerprint spectra. These analyses were performed in replicates of five. The mass spectra were then subjected to chemometric processing in the form of Kohonen SOMs. After initial preprocessing of the raw mass spectral data, minimum Redundancy Maximal Relevance (mRMR) and Sparse Discriminant Analysis (SDA) methods were applied in order to reduce the data to contain only the most significant variables required to create the models. The reduced data were then separated into training and validation sets in order to test the prediction abilities of the models. Mixtures of several species' ethanol suspensions at a given life stage were then created and analyzed to further test the models.

The results indicated that the DART<sup>®</sup>-HRMS spectral profiles of the blow flies analyzed were highly consistent between replicates but showed interspecies and life stage differences. These fingerprint profiles were then used as the basis for the creation of SOM models, which revealed the mass-to-charge ( $m/z$ ) values of the chemical components that were the most important for discriminating between and identifying different species at each life stage. The cross-validation results for the predictive ability of each life stage SOM were above 93%, and the external validation accuracy was 100% for all models. In the case of the mixture samples, preliminary results indicate 97% accuracy.

The DART<sup>®</sup>-HRMS chemical fingerprint profiles that were generated were found to be suitable for chemometric processing in order to accomplish species discrimination. DART<sup>®</sup>-HRMS is a rapid means to rapidly collect unique mass spectra for many different species and life stages of necrophagous insects. The SOM models that were built can be further expanded to include more species and families of insects and create a robust database to assist in the determination of insect species identity and by extension, postmortem interval.

#### DART<sup>®</sup>-HRMS, Entomology, Chemometrics

### E125 The Ability of Cotton, Polyester, and Wool to Retain Diatomaceous Evidence Following Submersion to Study the Postmortem Submersion Interval (PMSI)

Alexandra G. Rizzuto, BS, Keystone College, La Plume, PA 18440; Jillian Conte, PhD\*, Keystone College, La Plume, PA 18440

**Learning Overview:** After attending this presentation, attendees will understand how common fabrics retain diatomaceous evidence and how this information can be useful in an investigation involving victim submersion in a body of water.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing the knowledge of how diatomaceous materials are retained by different fabrics, assisting in the determination of crime scene location, transfer events, and, potentially, the PMSI.

Diatoms are unicellular, photosynthetic algae that are classified as *Chrysophyta* and Class *Bacillariophyceae*.<sup>1,2,3</sup> The microscopic nature of diatoms, which range in size from less than 5 to more than 500 microns, results in accumulations of 25-50 million cells in just one cubic inch of diatomite.<sup>1</sup> The relative abundance and small size of diatoms makes them ideal for forensic geoscience applications.<sup>4</sup> This area of forensics deals with comparison of environmental samples to establish or refute a common source.<sup>4</sup> The use of diatomaceous evidence in comparative trace analysis and relating it to postmortem events is currently an understudied area.

Historically, the forensic application of diatomaceous evidence has been limited to the diagnosis of drowning deaths.<sup>2</sup> The diatom test has been used for this purpose since 1942 and is based on the premise that diatoms do not occur naturally in the human body.<sup>3</sup> Diatoms enter the circulatory system and deposit themselves in organs, such as bone marrow and the brain.<sup>2</sup> Verma suggests that diatom analysis can be enhanced through analyses of submerged clothing or footwear in contact with the suspected drowning medium.<sup>3</sup>

The necessity of research into the forensic geoscience application of diatoms is further enhanced by the potential for diatoms to be utilized for the determination of PMSI.<sup>4</sup> The PMSI is the time interval between submersion and time of discovery of an item or victim.<sup>6</sup> Diatoms are initial colonizers of aquatic systems and they are dominant during algal succession.<sup>6</sup> This makes diatoms ideal organisms for PMSI determination. Zimmerman & Wallace were the first to develop a semi-quantitative approach to PMSI determination based on diatom diversity as a function of time.<sup>6</sup>

To date, only two studies have been conducted regarding the extraction of diatoms<sup>4,5</sup> from clothing, and both studies strictly used cotton.<sup>4,5</sup> Since clothing material is frequently recovered from crime scenes, it is important to understand how a variety of fabrics will retain trace materials. In forensic science, it is equally important to use optimized extraction techniques that provide a representative sample. Scott et al. developed a novel hydrogen peroxide extraction technique that yielded the highest number of diatoms and the most representative samples in comparison to the rinsing with water and rinsing with ethanol techniques.<sup>4</sup> Since the other two methods were not as representative of the reference samples, these should not be used in a forensic application where species composition is analyzed to determine source. To build on the current knowledge of how diatomaceous evidence is retained by fabrics, the following research question was proposed: Will the type of fabric affect the number of diatoms that are retained?

A 30% hydrogen peroxide extraction method was performed for three common fabric types (cotton, polyester, and wool) to retrieve embedded diatomaceous material. Resulting yields were examined using light microscopy and scanning electron microscopy. Slides were mounted with a mounting media suitable for the refractive index of diatoms. The research aimed to optimize the method for diatom extraction and compared the ability to yield diatomaceous evidence from cotton, polyester, and wool. The results for the optimized method were analyzed by one-way Analysis of Variance (ANOVA). An analysis of variance showed that the effect of type of fabric on the number of diatoms retained was significant,  $F(2,27)=32.067$ ,  $p=0.000$ . A Tukey post hoc test was conducted to determine which fabrics were different in retention. A relationship was found between cotton and polyester ( $p=0.206$ ). All other fabrics were significantly different ( $p<0.05$ ). This research furthers the knowledge of the forensic community by providing information about how different fabrics retain diatomaceous evidence.

### **F1 A Jurisprudential Analysis of the DNA Exam and Its Use as Evidence in Decisions of Brazil's Superior Court of Justice**

*Maria Eduarda A. Amaral\*, Porto Alegre, Rio Grande do Sul 90619-900, BRAZIL; Nereu J. Giacomolli, Porto Alegre 90619-900, BRAZIL*

---

**Learning Overview:** The goal of this presentation is to evaluate decisions of Brazil's Superior Court of Justice and to try to identify the importance given to the DNA exam as evidence in the decision.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a study about the scientific evidence and the DNA exam. This presentation will also initiate a discussion about the distance between the speech of different science areas and will examine the importance of collaboration and interdisciplinary communication.

A case law search was conducted on the website of the Superior Court of Justice on July 11, 2018, using the keywords "laudo pericial E DNA E penal" (the search was made in Portuguese).

Ten judgments were analyzed. The totality of the cases involved crimes of rape and/or indecent assault. In one case, the defense argued that it would be necessary to perform a DNA exam to prove the convicted person's ascendancy toward the victim. In this case, the magistrate understood that it would not be necessary to perform DNA, since the victim was adopted, and an ancestry also assumed in such cases. In another decision, the defense alleged that the collection of DNA occurred in an illegal manner and that the evidence would be unlawful. However, the magistrate understood that the DNA test was not the only element of evidence and that the collection was not illegal. In another decision, the defense requested the annulment of the judgment due to the lack of DNA evidence, and the magistrate understood that there was sufficient evidence and a DNA exam wasn't necessary. Furthermore, prior to the updating of the Brazilian Criminal Procedure Code conducted in 2008, it was necessary that the report be carried out by two official experts. At that time, appeals went to the Superior Court of Justice asking the validity of the expert report because it was not conducted by two official experts, and their qualifications were in question. In most of the decisions, report irregularities were not recognized or corrected. Thus, the reports were not used.

There is no consensus on the subject. The DNA exam is sufficient and robust evidence to support the decision for some judges. Others believe that more evidence is needed. Regarding the defense, it is noticeable that the DNA exam is highly defended or neglected depending on the importance that it may have for the defense. There is not a more rigorous assessment of the scientific method used to do the DNA exam.

The DNA exam was designed to be used in the medical science area and, over time, has been incorporated into the forensic sciences. However, legal writers frequently discuss about the methodology used in the DNA exam, including the collection process and handling, without deep knowledge about it. They question the accused's fundamental assurances and how the DNA exam could affect it. Thus, a discussion between both areas is extremely important so judges can understand what the DNA exam can be used for and what the limitations are regarding application to the law. In addition, forensic scientists will be able to realize that, although its technique is approximately 99.9% reliable, it will not always be used.

---

**DNA Exam, Forensic Science, Penal Process Evidence**

### F2 *Iter Criminis* and *Mens Rea*: A Methodology to Understand an Offender's True Intention Based on a Revision of the Concept of Guilt in Italian Criminal Law

Vincenzo Lusa, JD\*, Rome 00151, ITALY; Annarita Franza, PhD\*, Department of Experimental & Clinical, Florence, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance the Italian legal process provides to the criminal path (*iter criminis*), seeing as it is fundamental to undertaking an evaluation of an offender's true *mens rea* or the degree of culpability or insanity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by acquainting attendees with the advantages of using a criminal path legal model, which can split the criminal's behavior and thus define his actual intent and mental state.

A criminal path study can also ascertain whether the offender suffers from insanity, which may prove useful during the trial from a psychiatric and psychological point of view, with definite advantages for the defense, the accused, and the jury. In Italy, the criminal path is associated with an attempted crime, as set out in article 56 of the Italian criminal code. It is used to identify the moment in which the illegal activity of an agent becomes punishable. Article 56 states that: "whosoever carries out acts clearly intended to commit a crime, is responsible for an attempted crime, if the action is not completed or the event does not occur." In Italy, Article 56 is occasionally placed with such specific incriminatory laws as attempted murder (art. 56, 575 Italian Criminal Code).

The criminal path consists of the following parameters: (1) ideation, in which the offender sketches out the initial purpose on which the crime is based. In fact, the agent outlines in his psyche the criminal idea he wants to commit, which is then manifested by its conclusion; (2) preparation, where the agent arranges everything needed to execute the crime; (3) execution, where the agent carries out the conduct required for the crime to occur; and (4) perpetration, when the crime is committed. To be precise, the crime has been completed with all the elements defined by criminal law.

Intention must not be confused with the agent's volition, since it appears because of criminal intention. In fact, the latter constitutes the guilty party's true evil animus (cited in art. 108 of the Italian Criminal Code). Volition is seen as the manifestation of criminal intent (the latter is *mens rea* in the United States and *dolo* (malice) in Italy), which is completed with the offender's action. Volition is maintained until the crime has been concluded; even mental pathologies leading to incapacity to understand and to want can be inferred once a reliable diagnosis of the criminal path has been undertaken (as they are attached to the latter). In this regard, forensic neuroscience should also be considered. Regarding conscience and volition of action (*suitas*), what about taking criminal responsibility into account with criminal psychiatry? If this is not done, liability is correlated to the ability to be in full possession of one's faculties. Article 85 of the Italian Criminal Code states that no one can be punished for an act seen by law as a crime "if, at the moment of the act, [that person] was not responsible" and that "those who are in full possession of their faculties are responsible." It can be said that consciousness and volition may be considered as separate from a capacity to understand and to want, since mere consciousness and volition do not include the ability to comprehend the negative social value of actions that the offender performs and which, perhaps, in a moment of sanity, would never have been carried out (art.85, Italian Criminal Code). Finally, a full legal and scientific model will be suggested that can be used to evaluate an individual's actual *mens rea* through the criminal path.

#### *Mens Rea, Iter Criminis, Liability*

### F3 Judicial Aspects of Suicide Inducement in the Turkish Judicial System and a Review of the Erol Cetin Case

*Oktay Cavus, MSc\*, Üsküdar University, Istanbul 34430, TURKEY; Hatice Yılmaz, BSc\*, Üsküdar University, Istanbul 34662, TURKEY; Sevil Atasoy, PhD, Uskudar Universitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY; Tugba Ünsal, PhD, Üsküdar University Department of Forensic Science, Istanbul 34662, TURKEY*

**Learning Overview:** After attending this presentation, attendees will have a tool for comparative analysis of judicial aspects of suicide inducement and its application in Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an insight about the judicial aspects, code of conduct, and case report of suicide inducement in the Turkish judicial system.

Suicide has been interpreted in different forms throughout history. In general, it is considered as a violation of social order and rules and as a threat thereto. One who commits suicide is considered to be an offender both from religious and social points of view and thus, they are ostracized. All suicidal attempts are associated with multiple reasons, and social and individual influences are thought to play a role in such attempts. Since suicide, described as an individual's will to end his/her own life, is no longer considered as a crime, any involvement in a suicide attempt of such an individual is also excluded from punishment. To close this gap, suicide inducement is regulated as a crime in its own right. As a matter of fact, Article 84 of the Turkish Penal Code, Article 115 of the Swiss Penal Code, Article 78 of the Austrian Penal Code, and Articles 223-13 and 223-14 of the French Penal Code stipulate sanctions thereof. However, it is interesting that in contrast to other countries, in German Criminal Law, suicide inducement is not regulated as a crime and therefore, just like suicide itself, suicide inducement or providing the means therefor are also not punished. In Germany, the issue is handled within the framework of the causal agency. No one can be punished due to attempting to commit suicide. Because in such a case, a suicidal person will be put under pressure through punishment norms, and thus will be induced to commit suicide. If it is opted to punish an individual with suicidal tendencies, this will incite a person to commit suicide and achieve a result thereof. As it is not possible to recognize such sanction, such an approach will not be welcome by the function of Criminal Law. Suicide inducement is regulated by Article 84 of the Turkish Penal Code; it can be committed as an immoral offense.

If an individual commits suicide, the suicide inducer will be punished more severely. For a milder form of suicide inducement, the punishment is imprisonment for two to five years if a suicide attempt does not result in death, whereas if it results in death, it is stipulated that imprisonment will be four years to ten years. The instigator (involved in stimulation intention and decision-making by a suicidal person), inducer (involved in decision-making by a suicidal person), or the ones who intensify such a decision or help the suicide be committed will be punished. Suicide inducement is a crime in the nature of a willful act, and the offender may have committed a concrete part of such a crime by being involved in acts set forth in Article 84/1 of Turkish Penal Code. In the case that a causality relation cannot be established between suicide and suicide inducement, it will not be possible to talk about such a crime as suicide inducement. Suicide inducement is committed with a general wrongful intention. The causality relationship should be established between suicide inducement, a suicide attempt, and a suicide, and, secondarily, the inducer of suicide should have a wrongful intention thereof. For determining qualification of a suicide inducement act, the person influenced by such an act should have at least attempted to commit suicide. In such a case, suicide inducement is not eligible for an attempt, for such a crime to be called, the existence of attempter of suicide influenced by the inducer of suicide is a must, and such an outline is set forth in Article 84/1 of Turkish Penal Code, which regulates milder forms of suicide inducement. If an offender induces more than one person to commit suicide through the instrument of the same concrete act, the degree of punishment will be increased since the same crime is committed against multiple individuals.

Two offenders, who induced Erol Çetin to jump from the Bosphorus Bridge in İstanbul, Turkey, on August 3, 2016, are currently being tried in court and are expected to be convicted.

### F4 The Theory of Criminal Relativity: Using Genealogy Databases to Solve Crimes

*Donald E. Shelton, JD, PhD\**, University of Michigan-Dearborn, Dearborn, MI 48128-2406; *Frederick R. Bieber, PhD\**, Brigham & Women's Hospital, Boston, MA 02115

---

**Learning Overview:** After attending this presentation, attendees will have a deeper understanding of how genealogy DNA databases are being used to solve crimes and the technical, legal, and ethical issues involved.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by giving attendees the ability to understand how genealogy DNA databases are being used to solve crimes and the technical, legal, and ethical issues involved.

In 2018, using DNA-based genealogical research, police were able to arrest a former police officer who allegedly committed at least 12 murders, more than 50 rapes, and over 100 burglaries in California between 1974 and 1986. In numerous cases after the arrest of the suspect in the “Golden State Killer,” law enforcement investigators are now using genealogical databases in a different and much more effective way than previously available methods have allowed. The use of DNA Single Nucleotide Polymorphism (SNP) profiling has significantly changed the face of genealogical searching and those changes now offer new investigative methods of crime solving. Initially, DNA typing methods revolutionized the criminal justice system and led to the development of the Combined DNA Index System (CODIS) database of persons who had contact with the criminal justice system (prisoners, convicts and, in some states, arrestees). Subsequently the ability to extract DNA from ever-more-minute crime scene samples amplified its use in criminal investigations. Short Tandem Repeat (STR) -based familial searching made it possible to search CODIS at the state level—to search not just for perfect matches to crime scene evidence, but also for very close matches to possibly identify close (first-degree) relatives of the donor of a crime scene specimen.

Now, new DNA-based public genealogy databases can be searched for even more distant relatives of whoever leaves crime scene DNA evidence, regardless of whether their profile is in CODIS. Several new open-access genealogy databases now enable law enforcement to search for scores of even distant relatives by comparing thousands of SNPs typed from crime scene DNA. Investigators can submit the raw data files from the crime scene DNA to one of the new genealogy databases to find possible relatives of the person who left the evidence. While the suspect may not be in CODIS and may not have submitted his or her DNA to the genealogy site, the DNA of any of his or her relatives who have innocently submitted their data for genealogy search purposes can lead police to a range of possible persons of interest.

The SNP comparison process will be explained and differentiated from other traditional DNA-based familial searches. The results of DNA-based genealogy searching still require careful data analysis and follow-up investigation by police to further narrow the range of possible persons of interest based on age, locale, and other factors associated with the crime. Once a person of interest has been identified, police then need to obtain a known DNA sample from that person. This has been done surreptitiously using discarded DNA without a warrant (e.g., reportedly from a discarded tissue in the “Golden State” investigation). After that DNA profile is related to the crime scene specimen, the police then have the basis for a warrant. The entire process may raise potential issues under the Fourth Amendment, particularly considering the recent *Carpenter* United States Supreme Court opinions, as well as online e-privacy laws. The social, ethical, and policy implications of genealogics will also be discussed.

---

### Genealogy Databases, DNA, Crime and Genealogy

### F5 A Proposal for Legislative Oversight of Genealogical Websites

*Stephen B. Mercer, JD\*, RaquinMercer LLC, Rockville, MD 20852; Isabelle R. Raquin, LLM\*, RaquinMercer LLC, Rockville, MD 20852*

**Learning Overview:** After attending this presentation, attendees will understand the novel aspects of informational privacy for DNA and the importance of legislative regulation and oversight of DNA collection, retention, and distribution practices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework for evaluating DNA data banking practices and responding to ethical concerns with legislation that balances legitimate law enforcement and public health objectives with individual and family privacy interests.

DNA databanks are proliferating outside of the Combined DNA Index System (CODIS) and the regulatory framework that presently governs the collection, retention, and distribution of DNA samples and records. These shadow DNA databanks primarily exist at the local level and are maintained by local police agencies, by private companies that sell databank related services to police, and by private companies that sell direct-to-consumer test kits for genealogical and medical information.

Underregulated DNA databanks are a concern precisely for the reasons that explain their existence and proliferation: (1) police are able to avoid regulation and oversight of who they collect DNA from and how they retain or use DNA to investigate crime; (2) police can broaden the types of crime DNA databanks are used to investigate to more discretionary-based offenses (e.g., property crimes and other quality of life offenses); (3) police can perform familial searching in a state such as Maryland that prohibits the practice in its statewide databank; and (4) private companies with large databanks of DNA can have disproportionate influence over the course of medical research.

Although individual cases of law enforcement searching of genealogical websites have been widely reported, the overall utility of these underregulated public and private DNA databases is presently unknown because there are no uniform standards for the reporting of data about whose profiles have been placed in local or private DNA databanks, why or how DNA samples have been collected, and how DNA samples are retained, used, or further distributed. Without such reporting, the public and state lawmakers cannot know whether local or private DNA databanks are being misused or further linked to other public or private databanks. Moreover, any disparate impact or effect by race, ethnicity, or class will not be known.

Courts have largely taken a hands-off approach to regulating DNA databanks. Legislatures have recognized the need to regulate DNA collected and retained for use in CODIS, but only a few states have expressly addressed local databanks and no state has addressed the regulation of private DNA databanks maintained for genealogical or medical purposes but are also used to facilitate criminal investigations.

This lack of legislative oversight for local DNA databanks is troubling. Since the beginning of law enforcement, DNA databanking with the enactment of the federal CODIS law in 1994, the importance of legislative regulation, and oversight of DNA collection practices have been widely recognized. DNA databases “inevitably reflect the race, class, and geographic biases imbedded in police and judicial practices,” and as the former dean of the University of Maryland’s law school has noted, “[f]rom 1990 to 2004, Blacks were five times more likely than Whites to be incarcerated, and in 2000, Blacks and Latinos comprised 63% of incarcerated adults, even though together they represented 25% of the total population”—trends that are attributable to “racial profiling, discriminatory sentencing, and general racial bias in the criminal justice system ....”<sup>1,2</sup> Exactly because of the disproportionate representation of historically disfavored groups in the criminal justice system, they are also disproportionately represented in governmental DNA databanks.

On the other hand, it has been noted that private genealogical databases are skewed by race and class in the opposite direction. This has implications for the use of genealogical databanks to develop “personalized” medicine that target favored groups.

DNA is a powerful investigative tool to identify and apprehend criminal offenders, but its potential for abuse is real and must, therefore, be subjected to close legislative scrutiny and supervision. Statutory regulation of local police DNA collection and databank practices will clearly advance these ends. Model language is proposed for regulating local and genealogical DNA databanks.

### F6 Results of a Survey on Probabilistic Genotyping From the Legal Community

Michael D. Coble, PhD\*, University of North Texas Health Science Center, Fort Worth, TX 76107

**Learning Overview:** After attending this presentation, attendees will better understand the current state of training and the issues surrounding the use of probabilistic genotyping from the perspective of the legal community.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and legal communities by helping to: (1) determine how well the legal community is coping with the current change in DNA mixture interpretation using probabilistic genotyping software, and (2) show where and how training can help to improve the litigation of mixture interpretation and reporting using probabilistic genotyping software and likelihood ratios.

DNA mixtures of two or more individuals can be challenging to interpret for the forensic DNA scientist. Although guidance for autosomal Short Tandem Repeat (STR) interpretation of DNA mixtures from organizations such as the Scientific Working Group on DNA Methods (SWGDM) and the International Society for Forensic Genetics (ISFG) have been provided, the challenge of interpreting complex mixtures remains an issue for the forensic DNA community.<sup>1-3</sup>

Probabilistic genotyping, according to SWGDAM, “refers to the use of biological modeling, statistical theory, computer algorithms, and probability distributions to calculate likelihood ratios and/or infer genotypes for the DNA typing results of forensic samples (“forensic DNA typing results”).”<sup>4</sup> Over the past decade, there has been an “explosion” of software that uses a probabilistic approach to mixture interpretation. *All* of these programs use the likelihood ratio to convey the value of the evidence.

There are at least 45 laboratory systems in the United States that are currently using a probabilistic genotyping software system, with another 56 laboratory systems in some state of purchasing, validating, or implementing a program.<sup>5,6</sup> We are now at a tipping point for the use of probabilistic methods of mixture interpretation as the new “standard” for the forensic DNA community.

This presentation will provide the perspective of the legal community, through a survey conducted in late 2018, on the movement away from “binary” methods of interpretation for DNA mixtures to probabilistic methods of interpretation. Survey participants were asked about their access to training in probabilistic genotyping and likelihood ratios, how well they understand this change in interpretation and presentation of the results in court, and how well juries and judges have accepted these changes. The results will also provide advice from both prosecution and defense attorneys on issues involved with understanding and presenting this approach in court. Finally, a summary of training materials, literature, and other resources for the legal community will be presented.

#### Probabilistic Genotyping, DNA Mixture Interpretation, Likelihood Ratio

### F7 The Strengths and Limitations of Transfer DNA Evidence Recovered From Objects Handled by Multiple Individuals

*Leann G. Rizer, BS\*, Ypsilanti, MI 48197; Jonah W.P. Stone, BS, Indianapolis, IN 46241; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Cynthia Cale, MS, Strand Diagnostics, Indianapolis, IN 46241; Gay L. Bush, PhD, Strand Diagnostics, Indianapolis, IN 46241*

**Learning Overview:** After attending this presentation, attendees will better understand the strengths and limitations of transfer DNA evidence in situations in which multiple people handled the same objects and in which multiple DNA transfer events occurred. The goal of this presentation is to demonstrate the difficulty of predicting the mode of DNA transfer and handling order from DNA evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to a growing body of knowledge regarding transfer DNA and DNA evidence interpretation in medicolegal investigations.

Advances within the field of forensic science have allowed for an increase in the sensitivity of various technologies involved in the detection and typing of DNA evidence. As this sensitivity increases, so does the likelihood of detecting and amplifying DNA not associated with the criminal act. To better understand, explain, and interpret DNA recovered from evidentiary items, one must have a comprehensive understanding of the active and passive processes that lead to DNA deposition, as well as the numerous variables that influence the transfer of DNA between individuals and objects. Recently, there has been an increase in the number of transfer DNA samples submitted to forensic DNA laboratories for analysis. As a result, scientific studies regarding transfer DNA need to be conducted to better understand the strengths and limitations of transfer DNA evidence. Conducting systematic studies that test the limits of DNA transfer, understanding the factors that influence DNA transfer, and furthering the understanding of DNA transfer in various real-world scenarios will only act to bolster the interpretation of scientific evidence presented in criminal investigations.

This study expands upon transfer DNA research conducted by Goray and van Oorschot and explores the transfer of DNA in a simulated social setting.<sup>1</sup> Four participants handled pre-sterilized plastic objects (a jug and four cups). This served to simulate a social event in which multiple people pour beverages from the same jug in an open-air setting, as would be encountered in a restaurant or bar. The order and timing of handling were predetermined and controlled by the researchers to test for the various modes of DNA transfer (primary, secondary, and tertiary). The current study tests the following null hypotheses: (1) secondary DNA transfer will not occur and will not be detected on dominant hands, (2) tertiary DNA transfer will not occur and will not be detected on the cups, (3) a mixed DNA profile from all participants will not be found on the jug handle, and (4) the order of handling the objects cannot be discerned from the DNA data. The dominant hands of the participants as well as the cups and jug were swabbed at various times throughout the study to test for evidence of DNA transfer. The DNA was analyzed and interpreted following standard operating procedures.

DNA was detected in 92% of the samples collected in this study. However, only 50% of those profiles met casework requirements for interpretation utilizing the laboratory's current interpretation guidelines. Eighty percent of these samples were mixtures containing DNA from two or more contributors, and 60% had identifiable major and minor contributors. There was no correlation found between the DNA profiles obtained from the handled objects and the timing or length of contact the participants had with those objects. For the samples obtained from the participant's hands, the major profiles produced were consistent with the individual from which the swab was taken. Seventy-five percent of the profiles obtained contained extraneous DNA leading to complex mixtures.

These results illustrate the complex nature of interpreting DNA transfer that occurs in a social setting involving multiple individuals and multiple transfer events. In this study, the objects were pre-sterilized, the order of handlers and length of contact was recorded, and the handlers' profiles were known. Despite these controlled aspects, the order and timing of handling could still not be reconstructed from the DNA profile information. This study demonstrates the ease of DNA transfer between objects and individuals, illustrates the difficulty in predicting mode of DNA transfer based on the DNA typing results, and highlights the difficulty in interpreting the genetic data when multiple transfer events have occurred.

#### DNA Transfer, DNA Evidence, DNA Mixtures

### F8 Indirect DNA Transfer: The Impact of Contact Length on Skin-to-Skin-to-Object DNA Transfer

Cynthia Cale, MS\*, Strand Diagnostics, Indianapolis, IN 46241; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN 46227-3697; Gay L. Bush, PhD, Strand Diagnostics, Indianapolis, IN 46241

**Learning Overview:** After this presentation, attendees will appreciate the complex nature of DNA transfer. The goals of this presentation are to: (1) evaluate the indirect transfer of DNA to an object when a person serves as the vector of transfer, (2) to investigate the length of contact between two individuals that might result in the indirect transfer of DNA, and (3) to assess the impact of indirect DNA transfer on determining how evidence relates to a crime scene.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that indirect DNA transfer to an object can occur through brief skin-to-skin contact and that it can have a significant impact on understanding evidence in relation to a crime scene.

The following null hypotheses were tested: (Hn1) a single DNA profile of the direct handler will be the only DNA identified on each knife, and (Hn2) transfer DNA from the non-handler will result in an inconclusive profile unsuitable for statistical analysis.

The analysis of trace amounts of DNA from items possibly handled by a suspect during the commission of a crime often plays a crucial role in criminal investigations. In some cases, DNA left on an object can be the only link to the perpetrator. The increased capability to detect minute traces of DNA from a perpetrator at a crime scene has been a continuous goal of the forensic community. The increase in sensitivity in most cases is beneficial. However, it can also lead to the detection of extraneous DNA not related to the forensic investigation, which can complicate the identification of a suspect and increase the uncertainty of its evidentiary value.<sup>1</sup>

Empirical research has not only demonstrated the primary transfer of DNA via direct contact with an object, but also the indirect transfer of DNA whereby an individual's DNA is transferred to an object or another individual via an intermediary. The indirect transfer of DNA as an explanation for the presence of trace DNA samples at a crime scene appears to be becoming more prevalent in forensic investigations and during subsequent court proceedings.

This scientific research used handshaking to simulate contact that could lead to the indirect transfer of DNA. Participants shook hands continuously for varying lengths of time: 10 ( $n=24$ ), 30 ( $n=24$ ), 60 ( $n=24$ ), and 120 ( $n=24$ ) seconds. Knives were handled immediately following handshaking and were sampled after two minutes of handling. The samples were analyzed and interpreted following standard operating procedures.<sup>2</sup>

Data was obtained from 92 of 96 samples. Interpretable DNA profiles were obtained from 48 samples. The DNA yields for samples that resulted in interpretable profiles ranged from 50pg to 5ng. In 69% of the interpretable profiles, single-source profiles or mixed DNA profiles with the major component matching the primary contributor were obtained. Contributor inversions, where the non-handler matched the major component of a mixed DNA profile were observed: five at 120 seconds, four at 30 seconds, and one at 10 seconds. Indistinguishable mixtures of both contributors were obtained from four samples, making it difficult to identify the direct knife handler. In the remaining 44 samples, the presence of non-handler DNA and/or extraneous DNA rendered the profiles inconclusive.

The results of this scientific research support the concept that the identification of a DNA profile on an object cannot be considered proof of direct contact. Likewise, the amount of DNA recovered and/or the quality of the DNA profile obtained from an object cannot be used to infer the mode of transfer.<sup>3</sup> In addition, these results demonstrate that under experimental conditions that maximize DNA transfer and recovery, indirect DNA transfer to an object can occur with as little as ten seconds and as much as two minutes of continuous skin-to-skin contact.

The presence of indirectly transferred DNA on an object can make the identification of the direct handler difficult. DNA transfer does not render DNA evidence unreliable but represents an additional level of complexity in the analysis and interpretation of DNA profiles. Forensic DNA analysts should provide the court with an unbiased list of all possible modes of DNA transfer. In addition, forensic DNA analysts need to proceed with caution when addressing activity-level questions and base their opinions on published peer-review data rather than giving anecdotal responses.<sup>1,4,5</sup>

### F9 Investigating the Potential for Transfer DNA on Laboratory Gloves

*Caitlin C.M. Vogelsberg, MS\*, Michigan State University, East Lansing, MI 48824; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Cynthia Cale, MS, Strand Diagnostics, Indianapolis, IN 46241; Gay L. Bush, PhD, Strand Diagnostics, Indianapolis, IN 46241*

**Learning Overview:** After attending this presentation, attendees will understand the potential for transferring DNA to laboratory gloves and boxes during routine laboratory use. The goal is to identify technician-mediated contamination and prevent it through the development of appropriate quality control procedures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that while the transfer of DNA from technicians to routinely used laboratory items, such as gloves and glove boxes, is possible, current contamination prevention protocols in laboratories with restricted access may be sufficient in reducing this potential source of error.

DNA evidence is often a key factor in criminal cases and can have a profound impact on the outcome in the courtroom and the lives of the accused. Therefore, minimizing contamination from field evidence collection through the forensic DNA laboratory analysis is imperative for DNA profile interpretation. Enforcing strict use of personal protective equipment, such as wearing laboratory gloves, can decrease rates of technician-mediated contamination of evidentiary objects and cross-contamination between evidentiary items. This study investigated the possibility of contaminating laboratory gloves after prolonged box use in a variety of laboratory settings.

The study was conducted in two phases: (1) to assess whether the removal of gloves from both new and previously opened boxes of gloves by gloved and ungloved researchers transferred DNA to the gloves or glove box ( $n=15$ ), and (2) to assess the presence of transfer DNA on used and open glove boxes found in active academic and research laboratories ( $n=30$ ). Samples from both stages of the study were extracted and amplified using standard forensic DNA laboratory procedures at two analytical thresholds to assess the presence of DNA at increasingly sensitive levels.

In the first phase, only one sample taken from an open box of gloves yielded results at three loci. In the second phase, three samples collected from boxes in academic laboratories yielded quantifiable DNA. Two of these samples generated partial profiles at both analytical thresholds, and the third only produced results at the Amelogenin locus. However, none were from boxes in laboratories with strict contamination precaution procedures in place.

This study found no evidence of manufacturer contamination in the samples taken from unopened boxes of gloves marketed as sterile products. Therefore, the DNA detected on the gloves and boxes in this study was likely introduced by individuals in and around the laboratory.

The introduction of trace DNA from gloves could potentially complicate the interpretation of DNA typing results in cases of low-level profile mixtures, as is usually the case with forensic samples. However, by identifying potential routes of DNA transfer during the handling of evidentiary material, laboratory procedures can be implemented to reduce the risk of technician-mediated contamination.

The results of this study indicate that although contamination of laboratory gloves is possible through regular use, forensic laboratories with restricted access and strict cleanroom protocols may already have the appropriate measures to reduce this potential source of error.

---

#### Forensic DNA, DNA Transfer, DNA Contamination

### **F10 Post-Conviction DNA Testing: A Laboratory’s Perspective and Participation in a Multi-Agency Collaboration for the Identification and Evaluation of Post-Conviction Cases**

*Kerry A. Collins, JD\**, Massachusetts Department of State Police, Maynard, MA 01754; *Lynn A. Schneeweis, MS\**, Massachusetts State Police Crime Laboratory, Maynard, MA 01754; *Dorothea S. Collins, MLA*, Massachusetts State Police Crime Laboratory, Maynard, MA 01776; *Kristen Sullivan, MS*, Massachusetts State Police Crime Lab, Maynard, MA 01754

**Learning Overview:** After attending this presentation, attendees will understand the useful contributions a laboratory can make, outside of performing forensic analysis, in the assessment of cases for potential post-conviction testing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a model for collaborative, multi-agency efforts to identify cases potentially suitable for post-conviction testing and address logistical challenges encountered therein.

In 2012, Massachusetts passed Chapter 278A, a post-conviction DNA and forensic analysis law. As a result, in 2013, five criminal justice agencies within Massachusetts—the Committee for Public Counsel Services (CPCS), Middlesex County District Attorney’s Office (MCDAO), Middlesex Superior Court Clerk’s office, Suffolk County District Attorney’s Office, and New England Innocence Project (NEIP)—formed the Massachusetts Working Group (WG) on Post-Conviction Testing Assistance. This working group received funding through a Post-DNA Testing Assistance award for identifying DNA-based innocence claims in serious violent felonies, locating and testing evidence in said cases, and adopting best practices for inventory and storing evidence. In 2014, the working group recognized the potential benefits of expanding this partnership and invited the Massachusetts State Police Crime Laboratory (MSPCL), Boston Police Laboratory, and Suffolk County Superior Court Clerk’s office to join. The newly expanded working group subsequently received funding under the 2014 Department Of Justice (DOJ) Post-Conviction Testing of DNA Evidence to Exonerate the Innocent. The Working Group’s goal for these funds included conducting comprehensive evidence inventories in participating counties, creating a “best practices” guide for evidence management, and conducting a review of pre-2000 cases at MSPCL where microscopic hair comparison was performed.

The MSPCL’s initial contribution to this project focused on providing technical expertise on evidence handling and storage procedures. Laboratory personnel served as resources for police departments conducting evidence room inventories and provided guidance for inquiries as to improving the storage and packaging of pieces of evidence previously subjected to less than ideal conditions. Additionally, the MSPCL provided technical resources for the construction of a “best practices” guide for evidence management to assist the legal community.

The primary role MSPCL undertook in this project was to identify forensic cases within MA where microscopic hair comparisons had been performed and resulting associations between items of evidence and known samples were made. Criteria were determined by the WG to prioritize which categories of these cases would be identified for further review by CPCS and NEIP to assess for potential post-conviction DNA testing. A 20-year time frame of cases for review was established and over 20,000 serology cases were administratively screened to determine those in which hair was examined and associations were made.

During this project, the WG convenes regularly to evaluate progress toward these goals. Through this collaboration, the WG expanded the scope of their work to include: training on post-conviction cases for attorneys; developing a post-conviction template motion for DNA testing; drafting a discovery materials agreement between the MSPCL, MCDAO, and CPCS; and creating a DNA technology timeline for attorneys litigating post-conviction cases.

This presentation will include discussion of the achievements of the Working Group’s efforts over the past five years since its inception. Specific emphasis will be on the role of the MSPCL’s collaboration with the legal community in the identification and evaluation of the suitability of cases for post-conviction DNA testing.

---

#### **Post-Conviction, Multi-Agency Collaboration, DNA Testing**

### F11 False Confessions in Juveniles: Do Juveniles Know and Understand Their Miranda Rights?

*Crystal Cafiero, MFS\**, Carlsbad Police Department, Carlsbad, CA 92065; *Ismail M. Sebetan, MD, PhD\**, National University, La Jolla, CA 92037-1011; *Paul Stein, PhD\**, National University, La Jolla, CA 92037

---

**Learning Overview:** After attending this presentation, attendees will better understand the importance of providing juveniles with knowledge about the Fifth Amendment. Statistics of false confessions pertaining to juveniles will be examined. As a result, this presentation will highlight the importance of educating youth (and their caregivers) about their constitutional legal rights.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying factors that can cause false confessions and will examine different ways that can assist law enforcement personnel to prevent unknowingly obtaining a false confession. This presentation will look at possible procedural changes in law enforcement policy and how the community can work together to lower that risk of false confessions and reduce the economic impact of these. The study also examined whether there were differences in gender, as well as an understanding of the meaning of the term “in custody” between adults and juveniles.

This study, conducted via social media, was an internet-based survey of 100 adults above the age of 18 years, who were parents or guardians of a child and were asked whether they were aware of the different portions of the Miranda warning. It also asked if they believed the children under their care understood the same. The online survey was sent out via social media with the survey being conducted on Survey Monkey®. Participants were asked eight questions related to the Miranda warning and two demographic questions. Results to the survey questions were analyzed by a chi square test, and statistical significance was determined by *p value* <0.05 to the related survey questions.

Results showed that there was no significance difference between adult males and females when it came to what they understood regarding their children’s rights. When comparing the difference between men and women and their knowledge of juveniles being given food, water, or rest during an interrogation, there was no statistical difference ( $p>0.05$ ). When comparing men and women with the knowledge that the questioning must stop if the child asks for a parent or lawyer, there was a marginal difference ( $p=0.055$ ). The third hypothesis compared the difference between men and women and their knowledge that a parent does not need to be notified of an interrogation, which also showed no significance ( $p>0.05$ ). The last hypothesis tested was the difference between adults knowing the meaning of “in custody” and what they believed their children understood. There was a significant difference in this hypothesis ( $p=.001$ ). Children not understanding their rights could significantly raise the number of false confessions to crimes they did not commit. False confessions are a serious problem in our justice system, leading to tax dollars being spent on trials and incarcerations that should not happen, and possible lawsuits down the road for missteps taken during the investigation and trials. The findings of this study show that there is a much work still to be done in this field to find a solution to lowering false confessions.

#### False Confessions, Juveniles, Miranda Warning

### F12 A New Informed Consent in View of the 2017 Italian Law 219—Marketing and Communication

*Valentina Ronco, MD\**, Section of Legal Medicine D.I.M., Bari 70124, ITALY; *Fiorenza Zotti, PhD*, Bari 70124, ITALY; *Angela Pezzolla, Bari, ITALY*; *Eloisa Maselli, MD*, Bari 70122, ITALY; *Valeria Bruno, MD, D.I.M.*, Bari, Puglia 70124, ITALY; *Francesca Donno, MD*, University of Bari, Bari 70121, ITALY; *Davide Ferorelli, Bari, ITALY*; *Gianni De Giorgio, Section of Legal Medicine, Bari, ITALY*; *Federica Misceo, Bari, BA 70123, ITALY*; *Alessandro Dell'Erba, PhD*, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand that informed consent is a prerequisite for exercising the medical arts and is based not only on the law, but also on professional ethics.

**Impact on the Forensic Science Community:** This presentation will have an impact on the forensic science community by showing that a new type of informed consent is possible as well as desirable.

The Italian Constitution primarily recognizes and protects the inviolable rights of the person, including individual freedom and health, guaranteeing the citizen the respect of his free choice in terms of health treatments that he may, or may not, be required to undergo. Regarding informed consent, the 1992 National Bioethics Committee document “Information and Consent to the Medical Act” outlined its characteristics. The prevailing powers of jurisprudence define it as “a fundamental principle in terms of protection and health ... a real entitlement of the person in question.” On a national and European level, adequate information about health treatment is recognized and guaranteed in which every subject must provide a valid and preventive consent. Considering this, it is imperative to recall the legislative text No. 219 of December 2017, which, in Article 1, expresses itself in terms of informed consent and underlines how much the patient-doctor relationship is based on an individual’s self-determination.

A prospective study was carried out in collaboration with the Video Laparoscopic Surgery Department of the Policlinico of Bari and the University of Liverpool. The goal was to verify both the effectiveness and efficiency of both medical and legal purposes, being a consensus constructed according to the rules of marketing and communication.

The study includes the sampling of 54 patients undergoing laparoscopic cholecystectomy from April to June 2018. After formalization of their willingness to participate in the study, patients were randomized into the control arm and given the classic form for informed consent to the surgical intervention and experimental arm for the study of the innovative module. At discharge, a customer satisfaction questionnaire was administered, consisting of different items, all sharing an evaluative purpose, with the goal of highlighting whether the information included during the pre-operative phase was better conveyed by the classic or experimental questionnaire.

Fifty-four patients who had undergone laparoscopic cholecystectomy (29 females, 25 males) were recruited. Their average age was 53 years. The sample presents a level of education that is equally distributed (high school diploma 45%, college degree 55%). There was no statistically significant difference between the two groups by index of understanding ( $p=0.5568$ ), clarity of definition of the pathological process ( $p=0.6702$ ), or patient satisfaction ( $p=0.7062$ ). Subsequently, the analysis shifted to the interpretation of the Likert scale, both by evaluating the response trend within the general population and by evaluating the response within the two arms of the study, independently. It became evident that in total, without discerning between control and experimental arms, the study population considered the issue of giving consent to be a useful, clear, crucial tool for their condition as a patient.

The results (even considering the small size of the analyzed sample) demonstrate the equivalence of the two modules for both content and clarity. It is undeniable that the new, more concise, dynamic module, developed by a marketing expert, led to a more marked appreciation from those to whom it had been submitted. Therefore, modernizing the module’s tool could be a starting point from which to reduce the distance between the practitioner and the patient.

#### Consent, Marketing, Communication

### F13 *Voluntas Aegroti Suprema Lex Esto: Ethics in Real Life in New Italian Law*

Francesca Donno, MD\*, University of Bari, Bari 70121, ITALY; Valentina Ronco, MD, Section of Legal Medicine D.I.M., Bari 70124, ITALY; Davide Ferorelli, Bari, ITALY; Gianni De Giorgio, Section of Legal Medicine, Bari, ITALY; Fiorenza Zotti, PhD, Bari 70124, ITALY; Eloisa Maselli, MD, Bari 70122, ITALY; Valeria Bruno, MD, D.I.M., Bari, Puglia 70124, ITALY; Loreto Gesualdo, FP, Regional Transplantation Puglia Center, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the possible ethics rather than legal conflicts between the need to respect the patient's health self-determination and the role of the National Transplantation Commission that must guarantee the national health security.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework to balance the latent conflict between the right of the individual to refuse a treatment and the community interest to protect the national health.

Spirituality and religiosity are often underestimated, but they are influential factors in Western medicine, as demonstrated by Jehovah's Witnesses' experiences and their "religious restrictions" in the approach to the care system.<sup>1</sup>

There are studies in literature moving beyond "dyadic relationships" and caregiving contexts and contribute to a deeper understanding of care and relational conceptualizations of Witness patients' autonomy globally.<sup>1,2</sup>

In the Italian national context, the promulgation of Law 219, issued on December 22, 2017, "*Norme in materia di consenso informato e di disposizioni anticipate di trattamento*" (GU General Series n.12 on January 16, 2018) has modified the basic framework related to these topics by a systematic regulation of informed consent concerning the diagnostic-therapeutic practices and the introduction of the new institute of "*Disposizioni Anticipate di Trattamento*" (DAT—the Italian for Advance Healthcare Directive (AHD)—also known as a living will) as well as that referring to the "shared planning" of cure.

The L.219/2017 states the overcoming of Hippocratic ethical-deontological tradition: the patient's conscious and freely expressed will becomes the nodal point of the lawfulness of the medical-surgical treatment. Translating this innovative forensic matter in the field of transplant medicine is an essential operation.

This study conducted a critical analysis according to traditional criteria of the "triptych" legal medicine/ethics/law of a case received by the Regional Transplantation Puglia Center and its Third Commission. The story refers to a pair of siblings: the receiver is a man, 53 years old, suffering from chronic renal failure who has been in dialysis for three years. The most compatible donor is a 51-year-old female in the family affected by thalassemia trait. She is a Jehovah's Witness and therefore rejects blood transfusions because of her religious belief.

The case presented is a paradigmatic example of the latent conflict between the right of the individual and the community interest: the patient/receiver versus the donor/bearer of rights. The setting is in the frame of a public health national service, with its needs, health workers' rights/duties, and the economic limits and related allocation of resources according to the principle of the maximum benefit.

The resulting and essential question is: Who should be first? The patient, the donor, and/or the global "system?" Which criterion and scientific method should be used to harmonize the whole system to respect basic and basilar standards? And, mainly, can the risk intrinsically linked to medicine be overcome unilaterally? The transplant community will have to reformulate the method, criteria, organization, and routine procedures through a deep analysis about ethical-deontological assumptions and "new" normative provisions resulting in a concretely useful compromise.

### F14 The Potential and Problem of Academics as Forensic Experts

Carole E. Chaski, PhD\*, ALIAS Technology, LLC, Georgetown, DE 19947

**Learning Overview:** After attending this presentation, attendees will be able to evaluate academics for the role of forensic experts and analyze the academic Curriculum Vitae (CV) for trustworthiness and exaggeration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an argument for regulating academic experts and ways for evaluating the academic expert CV.

The role of academics as expert witnesses is full of potential yet fraught with problems. The potential is great. First, an academic with a doctorate can have an exceptional amount of knowledge in the general field, particularly in the areas of specialization as reflected in research grants and publications. Second, academics can discern differences between their own and another field's methods and discern when methods are being properly applied or not. Third, academics know the controversies and unsolved problems in their field. Fourth, academics know how different groups relate to "schools of thought" within their fields and the relative seriousness with which different schools of thought are taken. Fifth, academics can know specific technical details related to these schools of thought (e.g., arcane controversies, such as the proper/improper use of particular statistical procedures or stances regarding the use or non-use of data types or requirements for the doctorate). Sixth, academics know the respected, prestigious conferences and journals in their fields. Seventh, since most academics regularly lecture, an academic can express himself easily, especially if the academic teaches introductory courses as well as upper-level and graduate seminars.

Scandals concerning forensic science have focused almost exclusively on bad behavior within crime laboratories. These bad behaviors include falsified credentials, mishandling of evidence, etc. and are detectable because the crime laboratories are public facilities. However, the regulation of academics as forensic expert witnesses is left for a case-by-case basis, using the Rules of Evidence and evidence standards such as *Daubert*.<sup>1,2</sup> The case-by-case method may not be enough for two reasons. First, the hierarchy of doctorates shows that lawyers, as well as the jury, are to a degree intimidated by academic doctorates. Common parlance shows this: MDs are known as "real doctors," PhDs are known as "doctors," and JDs are called "lawyers." Thus, lawyers and judges may not feel qualified to evaluate academic experts realistically. Second, *Daubert* criteria are not applied consistently from case to case. One expert can be allowed to testify in one jurisdiction and not be allowed to testify in a different jurisdiction, even though the academic expert's credentials and testimony are essentially the same.

The forensic science community should look closely at regulating academics as forensic experts. Each potential has a downside, with eight additional problematic factors. First, many academics feel that they are not paid enough as professors. The primary motivation for consulting may be greed. Second, many universities seeking ways to be "relevant to the community" encourage faculty to supplement their incomes with expert witness consulting. Third, this approach brings media attention to the university and the expert, often during a case. If the academic wants to please his university masters, publicity is his friend, even if this publicity displeases his attorney masters. Fourth, this dual-income approach may be questionable as "double-dipping" from government coffers. Fifth, this dual-work approach will interfere with either the academic's teaching and publishing/writing schedule or the attorney's case schedule; one will suffer. Sixth, the academic's publications may change from actual research to case studies of the cases. Seventh, the case work may actually be performed by (under)graduate students rather than the professor. The confidentiality agreement usually does not extend to (under)graduate students since the attorney assumes that the academic expert is going to do the work. Eighth, the CV may reveal problems to other academics but not to lawyers. It may be necessary to hire another academic in the same field to review the CV, to have a chronological series of the academic's CV to reveal an illogical timeline of "worked cases." Tricks on the academic CV are presented.

Finally, this talk concludes with potential regulations for academics as experts so that the judicial system can be afforded all the benefits of academic expertise while avoiding the pitfalls during trial.

### F15 The Duty to Correct Erroneous or Inadvertently Misleading Forensic Science Testimony

*Sarah Chu, MS\*, Innocence Project, New York, NY 10013; Bryce Benjet, JD, Innocence Project, New York, NY 10013*

**Learning Overview:** After attending this presentation, attendees can expect to be better informed regarding circumstances in which testimony should be corrected and how it can be corrected.

**Impact on the Forensic Science Community:** Forensic science practitioners, service providers, and medical service providers have an active, rather than passive, duty to correct as scientists. This ethical duty requires scientists in the system to take proactive action when testimonial problems are identified, rather than await permission from legal actors of the system. This presentation will impact the forensic science community by providing examples of how this type of testimony may occur and provide support for solutions for addressing the problem.

Most post-conviction accountability schemes for correcting forensic science testimony problems and notifying the affected defendants are predicated on the issue rising to the level of: (1) negligence or misconduct, or (2) the misapplication of forensic science in which testimony exceeds the limits of the science. This presentation will discuss a third and less-frequently discussed category of forensic testimony problems—inadvertently or unintentionally misleading testimony.

Wrongful convictions can result from inadvertent mistakes—such as a sample switch—or from testimony that unintentionally becomes misleading based on proceedings of the trial that are beyond the forensic science practitioner’s control. It is acknowledged that forensic scientists routinely provide testimony in isolation, and attorneys will raise questions in their direct and cross examinations in pursuit of a trial theory that may not reflect ground truth or sound science. The forensic science practitioner, who may be the only party in the courtroom transactions who understands the scientific limitations of the forensic evidence at hand, may be offering expert testimony and providing honest and technically correct answers, but unknowingly imparting information that can mislead fact finders in a case. The impact of this inadvertently or unintentionally misleading testimony may be apparent to the forensic science practitioner during the case or may not be revealed until the hindsight of postconviction proceedings. When a forensic science practitioner’s testimony is misused, rendered misleading, or inadvertently mistaken, what can be done to support the expert in correcting the record?

Because there is currently no national oversight framework for Forensic Science Service Providers (FSSPs) and Forensic Medical Service Providers (FMSPs) in the United States, the criminal justice system relies on a patchwork of laboratory accreditation and state-level regulation to hold FSSPs accountable. Neither of these systems is comprehensive and complete as FSSPs and FMSPs continue to operate without accreditation and few states have a system in place to fully oversee the activities of FSSPs and FMSPs. Consequently, we rely on the forensic science community to self-regulate and we need it to have the capacity to correct problems regardless of the presence or absence of formal regulatory systems. Most existing accountability schemes for forensic science testimony, such as state forensic science commissions and Coverdell investigations, limit the scope of their duty to correct to cases where negligence or misconduct is ascertained. Categorizing problems in such a manner often requires a finding of fault or error that create barriers to comprehensively assessing testimonial problems and have no bearing on guilt or innocence. This study submits that the standard of care for forensic science systems to correct inadvertently or unintentionally misleading testimony is an ethical duty and is under-recognized because the most prominent cases of testimony correction are based on the identification of negligence, misconduct, or misapplication. The latter system is not a solution for addressing wrongful convictions as many forensic problems arise unintentionally. Forensic science accreditation guidance suggests that a forensic scientist try to prevent misleading testimony on the stand; both the guidance material and a change in science legislation facilitate methods of correction when a forensic science practitioner is made aware of problems arising from his/her testimony after the fact.

However, because forensic scientists may move on professionally or because they are typically removed from the litigation process, this presentation will demonstrate that requesting letters of correction from the institutional FSSP or FMSP when testimonial problems occur would be an additional method for fulfilling the forensic science practitioner’s duty to correct and notify. This presentation will use actual communications with FSSPs and an FMSP to illustrate how forensic science and medical practitioners and service providers approach the duty to correct problems with testimony. (This presentation will redact names of individuals from communications presented.)

#### Duty to Correct, Ethics, Testimony

### F16 The Ethical Boundaries of Presenting Expert Testimony in a Criminal Trial

*Walter M. Reaves, JD\*, Law Office of Walter Reaves, PC, Waco, TX 76701*

---

**Learning Overview:** The goal of this presentation is to address an issue that has been observed in the use of experts in criminal cases: the use of experts with minimal experience or knowledge of the subject they are testifying about, or experts who testify about subjects that are outside their area of expertise. Examples will be provided of cases in which testimony has been allowed, and the impact that testimony has had on cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the ethical issue of experts with insufficient experience or knowledge of the subject about which they are testifying.

This presentation is designed to raise awareness and generate discussion about the ethical obligations of forensic experts and attorneys when presenting testimony in a criminal trial.

The criminal justice system is an adversarial one. Both sides have the obligation to zealously represent their clients. A prosecutor has the added obligation to ensure that justice is done. That concept is easily stated, but harder to apply. At the outer limits, a prosecutor is prevented from presenting evidence they know to be false. In some jurisdictions, this limitation extends to evidence that would mislead the jury or encourage a false impression. Courts have been reluctant to find that line has been breached, and disciplinary authorities are even more reluctant to impose sanctions. The result is that the limits of zealous advocacy can vary from jurisdiction to jurisdiction and even between prosecutors in the same jurisdiction.

While this is always a potential problem, there are special concerns when experts are used. Jurors rely heavily on experts, assume that the prosecutor has researched their credentials, and believe they are qualified. Judges often rely far too heavily on prosecutors and routinely allow experts to testify. While the ultimate decision is up to the judge, the practical impact is that the State decides which experts are qualified. Far too often, little to no research has been done, other than checking with prosecutors, and prosecutors rely on the expert to educate them. While there are now more resources available to defense counsel, far too few defense lawyers take advantage of them. There is also a disparity in resources, and in some fields, there are few experts available to consult with defense lawyers. The result is that experts offered by the State often go unchallenged on both their qualifications and the subject matter of their testimony.

While there are limits placed on lawyers (even if they may be vague), there are even fewer limits on experts. Most experts are members of several different organizations. Some organizations may have ethical guidelines, while others don't. This presentation will explore what limits exist and whether there are any meaningful limitations, or whether each expert is left to his or her concept of what is right. Emphasis will be placed on the obligation experts have to inform prosecutors about the limits of their testimony, as well as what obligations they must meet with defense counsel, and whether there is any obligation to inform the courts about areas in which they may not be qualified.

The goal of this presentation is to encourage discussion and solicit proposals and suggestions to deal with these issues. Reliance on the courts has proved to be of little use and expecting prosecutors to limit the use of evidence that may help obtain a conviction is problematic. The hope is that not only will proposals and suggestions be identified, awareness of the issue will also be increased.

---

### F17 I Didn't Get It Wrong: Prosecutorial Denial in the Face of Forensic Evidence of Innocence

Alissa L. Bjerkhoel, JD\*, *California Innocence Project, San Diego, CA 92101*

**Learning Overview:** After attending this presentation, attendees will understand case examples in which the prosecution continued to vigorously defend the validity of convictions despite post-conviction forensic evidence showing innocence. This presentation will also cover the trend of prosecutors pursuing endless appeals or offering plea deals even when innocent petitioners have been successful in the courts.

**Impact on the Forensic Science Community:** The presentation will impact the forensic community by serving to identifying a trend in the law enforcement and prosecutorial communities to dismiss evidence of innocence and maintain tunnel vision in re-examining old cases. Several case examples will be discussed.

“These two bastards are guilty. I just can't prove it” –Jefferson County Assistance District Attorney Arthur Green, commenting on the exonerations of Ronnie and Dale Mahan.<sup>1</sup> And yet, if one cannot prove guilt, how can one be so confident they are, in fact, guilty?

It was 1998. Her body was lying on a pile of rocks on the bank of a prominent local fishing hole. She had been strangled to death. Her bra had been pulled up, exposing one of her breasts. Yet there was no evidence of a sexual assault. She had no drag marks or other injuries, indicating she was not strangled at that location; rather, she was placed there. The desert heat beat down on her for four days until two fishermen found her. A piece of rope (the ligature) and a broken man's wrist watch were found among other debris at the scene. The hunt was on for whoever owned that watch and for whoever could have done this horrific act.

“That's my watch.” Those would be the fatal words of James Rogers during his police interview. James was a coworker of the victim and the two, although separately married, were having an affair. It would turn out that James was mistaken about the watch and he did produce a similar watch to the police, but it was too late. They caught their man. Or did they? Subsequent testing of the watch revealed the profile of the victim's estranged stepson, 19 years old at the time and accused by the victim of molesting her children. His father was going through a contentious divorce with the victim. Further testing and a hit in the Combined DNA Index System (CODIS) revealed a second perpetrator—the stepson's cousin's DNA underneath the victim's fingernail. These results have been known for years and, yet, James remains in prison.

James's case is not unique. Lawyers working in projects and offices dedicated to the release of innocent prisoners have faced backlash from law enforcement and prosecutors, even in the face of seemingly clear-cut forensic evidence of innocence. They have encountered the “unindicted co-jaculator theory,” meaning that unknown semen on a victim can be explained away by simply claiming that there must have been two perpetrators. They have encountered claims that male DNA on a rape victim's clothing must have come from the victim washing the clothing in the same washing machine as the person whose DNA is found on the clothing. They have argued contamination in the crime lab, DNA evidence having come from someone sneezing on the victim's clothing, 8-year-olds being sexually active, someone stumbling across a murder victim's body and engaging in acts of necrophilia. The list goes on. And when that all fails, they have even accused lawyers of planting evidence.

The root cause of prosecutorial denial of innocence has still not been adequately defined. Perhaps it is psychological. It has been said that “[w]hen we are confronted with evidence that challenges our deeply held beliefs, we are more likely to reframe the evidence than we are to alter our beliefs.”<sup>2</sup> Perhaps it is political. Perhaps both. Whatever it may be, it is a flaw in our criminal justice system that does not seem to be getting better.

#### DNA, Innocent, Prosecutor

### F18 K-9 Evidence in the Courtroom

*Mary E. Cablk, PhD\*, Desert Research Institute, Reno, NV 89512*

---

**Learning Overview:** The goal of this presentation is to convey what constitutes defensible canine (K-9) training and deployment to non-K-9 experts. Attendees will learn about discovery materials in assessing a K-9, its handler, and the sniff(s), regardless of whether the case pertains to narcotics detection, trailing, or another K-9 discipline.

**Impact on the Forensic Science Community:** The impact of this presentation on the forensic science community is to improve understanding of a complex resource component of law enforcement and forensic investigation resource: the K-9 team.

The use of K-9s in law enforcement for the detection of illicit substances, human remains, crime scenes, and trailing (following the path of travel of an individual person) has a long history. Courts are generally of the opinion that K-9s are reliable. A properly trained K-9/handler team can provide valid, correct, accurate, and defensible information that informs an investigation. The K-9 belonging to an agency is administered as equipment and may be paired with multiple handlers over the course of its career. It is expected to perform reliably regardless of the capability, skill, training, or experience of its handler.

K-9/handler teams are not infallible, and it is generally accepted that K-9 teams are not perfect. How does an expert determine whether a sniff or a trail was reliable? What about the situation in which the K-9 is deployed to find evidence, such as a firearm or narcotics tossed during a pursuit, but none is located? Are all K-9 teams equal? This presentation will address these questions and others.

One role of the expert is to expose weaknesses in the K-9 team from initial training through pairing with a handler, maintenance training, certification, and deployment. Even when there are deficiencies in protocols, policy, and adherence to best practices or industry standards, canine evidence typically prevails in the courtroom.

There has long been a practice of minimal record keeping in the K-9 community with the belief that no fault can be found where no documentation exists. That archaic approach defies the direction and integrity of the forensic sciences today. There is no mystery as to how a reliable K-9 is trained, although pertinent information that is intended to support the reliability of the K-9 team is not conducted or maintained in a consistent, universally accepted manner. Every department has their own policy and there are as many standards as there are agencies and K-9 organizations. This creates opportunities for the expert to find fault and deficiencies within a department, within a unit, and with individual K-9 teams, where there may in fact be a rigorous practice employed, and the teams are truly reliable. As the K-9 community comes to embrace the science that supports proper training and thus produces an unmatched resource to forensic investigation, it will become increasingly difficult to discredit K-9 evidence. More importantly, the usefulness of K-9 evidence to an investigation will move toward meriting scientific support and away from being an art.

---

#### Canine, Best Practices, Probable Cause

### F19 Legal Theories for Prosecution of Opioid Overdoses Resulting in Death Under State and Federal Law Principles

M.J. Menendez, JD\*, *Organized Crime Drug Enforcement Task Force, Washington, DC 20530*; Barry K. Logan, PhD, *NMS Labs/CFSRE, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will be able to describe the theories of prosecution underlying state and federal investigations, prosecutions, and sentencing of cases involving single and polydrug overdose death cases. Attendees will also be able to explain the “but for” causation legal precepts set out in *Burrage v. United States* and describe how the Burrage case and its progeny apply to the federal, state, and local theories of prosecution.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting understanding and discourse on the criminal justice systems’ response to deaths caused by the opioid epidemic at local, state, and federal levels, providing attendees with a foundation to assess the deterrence theory of prosecution against other societal responses.

Per the Centers for Disease Control and Prevention (CDC), the rate of synthetic opioid overdose deaths in the United States rose from 3.1 to 6.2 deaths per 100,000 between 2015 and 2016, marking the first year that synthetic opioids became the most common type of opioid involved in overdose deaths. CDC’s statistics also report that more than 55% of opioid overdose deaths occurring nationally in the 12-month period ending November 2017 involved synthetic opioids, accounting for more than 27,000 overdose deaths. Against this stark tragedy, public health and public safety officials grapple with appropriate responses. Increasingly, federal and state law enforcement agencies and prosecutors have charged distributors of the drugs causing overdoses and overdose deaths. Federal prosecutors, working under *Burrage v. United States* and its progeny, as well as under the United States Sentencing Guidelines, focus investigation and prosecution efforts on death resulting from the distribution of a substance and “but for” causation.<sup>1</sup> State and local prosecutors charge a wide variety of offenses with varying mental states and proximate cause nexus requirements, including but not limited to First, Second, and Third-Degree Murder; Voluntary, Involuntary, and Reckless Manslaughter; Drug-Induced Homicide, Drug Delivery Resulting in Death, with attendant inchoate theories. Amid these decisions, the holding of *Burrage v. United States* stands, but the question of its applicability and limits under the various state charging theories lingers.<sup>1</sup>

This presentation will provide a classification overview of state prosecution theories for drug-involved overdose deaths, with particularized discussion of culpable mental states, proximate cause and nexus of drugs to death, and polydrug deaths as interpreted in judicial cases. The overview will enable attendees to argue the factual and legal nuances that cause seemingly irreconcilable outcomes among cases and related legal proceedings. The discussion will then highlight federal cases interpreting the 21 U.S.C. Section 841 “death resulting” enhancement, as well as United States Sentencing Guidelines amendments from 2018 affecting charging theories.<sup>2</sup> This presentation will conclude with a hypothesis for synthesizing the various theories of prosecution and their respective attendant penalties, allowing participants to assess the propriety of prosecuting overdose deaths in the various levels of the criminal justice system.

#### Reference(s):

### F20 Novel Psychoactive Substances, Fentanyl Analogues, and Scheduling: Federal and State Responses

*M.J. Menendez, JD\**, Organized Crime Drug Enforcement Task Force, Washington, DC 20530; *Barry K. Logan, PhD\**, NMS Labs/CFSRE, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will understand the temporary scheduling provisions of the United States Code and explain how the temporary scheduling factors were utilized to affect the scheduling of all fentanyl-related substances. Attendees will also gain familiarity with the methodology for various state law scheduling constructs as they relate to federal scheduling. Finally, attendees will learn of the most recent judicial authority interpreting the temporary scheduling and emerging novel psychoactive substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by synthesizing statutory and judicial authority relating to novel psychoactive substances and fentanyl analogues, as well as highlighting the challenges in interpretation and application that are endemic to the legal analyses.

The supply, distribution, and potency of illicitly manufactured fentanyl analogues and other illicit opioids in the United States drug markets continues to evolve. According to the Centers for Disease Control and Prevention's Health Alert Network report (November 7, 2018), seized drug submissions testing positive for fentanyl or fentanyl analogues were numbered at 25,460 reports in the first six months of 2017. Many states saw fentanyl or fentanyl polydrug deaths outnumber heroin deaths in 2017. The sophisticated testing methodologies and equipment required to detect and identify novel fentanyl analogs, combined with the rapid evolution in the structure of fentanyl analogs and novel psychoactive substances, continue to challenge and hinder law enforcement and public health responses into present day 2018.

In February 2018, the Acting Administrator of the Drug Enforcement Administration ordered temporary placement of all fentanyl-related substances into Schedule I of the Controlled Substances Act based on a finding that placement of the synthetic opioids into Schedule I was necessary to avoid an imminent hazard to public safety.

This presentation will present the legal framework for temporary scheduling under 21 U.S.C. Section 841, with particularized discussion of the legal reasoning and justification for scheduling all fentanyl-related substances.<sup>1</sup> The number of fentanyl analogs, illicit opioids, and novel psychoactive substances identified since the fentanyl-related substances announcement will be presented to engender discussion of the impacts of the order scheduling fentanyl-related substances. This presentation will then feature classifications of state law statutory and regulatory amendments resulting from the Drug Enforcement Administration's (DEA's) scheduling of fentanyl-related substances.

Fentanyl-related scheduling has also impacted federal legal precepts in charging, litigating, and sentencing fentanyl analogs. An overview of the judicial, statutory, and regulatory changes in federal law will be provided, with case studies on recent decisions interpreting the relationship and differentiation between the terms fentanyl analog and analog of fentanyl in the evolving legal landscape. The United States Sentencing Guidelines amendments from 2018 affecting fentanyl analogs and other novel psychoactive substances will also be presented.

### F21 Secure Continuous Remote Alcohol Monitor (SCRAM®) Test Results: Fact, Fiction, Puffery, Rhetoric, and Hokum

Donald J. Ramsell, JD\*, Wheaton, IL 60187; Gil Sapir, JD, Chicago, IL 60680

**Learning Overview:** After attending this presentation, attendees will understand the necessity of questioning SCRAM®-purported Transdermal Alcohol Concentration (TAC) test results when used to enforce alcohol abstinence, as it is now commonly used within the legal community.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing recognition of what may constitute marketing rhetoric regarding the accuracy and reliability of biomonitoring alcohol devices for use within the judicial system to establish court-ordered abstinence.

SCRAM® is designed to measure alcohol content as it diffuses through a person's skin as insensible perspiration. SCRAM's® operation is premised upon measuring volatile substances passing through the skin and alcohol excretion in human perspiration.<sup>1</sup> The device is manufactured by Alcohol Monitoring Systems, Inc. The device, worn as an ankle bracelet, is commercially available to law enforcement agencies and privately operated correctional institutions. It is primarily designed and marketed for court-ordered alcohol monitoring of TAC readings.<sup>2</sup>

SCRAMs® do have limitations. TAC does not directly correlate to Blood Alcohol Concentration (BAC) in a SCRAM®.<sup>3</sup> SCRAMs® are useful in general population biomonitoring of self-induced alcohol consumption as a passive preliminary testing device. Based upon the manufacturer's criteria, SCRAM® can only reliably detect the consumption of five or more standard beers or drinks, and 45.9% of all occasions of drinking one to three beers went undetected when using SCRAM's® 0.02g/dl as a threshold.<sup>4,5</sup> This presentation briefly reviews the manufacturer's material and the scientific literature for factual comparisons of marketing statements and purported test results.

Judges control the determination of "good science" and "evidential reliability" under *Daubert*.<sup>6</sup> Too often products are selected based on their price, convenience, and promotional marketing. In certain judicial proceedings, the standards for reliability of scientific evidence are reduced (i.e., probation violation hearings, parole revocation hearings, bond and bail hearings).<sup>7</sup> SCRAMs® are subject to lower standards of evidential proof. The misuse of scientific devices through dilution questions their appropriateness for legal responsibility.

SCRAMs® are not amenable to the same consistent and evidential alcohol measuring devices, such as breath alcohol instrumentation and gas chromatographs. SCRAMs® are not subject to equivalent uniform standards and regulations for approval, use, maintenance, and calibration, as are other alcohol detecting and measuring devices.<sup>8</sup> The units can be purchased without the same governmental oversight, and there are lower standards than those promulgated in the Driving Under the Influence (DUI) industry. SCRAM® presents selective marketing data and does not adhere to governmental or industry standards for reliability. Initial concern is whether the SCRAM® device is accurate and reliable to identify and measure TAC.<sup>5,9</sup>

Information provided by the SCRAM® manufacturer, published studies, court testimony, and reports from the National Highway Traffic Safety Administration (NHTSA) indicate that the transdermal devices cannot reliably detect levels of alcohol use from one to four (and perhaps up to six) drinks.

Arguably actual limitations of SCRAM® devices and TAC data is skewed or specious through marketing and other claims, which include, but are not limited to, claims stating: (1) it can detect levels of alcohol. Manufacturer information, published articles, court testimony, and the NHTSA indicate TAC devices cannot reliably detect levels of alcohol use from one to six drinks; (2) the SCRAM® device "eliminates testing gaps—no ability to miss a test or drink around testing schedules"; (3) "99.3% of clients (of SCRAM®) are completely sober and compliant every day"; (4) "the SCRAM® device has a greater deterrent effect than other monitoring devices"; (5) "SCRAM® CAM is calibrated using the same court-accepted methodology as evidential breath testing equipment"; (6) SCRAM® CAM has "single-source admissibility—no back up tests required"; and (7) device "conclusively distinguishes alcohol consumption vs. environmental alcohol sources."<sup>5,9-15</sup>

SCRAM's® claims are plausibly misleading or lack sufficient supporting evidence. It appears the use of SCRAM® beyond its intended judicial purpose is problematic. Questionable marketing claims underscore the need for vigilant implementation of good science and scrutiny by the consumer. SCRAM's® marketing of TAC results should not be considered scientifically credible or reliable.

### F22 Due Process and Ethics: Crime Laboratories Cannot Be Paid for Convictions

Michelle L. Behan, JD\*, Behan Ramsell P.L.L.C., Tucson, AZ 85718; Gil Sapir, JD, Chicago, IL 60680

**Learning Overview:** After attending this presentation, attendees will understand the necessity for identifying, exposing, and mitigating bias due to crime laboratory contingency fee revenue.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that contingency fees paid to laboratories upon conviction are unethical and unconstitutional.

Crime laboratories are bound by legal and scientific standards and a code of ethics to foster integrity, honesty, competency, and public trust. It is a violation of ethical canons, and substantive due process, for laboratory personnel to testify in criminal cases when they receive contingency fees should the defendant be convicted. Government crime laboratories were established to perform objective, reliable analysis to assist the justice system. Conscious and subliminal bias exist in crime laboratories, especially when exclusively controlled by law enforcement.<sup>1</sup> This relationship creates a pro-prosecution culture, with scientists an extension of law enforcement. Contingency fees paid to crime laboratories fosters additional bias and adversely affects both substantive due process and ethics. Public confidence in the justice system and integrity of evidence is paramount. It is eroded when fundamental fairness and trustworthiness are degraded or compromised.

Crime laboratories submit their budgetary requests to the state for funding. The legislature enacts revenue statutes for imposition of fees upon conviction. Currently, 17 states have statutes authorizing contingent fees paid to crime laboratories.<sup>2</sup> These fees are collected by the court and forwarded either to the crime laboratory or state fund for redistribution.<sup>2</sup> Contingent conviction fees vary by state and generate enormous revenue.<sup>3</sup> This revenue augments state crime laboratory funding. The revenue creates financial and ethical conflicts for laboratory personnel because their objectivity is compromised. Redistribution from a general fund does not remove the conflict; crime laboratories still receive the revenue. Privately funded laboratories may conduct forensic analysis. Unlike government crime laboratories, they are generally liable for the work product.

The laboratory director determines the facility's budget and distribution of funds within the laboratory. The laboratory personnel's testimony is indelibly tainted through their vested interest in securing funding for their laboratory and employment. Model ethical guidelines from professional scientific organizations prohibit any behavior which "diminish(es) confidence" in the laboratory's "competence, impartiality, judgment, or operational integrity."<sup>4</sup>

The 2009 National Academy of Sciences Report recommended mandatory adherence to a code of ethics, with enforcement and sanctions for violations<sup>1</sup>. However, laboratories may establish their own voluntary protocols and code of ethics. The International Organization for Standardization, the American Society for Crime Lab Directors/Laboratory Accreditation Board (ASCLD/LAB), and other organizational guidelines are voluntary and without viable sanctions.<sup>4</sup>

The Model Code of Professional Responsibility of the American Bar Association (ABA) prohibits witnesses from being "bribed or offered compensation that is contingent on the witness's testimony or the result in the litigation."<sup>5</sup> Forensic scientists are expected to be unbiased and objective and may not participate in any case where a contingency fee is collected. Ironically, scientists who are in violation of ethical canons may still testify. It is unconstitutional for a court budget to be funded in whole or in part by the funds collected upon conviction. The ABA prohibits fines, fees, and penalties from being appropriated to any local unit of government that supports a court.<sup>6</sup>

Criminal defendants have a constitutional right to a fair trial and equal justice. Defendants are deprived of their constitutional rights when a party with a financial or personal interest in the outcome is involved. Courts are expected to protect citizens from statutory legislation that violates due process.<sup>7</sup> Courts and counsel must act to protect the defendant from wrongful convictions based on biased results. Bias is not limited to any discipline. Prohibiting revenue-generating statutes is the appropriate solution.

Attorneys have a constitutional obligation to challenge evidence against the accused. Bias of a witness is never a collateral matter. Attorney competency includes exposing and eliminating bias. Lack of professional memberships, unenforceable codes of ethics, and non-accreditation do not prevent a crime laboratory from conducting and presenting its work product. Crime laboratory contingency fee payments disregard ethical canons of law and science, violate substantive due process guarantees to criminal defendants, and create an unacceptable conflict of interest for forensic scientists. Laboratories cannot be trusted if they have a financial incentive to produce a conviction.

6. American Bar Association Commission on Standards of Judicial Administration, 107 (1974).
7. Seventeen states permit assessment of crime laboratory fees contingent upon conviction. Only Tennessee held this arraignment to be constitutional under its state constitution. *State of Tennessee v. Rosemary L. Decosimo*, No. E2017-00696-SC-R11-CD (Aug. 23, 2018). No other state has ruled on this practice. The constitutionality however, does not change the ethics of whether this should be permitted. A potential conflict of interest exists. Privately funded laboratories may conduct forensic analysis. Unlike government crime laboratories, private laboratories are generally liable for the work product. North Carolina exempts private laboratories from liability for law enforcement work.

### **Ethics, Crime Laboratories, Contingency Fees**

### F23 New York City (NYC) Polo Grounds Murders: Was It Bernard Perez or “The Beast”?

*Kerry J. O’Connell, JD\*, The New York County District Attorney’s Office, New York, NY 10013*

**Learning Overview:** The goal of this presentation is to describe the steps taken to meet a claim of psychiatric defense to charges of homicide in a notorious New York City serial killing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing assistance in amassing, preserving, and presenting psychiatric evidence in a criminal trial.

Bernard Perez was convicted by a jury trial, after a host of crimes, for murdering Doris Drakeford and Jerry Pollard in two separate murders. In January 2001, Perez viciously murdered Doris Drakeford so he could take over her apartment in the Dykman Houses in Upper Manhattan, a public housing cluster called The Polo Grounds. At the time, Perez was staying with Drakeford, but when she told him he would have to leave, he decided to kill her. Perez knew that she was a drug addict and was not likely to be missed. Perez strangled her with an electrical cord, wrapped the body in a sheet, stuffed it into a shopping cart, wheeled her to the 207<sup>th</sup> Street bridge, then tossed her and the cart into the Harlem River, where it remained submerged until the spring thaw.

Perez was evicted in late May, just before the body was found, and needed another place to live. Bernard Perez enlisted the help of two friends and struck a second target in The Polo Grounds, Jerry Pollard. After plotting together for a day, Perez realized he should do more than just dump the body, so the murderous trio agreed they would dismember Pollard and dispose of his head and hands in New Jersey. The next day, Perez, Walker, and Williams accosted Pollard in the elevator, dragged him into his apartment, then finished him off. They then proceeded to methodically dismember his body in the bathtub. After they finished the job, Perez invited another friend up to Pollard’s apartment. The visitor saw the dismembered torso in the bathtub and later reported what he had seen to the police. The police later discovered Perez and Williams in the apartment, along with various parts of Pollard’s body wrapped in plastic bags. Other body parts were discovered in bags on the ground outside the apartment and in a nearby dumpster. At the precinct, after waiving his Miranda rights, Perez confessed to killing Pollard and Drakeford. Two of his lengthy, detailed statements were recorded on videotape.

Those statements and others were made after Perez declined any medical attention and said that he felt fine. However, he had made a half-hearted attempt to hang his 300 lb. frame in the jail cell immediately after his arrest, and after speaking to police and prosecutors, he was sent to Bellevue Hospital for a psychiatric evaluation. His attorney filed a notice of psychiatric defense, an affirmative defense in New York, and sought to prove that disability through an expert. The doctors at Bellevue who initially examined Perez concluded that Perez had an antisocial character structure with a long-standing pattern of committing and even enjoying violent, sadistic acts, but that he gave no evidence during the interview of any symptoms consistent with dissociative identity disorder.

At suppression hearings held many months later, Perez claimed that the confessions were false. However, in the Drakeford confession, Perez had concocted a bizarre story of being swept up in a retaliatory killing by drug dealers, who enlisted his help in disposing of the body. In the Pollard confession, when he was talking with Detective Davis, Perez never said anything about hearing voices, a strange being called the “beast” telling him what to do, or the walls turning red. But, in his videotaped statement, Perez claimed that he heard voices and saw things, and that he went through emotional stages. He said he had an alter ego, a “consultant,” that spoke to him even before he formulated the plan with Williams and Walker to kill Pollard. In preparation for trial with his expert, Perez gave a detailed history of communicating with his alter-ego named “The Beast,” who he averred caused a red color to permeate Perez’s surroundings when present, and who urged him to kill Pollard.

There was ample evidence in the hospital records, both sides’ expert reports, and in the confessions themselves to meet the affirmative defense, and Bernard Perez was convicted of both killings and sentenced to life without the possibility of parole. His two accomplices in the Pollard murder were likewise convicted, one by plea and the other after a separate trial.

This work presents a case study of an improbable psychiatric defense of a serial killer.

---

#### Homicide, Confession, Psychiatric Defense

### F24 The Evidentiary Standard for Authenticating Social Media Posts in Litigation

Stephanie Domitrovich, JD, PhD\*, Sixth Judicial District of PA, Erie, PA 16501

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the trial court’s authentication standards regarding expert testimony in relation to social media posts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing knowledge regarding authenticating social media posts.

Since social media and networking accounts can be faked or hacked, the Pennsylvania Superior Court three judge panel ruled in *Commonwealth v. Mangel*, a case of first impression in Pennsylvania, that social media posts cannot be authenticated in criminal cases unless prosecutors can present evidence of who actually authored said social media posts.<sup>1</sup>

The procedural and factual background follows. At a hearing on the State’s motion in *Limine*, the prosecution presented testimony of an Erie County Detective as a computer forensics expert. The trial court questioned the expert as to whether she could “testify to a reasonable degree of computer and scientific certainty” that the defendant had actually authored Facebook® posts and chat messages. The expert replied she could not so testify. The expert also testified she had not obtained an IP address for the Facebook® account in question. The trial court ultimately denied the motion in *Limine*.

On appeal, prosecutors argued trial court had applied a higher burden of proof than was required, but the Superior Court disagreed. Noting the issue of authenticating social media posts is one of first impression in Pennsylvania, the appeals court relied heavily on its own 2011 decision in *Commonwealth v. Koch*, which dealt with cellphone text messages.<sup>2</sup> The *Koch* court held that “authentication of electronic communications, like documents, requires more than mere confirmation that the number or address belonged to a particular person. Circumstantial evidence, which tends to corroborate the identity of the sender, is required.”

The PA Superior Court in *Mangel* pointed to various rulings by the United States Court of Appeals for the Second and Seventh Circuits, as well as state courts in Maryland, Massachusetts, Mississippi, and Texas, noting these courts required some evidence of authorship in order to authenticate social media posts. In *Mangel*, PA Superior Court stated the State “presented no evidence, direct or circumstantial, tending to substantiate that Defendant created the Facebook® account in question, authored the chat messages, or posted the photograph of bloody hands.” Moreover, prosecutors failed to produce any evidence that the defendant created or had access to the email accounts or phone number associated with the Facebook® account. Nor did prosecutors establish any relationship between the defendant and the owner of the phone number. In a separate footnote, the PA Superior Court noted the trial court correctly applied the expert testimonial standard when questioning the expert as to whether she could testify to a reasonable degree of certainty that the Facebook® posts were authored by the defendant. The PA Superior Court stated: “The mere fact that the Facebook® account in question bore Mangel’s name, hometown, and high school was insufficient to authenticate the online and mobile device chat messages as having been authored by Mangel.” The PA Superior Court further stated: “Moreover, there were no contextual clues in the chat messages that identified Mangel as the sender of the messages.” The prosecution also did not provide any evidence of the dates or times of the posts.

As emails, text messages, and social media data are increasingly used as common and powerful evidence at trial, new legal issues are being applied to the litigation process. Anyone collecting this evidence for use in criminal or civil litigation must authenticate and prove who owns the social media account, as well as provide at least circumstantial evidence of authorship of any specific posts, messages, or pictures. Direct testimony from the author admitting to having written the post or message in question is vital. Otherwise, parties wishing to use social media evidence must have circumstantial evidence as to authorship directly from social media companies, such as timestamps for messages, IP addresses for the devices making the posts, or other metadata.

#### Social Media, Evidence Admissibility, Authentication

### F25 Emerging Trends in Electronic Surveillance

Gary McDonald, Jr., JD\*, Dallas County Criminal District Attorney's Office, Dallas, TX 75063

---

**Learning Overview:** The purpose of this presentation is to educate attendees regarding emerging and restrictive trends in electronic surveillance search and seizure law.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the limitations of personal expectations of privacy in public places as it relates to the usage of electronic devices or personal movements.

This presentation will inform attendees about recent trends in electronic surveillance law and restrictive trends in case law from the United States Supreme Court. This presentation will provide insight into the Court's interpretation of an individual's expectation of privacy in public locations and discuss long-standing techniques employed by law enforcement that are limited by the Court's holdings. These investigative techniques will include discussions of the usage of historical cell site location information and toll records, together with such investigative devices as pen registers and trap and trace devices.

On June 22, 2018, the United State Supreme Court handed down its opinion in *Carpenter v. United States*.<sup>1</sup> In *Carpenter*, the Court extended the protections of the Fourth Amendment to cell site location information in the possession of wireless service providers, requiring a search warrant issued upon a finding of probable cause for law enforcement to access such information. Prior to *Carpenter*, the United States Supreme Court handed down its opinion in *United States v. Jones*. In *Jones*, the Court likewise extended the protections of the Fourth Amendment to law enforcement's installation and use of mobile tracking devices by holding that such investigative techniques constitute a search. Together, these cases recognize increasingly greater expectations of privacy in public places than have been historically recognized by the Court.

Historically, information held in the possession of businesses, such as electronic service providers, excluding the content of communications, has not been protected by the Fourth Amendment's warrant requirement. Indicative of this is that federal statutory provisions, as well as the statutes of most states, do not require a search warrant to access most information. This presentation will analyze the shift in historical perspective that contributed to the privacy interests recognized in *Carpenter* and *Jones*.

While statutory authority may exist in state and federal jurisdictions allowing law enforcement to access electronic customer data on standards lower than required by *Carpenter* and *Jones*, the Court has severely limited law enforcement's access to certain types of information by requiring judicial approval on a finding of probable cause. This presentation will provide insight into those differences.

After attending this presentation, attendees will have a greater understanding of electronic surveillance tools in use by law enforcement and how those tools benefit investigations. Attendees will also have a greater understanding of emerging trends in courts providing increasingly greater protections to an individual's expectation of privacy in certain information, including the nature and extent of judicial process required for law enforcement to access such information.

**Privacy, Searches, Electronic Surveillance**

### F26 Expert Challenges Using Industry Standards

*John J. Lentini, BA\*, Scientific Fire Analysis, LLC, Islamorada, FL 33036*

**Learning Overview:** After attending this presentation, attendees will understand: (1) there are objective standards for the knowledge required of experts in many forensic disciplines, (2) too many practitioners who hold themselves out as experts do not meet the minimum criteria for professional qualifications, and (3) a qualifications challenge is more easily crafted and more likely to succeed than a methodological challenge.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that challenging an expert on methodological grounds is often more difficult than simply challenging the expert's qualifications.

Federal Rules of Evidence (FRE) Rule 702 (and most states' Rules of Evidence) states, "A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if: (a) the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue; (b) the testimony is based on sufficient facts or data; (c) the testimony is the product of reliable principles and methods; and (d) the expert has reliably applied the principles and methods to the facts of the case."

Confronted with the possibility of challenging an expert opinion, most attorneys base their challenges on the four lettered requirements and are required to get into the weeds with an expert on the subject of methodology. Given the wide variety of forensic science disciplines, this places the lawyer in an almost impossible situation of arguing methodology with someone who is far more qualified to discuss methodology.

A strategy that is more likely to succeed is using the opening phrase of Rule 702 to challenge the qualifications of the expert. This does not require the attorney to go beyond learning what are the expectations of the discipline for training and knowledge. In some forensic disciplines, challenging qualifications will be difficult, but in others, it is the easiest means of persuading the court (or adverse counsel) that the expert will not be helpful to the trier of fact.

With respect to arson cases, unless an attorney specializes in insurance defense, he or she is likely to encounter one or two contested arson cases in a career. This necessitates consulting with an expert, but even a brief consultation will make the attorney aware that there exists an industry standard for the knowledge required to investigate fires.<sup>1</sup> Thus, the question becomes not "How did you reach your opinion?" but rather "Are you really qualified to express an opinion?" Per experience, the unfortunate answer to the second question is "No"—not if any kind of objective standard is consulted. A large cadre of supposedly professional fire investigators cannot explain the basic concepts of energy, power, heat flux, and fire pattern development. For example, there are many fire investigators who will be unable to tell you that a watt is 1 joule per second or explain the difference between energy and power or tell you the units used to measure radiant heat flux. When sponsoring counsel understands that their expert, who is likely to be the pivotal witness in a case, cannot demonstrate qualifications in even the most basic fire science, charges are likely to be dismissed or civil cases are likely to settle. No formal challenge is even necessary. If the court still allows the expert to testify, the jury will at least understand that they are hearing opinions from an unqualified individual.

This presentation will provide several examples of individuals who failed to demonstrate that they were even marginally qualified, and thus civil cases were settled or criminal cases were dismissed outright.

Several disciplines besides fire investigation (drugs, bloodstains, DNA, computer forensics) have adopted training guides or other documents that define the qualifications that experts should possess, and these can be used in a similar fashion.

### F27 National Fire Protection Association (NFPA) 921 in Court: Lessons From 500 Case Decisions Over a Quarter Century and Across Two Countries

Terry-Dawn Hewitt, LLM\*, McKenna Hewitt, Denver, CO 80224-3703; Wayne J. McKenna, LLB, McKenna Hewitt, Denver, CO 80224-3703

**Learning Overview:** For attendees who are involved with fire cases, the purpose of this presentation is twofold: (1) to highlight the reasons why judges have cited NFPA 921 Guide for Fire and Explosion Investigations in court decisions, and (2) to predict future issues likely to be raised in civil and criminal cases by evaluating revisions in the latest edition of NFPA 921 taken together with the large body of existing cases. For those who are involved in forensic science disciplines other than fire investigations, the lessons from the use of NFPA 921 in court may shed light on how issues based on industry standards in other fields could develop once more members of the legal community become familiar with such standards.

**Impact on the Forensic Science Community:** It is rare to have an industry standard or guide published as recently as 1992, which has produced such a huge body of written decisions from courts in not one, but two countries. With the increasing emphasis on standardization and certification that the National Academy of Sciences/National Research Council (NAS/NRC) Report has inspired, it is incumbent on lawyers and forensic science experts to understand the many ways that industry standards can be used in court.<sup>1</sup> This presentation will impact the forensic science community involved in fire investigations by summarizing the lessons to be learned from the NFPA 921 cases. It will affect those in other disciplines by identifying the types of issues that they can expect to face when the many ways that industry standards can be used in civil and criminal cases becomes widespread knowledge among lawyers and judges.

The first edition of NFPA 921 was published in 1992.<sup>2</sup> A year later, the first mention of NFPA 921 was made by a judge in a written court decision. In the 25 years since, there have been more than 400 written case decisions specifically mentioning NFPA 921 in the United States, and another 60 in Canada. These numbers do not include the thousands of cases across both countries where NFPA 921 is mentioned by experts in their testimony or reports, nor where it is referred to by counsel in written briefs or oral argument. While it is common practice for trial lawyers and experts to use “learned treatises” (the legal term for authoritative publications) in various ways, it is very rare for so many state, provincial, federal, and appellate courts in two countries to expressly mention an authoritative publication in reasons for their decisions.

This presentation will examine the past lessons and the future trends in fire investigations that can be learned from these court decisions. It includes a timeline analysis showing the growing influence of NFPA 921. A geographical breakdown is also incorporated so attendees can consider whether the use of NFPA 921 in court is truly an international phenomenon or simply concentrated in localized jurisdictions. The most significant issues that the courts have considered are delineated, as well as some of the litigation effects, such as disqualification of experts and post-conviction relief in criminal cases. The latest edition of NFPA 921 is then considered in the context of the existing case decisions to predict future issues in fire litigation.<sup>1</sup> Finally, lessons learned from NFPA 921 in court are generalized to provide insights for those in other forensic science disciplines as to ways that their industry standards and guides may be used in civil or criminal litigation.

### F28 Three Attorneys Participate in Fingerprint Proficiency Testing: Results and Observations

*Brendan P. Max, JD\**, Cook County Public Defender, Chicago, IL 60602; *Joseph Cavise, JD\**, Cook County Public Defender, Chicago, IL 60602; *Richard E. Gutierrez, JD\**, Law Office of the Cook County Public Defender, Chicago, IL 60602

**Learning Overview:** The goal of this presentation is to generate discussion regarding the level of competency assessed by current fingerprint proficiency tests and the limitations of inferences to be drawn from successful participation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by generating robust discussion of, and possibly reform to, current fingerprint proficiency testing practices.

Proficiency testing has long played a very important role in the forensic science community in general, and the forensic fingerprint community in particular. For years, fingerprint practitioners have relied on fingerprint proficiency testing results when making claims about the overall reliability of the Analysis, Comparison, Evaluation-Verification (ACE-V) method when making assertions about the reliability of particular forensic laboratories and when making assertions regarding the level of competency of individual fingerprint examiners. Some within the fingerprint community have pointed to extremely high passage rates when asserting that the overall error rate in the discipline is low. Separately, laboratories routinely include participation in proficiency testing as a major component of quality assurance programs. Forensic laboratories point to near-universal passage of fingerprint proficiency tests as an important indicator of a lack of quality assurance problems within laboratories, and as an indicator that substantial retraining of fingerprint examiners is not necessary. Finally, individual forensic fingerprint examiners routinely testify during expert *voir dire* to their participation in annual fingerprint proficiency testing.

Especially in the case of uncertified fingerprint examiners, results of fingerprint proficiency testing are often the only objective evidence offered as a means to establish the competency required to be admitted for testifying as an expert in a criminal trial. In this regard, fingerprint examiners regularly tout error-free passage of fingerprint proficiency testing as an important signal to the criminal justice system that they can competently conduct forensic fingerprint examinations and reliably associate a latent print with a suspected source. However, each of these assertions that are based on participation in fingerprint proficiency testing—low overall error rates, lack of quality assurance problems, and individual examiner competency—are only supported in a meaningful way if the fingerprint proficiency tests are rigorous enough. Fingerprint proficiency tests that are too easy do not provide an accurate indication of overall error rates in the field.<sup>1</sup> Similarly, easy fingerprint proficiency tests do not meaningfully advance quality assurance programs, as they are not designed to detect important breaking points within a laboratory and across the discipline, and therefore provide only minimal guidance for retraining of examiners. Finally, successful participation in easy proficiency testing by individual fingerprint examiners should not indicate competency in any but the easiest comparisons encountered in casework.<sup>2</sup> Given the critical question of whether current fingerprint proficiency tests are easy or rigorous, this study sought references in the scientific literature to answer this important question. Finding very limited discussion of fingerprint proficiency testing by practitioners in the discipline, this study sought to investigate this question in one modest way—through participation in 2018 fingerprint proficiency testing.

This presentation will include discussion of the results of participation in fingerprint proficiency testing (a combined 33 consensus responses out of 36 fingerprint comparisons with no false positive errors). Through further discussion of the study's participants' obvious lack of formal training in forensic fingerprint comparisons, as well as a detailed discussion of the test itself, it will be suggested that the current fingerprint proficiency testing regime is not rigorous and needs to be reformed.

#### Fingerprints, Proficiency Testing, Competency

### F29 The Regulation of Forensic Science Evidence in Europe

*Joelle V. Vuille, PhD\*, University of Lausanne, Lausanne 1015, SWITZERLAND*

---

**Learning Overview:** The goal of this presentation is to discuss the current state of regulation in forensic science in various European countries, highlighting the benefits and challenges that current regulation regimes pose in terms of a fair administration of justice and some of the regulatory trends that can be expected in the future.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering an alternative perspective on forensic science regulation by discussing the options taken by European countries on the matter in various forensic disciplines and the challenges that such regulatory schemes raise with regard to the right to a fair trial.

The ability of forensic practitioners to provide the fact-finder with accurate information has been questioned in the past decade. In the United States, several forensic disciplines have been denounced as lacking empirical validation, relying too heavily on the subjective opinion of individual experts, and having inconsistent and sometimes shoddy practices. Institutions have thus been tasked with harmonizing existing regulation, reforming outdated rules, and developing new standards when needed. In turn, these efforts have given rise to vigorous debates in the forensic and legal communities.

In Europe, each country regulates the production and use of forensic science evidence in their own criminal proceedings. Very few efforts have been made to develop a coherent system of regulation, although the growing number of transnational prosecutions and the increase in exchange of evidence between countries would require some form of harmonization. Besides, it could be argued that some practices run counter to the right to a fair trial as guaranteed by the European Convention on Human Rights because they do not give the parties an opportunity to substantively assess the robustness of the expert conclusions presented in a given case.

Using practical examples, this presentation will show how forensic science evidence is currently regulated in the criminal justice systems of Europe. It will highlight the high degree of variability in regulation between different countries and disciplines, and its consequences in terms of the administration of justice. Finally, it will illustrate what dangers such unsystematic regulatory regimes pose in terms of the rights of the parties (notably, the defense). Finally, the presentation will offer an evaluation of the relevance of current regulatory regimes considering existing knowledge in the fields of forensic science, law, and governance.

#### Regulation, Standards, Europe

### F30 The International Criminal Court and the Forensic Science Community

Victor W. Weedn, MD, JD\*, The George Washington University, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will be familiar with the International Criminal Court and understand the role of the forensic science community in matters of the court.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by familiarizing attendees with the court and the role of forensic science in court prosecutions.

**Brief Synopsis:** International criminal prosecutions of the International Criminal Court (ICC) use forensic evidence. A Scientific Advisory Board (SAB) of the Office of The Prosecutor (OTP) oversees this evidence. It is thought by some that the Academy should participate in this board.

The ICC is the product of the Rome Statute, which was adopted in 1998 and went into force in 2002.<sup>1</sup> The ICC is located in the Hague, Netherlands. The ICC follows in the tradition of the Nuremberg trials, and the International Criminal Tribunal for the former Yugoslavia (ICTY) and the International Criminal Tribunal for Rwanda (ICTR) tribunals. Unlike these *ad hoc* predecessors, the ICC is a permanent standing fixture.<sup>2</sup>

The ICC is an international organization (IO), independent from, but associated with, the United Nations (UN). The International Court of Justice (ICJ) is the primary judicial organ of the international community for settling civil disputes between nation-states, while the ICC prosecutes criminal cases.

Through prosecution of crimes against humanity, the hope is that the ICC will be an instrument of world peace. It is the court of last resort for the most serious crimes of concern to the international community. Specifically, the court has jurisdiction over genocide, crimes against humanity, war crimes, and crimes of aggression. The Statute allows the ICC to prosecute crimes committed on the territory of a court member or by a national of a court member. A member state may refer a situation, the UN Security Council may do so, and the prosecutor may, under the so-called *proprio motu* power, initiate an investigation. The ICC accepts cases when national judicial systems are unable or unwilling to prosecute. The ICC will not prosecute persons under the age of 18 years.

The ICC is governed by the *Assembly of State Parties*, which consists of representatives of the current 123-member states. Many of the world's major powers are not members, citing national sovereignty concerns. The ICC consists of four organs: The Presidency, The Chambers, The Office of the Prosecutor, and The Registry. The ICC is dependent upon cooperation of nations to do its work; it has no police force of its own.

The ICC has had to establish its own criminal law, but to date does not yet have a well-developed and robust body of evidence law. Forensic evidence is used in the prosecutions. A Forensic Science Section was created in the Office of the Prosecutor. Dr. Eric Baccard was the first head of the Section. Forensic pathology and forensic anthropology were the primary scientific evidentiary disciplines, but now digital evidence and satellite imagery play a larger role. The American Association for the Advancement of Science (AAAS) has recently published recommendations with regard to geospatial evidence.<sup>3</sup>

The creation of a Scientific Advisory Board (SAB) was recommended by Dr. Baccard in 2005 and 2007, and then was incorporated into the recommendations of the Human Rights Center of the UC Berkeley Law School in 2012. A planning meeting was held in 2013. The inaugural meeting of the SAB was held in 2014. Dr. Duarte Nuno Vиейro was elected the first SAB Chair. The SAB is composed of the Presidents, or their designees, of 18 international forensic and legal medicine associations. The SAB membership does not include the American Academy of Forensic Sciences (AAFS); as the AAFS is the largest international forensic science organization, this seems unfortunate.

**THIS ABSTRACT WAS NOT PRESENTED.**

### F32 Self-Determination and Living Wills: The Actual Italian Context After the Promulgation of the 2017 Law 219 on End of Life Issues

*Matteo Scopetti, MD, Sapienza University of Rome, Rome, 00161 ITALY; Vittorio Gatto, MD, Sapienza University of Rome, Rome, 00161 ITALY; Alessandro Santurro, MD, Sapienza University of Rome, Rome, 00161 ITALY; Mariantonio Di Sanzo, MD\*, Rome, ITALY; Raffaele La Russa, MD, Rome, Lazio, ITALY; Paola Frati, PhD, Department of Anat Histol Forensic and Orthop Sciences, Roma 00161, ITALY*

**Learning Overview:** After attending this presentation, attendees will better understand how informed consent and living wills are actually regulated in Italy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the innovative principles and the provided solutions to an issue not yet explicitly regulated in the Italian context.

The Italian Parliament has recently approved the Law 219/2017 regarding “Rules on informed consent and advance provisions of treatment.” This presentation aims to briefly outline the key points of the Law in order to provide meaningful insights on the end of life issues for health care stakeholders. The provision has been analyzed in consideration of Italian deontological, juridical, and jurisprudential context as well as the statements of the “Convention on Human Rights and Biomedicine.”

The current legislation addresses the sensitive issue of informed consent, regulating the modalities of expression and revocation, as well as the advance provisions of treatment, in order to allow the individual to declare his or her orientation on the end of life, in the event of an impossibility to express one’s own will.

The normative text of Law 219/2017 is composed of eight articles. The first article is dedicated to informed consent, with particular attention to the relationship of trust between doctor and patient, with the involvement of the family members of the latter, the cohabitant, or other trusted persons. The same article regulates the right to information of every person to know their health conditions and therefore, to be informed in a comprehensible manner in relation to the diagnosis, prognosis, risks, and benefits of health treatment and the consequences for the case of rejection of the treatment itself. Informed consent can be expressed in writing and must be included in the medical record, even if it is possible to express this consent by videotaping or other electronic communication equipment. Informed consent can always be revoked, and the principle is established that every person of age, obviously capable of understanding and wanting, has the right to refuse any medical treatment. In cases of emergency situations, the doctor is always obliged to ensure essential health care to the patient, respecting, if possible, the will of the same. According to the provisions of the third article, informed consent from minors is expressed or refused by parental responsibility. Consent may also be expressed or refused by the support administrator, where appointed, considering the will of the beneficiary.

The second article is dedicated to the treatment of pain or the prohibition of unreasonable obstinacy in treatment in the final phase of the patient’s life. In particular, the physician is obligated to work to alleviate the patient’s suffering, even in cases of refusal of consent to health treatment, through the provision of palliative care.

Article 4 deals with the advance provisions of treatment, acts in which any adult person who is capable of understanding and is willing, can express their preferences and convictions regarding health care, being able to also appoint, by written deed, a fiduciary subject that represents him/her in relations with the doctor and the hospitals.

In the fifth article, the Law provides for the possibility of defining a shared care plan between doctor and patient, to which the health professional is obliged to comply if the patient is unable to give his consent.

In view of the stated principles, the Law represents a crucial novelty, dealing with relevant issues that have been the subject of contradictory judgments ruled upon by the Italian courts. In fact, the provision guarantees the patient’s right to self-determination, dignity, and well-being through the regulation of the relationship between patient and doctor. Although the law states essential principles, some inconsistencies remain, especially regarding the issue of minors. For this reason, it is necessary to continue to deepen the collaboration between health professionals, bioethicists, and jurists in order to translate the new rules into practice.

#### Self-Determination, Living Wills, End of Life

### F33 Depleted Uranium and Cancer Risk: A Case Report

*Martina Fichera, MD\**, University of Catania, Catania 95123, ITALY; *Giuseppe Davide Albano, MD*, Foggia 71121, ITALY; *Aldo Liberto, MD\**, University of Catania, Catania 95123, ITALY; *Francesco Amico, MD*, Medicina Legale, Catania 95123, ITALY; *Maria Tea Teodoro, MD*, Catania 95123, ITALY; *Massimiliano Esposito, MD\**, University of Catania, Catania 95123, ITALY; *Diego Geraci, PhD*, Catania 95100, ITALY; *Orazio Cascio, MD*, University of Catania, Catania, ITALY

**Learning Overview:** The goal of this presentation is to examine the effects of uranium exposure on human health and disease. In this presentation, the case of an Italian soldier who has contracted brain cancer is discussed. The case of human uranium exposure during military missions came to the attention of the judicial authorities during arranged investigations of inspection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the relationship between environmental pollution by depleted uranium and the possible effects on cancer.

The purpose of this work is to analyze the relationship between environmental pollution from depleted uranium and possible health effects. Depleted Uranium (DU) is generally considered an emerging pollutant and is a known carcinogen. DU has been hypothesized to represent a hazardous element both for exposed soldiers and the inhabitants of polluted areas in the war zones. In Afghanistan and Iraq, it was shown that the illnesses and deaths of military personnel were related to environmental pollution caused by the explosion of depleted uranium munitions. The harmful effects on personnel exposed without protection are known, especially in the famous “Gulf syndrome” that affects many United States military directly (with oncological diseases) and indirectly (malformations of the children of soldiers returning from Iraq). These diseases were then recognized by the American government and by the military and these families were compensated. Also, the Balkan region suffers from DU pollution in many areas and the effects of this can damage public health through poisoning and the increase in incidence of various cancers. The overall incidence of lung cancer, leukemia, and lymphoma has increased in Italian soldiers exposed and several judgments of the Court of Cassation have recognized the causal link between exposure to DU and the development of tumors, condemning the Ministry of Defense to pay damages.

Unlike the United States military, Italian soldiers on mission in these territories did not have the necessary protective devices and Italian military personnel were in contact with DU. The equipment provided for the military personnel was not adequate and did not meet the standards established for the territories with possible contamination by Nuclear, Biological and Chemical (NBC); the army has been exposed to significant risk factors (i.e., air pollution, toxic contamination, exhaust fumes, and chemical solvents used to clean weapons) that would contribute to cancer development.

**Case Report:** An Italian navy sergeant who was exposed to DU during missions in Kosovo, Yugoslavia, and Albania from 1999 to 2001 and who has no cancer or anamnesis for cancer. The military has been exposed to carcinogenic risk factors, in particular the toxic contamination caused by the dispersion of heavy minerals in the environment produced by the explosion of DU munitions and the contamination of water and air in the workplace. In 2006, after the onset of neurological symptoms (convulsions), the Italian soldier was admitted to the hospital and was diagnosed with a brain tumor—oligoastrocytoma. The tumor was treated surgically and with radiation, yet eventually caused the sergeant’s death in 2013.

Although oligoastrocytoma does not belong to tumors more frequently related to depleted uranium exposure, exposure to this substance is highly likely to have led to the onset of cancer and subsequent death.

#### Oligoastrocytoma, Depleted Uranium, Cancer Risk

### F34 Should Forensic Science Rely on Opinions or Factual Data? The Role of Forensic Metrology

Alessandro M. Ferrero, MSc, Politecnico di Milano, DEIB, Milano 20133, ITALY; Veronica Scotti, LL.M\*, Politecnico Di Milano, DEIB, Milano 20133, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the role played by forensic metrology in changing an opinion, including competent opinions based on scientific data, into a set of factual data within which the information we are looking for lies with a given probability.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the manner in which expert testimonies aimed at reporting on experimental tests (i.e., fingerprint comparisons, DNA comparisons, exceeded thresholds, etc.) become more complete and informative if reported in a metrologically sound way, including the evaluation of measurement uncertainty.

Despite the emphasis given by the 2009 National Academy of Sciences (NAS) Report and the 2016 President's Council of Advisors on Science and Technology (PCAST) report to the need for scientifically validated forensic methods, it is still common to refer to forensic-science *opinions*, even when the expert witnesses are reporting the results of experimental tests or activities.<sup>1-3</sup>

The PCAST report clearly emphasizes the demand that the scientific validity of forensic science methods is assessed before these same methods can be considered in courtrooms.<sup>2</sup> In other words, forensic methods should provide scientifically validated data, not opinions. The report also provides indications on how to assess this validity through the definition of the *foundational validity* and the *validity as applied*, but unfortunately, it fails to show how such terms can be quantitatively evaluated.

Probability is generally considered to provide such a quantification or, at least, through the evaluation of suitable *likelihood ratios*, provide a quantitative way to assess which one, between two hypotheses, is the most probable.<sup>3</sup>

The major drawback is that probability may not provide an undoubtable answer in all specific situations (Does this fingerprint belong to the defendant? Does this DNA pattern belong to the suspect?), since it is generally evaluated on available databases and does not consider the employed instruments, the influence quantities, the operator, and other variables.

This presentation seeks to show how metrology can overcome this potential drawback, since the good measurement practice does consider all possible contributions to uncertainty, from the *definitional* contribution that quantifies the foundational validity to the many instrumental contributions that quantify the validity as applied.<sup>4</sup>

The result is still a probability, or better, a standard deviation (standard uncertainty) that yields an interval of possible values, built about the measured value, within which the unknown true value of the quantity subject to measurement is supposed to lie with a given coverage probability.<sup>5</sup>

It will also be shown how, starting from such a coverage interval, it is still possible to evaluate a likelihood ratio, if needed, which is now based on specific data related to the considered measurement or test and is supposed to be more reliable in helping the trier of fact render a fair decision beyond any reasonable doubt.

#### Opinions, Data, Uncertainty

### F35 A Metrologically Sound Assessment of Blood Alcohol Concentration (BAC) Through a Breath Alcohol Concentration (BrAC) Measurement

Alessandro M. Ferrero, MSc, Politecnico di Milano, DEIB, Milano 20133, ITALY; Veronica Scotti, LLM\*, Politecnico Di Milano, DEIB, Milano 20133, ITALY

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the different sources of uncertainty that affect BAC measurements when performed through a BrAC measurement, especially when the major source of inaccuracy does not come from the employed instrument but is implied in the way BrAC is reported to BAC.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a metrologically sound approach to BAC measurement and by understanding its uncertainty when it is obtained through a roadside BrAC measurement. The multiplicative coefficient to get BAC from BrAC is discussed and how its foundational validity can be stated will be shown, beginning with the available literature and quantified in terms of definitional uncertainty.

Roadside BrAC tests have become the standard method to assess BAC in drivers and represent the most effective tool to fight against DUI crimes in most developed countries. On the other hand, the validity of the obtained measurement results is often challenged and the employed BrAC instruments are considered the major cause of inaccuracy.<sup>1,2</sup>

However, from a strict metrological perspective, this contribution to measurement uncertainty only represents the instrumental uncertainty contribution and yields a quantification of the *validity as applied*, as defined by the President's Council of Advisors on Science and Technology (PCAST) report.<sup>3,4</sup>

Another important contribution to uncertainty, the definitional uncertainty contribution, that quantifies the *foundational validity*, as defined by the PCAST report, has not been considered nor quantified. As a matter of fact, the choice of the proportionality factor to convert the measured BrAC into a BAC, is critical and represents the major source of uncertainty of this method.<sup>3,4</sup>

This presentation seeks to show how this contribution can be quantified, beginning with the data available in the scientific literature combined with the instrumental uncertainty to evaluate the overall uncertainty in the determination of a BAC starting from a BrAC measurement.<sup>5,6</sup>

This presentation will also show how, starting from the obtained uncertainty value, it is possible to evaluate the probability that a BAC value higher than a given threshold may actually be lower than the threshold, thus quantifying the doubt of not making a right and fair decision.

### F36 Preferred Crime Scene Documentation Methods

*Giovanna M. Vidoli, PhD\**, University of Tennessee, Knoxville, TN 37996; *Michael W. Kenyhercz, PhD*, Department of Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96816; *Joanne Devlin, PhD*, University of Tennessee Department of Anthropology, Knoxville, TN 37996; *Jason J. Keller, MFS, NCIS*, Great Lakes, IL 60088

**Learning Overview:** The goal of this presentation is to provide the forensic science community with data regarding the monetary, temporal, and interpretative advantages or disadvantages of utilizing 3D laser scanners in scene documentation as compared to traditional documentation methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data on how 3D scanned products perform compared to other documentation methods and how much novel data can actually be gleaned from the scans as compared to traditional mapping methods.

Technological advances have allowed for a decrease in the costs associated with 3D laser scans and an increase in the availability of scanners for crime scene investigators. However, the value of this new technology in crime scene documentation as compared to traditional techniques (i.e., hand-drawn maps, photographs) is largely unknown. This presentation will provide the scientific and medicolegal community with quantitative data on a layperson's and a forensic professional's interpretation and assessment of traditional scene documentation and 3D laser-scanned representations of potential crime scenes. This presentation's proposition is that 3D laser-scanned images do not always provide the best information to a jury.

A total of four indoor and eight outdoor mock crime scenes involving human remains, or a proxy, were documented using a 3D laser scanner and multiple traditional means, including photographs, hand-drawn and total station/GIS maps, and detailed notes. The outdoor scenes included human skeletal or mummified remains on the ground surface and in burials established at the Anthropology Research Facility at the University of Tennessee, Knoxville. Following documentation, 200 people were surveyed and asked to review and compare the documentation products. Respondents were required to rank the method that best represents a given crime scene scenario with respect to human remains and associated evidence. As a result, there is quantifiable data regarding the effectiveness of 3D laser-scanned images as compared to traditional documentation images. In addition, this study conducted cost/benefit analysis for all documentation methods, noting the time and expenses (personnel and equipment) associated with each method. This will provide agencies with data in making training and budgetary decisions regarding the acquisition of such instrumentation.

The survey results indicate that while many participants appreciate the detail and clarity provided by 3D scanning, the use of such may not always be the most effective and/or efficient use of an agency's resources. For the current study, examination of the age cohort on respondent answers was analyzed. The age cohorts were grouped by 18–22 years ( $n=5$ ), 23–30 years ( $n=12$ ), 31–45 years ( $n=32$ ), 46–60 years ( $n=25$ ), and 61+ years ( $n=51$ ). Evidence preference was analyzed with a Kruskal-Wallis test in R. Results indicate that respondent age cohort does not impact the preference on site recording media. Overall, there is a preference for 3D renderings, with 80.2% preferring this media for site presentation. Photographs were the second most preferred method, with a 14.9% preference, followed by hand-drawn maps (3.3%), then 2D maps (1.6%). The 18–22 year cohort had a 100% preference for 3D renderings; the 23-30 year cohort was more varied with a 66.7% preference for 3D renderings, 12.7% for 2D maps, and 8.3% for hand-drawn maps and photographs, respectively. The 31-40 year age cohort had a 70.9% preference for 3D renderings, 22.6% for photographs, and 6.5% for hand-drawn maps. The 41-60 year cohort had a 96% preference for 3D renderings and 4% for hand-drawn maps. Last, the 61+ year cohort had a 79.6% preference for 3D renderings and 20.4% for photographs.

#### 3D Scanning, *Voir Dire*, Crime Scene Documentation

### F37 Developing an Introductory Analytical Science Training Program for Lawyers and Judges

Nicolas R. Hughes, JD\*, Harris County Public Defender's Office, Houston, TX 77002; Ashraf Mozayani, PharmD, PhD, Texas Southern University, Houston, TX 77004; Jasmine M. Drake, PhD, Texas Southern University, Houston, TX 77004

**Learning Overview:** After attending this presentation, attendees will better understand the role of analytical science in criminal cases and how to educate lawyers and judges regarding analytical evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing an easily replicated model for a basic analytical science training program to improve the competency of lawyers and judges who encounter analytical evidence.

Scientific evidence is often the most persuasive evidence in a case. The 2009 National Academy of Sciences poignantly discussed the legal profession's insufficient understanding of scientific evidence.<sup>1</sup> A lawyer must be able to competently challenge scientific evidence to satisfy the Constitutional right to counsel.<sup>2</sup> A lawyer cannot ethically represent a client unless the lawyer is able to effectively challenge scientific evidence.<sup>3</sup> Failure to effectively challenge scientific evidence can result in wrongful conviction.<sup>4</sup>

Advances in analytical science have increased the sophistication of and reliance upon analytical evidence in the courtroom. Gas Chromatography/Mass Spectrometry (GC/MS) is used by many forensic disciplines to confirm the identity of unknown substances. DNA analysis is often used to connect evidence to a person. Analytical evidence is commonly encountered in many types of criminal cases, including prosecutions involving drugs, Driving While Intoxicated (DWI), and sexual assault. A metropolitan laboratory may annually analyze thousands of pieces of evidence affecting thousands of criminal cases.

While existing programs offer lawyers analytical science training, these programs are too expensive and too small to reach the entire legal community.<sup>5</sup> Existing programs are like a bespoke suit—high-quality and tailored for a specific fit—but the majority of people are better served by an affordable, nice suit from the rack of a department store. The Forensic Science Learning Lab, Harris County Public Defender's Office, and the National Association of Criminal Defense Lawyers partnered ("the Partnership") to create a model for an adaptable, expandable, cheaper alternative to other analytical science training programs while providing high-quality education. Similar programs can be offered by a wide range of qualified professionals nationwide. Programs can use existing educational facilities and funding resources to provide cheap or free training to lawyers and judges.

A basic analytical science course addresses the theory and knowledge needed to understand analytical evidence. The Partnership's model for a basic GC/MS training program includes the principles of GC/MS, methodology, documentation, data analysis, instrument design and maintenance, sample preparation, and demonstrations. The model features legal topics including the aftermath of the 2009 National Academy of Science Report, discovery, expert witnesses, and *Daubert/Frye* challenges.<sup>1</sup> Programs are tailored by jurisdiction and can include in-laboratory exercises and interactive problems. The Partnership is currently creating a lecture-based DNA program using the same general model used to create the GC/MS program.

Lawyers and judges need training regarding scientific evidence. Analytical science is commonly encountered in criminal cases and can be critical evidence. Basic analytical science training programs play an important role in the effective representation of the accused and in ensuring fair trials. The Partnership's model for an introductory analytical science training program is an adaptable, expandable, cheaper alternative to other programs and can meet the legal community's need for better scientific training.

### **F38 To Disclose or Not To Disclose: How Outcome-Based Case Theory Guides Information Gathering in Mental Health Evaluations**

*Jason D. Ricke, JD, LLM\*, Office of the Public Defender, Upper Marlboro, MD 20772*

---

**Learning Overview:** After attending this presentation, attendees will understand how trial attorneys have conflicting views about whether to gather certain types of mental health data related to a defendant and whether unhelpful information is required to be disclosed to an expert witness working on the case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that expert witnesses rely on attorneys and their teams to provide comprehensive and accurate information about defendants when conducting mental health evaluations, and how attorneys may intentionally fail to acquire certain records or fail to disclose to their expert records that they deem unhelpful to the ultimate outcome they are seeking. The quality of a forensic expert's opinion is limited by the quality of information that forms the basis of that opinion. When an expert's conclusion is based on incomplete or inaccurate information, their opinion is subject to exclusion or attack on cross-examination.

Court-ordered mental health evaluations are legally significant in the context of competency to stand trial and criminal responsibility. Typically, when a court orders an evaluation, the attorneys from the government or the defense are responsible for acquiring information or mental health records to be used by the expert in forming their opinion. Attorneys may strategically choose to sacrifice a comprehensive record in order to obtain their desired result.

**Do They Have Time?** In state court prosecutions for cases not considered high profile, judges and attorneys are under constant pressure to resolve cases quickly and without unnecessary delay. Even if an assertion of incompetency to stand trial or lack of criminal responsibility is alleged, the court pressures the parties to resolve the case. The government and the defense may temper their efforts to obtain records in the name of efficiency, especially if they know those results may be harmful to the outcome they desire.

**Do They Have To Worry About the Opposing Party?** Attorneys on both sides of a mental health evaluation consider not only the forensic evaluator, but also opposing counsel and the assigned judge. If one party does not believe the other side will put forth efforts to uncover the missing or incomplete information, a calculated decision to purposefully withhold certain records could still produce the desired result. A detailed attorney thoroughly working up the case poses more of a threat to the unprepared expert.

**Do They Have to Disclose the Records?** Ethical rules for attorneys do not directly address disclosure of records to an expert witness, especially when the disclosure of those records is harmful to the interests of a defendant. While the prosecution may have a heightened responsibility to seek justice, if either side could access harmful information, a defense attorney may be acting against the interests of the defendant by providing certain information to an expert witness.

Mental health evaluations pose a unique challenge in seeking the truth because the information used to base those opinions is not consistent from case to case. As long as attorneys remain the gatekeepers to what information is given to and used by mental health evaluators, attorneys will continue to shape the results of those evaluations to each side's respective theory.

### F39 The Impact of Forensic Evidence on Drug-Related Offense Sentencing Outcomes

*Jennifer W. Bourgeois, MS\*, Texas Southern University, Houston, TX 77004; Jasmine M. Drake, PhD\*, Texas Southern University, Houston, TX 77004*

---

**Learning Overview:** After attending this presentation, attendees will understand the intersection of forensic science and criminal justice case processing and the implications for policies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying trends in criminal justice case processing associated with drug-related offenses and identifying sources for backlogs by pinpointing specific reasons for untested forensic evidence and its influence on the cases of drug-related offenses.

This report will use Harris County District Clerk Court records and other available data to assess the relationship between untested forensic drug evidence and case dispositions. Recently, the Houston Forensic Science Center has taken steps to clear a backlog problem in its laboratory. The crime laboratory is not immune to recurring backlog problems or other struggles. The plan will span a period of ten months and would require \$2 million dollars to outsource DNA testing for approximately 1,000 cases. DNA sections within a crime laboratory are not the only divisions impacted with untested evidence. Toxicology and controlled substances sections can have long turnaround times, up to several months.

Regardless of the growth of forensic science services, published research related to the impact of forensic evidence and predictors of sentencing dispositions for drug-related offenses is lacking. The results of the first nationwide survey on untested forensic evidence was published in 2009. There are various reasons why evidence may not be tested, but there is a gap in the literature that discusses the impact on defendants and sentencing outcomes. Specifically, a question that is often not discussed is the relationship between untested evidence and the likelihood of someone accepting a plea deal. As a result of backlogs in crime laboratories, the criminal justice system can expect to see individuals make decisions that will have lasting consequences on their lives without the analysis of forensic evidence. Improper procedures and evidence tampering have troubled many crime laboratories across the nation, which has impacted past convictions and several thousand additional criminal court cases. Lengthy backloads have lasting concerns in each step in the criminal justice system process. Prior literature indicates inconsistencies in the relationship between forensic evidence and sentencing. Given the limited research on backlogs and its consequences on the front end of the criminal justice system, there is urgency in needing prompt action for reforming both forensic science and criminal justice practices.

Crime laboratories must work closely with law enforcement and the court system to ensure fair due process of law. Therefore, this report contributes a guide to identify sources for backlogs in a local crime laboratory by pinpointing specific reasons for untested forensic evidence and its influence on the case processing of drug-related offenses.

---

#### Drug Evidence, Criminal Justice, Sentencing Outcomes

### F40 Problems and Possibilities With Foreign DNA in a Capital Post-Conviction Defense Investigation

*Matilde J. Carbia, JD\*, New Orleans, LA 70112; Kevin Riach, JD\*, Fredrikson & Byron, PA, Minneapolis, MN 55402*

---

**Learning Overview:** After attending this presentation, attendees will understand creative solutions to the problems inherent in developing foreign DNA evidence in post-conviction, including: (1) resistance by the state and the courts to further development of old forensic evidence, (2) the need to use outdated or obsolete technologies to process newly collected forensic evidence to compare profiles developed in decades-old crimes, (3) the limitations of current technologies to process degraded forensic evidence, and (4) the practical challenges of incorporating newly processed and newly discovered forensic evidence in a post-conviction case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping attendees gain insight into the obstacles defense counsel faces when confronted with cold case DNA evidence and limited avenues for developing new forensic information, as well as practical solutions to these problems.

This presentation recently used the DNA profile developed from blood found at the scene of a 20-year-old quadruple homicide to connect an alternative suspect to the crime. In 1996, the state developed a profile from blood found on a red jacket left hanging at the crime scene that did not match the victims or the defendant. The profile was developed using the now-outdated DQ Alpha and Polymarker DNA technologies. Post-conviction counsel filed a motion for additional testing, based in part on this previously unidentified sample, which was opposed by the state and denied by the court. Years later, post-conviction counsel obtained DNA from an alternate suspect and located a lab that could still perform DQ Alpha and Polymarker DNA testing. That lab developed a profile from the newly collected sample that is the same as the previously unknown profile on the red jacket. This evidence was used to support a testing motion that led to the examination and testing of multiple items from the crime scene, the development of 24-plex Short Tandem Repeat (STR) and Y-Filer® profiles that confirmed the DQ Alpha and Polymarker testing and the development of additional evidence that was used in post-conviction.

This presentation will include discussion of the lessons learned from this experience. This presentation will discuss finding a qualified DNA lab that can apply outdated technologies to newly discovered evidence and how to develop new forensic evidence from old and degraded samples to advance your case, including the limits of the new technologies. This presentation will suggest strategies to strengthen post-conviction testing motions including the use of bloodstain pattern analysis to inform testing decisions and support the significance of DNA analysis.

**Investigation, DNA, Defense**

### **F41 The Forensic Use of Closed-Circuit Television (CCTV) Surveillance Cameras in Italy: A Standard Procedure in Criminal Investigations to Enhance the Impact on Decision Making**

*Donatella Curtotti\**, Università di Foggia, Foggia, Puglia 71121, ITALY; *Sebastiano Battiato, PhD\**, Università di Catania, Catania 95125, ITALY; *Vittorio Rizzi\**, Direzione Anticrimine Polizia di Stato, Roma, ITALY; *Oliver Giudice, PhD\**, Roma 00044, ITALY; *Antonino Paratore, MS\**, ICTLab S.R.l. Spinoff of Università di Catania, Catania 95125, ITALY; *Wanda Nocerino\**, University of Foggia, Foggia, ITALY

---

**Learning Overview:** The objective of this presentation is to share the Italian experience and its related protocol to improve the evidential use of images in criminal trials. In many states and jurisdictions, there are still no such rules and protocols.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the increased competence in the use of images by investigators, as well as representing a good practice of collaboration between academics and investigators.

Often CCTV is a powerful tool in criminal investigations for many types of crime. Video and images contain important information on “who, when, and how” the crime has been committed. They also provide useful evidence in court. Today, the forensic value of video and images is limited by several factors. Those factors include the lack of a standard procedure for the collection by investigators and experts in a forensic way such that the evidence can be admitted at trial.

In Italy, there is no operative procedure on the use of images in criminal proceedings. Investigators do not have rules on identification, preservation, or the collection and analysis of video and images of CCTV surveillance cameras. Recent judgments of the Supreme Court have declared this type of evidence not admissible because it has not been handled in a forensic manner.

Because of the increasing use of images in criminal trials, Italian universities in collaboration with Polizia di Stato have drafted an investigative check list. Polizia di Stato (Italian State Police) asked the University of Foggia and the University of Catania to create an operating protocol to be distributed among its investigators throughout the country, after having subjected it to multiple verification processes to ensure its reliability.

This verification process has been thus standardized: (1) questionnaires distributed to all investigators of Polizia di Stato on their investigative habits on CCTV surveillance cameras; (2) elaboration of the questionnaires and drafting of the protocol by academic experts of criminal procedure and of computer science; (3) sharing of the protocol with prosecutor offices; (4) disclosure of the operative protocol through lectures presented to all investigators of Polizia di Stato; (5) experimentation of the operative protocol; (6) results of the experimentation and possible modifications of the protocol; and (7) official acquisition of the investigative protocol as an intervention guideline.

The protocol covers all stages of the investigation, including verification, identification and system description, preservation, collection and evidence acquisition, chain of custody, presentation, and reporting results. The parties involved are the investigating officer, the legal advisor, and a digital forensic expert.

---

#### **Surveillance Cameras, Criminal Trials, Operative Protocols**

### F42 Dead or Alive: A Bioethics Approach to the Understanding of Brain Death Diagnosis by Families and Courts—A Report on Two Cases From the United States and Argentina

*Maria Susana Ciruzzi, PhD\*, Hospital Nacional de Pediatría Prof. Dr. Garrahan, Buenos Aires 1045, ARGENTINA*

**Learning Overview:** After attending this presentation, attendees will understand the challenges that come with a brain death diagnosis, and the dilemmas that surround decision making at the end of life with families, especially in cases of a child or a young adult. Attendees will see how the ethics of care shows a unique understanding of suffering and denial in families of a brain-dead patient and how poor and insufficient a simple legal approach can be, as it seems not to afford an answer that would overcome the despair and sadness of the patient's family. Attendees will also see the courts' understanding of a medical diagnosis and the difficulties legal professionals face when trying to analyze a medical decision from a legal approach.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing key aspects of the important role of bioethics in delivering bad news for families in medical situations at the end of life and the challenges professionals of the law, the courts, and the forensic sciences must deal with in order to guarantee surrogate decision making, the patient's dignity, and a good understanding of the medical diagnoses from courts.

Brain death is a hard diagnosis to make and even harder for families to accept. The idea of a corpse beating and breathing is extremely challenging to personal and religious beliefs. Fear always surrounds brain death diagnosis—the health team fears to err on the diagnosis and families fear to let go of their beloved one before his/her time.

The brain death definition states that death is “the irreversible cessation of all functions of the entire brain, including the brain stem.” This definition is found in the Uniform Declaration of Death Act (1981) of the United States and in the Organ Transplantation Act (24193) and the National Protocol for the Certification of Brain Death under Neurological Criteria, both from Argentina.

The diagnosis of brain death has important ethical, legal, and clinical implications. Although the concept of brain death is long-established criteria, how brain death is determined in practice can vary. These differences in practices can contribute to confusion, particularly on the lay public, but also in the courts.

Usually, a family's refusal to accept the diagnosis of brain death, the proper consideration of a patient's or a family's religious and personal views of death and perspectives on organ donation, and how accommodating hospitals should behave toward bereaved families can spark much controversy and debate. The goal is to present the challenges that a brain death diagnosis brings to health teams, families, and courts at the crossroads of medicine, individual rights, and a legal approach.

Brain death will be examined through two cases: Jahi McMath, a 17-year-old girl whose parents defied a brain death diagnosis, and the Ahumada Nuñez Case and the Argentine court's decision in a criminal case with a young brain death victim.

This presentation will show how juridification of clinical practice can lead to therapeutic obstinacy and can also result in a self-fulfilling prophecy: asking a judge about a medical decision that should have been decided between doctors and the patient/family, according to a legal and bioethical framework that opens the chance of legal scrutiny over doctors' decisions. Involving courts in clinical practice can lead to judicial obstinacy, can harm the patient's dignity, and shatter the family's deepest loving feelings.

Bioethicists in the clinical environment are tasked with being respectful to all parties when there is conflict, trying to reach a consensus in which agreement is quite challenging. Palliative care can be a better approach to help families cope with a brain death diagnosis and to help health care professionals do what is in the best interests of the patient.

This presentation seeks to provide a unique insight into how doctors and courts respond to the changing medicolegal culture and its consequences on patient care. The complexity of decision making at the end of life suggests a multidisciplinary approach, which must include training of health professionals and courts, as well as societal education and engagement.

This presentation will highlight the importance of ethical discussion by healthcare professionals about their everyday decision-making practice and how this can be influenced by changes in the law. This presentation will also raise questions about the ethical role of the law in the decision-making process.

This presentation will conclude that all that is needed is **diligence** in acquiring professional and scientific knowledge; **dedication** to the patient and family's needs, doubts, and fears; and **devotion** to truth, care, and empathy.

---

#### Brain Death, Juridification of Clinical Decision, Bioethics

### F43 Justice Cannot Happen in a Vacuum: Toward a Better Representation of the Science, the Client, and the Case Through Open Communication

*Charlotte J. Word, PhD\**, North Chesterfield, VA 23235-0153; *Terri Rosenblatt, JD\**, The Legal Aid Society, Bronx, NY 10451; *Raymond Valerio, JD\**, Bronx County District Attorney, Bronx, NY 10451; *Heather H. Degnan, PhD\**, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** The goals of this presentation are to educate analysts, prosecutors, and defense lawyers about each other's respective role and perspective on a criminal case to promote accurate and clear communications regarding scientific conclusions between the prosecutor, defendant, law enforcement, and the trier-of-fact (i.e., judge, jury). This presentation will demonstrate how open communication benefits each participant in a criminal case and ultimately best serves justice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of the roles and perspectives of the other participants in a criminal case and by providing tools to better communicate with each other. This presentation will impact attendees by increasing their competence and performance in their respective roles of representing the defendant, the government, or the scientific data through meaningful, open, and transparent communications.

**Hypothesis:** More effective, transparent, and well-informed communication between analysts, prosecutors, and defense lawyers about scientific findings aid in making critical decisions and lead to a better representation of the scientific data in criminal litigation.

The American system of justice is, by design, an “adversarial” system. Yet we are in an interrelated polygon of communication where we rely on information from each other to best do our respective jobs. The prosecutor must prove the government’s case beyond a reasonable doubt, and the defense attorney must present reasonable doubt to the finder of fact. As Chief Justice John Roberts wrote, “Federal prosecutors, when they rise in court, represent the people of the United States. But so do defense lawyers—one at a time.”<sup>1</sup> However, forensic scientists represent neither the “people” collectively, nor the defendant individually. Instead, they represent the scientific data in the case and the integrity of their laboratory’s work.

While the defense attorney’s and the prosecutor’s roles may be necessarily at odds, the forensic scientist is neither side’s ally nor adversary. Yet many analysts express concern about disappointing prosecutors or facing antagonistic cross-examinations by defense attorneys. These concerns, both by individual analysts and laboratory management, along with excessive workloads for all parties, can lead to policies that restrict communications between the scientists and the lawyers. Reports and testimony may communicate conclusions that comport with laboratory policies and procedures. However, restricted follow-up communications may lead to inadequate, or even misleading, representation of the data and their conclusions when the lawyers and/or fact finders are ill informed. This may ultimately result in unintended serious legal consequences (e.g., wrongful convictions, releasing the true perpetrator).

This presentation will explain the roles of the prosecutor, defense lawyer, and analyst in a panel discussion with members of each respective group. The defense perspective will explain the “one at a time” approach to defending the people of the United States and the constitutional duty to provide zealous advocacy for each client in each case. The defense panelist will discuss best practices for evaluating forensic evidence in constructing a theory of defense and advising an individual client. These goals are not aimed at discrediting sound science or making the analyst look foolish. Instead, they are geared toward contextualizing the science in a way that comports with the lawyer’s duties.

The prosecution perspective will explain the government’s need to understand the forensic evidence clearly. Once the prosecutor comprehends the forensic evidence, it can be presented unambiguously at all stages of the criminal justice process. How forensic evidence can inform charging decisions, plea negotiations, and trial strategy will be discussed. The importance of open communications with the analyst and the laboratory about the meaning of the conclusions and the manner in which the test was performed will also be discussed.

Ways in which laboratories can successfully work in an unbiased and neutral manner with everyone will be discussed. Best practices for reporting findings, providing effective testimony, and facilitating open communications will be presented. Examples of incomplete, misleading, or confusing report wording and testimony from actual case reports and transcripts will be presented and discussed.

This presentation will recommend steps that everyone involved in a criminal case can take to improve communications. Defense lawyers, consistent with their obligation to provide “effective assistance of counsel” must seek out training in forensic science and educate themselves before taking on a case. Prosecutors’ offices also must provide training to line attorneys in the capabilities and limitations of forensic science and how to accurately and fairly explain scientific evidence to a jury. Laboratories must openly and transparently provide information and encourage pre-trial meetings with all attorneys involved to ensure the data and conclusions, and their limitations, are effectively communicated.

### F44 You Are the Judges! An Interactive Session in Forensic Medicine and Pathology on the Admissibility of Scientific Evidence in Shaken Baby Syndrome (SBS) and Abusive Head Trauma (AHT) Cases

W. Milton Nuzum III, JD\*, Supreme Court of Ohio, Columbus, OH 43215; Stephanie Domitrovich, JD, PhD\*, Sixth Judicial District of PA, Erie, PA 16501

**Learning Overview:** After attending this presentation, attendees will better understand the trial court's admissibility standards regarding expert testimony through interactive audience participation of the application of these standards in several case studies regarding forensic pathology issues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the knowledge of the factors for admitting scientific evidence in several specific case situations in the area of forensic pathology in both *Daubert* and *Frye* jurisdictions.<sup>1,2</sup>

Understanding the role of judges as gatekeepers will assist attendees in this session with comprehending and appreciating the critical admissibility decisions judges make as gatekeepers of scientific evidence in our courtrooms. *Daubert v. Merrell Dow Pharmaceuticals, Inc.* is the leading case regarding this gatekeeper role of admissibility decision-making.<sup>1</sup> The United States Supreme Court in *Daubert* defined the judge's role as a gatekeeper for admitting scientific knowledge to assist the triers of fact in understanding the evidence. Judges should admit conclusions that will qualify as scientific knowledge if the proponents of such evidence can demonstrate such conclusions are the products of sound scientific methodology derived from the scientific method. In order to be admissible, this evidence must be reliable and relevant. Understanding the expert's methodology is critical to effective, efficient, and proper judicial gatekeeping.

In explaining this evidentiary standard, the *Daubert* Court provided several factors for trial judges to consider: (1) whether a theory or technique can be (and has been) tested, (2) whether the theory or technique has been subjected to peer review and publication, (3) the known or potential rate of error of a particular scientific technique, (4) the existence and maintenance of standards controlling the technique's operation, and (5) a scientific technique's degree of acceptability within relevant scientific communities. The *Daubert* Court also emphasized that these five factors under Federal Rule of Evidence 702 are applied by trial judges in a flexible manner. Trial judges have great discretion in deciding on the admissibility of evidence under Federal Rule of Evidence Rule 702 and appeals from *Daubert* rulings are subject to a very narrow abuse-of-discretion standard of review.

Moreover, Federal Rule of Evidence 702 requires the following for expert testimony: A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if: (1) the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue; (2) the testimony is based on sufficient facts or data; (3) the testimony is the product of reliable principles and methods; and (4) the expert has reliably applied the principles and methods to the facts of the case.

Also, under Federal Rule of Evidence 403, the trial judge may exclude relevant evidence if its probative value is substantially outweighed by the danger of unfair prejudice, confusing the issues, misleading the jury, undue delay, wasting time, or needlessly presenting cumulative evidence. Federal case law recognizes certain situations call for exclusion of evidence that is of unquestioned relevance. These situations entail risks ranging from inducing decisions on purely emotional bases to confusing or misleading jurors. Trial judges must balance the probative value of and need for this evidence against the harm likely to result from admitting said evidence.

Several state courts still apply the *Frye* standard instead of the *Daubert* standards. Trial judges in *Frye* jurisdictions in essence defer to the scientists and admit expert opinion based on scientific techniques only when the techniques are generally accepted as reliable in the relevant scientific community.

This presentation intends to focus this session on teaching participants to apply the trial courts' admissibility standards regarding expert testimony through the vehicle of interactive audience participation. This presentation will examine SBS and AHT cases under various court rules and case law to examine how courts make decisions on expert testimony in actual court cases. This presentation will address issues such as: How are SBS and AHT presented in the courtroom? Should expert testimony regarding SBS be admitted as scientific evidence to show that the baby's injuries were intentional? What are the clinical findings by experts in these cases? Is SBS considered by the courts as junk science? Can SBS cause fatalities and what does the scientific research indicate? Are these concepts acceptable in *Frye* states?

### F45 Forensic Validation, Error, and Reporting: A Unified Approach

Mark W. Perlin, PhD, MD\*, *Cybergenetics, Pittsburgh, PA 15213*

**Learning Overview:** After attending this presentation, attendees will understand how validation studies and match error are two sides of the same coin. Trial lawyers can apply these methods to ensure DNA evidence reliability in the courtroom.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping trial lawyers better understand and explain DNA limitations in criminal justice.

Federal Rule of Evidence (FRE) 702 requires reliable scientific evidence from expert witnesses. The *Daubert* standard specifically includes prongs for validation testing and error rate determination.<sup>1</sup>

Simple DNA evidence comes equipped with a built-in false positive error rate, the Random Match Probability (RMP) that states the chance of adventitious match to an uninvolved person. More complex evidence arises with small amounts of DNA or mixtures of several people. To address uncertainty, Likelihood Ratios (LRs) are used to quantify match strength.

Validation studies measure DNA match information on representative data sets. Match specificity is assessed by comparing many uncertain genotypes with many unrelated references, producing a large set of non-matching LR values. A histogram of these numbers on a logarithmic scale shows the log(LR) distribution of non-matching comparisons. These many-to-many, evidence-to-reference comparisons provide a frequency framework for assessing a laboratory's mixture data or interpretation method.

The match specificity histogram can be used to estimate the false positive error rate in an individual case. Comparing an evidence genotype with a suspect reference yields a match statistic. Positioning this log(LR) match value along the histogram shows how often a false match would occur. The validation fraction exceeding the reported log(LR) value is an error estimate of the Probability of Misleading Evidence (PME). PME generalizes RMP to handle inexact DNA matches.

The specificity histogram can be *directly* constructed from a validation's probabilistic genotypes, *without* reference sample comparisons. Information theory lets a computer assemble a composite log(LR) distribution from the distributions of many uncertain genotypes. This elegant, many-to-none approach accelerates validation studies.

A log(LR) specificity histogram can also be developed for a single evidence item. Older statistical approximations construct a one-to-many comparison of the uncertain genotype against many unrelated references. However, a more precise one-to-none *direct* construction immediately computes a numerically *exact* genotype specificity distribution solely from the evidence genotype, without making any reference comparisons. This direct approach is fast and accurate and enables routine error reporting.

The log(LR) specificity distribution is inherent in a genotype's probability description. Comparing evidence with a suspect produces a log(LR) value. Positioning this reported match value within the frequency context of the specificity distribution yields an error rate for false match. The fraction of specificity matches exceeding the suspect's statistic provides the PME—the chance this evidence would be as strong against someone who didn't leave their DNA. This error rate is based on the actual DNA evidence in the case, not on a validation study done at another time and place by other people on unrelated DNA samples under idealized laboratory conditions.

For a reported match statistic, FRE 403 would suggest that a focused, evidence-derived error rate is more relevant than a generic, validation-derived error rate. Reporting on facts in evidence has greater probative value. A more germane, evidence-based error rate can better assist a trier of fact.

Probability is readily communicated with whole numbers (for example, as “one in N people would match the evidence as strongly as does the suspect.”)

With smaller match statistics (e.g., under a million), reporting PME error provides a frequency context for understanding what LR information means. Moreover, a numeric error is more precise than a verbal equivalent.

An exclusionary match statistic also has PME error. Defenders can use these false negative error rates to contextualize exculpatory DNA evidence.

This presentation provides a unified view of evidence and validation error rates. Case examples show how inclusionary and exclusionary match statistics, along with error rates, are presented in court. Direct error determination for evidence items may reduce the need for large-scale validation studies. Normative science reports relevant error for measured variables. *Daubert* encourages such error reporting in forensic science.

A unified approach to forensic validation and match error will be presented. This presentation will offer useful perspectives on DNA evidence reliability.

### F47 Caught by the Laws of Physics

*Peter J. Diaczuk\*, Penn State University, State College, PA 16802; Xiao Shan Law, BS, Pennsylvania State University, Brooklyn, NY 11223*

---

**Learning Overview:** After attending this presentation, attendees will understand a specific event, including several anomalies that led to controversial theories about the event, and how high-speed photography elucidated a serious misunderstanding of firearm dynamics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how an objective assessment of the evidence supported one of the competing theories of the case.

The death of a young woman several years ago in St Augustine, FL, was investigated by local law enforcement agencies. During the investigation, there was controversy regarding whether her death would be pronounced a suicide or homicide. She was killed by a single shot into her mouth by a .45 caliber handgun. The young woman also sustained an injury directly above her eye, which was just one of many anomalies in this case that initiated considerable controversy between those who supported the suicide theory and those who supported the homicide theory. One preposterous theory about the cause of the victim's eye injury was that it was caused by the firearm lurching forward, in the same direction of the bullet, upon being fired in what may be described as "negative recoil." The firearm had a tactical flashlight mounted on its proprietary under-rail, with a knurled bezel surrounding the parabolic reflector. The knurled bezel was very likely the cause of the victim's eye injury, but the question of how and when it happened needed to be explored. The Laws of Physics clearly prevent the firearm from moving forward upon being discharged, but sometimes the Laws of Physics are not well understood by those unfamiliar with them. Fortunately, high-speed photography can clarify very fast events that may otherwise evade understanding, or skepticism, in the tenets of science.

One theory of the incident proposed that the firearm lurched forward upon firing, which resulted in the bezel of the attached tactical flashlight to cause an arc-shaped injury over the victim's eye. That scenario would require the firearm to be used upside down to fire the fatal shot into the victim's mouth, almost simultaneously causing the eye injury with the aforementioned "negative recoil." This clear breach of physics can easily be visualized and disproven using high-speed photography, which was used in this project to elucidate the relative motion of the firearm and the bullet. The same model firearm and ammunition were used during several experiments concerning recoil, including supporting the firearm on strings and firing it remotely. A review of the frame-by-frame images taken during tests when the firearm was discharged revealed the bullet left and completely cleared the barrel before the slide began to move rearward. It only moved *rearward*, opposite the direction of travel of the bullet, not forward. This rearward-only motion of the firearm upon discharge obviously included the attached tactical light, contradicting notions that the tactical light caused the victim's eye injury at the same time that the fatal bullet was fired.

Other anomalous aspects of this event that will be discussed include two shots being fired at the scene and the locations of the two discharged cartridge cases with respect to the position of the firearm. Attendees may draw their own conclusions about this event after the facts are presented.

### Suicide, Homicide, Recoil

### F48 Recent Legal Measures Against Stalking in India

*Anil Aggrawal, MD\*, Maulana Azad Medical College, New Delhi 110002, INDIA*

---

**Learning Overview:** After attending this presentation, attendees will have learned the latest legal measures against stalking in India. Stalking is a widely prevalent problem and an attempt will be made to present a comparative aspect of laws in different parts of the world, giving attendees an insight into the strengths and weaknesses of legal measures against stalking in different jurisdictions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stimulating further inquiry and research into the specific sexual behavior of stalking. Attendees will be educated about the problem of stalking in India and the recent legal measures that have been taken against this practice. The impact of this new law on the practice of stalking will be discussed.

**Background:** Stalking refers to a constellation of repeated and persistent behaviors to impose unwanted communication or contact on another person. Communication can be via emails, graffiti writings, letters, paper notes, telephone calls, or texts. Unwanted contact can be appearing in places the victim is expected, approaching the victim, following the victim, maintaining surveillance, and visiting the victim's home, family, or friends. Additional behaviors may include ordering goods or canceling appointments on the victim's behalf or initiating bogus legal actions. Physical assaults, property damage, and threats may accompany stalking. Approximately 80% of stalking is done by men.

**Content:** The Government of India has now introduced a new section, s354 D, in the India Penal Code, which is far more strict than that prevalent in many other parts of the world. On the first conviction, there is imprisonment (simple or rigorous) of up to three years and a fine (any amount.) On the second or subsequent conviction, there is imprisonment (simple or rigorous) of up to five years and a fine (any amount). The law against stalking in India and some recent case studies will be discussed. This law will be compared and contrasted with those in other parts of the world. Sometimes stalking is followed by rape, sexual assault, and/or murder. If these crimes are committed, more sections of law are attracted, and the entire crime becomes more complex. In India, it is seen that victim responses, although quite normal, may inadvertently elevate risk. A victim may respond aggressively or disrespectfully to an obsessional follower out of frustration or fear, unintentionally wounding the subject's fragile ego. Victims may fail to take the safety suggestions of law enforcement and demonstrate a lack of security consciousness. Forensic counselors are now advising victims of stalking not to respond aggressively or disrespectfully. This is one of the measures suggested to attendees, so they can provide this type of counseling in their own countries.

### Abnormal Sexuality, Stalking, Sex Crimes

### F49 Law N. 24 of March 2017 and the Italian National System of Guidelines (SNLG): Bureaucratization of Medicine in the Name of Security of Care or a Spending Review?

*Federico Patanè, MD\*, Catania 95123, ITALY; Massimiliano Esposito, MD, University of Catania, Catania 95123, ITALY; Martina Fichera, MD, University of Catania, Catania 95123, ITALY; Pasquale Malandrino, MD, University of Catania, Catania 95123, ITALY; Orazio Cascio, MD, University of Catania, Catania, ITALY; Monica Salerno, MD, PhD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Cristoforo Pomara, MD, PhD\*, Catania, ITALY*

**Learning Overview:** The purpose of this study is to review the clinical and judicial implications after the approval of Italian law N. 24 from March 24, 2017.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to the fact that any attempt to bureaucratize medicine could lead to reduced trials, but also to worse treatments, slowing down scientific research, and relegating the medical personnel as a mere executor of guidelines without taking into consideration the specificity of each patient.

In recent decades, the medical error and the risk management action required to prevent organizational dysfunctions and litigation regarding medical malpractice (and anything else that could compromise the security of care) has increased exponentially, becoming a controversial phenomenon.

Although the first to introduce this was the English jurist Sir William Blackstone in 1768, who in his Commentaries on the Laws of England (1768) coined the term *mala praxis* (which then became malpractice) referring to medical activity, it is only from the 1980s (and almost exclusively in the United States) that the medical error and its consequences became a “problem: for medicine.

The Italian national health care system has suffered from many claims and judiciary trials against health care professionals, thus implying significant economic losses and wasting of resources.

The law N. 24 from March 24, 2017, was an attempt to address these issues, trying to limit these trials by the optimization and improvement of the quality of health care services. Furthermore, it tried to fasten the official recognition of guidelines and scientific literature and optimize the trials if the health care professional adopts these guidelines. Without the mentioned recommendations, the health professionals should adopt the best clinical practices.

The guidelines are recommendations defined by scientific evidence, with the goal of ensuring the appropriateness of a clinical choice. This is the reason it is not considered a dogmatic truth, that is an imperative one, but a conventional truth decided by a community of experts.

The new law attempts to reach these goals through the establishment of a National System of Guidelines. Any new guideline needs to be drafted by a recognized group, institution, or organization before being submitted and published on a nationwide scale. Every guideline then needs to be updated every two years. In addition, the law tries to minimize lawsuits by requiring the injured patients to attempt to reach an agreement with the medical personnel before appealing to courts.

These strategies lead to many questions and debates: Is a national overview the right approach in keeping the guidelines up to date? What if a new, better, international, and well-recognized guideline is released, but the national guideline is still obsolete and disagrees, even if only partially, with the international guidelines? Which guideline should the health care professionals follow? Why should a health care professional take the responsibility to choose the best treatment for the patient, when the guidelines approved by the Ministry of Health can relieve him from responsibility, if this could cause further damage to the patient? Do these approaches really reduce litigation?

This law, while protecting the doctor from his responsibilities, seems to institutionalize the negative phenomenon of defensive medicine in a mass effect and to create the conditions for a national “cook book medicine,” which should be considered in view of two dangerous connected scenarios. The patient could no longer be treated as such, but only because of the professional risk it represents, and the physicians/researchers could have permanent loss of any interest in research.

The debate about law N. 24 from March 24, 2017, is still open and far from reaching its conclusion.

**THIS ABSTRACT WAS NOT PRESENTED.**

## G2 Forensic Odontology Education in Indonesia

*Nurtami Soedarsono, PhD\**, Faculty of Dentistry Universitas Indonesia, Jakarta, DKI Jakarta 10430, INDONESIA; *Masniari Novita, PhD*, Faculty of Dentistry Jember University, Jember 68121, INDONESIA; *Elza I. Auerkari, PhD*, Faculty of Dentistry Universitas Indonesia, Jakarta 10430, INDONESIA

**Learning Overview:** The goal of this presentation is to describe the development of forensic odontology postgraduate education in Indonesia. After attending this presentation, attendees will understand the importance of further education in the field of forensic odontology closely linked to the enforcement of human rights and law enforcement in Indonesia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the need for the development of appropriate training modules to provide forensic odontology practitioners who are credible, experienced in the field of forensic odontology, skilled in handling cases, and able to provide expertise in a court of law. By understanding a comprehensive forensic odontology training module, it is expected that forensic odontology experts will have the ability to implement such training in the development of forensic odontology education in their respective countries.

Indonesia is an archipelago country located in the Ring of Fire at a meeting of several tectonic plates. This position makes Indonesia prone to both natural and man-made disasters. Under these conditions, Indonesia needs a large number of forensic experts, including forensic odontology experts. The role of a dentist becomes important as a first-responder resource as well as forensic expert.

The first postgraduate forensic odontology program in Indonesia was established in 2012. This master's program is designed to: (1) provide students with a general view of forensic pathology and a broad knowledge of forensic odontology; (2) develop students' analytical ability by conducting research in forensic odontology; (3) create professionalism in the field of forensic odontology; and (4) prepare students to pursue careers related to forensic science and have a good networking forensic organization. Lectures, laboratory exercises, and research are delivered to complete this program. In 2015, the Indonesian Dental Association established a forensic odontology college, mandated to formulate a specialist curriculum in the field of forensic odontology. This specialist program differs from a master's program, with an emphasis on students' skill development in forensic odontology. This program aims to: (1) provide students with a broad knowledge of forensic odontology; (2) train and develop students' skill in technical procedures of forensic odontology; (3) involve students and develop their skills in collaborative forensic investigations; (4) create professionalism in the field of forensic odontology; and (5) encourage students' involvement in national/international forensic organization networking. This specialized course is implemented through lectures, laboratory and clinical trainings, and casework. Collaboration with experts in the field of forensic pathology is indispensable in the forensic odontology postgraduate programs. Additionally, a collaboration with the police, disaster management agencies, and other relevant parties can support this quality education and provide students the best training.

### Forensic Odontology, Postgraduate Program, Training Modules

### G3 A Review of the Published Research on the Use of Overlays for the Analysis of Bitemarks in Skin

John P. Demas, DDS\*, Brooklyn, NY 11209

**Learning Overview:** After attending this presentation, attendees will understand the published research to date relating to the ability of the forensic odontologist to accurately interpret bitemarks on skin in regard to their source and the scientific support for said interpretation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing the discussion of the use of bitemark analysis in the courts.

The hypothesis that human or animal dentitions can leave identifiable patterned impressions on skin (human or otherwise) after having bitten said substrate seems intuitive. The underlying assumption is that individual dentitions are just that—unique. For the purposes of this presentation, that assumption will be a given, as this presentation will not discuss the literature in support or opposed to the unique nature of dentitions but will simply stipulate that human dentitions are unique.

Carrying the hypothesis one step further, it had been put forth that one could identify the originator of a bitemark (the biter) via analysis of the shape and pattern of the mark and comparison with overlays of dentitions of the individuals who may have made the mark.

Research to investigate this hypothesis was undertaken in the 1970s, then after a nearly two-decade hiatus, research began again in the 2000s. In the intervening years, most of the published articles referencing bitemarks dealt with individual cases or an odontologist's preferred methodology rather than an exploration of the validity of the hypothesis or the faithfulness or reliability of skin (human or porcine) as a recording medium. This change of focus may have been due to the notoriety afforded odontologists after the Ted Bundy conviction and/or the enthusiasm with which bitemark analysis was embraced by law enforcement in this country.

This presentation will offer a summary of the research performed, the conclusions, and the recommendations of this study.

The 2009 publication of the National Academy of Sciences Report, *Strengthening Forensic Science in The United States, A Path Forward*, noted in the Summary Assessment of bitemark analysis that: "Although the majority of forensic odontologists are satisfied that bitemarks can demonstrate sufficient detail for positive identification, no scientific studies support this assessment, and no large population studies have been conducted. In numerous instances, experts diverge widely in their evaluations of the same bitemark evidence, which has led to questioning of the value and scientific objectivity of such evidence ... the committee received no evidence of an existing scientific basis for identifying an individual to the exclusion of all others. That same finding was reported in a 2001 review, which 'revealed a lack of valid evidence to support many of the assumptions made by forensic dentists during bitemark comparisons.' Some research is warranted to identify the circumstances within which the methods of forensic odontology can provide probative value."<sup>1</sup>

In addition to reviewing the above-captioned research, this presentation will touch upon the topic of wrongful convictions and why they may have occurred, and an alternative path forward will be offered.

**Bitemark Research, Hollow Volume Overlays, Wrongful Conviction**

## G4 Bitemark Moratorium Part 1: Past Culture and Present Thinking

Cynthia Brzozowski, DMD\*, Sea Cliff, NY 11579; Robert E. Wood, DDS, PhD, Ontario Forensic Pathology Service, Toronto, ON M5G 2M9, CANADA; Franklin D. Wright, DMD\*, Hamilton County Coroner's Office, Cincinnati, OH 45230

**Learning Overview:** After attending this presentation, attendees will understand: (1) the failures of bitemark evidence in some of the wrongful conviction cases in the United States, (2) the recommendations made by the Texas Forensic Science Commission, (3) the current scientific research, and (4) a potential outline for empirical bitemark studies as a path forward.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that the culture and evolution of bitemark thinking has changed greatly since the publication of the National Academy of Sciences Report in 2009 and that the research to support more current bitemark guidelines remains absent.<sup>1</sup> This presentation will illustrate the fundamental issues of bitemarks that require scientific validity and, potentially, how this may be accomplished.

The “comparison sciences”—forensic feature comparison methods in criminal cases in the United States—have come under increased scrutiny and pressure from both the scientific and legal communities. In large part, this is due to the lack of a scientific underpinning, examiner reliability, and validation. Bitemarks are included in the category of subjective feature comparison methods that are based on examiner interpretation and experience. Three independent scientific panels—the National Academy of Sciences (NAS), the President’s Council of Advisors on Science and Technology (PCAST), and the Texas Forensic Science Commission (TFSC)—have all concluded that there are no scientific studies that validate examiner reliability or establish accuracy of bitemark analysis and comparison methods.<sup>1-3</sup> Proficiency testing is essential for all fields of forensic science, yet remain absent in bitemark analysis and comparison methodology. Calculation of an error rate is essential for assessing probative evidentiary forensic value in criminal cases in which an individual’s life, placement of minor children, and liberty is at stake.

In April 2016, after a six-month investigation by the TFSC, the panelist of scientists and attorneys recommended a moratorium on bitemarks in criminal cases in the state of Texas pending further research demonstrating sufficient examiner reliability and validity. The commission’s decision was a result of a comprehensive review of the past and current bitemark literature as well as testimony heard from several American Board of Forensic Odontology (ABFO) Diplomates and others within the scientific community. The shockingly poor results of one study constructed to examine the most basic aspect of bitemarks and to assess levels of agreement in determining if patterned injuries in skin were made by teeth or not captured the attention of the Commission. If there are not reliable criteria to define a pattern injury as a bitemark, then trying to analyze and compare the pattern to suspect dentitions cannot be scientifically supported.

The number of wrongful convictions and indictments based on bitemark evidence in the United States currently stands at 31. Some believe the ABFO has addressed the underlying failures of these cases by changing their standards and guidelines accordingly. This may be a good first step. However, in a recent 2018 editorial in the *Journal of Pathology and Medicine*, several authors wrote: “Understanding the causes and attempting to clarify where, how, and why the wrongful convictions occurred is necessary to be able to take measures to reduce the likelihood of such failures from happening again.”<sup>4</sup> This is a worthy goal that can only be partially fulfilled by looking backward at errant cases. The NAS Report and the independent scientific panels have said that there needs to be scientific data to support the recognition, analysis, and, where appropriate, comparison of bitemark patterns’ attribution to suspect dentitions.

This presentation will address some of the bitemark evidence and expert testimony in four recent wrongful convictions, review the current status of bitemark methodology, and outline a potential science-based path forward.

### Bitemark, Moratorium, Wrongful Convictions

## G5 Bitemark Moratorium Part 2: Moving Forward

Cynthia Brzozowski, DMD, Sea Cliff, NY 11579; Robert E. Wood, DDS, PhD\*, Ontario Forensic Pathology Service, Toronto, ON M5G 2M9, CANADA; Franklin D. Wright, DMD, Hamilton County Coroner's Office, Cincinnati, OH 45230

**Learning Overview:** After attending this presentation, attendees will better understand the current status of bitemark methodology and a potential outline for empirical studies as a path forward.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the fundamental issues of bitemarks that require scientific validation via research. Until and unless proven methods in bitemark identification, analysis, and comparison can be scientifically established, a moratorium on the use of bitemark evidence in criminal cases should be in place.

Guidelines and standards established in the 1970s by the American Board of Forensic Odontology were based on the experience, knowledge, and training of the bitemark examiners. While the language and terminology has evolved over time, a scientific underpinning of the methods used in bitemark pattern identification, analysis, and comparison still do not exist.<sup>1-3</sup> When the Federal Rules of Evidence adopted the *Daubert* Standard, bitemark evidence grandfathered in by historically being recognized as generally accepted by past court rulings as precedent. In today's environment, "generally accepted" evidence based on "experience, knowledge, and training" is no longer acceptable without a quantitative empirical scientific underpinning. Past wrongful convictions and indictments in the United States, Canada, the United Kingdom, and other countries have shown that opinions of even the most experienced forensic dentists are fallible.

A bitemark literature search from 1966 to 2006 revealed that only 15% of all published papers were empirical studies. The vast majority were case reports of human bitemarks.<sup>4</sup> Previous empirical studies conducted to assess error rates in bitemark analysis using porcine skin have problems with scientific external validity.<sup>5,6</sup> Only a few studies have been conducted using "real-life" bitemarks to assess levels of expert training on interpretation of bitemarks and comparisons to a dentition.<sup>7-11</sup> Though the level of disagreement among forensic dental experts is troublesome, some studies show that expert disagreement is related to the quality of the evidence.<sup>12</sup> Each research study has its flaws, but to be able to move forward, the following basic questions need to be answered: (1) Can a pattern injury be reliably determined to be a bitemark or not?; (2) How does one determine whether a purported bitemark possesses sufficient evidentiary value to warrant further investigation or comparison?; and (3) Can a given dentition be excluded or not excluded as having made the bitemark?

This presentation will highlight a path forward for proposed studies whose goal is to provide a framework that may or may not establish justification for the recognition of bitemark patterns, their analysis and, where appropriate, comparison to suspect biters. Lacking this scientific underpinning, bitemark pattern injury attribution to a suspect should not be introduced as evidence in criminal cases going forward and even bitemark recognition should be undertaken with caution.

### Bitemark, Moratorium, Empirical Studies

## G6 What We Can Learn From Cadaver, Volunteer, or Actual Case Material in the Analysis of Bitemark Evidence Using the Full Spectrum of Photographic Techniques

Richard R. Souviron, DDS\*, Coral Gables, FL 33134

**Learning Overview:** After attending this presentation, attendees will learn the value of different modalities of experimentally produced bitemarks, the analysis of each type of experimental bitemark, and its value when applied to “real-life” cases. The full spectrum of forensic photographic techniques will be shown and their advantages for use in real-life bitemark analysis.<sup>2-4,5-7</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the full spectrum of forensic photographic techniques and their advantages for use in real-life bitemark analysis.

The limitations of laboratory bitemark research techniques vis-a-vis actual case material will provide some useful objective evidence for practical application. When applying the different forensic photographic techniques to the laboratory-produced bitemarks and evaluating the results, one will learn the value of each of these techniques.<sup>1,7,6</sup> Then, when applying these results to actual bitemark cases, there should be improvement in the final analytical results.

To date, laboratory research with bitemarks has been limited to producing bitemarks on cadavers, anesthetized fetal pigs, and live human volunteers. This has been done with plastic teeth mounted on a mechanical device (vice grips) using hand/arm pressure with a vertical closure on a non-moving subject. In all this research, there is no movement on the part of the subject, real teeth are not used, and the muscles of mastication are only approximated. These experiments, although providing some valuable information, are not a real-life duplication of bitemarks inflicted by the victim on the attacker or by the attacker on the victim.

The results of laboratory bitemark research can be augmented by using ultraviolet light, Alternate Light Source (ALS), in addition to ambient light for the enhancement of surface detail and Infrared (IR) light to help analyze wound depth.<sup>2-4,6</sup>

The basic information from laboratory-produced bitemarks on cadavers, fetal pigs, and human volunteers, along with the full-spectrum forensic photographic techniques, when applied to real-life bitemark cases, should produce increased accuracy and be based on some degree of scientific research.<sup>1,4,5</sup>

The analysis of real-life bitemarks in human flesh may produce valuable information for the authorities in the pursuit of justice. The comparison of the suspected biter’s teeth to the bitemark left on the victim should be tempered with the many variables that occur in the actual situation.<sup>1,2,5,7</sup> The distortion that occurs due to many various factors, such as the movement of both parties, the elasticity of the skin in the area bitten, and the amount of tissue bitten.

The one constant in bitemarks is that the DNA of the biter may be obtained. In many cases, this can make an identification or an exclusion to a reasonable degree of certainty. However, the analysis of the pattern injury can provide useful information not only for exclusion or inclusion of the biter, but other information, such as position of the biter, adult versus child, age of the bite in relation to time of death, etc. The addition of forensic photographic techniques can enhance such an analysis.<sup>3,5-7</sup>

### Reflective Ultraviolet, Analysis, Comparison

## G7 A Bitemark Case

*John Berketa, PhD\*, University of Adelaide, Norwood, South Australia 5067, AUSTRALIA*

---

**Learning Overview:** After attending this presentation, attendees will gain an appreciation that, in carefully selected cases, bitemark analysis may still play a role in bringing justice and allow some sort of closure to the relatives of victims.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by balancing recent media and board announcements regarding bitemark analysis that proved to be useful.

Cases involving bitemark analysis have lately been embroiled in controversy. The 2009 Report from the National Academy of Sciences and the President's Council of Advisors on Science and Technology (PCAST) have been scathing in the conclusions reached from poor bitemark evidence presented to courts of law. Following DNA evidence and work by the Innocence Project in the United States, people wrongly convicted have been rightly released. More recently, the Texas Forensic Science Commission suggested the halting of bitemark evidence until more scientific proof is provided.

A case involving the homicide of a young female victim will be presented, including the scenario at the scene, the initial investigations taken, the preliminary report, and the analysis of the images. Following queries from the police, further investigations undertaken that could possibly assist jurors in understanding the dynamics of the case will also be presented. The final report with the conclusions given will also be presented.

The outcome of this case led to the conviction of the suspect in which DNA evidence was restricted due to the accused proactively destroying evidence that could have produced samples and a delay in the discovery of the body. The accused received a life sentence with a minimum 25-year non-parole period. The absence of bitemark evidence in this case would have most likely allowed the dismissal of the charges against the accused.

The clear majority of possible bitemark evidence presented to odontologists is of poor quality for an analysis to be undertaken. The pressure exerted on forensic odontologists from legal authorities to analyze these possible injuries may be great and, together with emotional bias, may lead to a situation in which the conclusions are overstated. Poor evidence should not be accepted and stated as such in a preliminary report. However, if the evidence is suitable in quality to be investigated, and appropriate legal procedures followed, it would seem to be a miscarriage of justice not to present the evidence to the court.

---

### **Bitemark, Analysis, Conviction**

### G8 From Gerontophilia to Fruit Biting: A Series of Bitemark Cases in Hungary

*Armin A. Farid, DMD\*, Budapest 1067, HUNGARY*

---

**Learning Overview:** After attending this presentation, attendees will understand that bitemarks are found in certain rare cases and continue to provide reliable additional evidence in crimes involving murder, rape, abuse, and even burglary.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how biting occurs in every country. Public awareness, through the help of the mass media and continued education of first responders to recognize bitemarks, helps to bring to light these patterned injuries that assist as auxiliary evidence to solve a criminal act.

In addition to its long history in educational and theoretical fields in Hungary, human bitemark analysis is becoming ever more integrated into police investigation work today. Since 2008, continuous media campaigns and educational programs put into place for training Hungarian crime scene technicians have helped raise awareness of the importance of bitemark analysis among the police as well as the general public, resulting in the reporting of several bitemark cases within a short period of time. Nearly all private and public television channels have covered reports and documentaries on bitemarks, their analysis, and the implications in solving criminal cases, thus educating the public of their value in proving a suspect's guilt or innocence.

A recent murder case in the north of Hungary was of particular interest, as it involved the rape and murder of a 75-year-old woman by a 25-year-old man, who bit the victim's right breast, leaving a deep bitemark, which was only discovered during autopsy as the victim was presumed to have died of natural causes at home. While the investigation of this case was at full speed, in another town in central Hungary, a series of burglaries were investigated, resulting in the finding of a bitten apple at one crime scene and a bitten pear at another crime scene.

This study seeks to prove that the act of biting exists in every country. The importance of safeguarding accurate forensic evidence goes hand-in-hand with honesty and the dedication of experts who engage in the admirable work of public service in upholding the highest standards of ethics, truth, and justice.

### **G9 The Impact of the First International Forensic Odontology in Human Rights Workshop in the United Arab Emirates**

*Salem Altalie, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES; Emilio Nuzzolese, PhD\*, Dental Team DVI Italia, Bari 70124, ITALY; Joe Adserias-Garriga, DDS, PhD, Texas State University, Forensic Anthro Dept, San Marcos, TX; Alexander S. Forrest, MDS, Griffith University Nathan Campus, Nathan, Queensland 4111, AUSTRALIA*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the forensic odontologist's role in human rights, as well as the critical part of restoring human identity and dignity to unidentified human remains using dental information.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as an example of how to increase awareness of humanitarian forensic odontology.

A forensic odontology workshop was held at a forensic science conference in November 2017 at Abu Dhabi, United Arab Emirates (UAE). The conference focused on the latest innovations and challenges facing the forensic science community. The full-day workshop in forensic odontology was offered for the first time in the UAE by four international experts. It was organized by the Medical Examiner Office of Abu Dhabi Police in partnership with Forensic Odontology for Human Rights (FOD4HR). FOD4HR is an international, non-governmental group with more than 100 experts in forensic odontology that promotes best practice in human identification and human rights protection.

The topics covered for this study were age estimation, dental identification, anthropology comparison, and pattern injuries analysis and concluded with a panel discussion session. The workshop was designed to be theoretical through the examination and interpretation of reported cases. In addition, there were hands-on exercises to enhance skills and encourage the exchange of participants' experiences.

To assess the impact of the forensic odontology workshop, statistical analysis was based on a questionnaire completed by attendees to evaluate the effectiveness of the workshop. Only 12 participants were selected, out of 22, who work in the police force in the training department of Abu Dhabi Police. The demographics of attendees were nine general dentists, eight forensic scientists, three dental students, and two disaster victim managers.

As a result, there was a significant increase in the level of workshop learning objectives in knowledge, skills, and behavior by overall 41.14%, which increased from pre-workshop 32.81% to 73.95% post-workshop. The statistical results of the questionnaire revealed 94.44% participation satisfaction on the efficacies of the lecturers. In addition, 93.76% of the ability to execute the specific session on the topics were discussed.

In conclusion, the workshop revealed an overall of 93.75% impact on attendees. Furthermore, requests were made to broaden the scope of the topics discussed in forensic odontology, such as the role of odontology in migration and human trafficking. Forensic odontology can be a powerful resource for human rights anywhere in the world, which encourages the continual effort to conduct future humanitarian forensic odontology workshops.

**THIS ABSTRACT WAS NOT PRESENTED.**

## G11 Profiling an Unknown Castaway: “The Philly Cocoa Man”

John B. Nase, DDS\*, Dental Forensic Services of Indian Valley, Harleysville, PA 19438

**Learning Overview:** After attending this presentation, attendees will be able to outline how dental adult age assessment and georeferencing through chemical and elemental isotope analysis contribute to an unknown victim profile.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing how emerging anthropological isotope science can be used alongside time-tested dental age estimation techniques in some unknown decedent cases.

On May 11, 2015, the container ship *Sian-C* transporting cocoa beans from Côte d’Ivoire (Ivory Coast, Africa) docked in the Port of Philadelphia, PA. An unidentified black male was discovered in the cargo hold by United States customs during inspection and fumigation. Foodstuffs, water, and a set of clothing were adjacent to the body. No forms of identification were found within the cargo hold, and personal effects were limited to a jumpsuit and non-descript metal rings. Fingerprint processing was completed and run through both the Integrated Automated Fingerprint Identification System (IAFIS) and United States Homeland Security databases for undocumented workers, terrorist watch lists, and foreign nationals with no hits. The National Missing and Unidentified Persons System (NAMUS) submission has not produced a positive match to date.

The dental examination revealed no restorations or untreated gross decay. However, maxillary and mandibular acrylic, removable partial dentures were found. The results of three adult age estimation methods were in accordance with one another. Method 1, the Kvaal 1995 study, determined the decedent’s age as 26.57 years with a standard error of estimation of 8.6 years.<sup>1</sup> Method 2, the Cameriere 2007 study, determined the decedent’s age as 24.95 years with a standard error of estimation of 3.62 years.<sup>2</sup> Method 3, the Bang and Ramm 1970 study, determined the decedent’s age as 33.48 years with a 95% confidence interval of 9.46 years.<sup>3</sup>

A comparison of the isotope ratios of enamel verses bone samples can yield patterns of migration when an individual moves from one geographic region to another region through their lifetime.<sup>4-8</sup> This analysis was undertaken to confirm that the decedent was likely from the ship’s port of departure, to rule out the possibility that he gained access to the ship’s hold while in Philadelphia and further define his places of residence. Samples of teeth, mandibular bone, and rib were collected for georeferencing.<sup>9,10</sup> Both stable and heavy isotope analyses were completed for the following elements: Carbon ( $\delta^{13}C$ ), Oxygen ( $\delta^{18}O$ ), Strontium ( $^{87}Sr/^{86}Sr$ ), and Lead ( $^{206}Pb/^{204}Pb$ ,  $^{207}Pb/^{204}Pb$ ,  $^{208}Pb/^{204}Pb$ ).<sup>11,12</sup> The chemical and elemental isotope testing indicates the decedent was likely born outside of the United States. The enamel and bone data are consistent with an origin of birth in the African continent, as well as living in Africa the last several years of life.<sup>13</sup> When the strontium and lead isotope values are plotted on a bivariate graph, they fall closest to the known range of values from Nigerian enamel samples in comparison to data from the United States and Europe.<sup>14</sup> The  $\delta^{18}O$  values for the bone sample also fall within the West African region. Additionally, the  $\delta^{13}C$  values for decedent USF17-041C are consistent with the mixed C3 and C4 food crops found within West Africa. Overall, the findings are consistent with origin in West Africa, which includes Côte d’Ivoire and other countries in the region.<sup>15</sup>

A victim profile was compiled that consisted of reconstructive facial drawings, sketches of several tattoos found on the body, an anthropological examination, the dental age assessment, and isotope analysis results.

In conclusion, this case shows a multi-modal victim profile generated utilizing several technologies and forensic specialties.

### G12 When a 70-Year-Old Mummified Baby Falls on Your Head: Collaboration in a Multidisciplinary Team

*Corinne D'Anjou, DMD\*, LSJML, Saint-Lambert, PQ J4P1Y2, CANADA; Caroline Tanguay, MD\*, Montreal, PQ H2K 3S7, CANADA*

**Learning Overview:** After attending this presentation, attendees will understand the importance of a multidisciplinary team approach in an unusual medicolegal death investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how experts from multiple disciplines can work together, each bringing their own experience and expertise, in a team approach to efficiently dissect the evidence in a unique and challenging case.

The case began with the discovery of human remains during a remodel of the basement of a century-old house in Westmount, Quebec, Canada. The remains, wrapped in journal paper, appeared to be of a very young child or fetus. They consisted of an almost complete mummified fetus, still in a fetal position with its arms flexed and the lower limbs folded over the trunk and crossed.

Following an anthropological consultation, the lower limbs were moved, which exposed a portion of the umbilical cord. In the absence of internal organs and biological environment, the umbilical cord specimen, along with the right humerus and left femur, were submitted to the forensic biology section of the Laboratoire de Sciences Judiciaires et de Médecine Légale to be analyzed and potentially provide a biological profile to aid with the investigation. The fetus presented no evidence of traumatic injury.

Determining the gestational age of the remains and finding any other evidence that could lead to valuable clues as to the nature of the death and origin of the remains were critical to the investigators.

A forensic document specialist examined the several newspapers that were found with the remains to help determine a possible timeline surrounding the events. A daily schedule of a film that was originally released in 1948 was found within the newspapers. This discovery led the investigators to meet with a lady, now 78 years old, who lived in the house during that time. From interviewing her, they were able to get a better understanding of who inhabited the house around that time. Given the Hollywood-like history of the household and the multiple possibilities of parenthood, she agreed to provide a DNA sample to allow a comparison with the remains.

Forensic pathologists, anthropologists, and odontologists examined the remains visually and radiographically to provide an estimated gestational age utilizing various techniques, from the osseous centers in the hands and feet to the developing primary dentition.

In conclusion, with the multidisciplinary approach involving forensic pathologists, anthropologists, biologists, odontologists, and document specialists, the discovered remains were thoroughly examined, and an estimated age and DNA profile were provided to the investigators to help determine the origin, timeline, and circumstances surrounding the discovery of the mummified remains.

### G13 Fetal Maceration and Dental Age

Mark W. Crumpton, DMD\*, Maryville, TN 37803; James M. Lewis, DMD, Madison, AL 35758; Darinka Mileusnic, PhD, MD, Regional Forensic Center, Knoxville, TN 37920; Murray K. Marks, PhD, University of Tennessee, Knoxville, TN 37920

**Learning Overview:** The goal of this presentation is to demonstrate fresh and decomposed fetal maceration techniques, tooth bud dissection from jaws, and age assessment from a dissected specimen using published standards.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating a methodology for recognizing, harvesting, and reporting on crown and root growth for age assessment in fetal viability.

This presentation provides traditional and expedited instructions for processing fetal remains, especially the oro-facial elements, to perform assessment of dental age. Because of their rare occurrence, the discovery of fresh, decomposing, disfigured, or skeletal fetal remains engenders a heightened awareness by the forensic pathologist primarily concerned with age in relation to viability. With decomposed, mutilated, or isolated remains, the anthropologist can assess “human” or “non-human” and will focus on long bone measurements and other skeletal maturity indicators to help assess age. Crucial for the pathologist: “Is this fetus beyond the age of viability and how long will it take to obtain an age assessment?” Equal to sub-adult remains, dental development is the most precise means of age assessment in the fetal skeleton. Dental age assessment involves: (1) dissection and maceration of soft tissues, (2) recognition of craniofacial bones and partially mineralized crowns in decomposing remains, and (3) excision and preservation of tooth buds for metric analysis.

Twelve fetuses ranging in age from 18 to 39 weeks were dissected and macerated using low power dissecting microscopy, magnifying loops, and lenses for limb, torso, and head removal. Parts were placed in glass jars with distilled water that was changed monthly. There was no heat or chemical treatment, which can compromise the structural integrity of the initial fragile mineralized tissues. Sloughed-off soft tissue was removed during decomposition by pouring off the water through a 14- and 18-gauge sieve. Cartilaginous epiphyses enlarge and separate easily from the metaphyses. Skull bones gradually separate along fontanelles. Extraction and wet preservation of tooth buds may be performed anytime during the soft tissue sloughing process. The dentoenamel junction separates easily and particular care is required to identify and retain the dentin. Teasing the crown out of the follicle is easier earlier in the decomposition process prior to later expansion of the follicle. Later, tooth buds may slough off with gingival tissue making identification more challenging. Dissolving fetal soft tissues is best achieved in the distilled water solution with complete skeletalization of a fresh fetus in four months. Sunlight exposure did not appreciably increase decomposition time. Decomposed “wet” remains are easier to dissect compared to desiccated remains that require extensive and careful dissection. Desiccated jaws and tooth buds need hydration to enlarge and loosen from hydrated alveolar bone. While any alcohol solution should be avoided because of tissue distortion, formalin submersion of the tooth buds will enhance preservation, though may render the follicle more tenacious to dissect. Kraus and Jordan age-assessed the largest sample of fetal deciduous teeth and that standard is still valuable today.<sup>1</sup> Partial to completely mineralized crowns, especially molars, are well-correlated to gestational age. Regardless of the condition of the jaws, a dissecting microscope, magnifying loops, lenses, and a good light source are used in combination to allow the dentist to perform the oral autopsy in a timely manner to provide the forensic pathologist an estimation of age.

## G14 The Effects of Third Molar Impaction Parameters on Third Molar Development and Related Age Estimation

Rosalina Intan Saputri, DDS, MSc\*, Department of Imaging & Pathology, KU Leuven, Leuven, Vlaams-Brabant 3000, BELGIUM; Jannick De Tobel, MD, Ghent University, Department of Radiology, Gent, Oost-Vlaanderen 9000, BELGIUM; Patrick W. Thevissen, PhD, KU Leuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand how third molar impaction parameters affect third molar development and related age estimations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing proof that third molar impaction parameters have a clinically small effect on third molar development. This implies that in forensic practice, no distinction is necessary between impacted and non-impacted third molars for age estimation.

Third molar development is used to estimate age in subadults. However, the incidence of third molar impaction is high.<sup>1</sup> If third molars are impacted, their development may be affected, and it may have consequences for the performed age estimations.<sup>2</sup>

The goal of the current study was to evaluate the effect of third molar impaction parameters on third molar development and related age estimations. Parameters, such as contact between third and corresponding second molar, retro-molar space availability, and angulations between third and corresponding second molar, were examined on 5,279 panoramic radiographs. The radiographs were selected from 1,031 subjects (473 male, 558 female) with ages ranging between 3.2 and 23.5 years old. Based on the measured status of contact and angulations between third and corresponding second molar, an impaction status was assigned. All present third molars were staged according to the Köhler et al. staging technique.<sup>3</sup> A linear model was used to evaluate the difference in age between third molars with and without impaction. The model contained fixed effects of impaction (no/yes), stage, and sex. The same model was used to compare age as a function of contact between third and corresponding second molar and retro-molar space availability. For angulations between third and corresponding second molars, a quadratic function was used to describe the relation with age. The model has been fit separately for each third molar position. Significant differences were found in mean age as a function of presence of contact between third and corresponding second molar and retro-molar space availability, depending on third molar position and on stage. There was a significant linear relation between angulations and age, depending on stage. An impaction status was assigned to third molars in contact with the corresponding second molar and with angles between third and second molar  $< -22^\circ$  or  $> 18^\circ$  for the upper third molars and  $< -17^\circ$  or  $> 12^\circ$  for the lower third molars. There was a significant difference in age between impacted and non-impacted third molars. However, all the differences were clinically small ( $\leq 0.65$  years) and, for each third molar, the overall age of third molars with impaction was younger than third molars without impaction. Therefore, impacted third molars can be examined for age estimation purposes equally as non-impacted third molars.

### Forensic Odontology, Dental Age Estimation, Third Molar Impaction

## G15 Age Estimation in Children and Subadults Combining Ratios of Pulp and Tooth Area With Tooth Development

Manasa Ravoori, BDS\*, KULeuven, Leuven B3000, BELGIUM; Jannick De Tobel, MD, Ghent University, Department of Radiology, Gent, Oost-Vlaanderen 9000, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand why adding pulp and tooth ratios to tooth development on panoramic radiographs is of limited value for age estimation in children and subadults.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing why adding pulp and tooth ratios to tooth development on panoramic radiographs is of limited value for age estimation in children and subadults.

**Introduction:** Dental age estimation methods are mainly based on tooth development or on morphological changes observed in teeth.<sup>1</sup> In children and subadults, certain teeth are mature and start forming secondary dentin. Combining the age-related information of these secondary dentin formations and tooth development may improve the age prediction performances in children and subadults.

**Goal:** To detect if, in children and subadults, secondary dentin formation provides added age prediction information to tooth development.

**Materials and Methods:** Retrospectively panoramic radiographs of 453 subjects (228 females and 225 males) in the age range between 8 and 25 years were selected. The radiographs were imported in image-ameliorating software (Adobe® Photoshop®) to measure the pulp and tooth areas in the crown and the crown plus root portion of teeth 33 and 36 (Fédération Dentaire Internationale (FDI) nomenclature). For both teeth, the respective ratio between pulp and tooth area in the Crown (CR) and the Crown plus Root portion (CRR) were calculated. The development of the lower left seven permanent teeth and all present third molars were staged according to the Demirjian et al. and the Köhler et al. staging technique, respectively.<sup>2,3</sup> Within the group of children, it was verified for each of the ratios separately whether they contribute additional information to the age estimation based on the Willems et al. age estimation method.<sup>4</sup> To this purpose, a regression model for age was used with the prediction based on the Willems et al. method and the ratio as predictors. To evaluate the total dataset, the added value of the ratio information to the Kohler staging a similar approach was used. The age estimation based on the Kohler stages of the third molars was obtained applying Bayes rule with a multivariate continuation-ratio model as conditional distribution.<sup>5</sup> To quantify the age prediction performances of the models, the Mean Error (ME), Mean Absolute Error (MAE), and Root Mean Squared Error (RMSE) were calculated.

**Results:** Within the group of children, the CRR in tooth 36 significantly added information to the Willems et al. method, for males ( $p=0.0073$ ) as well as for females ( $p=0.0002$ ). However, the improvement in MAE was small and not significant (decrease in MAE=0.032 years (SD=0.303),  $p=0.09$ ). The CR for tooth 36 added significant information to the Willems et al. method within females, but the change in MAE was not significant. Neither for the CRR, nor the CR measured in tooth 33, was there any evidence that they contributed information to the Willems et al. method.

Neither for the CRR, nor the CR measured in tooth 36, was there evidence that they added information to the Kohler et al. stages. Only for males was the addition of the CRR significant, but this was not reflected in a significant decrease of the MAE. The MAE was significantly higher (but small) when adding the ratio information for females. Neither for the CRR, nor the CR measured in tooth 33, was there any evidence that they added information to the Kohler et al. stages.

**Conclusion:** On panoramic radiographs in children and subadults, pulp and tooth ratios were used as a measure of secondary dentin formation, but they did not provide added age prediction information to tooth development.

### Forensic Odontology, Dental Age Estimation, Tooth-Pulp Area Ratios

## G16 The Influence of Lower Third Molar Segmentations on Automated Tooth Development Staging Using a Convolutional Neural Network Approach

Rizky Merdietio Boedi, MSc\*, KULeuven, Leuven B3000, BELGIUM; Nikolay Banar, MSc, KULeuven, Leuven B3000, BELGIUM; Jannick De Tobel, MD, Ghent University, Department of Radiology, Gent, Oost-Vlaanderen 9000, BELGIUM; Jeroen Bertels, Wilsele, Vlaams-Brabant 3012, BELGIUM; Dirk Vandermeulen, PhD, KULeuven, Leuven B3000, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand how segmenting the lower third molar on panoramic radiographs affects automated stage allocation performance for age estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the consecutive steps needed in an automated age estimation procedure based on third molar development. In particular, the choice of an optimal tooth segmentation technique will be discussed.

**Introduction:** In an automated age estimation method based on third molar development, an automated developmental stage allocation technique can be integrated. De Tobel et al. established a pilot set up for such an automated technique, based on panoramic radiographs.<sup>1</sup> First, they manually selected a rectangular Region Of Interest (ROI) around the lower left third molar. Second, deep learning was used to further process the ROIs with a Convolutional Neural Network (CNN).<sup>2</sup> The network investigated a way to automatically allocate stages to the third molars. However, the used ROI contained information of surrounding anatomical structures (e.g., periodontal ligament, bony structures, inferior alveolar nerve canal). It can be assumed that segmenting only third molar information will reduce noise from these structures and will ameliorate the automated stage allocation performances.

**Goal:** To establish and validate an automated staging technique for third molar development after rough and full segmentation on panoramic radiographs.

**Materials and Methods:** Two human observers staged each lower left third molar in consensus, according to a modified Demirjian staging technique (ten stages).<sup>3</sup> A third observer acted as a referee in case of disagreement between the first observers. Per stage and per sex, 20 radiographs were included, and their stage classification acted as the gold standard. The images were imported in Adobe® Photoshop® CC 2018 and segmented using built-in tools. Three types of segmentation were processed: Box segmentation (B, similar to De Tobel et al., Rough tooth Segmentation (RS), and Full tooth Segmentation (FS).<sup>1</sup> CNN DenseNet201 from Keras API with TensorFlow backend was used for automated stage allocation in the three types of segmented images.<sup>4</sup> The automated staging was compared with the gold standard staging in general and per stage. Stage allocation performance was evaluated using a five-fold cross-validation between the automated and the gold standard stages, using 80% of the images for training and 20% for testing.

**Results:** The FS technique had the best overall results with 61% of correctly allocated stages, a mean absolute difference in stage allocation of 0.53 stages and a mean linear weighted kappa of 0.84. Per stage and for all segmentation types, the final root stages were the most difficult to distinguish from each other. The five-fold cross-tabulation indicated that misallocated stages were mostly neighboring stages.

**Conclusion:** Segmenting the third molar from the panoramic radiographs increased the overall stage allocation performance. The FS is advised to be integrated in an automated dental age estimation process.

## G17 Age and Sex Estimation of Ajnala Skeletal Remains From Trace Elemental and Radiographic Analysis of Molar Teeth: A Comparative Forensic Odontological Study

Jagmahender Singh Sehrawat, PhD\*, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA

**Learning Overview:** The goal of this presentation is to estimate sex and age of the unknown human skeletal remains excavated from an abandoned well by using the customized regression and discriminant function formulas developed from elemental composition of molars and radiographic Pulp-Tooth area Ratio (PTR) of canines of known teeth. A comparative significance of elemental and radiographic methods for sex and age estimation to add to the existing forensic anthropological literature will also be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternate combined approach for objective and reliable age estimation from dental remains, in addition to existing dental, anthropological, and biochemical methods. Both the techniques are relatively cheaper and faster, delivering comparatively reliable results with higher accuracy rates.

Teeth generally serve as repository of valuable biological information about an individual, and they can reveal information about biological identity, residential mobility patterns, dietary habits, growth and development, exposure to disease and pollutants, social and geographical status of an individual or population groups, etc.<sup>1,2</sup> Trace elements usually get deposited in human hard tissues upon their prolonged consumption in dietary intakes, which, in turn, can decode lifetime events and activities of an individual to facilitate their identification. The elemental composition of human teeth has been widely studied from medical, public health, and dietetics perspectives, but has rarely been explored for forensic anthropological purposes. The requirements and preferences of food items vary with sex, age, disease, health, and geographical status of an individual. The amount of trace elements deposited in the human hard tissues can be used as a reliable indicator of their biological identity.<sup>3,4</sup>

The goal of the present investigation is to characterize the elemental profile of contemporary human teeth from some northwest Indian states and apply the discriminant functions and regression equations developed from known teeth samples to the elemental profile of unknown ancient teeth excavated from an abandoned well situated underneath a religious structure at Ajnala, Amritsar, India. Thousands of unknown human skeletal remains (along with some contextual items) were excavated non-scientifically by amateur archaeologists from the well in early 2014, after obtaining clues from some written records in the form of a book.<sup>5,6</sup> The identity of these remains posed a serious challenge for the investigators because of their badly damaged and seriously commingled nature. Hence, multitudes of anthropological, biochemical, radiological, and molecular techniques were used with the remains to arrive at their valid objective identifications. The main objective of the present study was to reconstruct the probable biological age of the remains from elemental and radiographic analysis of known molars collected from contemporary individuals and applying the developed customized logistic regression and discriminant formulas. Four hundred eighty human molar teeth (230 contemporary and 250 ancient teeth) were used for their elemental composition using a Wavelength Dispersive X-Ray Fluorescence (WD-XRF) analyzer and 703 canines were used for radiographic Pulp-Tooth area Ratio (PTR) estimation from their apical images using Gimp software. PTR was calculated by dividing the ratio of tooth pulp chamber by its outer surface area marked using apical radiographic images of the tooth. Sex prediction was performed using tooth measurements and customized logistic regression formulas for nearly every maxilla/mandible sample. Age estimates of the remains ranged between approximately 20–50 years using both the elemental and radiographical methods. These results corroborated other methods of age estimation, including skeletal anthropological techniques and biochemical analysis. Sex assessment from odontometrics and PTR showed that approximately 90% of the samples were categorized as males.<sup>7</sup> This potentially endorsed the written record theory that these remains do indeed belong to the 1857 conflict.<sup>8</sup>

### Forensic Anthropology, Age Estimation, WD-XRF and Pulp-Tooth Area Ratio

## G18 Magnetic Resonance Imaging (MRI) of Third Molars, Clavicles, and Wrists for Age Estimation: A Combined Bayesian Approach

Jannick De Tobel, MD\*, Ghent University, Department of Radiology, Gent, Oost-Vlaanderen 9000, BELGIUM; Elke Hillewig, MSc, Universiteit Gent, Vakgroep Radiologie, Gent 9000, BELGIUM; Ines Phlypo, DDS, Universiteit Gent, Vakgroep Tandheelkunde, Gent 9000, BELGIUM; Michiel B. de Haas, BSc, Netherlands Forensic Institute, The Hague 2497 GB, NETHERLANDS; Mayonne Van Wijk, MSc, Netherlands Forensic Institute, The Hague 2497 GB, NETHERLANDS; Steffen Fieuws, Leuven, VB, BELGIUM; Koenraad L. Verstraete, PhD, Universiteit Gent, Vakgroep Radiologie, Gent 9000, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand how combining MRI of third molars, clavicles, and wrist for age estimation leads to a sounder age estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by elaborating on the emerging field of radiation-free age estimation by means of MRI. It will be demonstrated that age estimation performance increases when combined information is used, provided that an appropriate statistical approach is applied.

**Background:** Currently, forensic age estimation in living adolescents and subadults is based on radiographs and Computed Tomography (CT) imaging.<sup>1,2</sup> These techniques imply an exposure to ionizing radiation outside a medical diagnostic or therapeutic indication. Therefore, their use is prohibited in age estimation cases in several countries. Moreover, these techniques have mostly been studied applied to one anatomical structure at a time in a retrospective design. Unfortunately, to this day, we do not know how the development of different anatomical structures correlate to each other. Consequently, we do not know how to appropriately combine results from studies focusing on one structure at a time.

To counter these drawbacks of the current approach, several research groups are studying the use of MRI of different anatomical structures for age estimation in living adolescents and subadults. So far, only one group has published results of a combined MRI approach, including third molars, both clavicles, and the left wrist.<sup>3</sup> Based on deep convolutional neural networks, they obtained a mean absolute error of 1.14 years (standard deviation 0.96 years). They defined the proportion of correctly identified minors as sensitivity, which equaled 88.6%. However, they did not report how the development of the different anatomical structures correlated to each other.

**Purpose:** (1) To introduce a Bayesian approach for age estimation based on MRI of third molars, both clavicles, and the left wrist; (2) to study its age estimation performance and its ability to discern minors from adults; and (3) to study how the development of the different anatomical structures correlates to each other.

**Materials and Methods:** According to the Ghent protocols, 3-Tesla MRI was conducted of all third molars, both clavicles, and the left wrist in 302 healthy Caucasian volunteers (160 females, 142 males) between 14 and 26 years of age.<sup>4-6</sup> Images were then assessed, applying an optimal staging technique for the development of these anatomical structures, as suggested in previous papers.<sup>5,7,8</sup> Several human observers assessed the images to study reproducibility. Consequently, the data were imported into the Leuven validated Bayesian ad hoc procedure for age estimation.<sup>9</sup> This allowed defining the correlation between the different anatomical structures' development. Moreover, the Bayesian model allowed comparing age estimation performance when different combinations of anatomical structures were included in the model. Accuracy of the models was compared by calculating the Mean Absolute Errors (MAE) and Root Mean Squared Errors (RMSE). Furthermore, the width of confidence intervals and their coverage were calculated, as was the ability to discern minors from adults by comparing diagnostic statistics (sensitivity, specificity, and discrimination slope) and calculating probabilities to have reached the 18-year threshold.

**Hypothesis:** Combining the MRI information of all third molars, both clavicles, and the left wrist will render a better age estimation performance than the separate approaches in living adolescents and subadults. Since this is ongoing research, there were no results available at the time this abstract was submitted to confirm or reject the hypothesis.

### **Age Estimation, Combined Dental and Skeletal, Magnetic Resonance Imaging**

## G19 The Use of Cone Beam Computed Tomography (CBCT) to Examine the Relationship Between Mandibular Bone Density and the Disappearance of the Clarity of Root Pulp Visibility (RPV) and Periodontal Ligament Visibility (PLV)

Victoria S. Lucas, PhD\*, King's College London Dental Institute, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, London SE1 9RT, UNITED KINGDOM; Graham J. Roberts, MDS, King's College London, London SE1 9RT, UNITED KINGDOM; Mark D. Viner, MSc, Cranfield Forensic Institute, Shrivenham, Wiltshire SN6 8LA, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will be aware of the potential for CBCT to measure the dimension of bone buccal to the roots of the mature lower third molar. Attendees will be able to understand how the increase in the dimension of bone buccal to the mature third molar contributes to the gradual obliteration of both RPV and PLV.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to increased precision when estimating the probability that a subject is over 18 years old.

**Introduction:** The loss of visibility of RPV and PLV related to lower mature third molars (Demirjian Stage H) has been reported by European workers with more recent confirmation of their findings.<sup>1-4</sup> Although the Balance of Probability was 50% for civil cases in the United Kingdom, the Immigration Court is now demanding "beyond a reasonable doubt," which is 100% certainty.

It is perceived that the CBCT will offer the opportunity to measure the thickness of dentin and bone leading to loss of RPV and PLV.

**Materials and Methods:** Approval for the study was obtained from Guys and St. Thomas's NHS Trust (IRAS 231512). CBCTs and corresponding Panoramic radiographs (DPTs) were drawn from the radiographic archive. Three points were identified in the sagittal plane at the bifurcation, half way down the root and approximately 1mm up from the root apex. The view was switched to the horizontal plane and, at each of these points, the distance from the buccal pulpal wall to the buccal surface of the bony cortex was measured.

For both RPV and PLV separately, the measurements were averaged to give a single figure for the buccal bone dimensions.

### Results:

There was concordance between the Left and Right sides (Table 1)

Bone Dimension	Right			Left			t	p
	n	$\bar{x}$	sd	n	$\bar{x}$	sd		
RPV	15	8.0	0.88	18	7.85	1.24	0.3928	0.6971
PLV	15	8.7	1.19	18	8.49	1.24	0.1849	0.8545

There is no significant difference in the thickness of buccal bone between the left and right sides of the mandible;  $n=17$  for left side PLV as some measurements contributing to the average could not be made.

There were slight differences between females and males (Table 2)

Bone Dimension	Females			Males			t	p
	n	$\bar{x}$	sd	n	$\bar{x}$	sd		
RPV	16	8.01	1.14	11	8.17	0.97	0.7093	0.3547
PLV	16	8.46	1.14	11	8.09	2.55	-0.5083	0.6157

This indicates a slight trend toward slightly thinner buccal bone in females compared with males for RPV. This trend is reversed for PLV.

**Discussion:** These data confirm that the bone buccal to the lower left third molar has symmetrical growth on both the left and right sides. This is important because it has been suggested that differences in the appearance of the left and right sides of dental panoramic tomographs account for differences in RPV and PLV assessments.<sup>5</sup> It has not been possible to fully resolve this issue because in the present study, there are insufficient DPTs to match with the corresponding CBCTs of individual patients. This would be a specific topic for future work.

**Conclusions:** The important outcome is the strong similarity of the mandibular bone dimensions on the left and right sides.

The CBCT technique has shown great potential for overcoming the limitations of the DPT technique for assessing RPV and PLV of the mature third molar.

**Root Pulp Visibility (RPV), Periodontal Ligament Visibility, Bone Dimensions**

## G20 UT-Age 2018: An Updated Tool for Third Molar Development Age Assessment

Leigh-Ann Schuerman, DMD\*, Cave Creek, AZ 85327; James M. Lewis, DMD, Madison, AL 35758; David R. Senn, DDS, University of Texas HSC San Antonio, San Antonio, TX 78229-3900

**Learning Overview:** After attending this presentation, attendees will understand the advantages of using the automation, report formatting, and data storage features of a computer program for third molar age assessment cases. Updates to one such program, UT-Age, will be discussed and demonstrated.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the use of a computer program, UT-Age, to standardize, automate, and create databases for third molar age assessment cases. UT-Age 2018 now incorporates censored Stage H data, the ability to calculate probability for varying jurisdictional legal ages of majority, and now permits report editing in Microsoft® Word®.

UT-Age was originally developed in 2002 as a Microsoft® Access®-based application and database. In 2008, UT-Age was updated to a .NET Framework using Microsoft® Access® as the database. In 2018 .NET framework provides a large body of pre-coded solutions to common program requirements and manages the execution of programs written specifically for the Microsoft® operating system. UT-Age 2018 continues the use of .NET Framework and therefore is intended for use on Windows® operating systems.

UT-Age 2018 incorporates many of the same features as previous versions of UT-Age. This computer application archives data for third molar age assessment cases, cataloging the subject's case number, name, ancestry, sex, facial photographs, stated date of birth, and radiograph(s). Based on the user-entered stage of morphologic development of the third molars present, the program calculates the average mean estimated age of the individual, and the average age interval to two standard deviations. Previous versions of UT-Age calculated the average empirical probability of the individual having attained her/his 18<sup>th</sup> birthday only. However, UT-Age 2018 now allows the investigator to select the target age for which empirical probability will be calculated.

These UT-Age features can: (1) assist by providing information to those involved with human trafficking cases, (2) provide information to those charged with helping to protect juveniles in custody from being incarcerated with adults (or adults with juveniles), (3) provide information to assist with the defense of criminal and/or civil prosecution of undocumented individuals, and (4) provide information for other cases involving adolescents or young adults (with third molars) regardless of the situational or jurisdictional questioned age.

Publications and presentations, including at the American Academy of Forensic Sciences, have reported the importance of censoring the terminal morphologic developmental stage of the Demirjian staging system (Stage "H"). Censored Stage "H" data for Kasper et al., 2009; Blankenship, Lewis and Senn, 2010; and Mincer et al., 1993, has been recently published.<sup>1</sup> UT-Age 2018 includes updated statistical population data intended to improve the reliability of the reported age estimations for individuals that have third molars that have reached the terminal stage "H."

The UT-Age 2018 application will be available by February 2019 for online download on two websites: [utforensic.org](http://utforensic.org) and [gsm.utmck.edu/dentistry/fellowship.cfm#forensic](http://gsm.utmck.edu/dentistry/fellowship.cfm#forensic).

### Dental Age Assessment, UT-Age, Third Molar

## G21 The Dental Age Research London Information Group (DARLInG) Development of a Database of Dental and Related Data to Enable Logical Dental Age Estimation (DAE)

Graham J. Roberts, MDS\*, King's College London, London SE1 9RT, UNITED KINGDOM; Victoria S. Lucas, PhD, King's College London Dental Institute, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, London SE1 9RT, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand the techniques involved in developing a database for dental age estimation, and the advantages of the referential integrity a database confers by ensuring robust data output to Microsoft® Excel® and Stata statistical software. Attendees will see that the integration of the DARLInG database output with Draft Age Estimation Quick Sheets™ completes a program of innovative database and spreadsheet work that enables quick and reliable estimates of age in children, adolescents, and young adults.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the combination of the DARLInG database and the Draft Age Estimation Quicksheets™ to achieve rapid dental age estimation based on a dental panoramic tomograph.

**Introduction:** Data processing of Ages at Assessment (AaA) of Tooth Development Stages (TDS) becomes unwieldy when several thousand cases are included in the Reference Data Set (RDS). This is the main difficulty limiting numerical data management to Microsoft® Excel®. The Microsoft® Access® database overcomes this problem by enabling the use of specially fabricated forms that enables data entry in a convenient way. There are four components to the Microsoft® Access® database.

**Access Tables:** These form the principal component of the data management process. A single table for personal data is defined within the DARLInG database. This uniquely identifies every subject from whom data are derived. A feature of the database is that all the data are cross-sectional. Thus, bias from canalization does not enter the processing of dental age estimation assessments.<sup>1</sup>

The individual fields for data are defined within the table. This is important as once the data are exported for statistical analysis, the field definition is exported with it. The consequence of this is that a categorical field that defines gender must be created with this in mind, so when exported to a statistical software package, the definition of female or male is immediately apparent. Similarly, with data for ages or measurements, the fields are defined as numerical values so that statistical computations can be carried out appropriately.

Crucial to the importance of the Tables is the use of a Primary Key. In the DARLInG database, this is the field that enables the data from subjects to be uniquely and precisely linked. The field name used is "idno" (Identity Number). When data for a new subject is entered, the Primary Key definition generates a random number from -1,00,000,000 to +1,000,000,000. This ensures that the idno cannot be duplicated and is irrevocably linked to all the data for a single case. This is the principle of Referential Integrity.

**Access Forms:** These are created using the data fields present in the tables related to the database. The use of forms enables the 128 fields from the Demirjian TDS to be presented as a box matrix on one single computer screen. Thus, accurate and quick data entry are possible.

**Access Queries:** This is held in the databases and is extracted to enable meaningful data sets to be created. For example, the gender and age of a subject from one table, TDS from a separate table, and perhaps Stages of Development of the wrist bones from a third table. All of these are tightly linked by the idno, which is the primary key.

**Access Reports:** Data selected from the database are presented in an easily comprehended form. The DARLInG database does not use Reports, as the queries are exported to Microsoft® Excel® because the exported data is linked into Draft Age Estimation Quick Sheets™.

This serendipitous collaboration means that the two software-developed procedures can be used to provide immediate and reliable estimates of dental age.

To date, there are 15,411 cases in the DARLInG database utilizing information from data on Demirjian, Haavikko, and Moorrees TDS, Cervico Vertebral Maturation, root canal width, root pulp visibility, and periodontal ligament visibility, and data from hand wrist X-rays, sterno-clavicular joint radiographs, and measurements from cone beam computed tomographs.

There are Demirjian TDS data from five different ancestral groups.<sup>2</sup> This enables comparison of DAE assessments using *exactly* the same methodology.

### DARLInG, DAE Database, Dental Age Estimation

## G22 Using Photoshop® for Odontology Doesn't Have to Bite

David Witzke, BA\*, San Diego, CA 92103

**Learning Overview:** After attending this presentation, attendees will understand digital imaging concepts and how they should be applied in a forensic environment. Attendees will also gain a basic understanding of the tools available in Adobe® Photoshop®, as well as how to apply them when creating images for analysis and comparison, and how to discuss the processes in the courtroom.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the basic concepts and guidelines of digital imaging and how to ensure that those concepts are applied properly so another innocent person is not sent to jail because someone was using technology improperly.

In 1979, the Connecticut State Supreme Court was the first court to adopt ground rules for the admissibility of computer-enhanced evidence to safeguard the right of defendants to challenge its reliability in accordance with *Federal Rules of Evidence* 901.<sup>2</sup> In its 1979 ruling in *American Oil Co. v. Valenti*, the court stated that there must be "... testimony by a person with some degree of computer expertise, who has sufficient knowledge to be examined and cross-examined about the functioning of a computer."<sup>3</sup> It further stated that evidence presented using state-of-the-art computer technology must be accompanied by an expert's explanation of how the process works and must allow for cross-examination on whether the evidence was in any way manipulated or altered. The court also adopted the guidelines regarding admissibility of evidence presented via computer-based technology set forth in *Federal Rules of Evidence* 901.<sup>2</sup>

In a 2004 case, *State of Connecticut v. Alfred Swinton*, the Connecticut Supreme Court reiterated the rule that there must be "testimony by a person with some degree of computer expertise, who has sufficient knowledge to be examined and cross-examined about the functioning of the computer" but also took the opportunity to clarify its 1979 position on the guidelines set forth in *Federal Rules of Evidence* 901.<sup>4</sup>

In the Swinton case, the odontologist could not answer basic questions about the technology; he could not explain the process used for creating the overlays; and he could not answer whether Adobe® Photoshop® was used in the field by other odontologists. Yet Alfred Swinton was found guilty based upon the presentation of evidence (using an overlay created in Adobe® Photoshop®).<sup>5</sup>

During the trial, the odontologist testified with "a reasonable medical certainty without any reservation" that the bitemarks on the victim were created by Alfred Swinton. However, in an affidavit submitted as part of Swinton's petition for a new trial, the odontologist recanted his trial testimony. The odontologist wrote: "I no longer believe with reasonable medical certainty—or with any degree of certainty—that the marks on Ms. Terry were created by Mr. Swinton's teeth, because of the recent developments in the scientific understanding of bitemark analysis." After 19 years in prison, Alfred Swinton was exonerated and released from prison.

The information, technology, and techniques demonstrated in this presentation will provide answers to the questions raised in *Federal Rules of Evidence* 901 (also known as the "Swinton Six").<sup>6,7</sup>

This presentation will reveal how resolution effects image quality and image size, which influences how images are displayed or printed. It will also show how these digital imaging concepts and guidelines ensure the highest level of accuracy and detail when capturing digital images of dental impressions and bitemarks.<sup>8</sup>

Without this knowledge, it is impossible to create overlays properly for detailed analysis (annotation), comparison, and evaluation. It is equally important to recognize the loss of information (degradation of image quality) that can occur when certain file formats are used to store digital images. Together, these concepts and guidelines play a significant role in the scientific understanding of bitemark analysis and comparison.

## G23 Digital Image Processing for the Forensic Dentist

*James McGivney, DMD\*, St. Louis, MO 63119*

---

**Learning Overview:** After attending this presentation, attendees will: (1) be able to differentiate between malicious and non-malicious image processing; (2) be aware of the existence and availability of several computer apps used to change digital graphics; and (3) know how to crop, resize, and change the format of digital images.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing forensic dentists to be aware of how digital images can be manipulated.

Digital images are captured, viewed, manipulated, shared, and stored by forensic dentists. Computers and digital records encompass two distinct fields in forensics. Computer forensics, also known as computer forensic science, is a branch of forensic science pertaining to evidence found in computers and digital storage media, while forensic photography, also referred to as crime scene photography, is an activity that records the initial appearance of the crime scene and physical evidence as an aid in investigation and to provide a permanent record for use in the courts and the legal system.

The forensic dentist needs to be aware of the difference between malicious and non-malicious image processing. The purpose of malicious image processing is to deceive the viewer. In dental radiography, caries, fracture, and other pathology can be added to a digital image to aid in obtaining reimbursement from a third-party payer.

Non-malicious image processing makes a graphic easier to view and may highlight the detail in a specific portion of the graphic. The cropping of an image allows the eyes to focus on the subject, while eliminating extraneous elements. Adjusting the brightness, contrast, and color balance of a poorly exposed photograph can yield a more pleasing and informative image.

The marking detail of individual teeth in a bitemark graphic can, at times, be enhanced by adjustment of the color levels. This type of image processing is known as feature extraction and is intended to facilitate human interpretation.

In bitemark images, four distinct types of distortion have been identified, some of which can be corrected by image processing.

The processing of an image leaves tell-tale signs. The detection of image processing relies on various techniques and is known as recognizing if a graphic has been “photoshopped.” The presence of signs of image processing can range from very subtle to quite evident. Shadows and reflections should be realistic in location, size, and depth. Skin color should not appear too perfect or polished. Round selection tools may leave obvious circular patterns in the manipulated graphic. Areas that show excessive blurring and the presence of irregular or broken lines in patterns also reveal evidence of image manipulation.

The working knowledge of the use of several computer applications will benefit the forensic dentist. These applications include the GIMP image manipulation program, Windows® Snip® tool, and Google’s® reverse image search. These apps are available online at no charge. This presentation will guide the forensic dentist in the utilization of these apps to process images and to detect the presence of image manipulation.

---

**Digital, Image, Forensic**

## G24 Improvements to Digitized Radiographic Images Using Adobe® Photoshop®

*Robert E. Wood, DDS, PhD\*, Ontario Forensic Pathology Service, Toronto, ON M5G 2M9, CANADA; David Sweet, OC, DMD, PhD, BOLD Forensic Lab at UBC, Vancouver, BC V6T 1Z3, CANADA*

**Learning Overview:** After attending this presentation, attendees will have improved their understanding of: (1) problems that exist when faced with underexposed or overexposed radiographs in comparative dental identifications; (2) methods to use a raster graphics editor to change exposure factors of problematic radiographic images; and (3) simple, straightforward steps that can be taken to adjust the radiodensity of images.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing attendees' understanding of the issues and provide methods to improve their approaches to routine dental identification casework (increased performance).

It is believed that most odontologists are faced routinely with analogue intraoral radiographs within supplied antemortem records from missing persons that are not optimal for use in comparative dental identification cases because of image mode, exposure, and radiodensity limitations.

This presentation will discuss problematic issues that the forensic odontologist often faces when responding to requests for forensic physical comparison of dental records produced on unidentified found human remains to dental records of a missing person. Typically, because of available circumstantial evidence, death investigators have already established a putative identification of the human remains. For example, when a wallet is found among the possessions on or near the body or the decedent is the driver of a registered motor vehicle with a license plate and vehicle registration number. This putative identification then must be confirmed through reliable methods. Based on the investigative leads and this putative identification, a search is conducted for the person's Antemortem (AM) dental records.

Postmortem (PM) dental records are produced by the odontologist at the time of the dental examination during the dental autopsy. Quality control measures are used by the odontologist to determine if the PM records meet the standard of care for living persons by the person's dentist of record. This will ensure that the interpretation of data from the PM records can be directly compared to the data present in the AM records from the missing person. If the PM dental records (e.g., PM radiographs) are determined to be suboptimal, the attending odontologist can re-take them to obtain high-quality data that will enable direct comparisons to any available AM records.

The quality of AM dental radiographs obtained from the missing person's dentist of record may be suboptimal, with variations in radiodensity and exposure factors, processing errors, etc. Of particular concern are analog, film-based AM radiographs that are supplied and are the only ones available. These AM radiographs may be original films, digital images, or scanned images produced from the original films. There are various reasons why the dentist of record may not have been able to produce high-quality AM films. A patient's fear of radiation exposure; tolerance of closing the mouth to hold the image receptor or film packet adequately; the over- or underexposure of the image by the X-ray generator from mistakes or misunderstanding of the dental assistant; and improper development, fixation, or washing of the film prior to long-term storage are but a few examples of how less-than-ideal AM radiographs may be present in a submitted dental record for any missing person. Further problems arise when film-based images are copied for submission into the death investigation system since copy-film does not contain information regarding directionality. How can the odontologist maximize the ability to interpret adequately what is recorded in such problematic radiographs?

Methods are available to the odontologist to increase the ability to review, find, and employ various key dental traits useful in forensic comparisons. These methods enhance the ability for the odontologist to visualize data that is present but is hidden or masked by the problem factors previously mentioned. By making corrective adjustments to problematic AM films or scanned images, meaningful comparisons may still be possible.

Adobe® Photoshop® is a raster graphics and image editor that is used on Windows® and MacOS® computers for imaging processing. This computer application has become so popular that it is considered a generic trademark and the word "photoshop" is often used as a verb when one is describing the process of adjusting an image. Methods utilizing Photoshop® will be demonstrated during this presentation to allow attendees to appreciate the dramatic and significant changes that can be achieved with simple steps to change certain images factors, including but not limited to color versus grayscale image modes, exposure factors to change the tonal range, and color balance of an image (i.e., levels adjustment), etc. A handout will be available in PDF format that will summarize these steps.

---

### Odontology, Dental Identification, Image

## G25 Digital Techniques for Dento-Facial Superimposition

John B. Nase, DDS\*, Dental Forensic Services of Indian Valley, Harleysville, PA 19438

**Learning Overview:** After attending this presentation, attendees will be able to outline a method of utilizing postmortem and antemortem victim portraits with Adobe® Photoshop® CS and other software to generate both still and sequential “movie” comparisons of the visible smile. Attendees will also be able to appreciate how computer techniques learned in bitemark comparison and age estimation can be repurposed for dento-facial superimposition. A case report using this method that supported a positive victim identification will be presented. Current limitations and recommendations will also be discussed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing an alternate dental method via digital images to support identification of a presumed victim when traditional antemortem dental records do not exist or are not recovered.

In March 2018, a decedent was recovered from the water. The probable victim’s identification was presumed from circumstances of a one-week missing 72-year-old woman with Alzheimer’s disease from northeast Philadelphia, PA. Although there were no existing antemortem dental records for the presumed victim, her anterior dentition was reported as “distinctive,” and the family had supplied several family photographs exhibiting her smile. The medical examiner asked to perform a photographic dento-facial superimposition to corroborate other findings.<sup>1</sup>

As instructed, included in the autopsy were several digital images of the decedent’s face, to include lip retraction and a two-legged, photomacrographic #2 scale, from several angles. The postmortem image with the closest matching plane of view was superimposed onto one of the digitized antemortem images, utilizing digitally constructed hollow volume and solid volume exemplars using Photoshop® CS. All images used for overlay comparisons were individually scaled to a 1:1 ratio, first using the photometric scale in the postmortem image, then scaling the antemortem image by using the maximum width of the left central incisor as the standard in both. Metric analysis of anatomical landmarks, using the corrected image scale, was also performed as appropriate. Comparison of the maxillary and mandibular portions of the known dentition to the hollow and solid volume exemplars of the presumed dentition were analyzed for concordance with respect to arch width; the morphology, positions, angles, and spacing of individual teeth; and incisal edge topography.<sup>2,3</sup> As a visual aid to presenting the comparative findings, the images in the Adobe® Photoshop® CS workspace were then exported to Techsmith Camtasia software to create a sequential video file.

The unidentified decedent demonstrated individual arch and tooth characteristics that were consistent with the dentition of the presumed individual, with no unexplainable discrepancies. Therefore, the visible dentition of the presumed individual could NOT be excluded as being the same as the decedent. This conclusion supported the medical examiner’s corroboration of findings in a positive identification.

In conclusion, this case shows utilization of digital tools and techniques, borrowed from other odontological disciplines, in the dento-facial superimposition of strategically produced postmortem coronal head images to family photographs to corroborate unknown victim identification.

### G26 Combining 3-Dimensional (3D) Technology With the Traditional 2-Dimensional (2D) Smiling Photographs to Aid in Accurate Forensic Dental Identification

*Gowri V. Reesu, MSc\*, University of Dundee, Dundee, Scotland DD1 4HR, UNITED KINGDOM; Scheila Manica, PhD, University of Dundee, Dundee, Scotland DD1 4HR, UNITED KINGDOM; Gavin F. Revie, PhD, University of Dundee School of Dentistry, Dundee, Scotland DD1 4HR, UNITED KINGDOM; Peter A. Mossey, PhD, University of Dundee School of Dentistry, Dundee, Scotland DD1 4HR, UNITED KINGDOM*

**Learning Overview:** After attending this presentation, attendees will better understand the application of 3D technology in accurate forensic dental identification using smiling photographs and will appreciate the difference in certainty of conclusions reached with other comparison methods. Additionally, attendees will learn the advantages of using 3D software in the field of forensic odontology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring a novel technique for increasing the accuracy in dental identification, which supports further research in the field.

**Background:** Accurate human identification is of utmost importance for humanitarian, legal, and social reasons. The methodology of comparative identification is based on comparison of Antemortem (AM) and Postmortem (PM) records. However, as with many methods used in human identification, traditional forensic odontologic techniques can at times be unsuitable for reasons including lack of dental records and when information from available dental records is irrelevant to investigation. Smile photographs may emerge as valuable alternative sources of AM data in the forensic environment. They specifically register the unique features of the anterior dentition while recording the shape, position, angulation, incisal alignment, and occlusal relation of visible maxillary and mandibular teeth.

Technological advances in 3D imaging enable useful techniques for the interpretation of smile photographs with human identification purposes. Facilities such as 3D surface laser-imaging technologies have spawned new applications in dentistry. Using a laser scanner, dental plaster models can be converted into 3D images that may be viewed in any preferred orientation and may be subjected to quantitative analysis.

**Goal:** To explore novel odontological methods by comparing 2D digital smiling photographs with 3D dental models.

**Materials and Methods:** The study sample consisted of 35 randomly selected smiling photographs of patients who gave consent to participate in research in the Orthodontics Department, Dundee Dental Hospital, Dundee, Scotland. The photographs of the subjects obtained for this study were of varying quality. The smiling portion in the images were cropped and archived, and these images were considered as AM images.

Thirty-one dental casts of the same photographic sample were retrieved from the orthodontic laboratory, which were archived for treatment purposes. All the dental casts were laser scanned to create indirect 3D digital images of dental models and were considered as PM digital models. This study was conducted in two phases. In phase one, 31 digital 3D models were visually compared with 35 of the smile photographic samples showing upper and lower front teeth (canine to canine). The opinions were reached based on the International Criminal Police Organization (INTERPOL) Disaster Victim Identification (DVI) guidelines: Identity Established, Probable, Possible, and Exclusion. After a wash-out period of a week, the second phase of comparison was made using 3D Rhinoceros® software in which the selected 2D AM photograph was superimposed with the 3D digital model, with emphasis on incisal contours of anterior teeth and any morphological traits. Both methods of comparison were performed by the principal investigator.

This study hypothesizes that a valid imaging technique will aid in increasing the accuracy of human dental identification by comparing smiling photographs with dental models. The justification is based on shape, dimensions, and alignment of teeth of an individual, which can comprise a specific and unique set.

**Results:** Phase 1—In direct comparison of AM photographs and PM dental models, conclusions were reached in 26 cases (identity possible: 16; probable: six and four as established) only; one was wrongly identified, and it was not possible to form an opinion in four cases. Phase 2—With the application of 3D comparison software, conclusions were reached in all the 31 samples (identity possible: seven; probable: 13 and 11 as established) and were correct. This 3D technique made it possible to reach opinions in more cases than when compared to direct comparison. A significant increase in certainty among the opinions reached was observed when using the 3D comparison software.

In summary, it was possible to reach a conclusion in more cases when using the 3D comparison software, and those conclusions expressed a higher degree of certainty, which is the crux of this study as to whether the 3D comparison software adds significant value.

#### Forensic Dental Identification, Smile Photographs, 3D Comparison

## G27 The Prevalence of Morphological Variations of the Maxillary Sinus in Panoramic Radiographs of Caucasian Individuals

Ludovica Gorza, MSc\*, Padova 35125, ITALY; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand morphologic classifications of the maxillary sinuses and the surrounding morphological features observed in panoramic radiographs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insights into the frequency and variability of anatomic parameters of the maxillary sinuses observed in panoramic radiographs and will allow quantifying of their identifying performances.

**Introduction:** In contemporary comparative forensic dental identification practice, the collected Antemortem (AM) evidence contains mainly descriptive registrations and 2D radiographic images. Therefore, certain anatomical characteristics of the maxillary sinus that are visible in 2D radiographs can contribute to the positive identification of unknown individuals.<sup>1,2</sup>

**Purpose:** The goal of this study was to classify specific morphologic parameters of the maxillary sinuses on panoramic radiographs and to quantify their variability for human identification purposes.

**Materials and Methods:** Retrospectively, 500 digital panoramic radiographs from Caucasian male (250) and female (250) individuals between 10 and 70 years old were collected. The following parameters of the maxillary sinuses were analyzed: unilateral or bilateral presence; the peripheral shape; the symmetry of the peripheral contours; the geometry of the medial walls; the unilateral or bilateral visibility of the infraorbital canal, the pterygomaxillary fissure and the infraorbital ethmoidal air cells; the shape of the innominate line of the zygomatic process and the antral septa; the topographic relation between the roots of posterior teeth and the sinus floor; and the presence of alterations in the mucous membrane and cortical bone. Moreover, the maximal height, maximal length, and the area and distance between the right and left sinuses were also measured using GIMP 2.10.4 for Windows®. For inter- and intra-observer reliability tests, randomly 40% of the radiographs were re-assessed and analyzed with Kappa statistics. Analysis of Variance (ANOVA) statistics were applied to quantify the variability of each parameter and to classify them in function of their identifying ability. The analyses were performed sex-specific and compared between left and right maxillary sinus.

**Results:** Currently, not all collected data has been analyzed, but intermediate results and this study hypotheses indicate that: (1) there is a significant prevalence of present maxillary sinuses; (2) the overall peripheral shape of the maxillary sinus has significant variability, with asymmetrical sinuses being more prevalent; (3) the medial walls have mainly oblique medial orientations; (4) there is a high prevalence of visibility of the infraorbital canal, the pterygomaxillary fissure, and the innominate line of the zygomatic process; (5) there is a low prevalence of infraorbital ethmoidal air cells and alterations in the mucous membrane and the cortical bone; (6) the prevalence of antral septa is statistically significant in edentulous or partially edentulous maxillae compared to dentate maxilla; (7) the prevalence of roots projecting in the maxillary sinus is significant; and (8) there is no statistically significant difference in the measures between female and male and right and left sinuses. Certain morphologic parameters of the maxillary sinuses observed in panoramic radiographs can be considered as additional odontological identifiers.<sup>3-6</sup>

**G29 WITHDRAWN**

### G30 When Arson Becomes Murder: Antemortem Records Fire the Identification Process

*Randolph L. Mitchell, DMD\*, Lyons, NY 14489*

**Learning Overview:** After attending this presentation, attendees will have learned to await the development of all possible leads for antemortem dental records after a death that has rendered the victim unidentifiable by conventional means. Attendees will learn to have patience as the investigation of the death continues and to avoid the temptation of trying to make a positive identification without adequate records to support the identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by opening the minds of the investigative team when searching for antemortem information by increasing their awareness of some unusual local sources of this information at the scene. This information can narrow their records search to a much more focused area, speeding the acquisition of the antemortem information and making the positive identification possible.

Often, when the decedent is found in a location where there was no known person living and with no personal effects available, the investigators seem to be at a dead end right from the beginning and must be creative in their investigative techniques to find a logical starting point to determine a “believed to be.” Acquiring the necessary Antemortem (AM) records needed to make a solid dental identification is also very challenging in these cases.

This is perfectly illustrated in an actual case study of an arson case in which the decedent was found with no real identifiers for the investigators to use. The body was literally unrecognizable, burned to the point where there was no intact skin on the body for fingerprinting to be used or even an idea of who to match DNA with. The postmortem dental examination and charting was fairly routine. Even though several of the dental structures were damaged by the fire to the extent that they would be useless for identification purposes, there were several teeth intact that had dental restorations that could be used as excellent exemplars in a dental identification, given some records with which to compare them. There was absolutely no logical place to start the search for AM dental records.

The investigators caught a real break after several days that began to clear the picture of a possible lead on who the victim of this arson was. Some of the local inhabitants of the area knew that someone had been living in the structure that was burned, but since they were homeless and only knew each other by “street names,” more research would be necessary. Eventually, through some information garnered by the investigators from a governmental agency, a possible name for the John Doe was offered. Since the decedent was believed to be homeless, the search for dental records spread outward from the center of a circle defined by the fire scene. Clinics that provide health service to patients who are on social service benefits were checked to see if they had provided services to someone of that name. Dental records were located for a person of that name at one of the local clinics; those records were compared to that of John Doe and yielded a positive identification of the decedent. Once again, the importance of the AM records in making a dental identification is driven home by this case.

#### Sources, Records, Identification

### G31 The Mystery of the Unidentified Human Remains Found Wrapped in Dental Packing Tape and Its Dental Biography

Francesca Tarantino, MD\*, Bari 70124, ITALY; Maricla Marrone, MD\*, Bari 70124, ITALY; Stefania Lonero Baldassarra, Bari 70124, ITALY; Maria M. Lepore, Bari 70124, ITALY; Emilio Nuzzolese, PhD\*, Dental Team DVI Italia, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the application of best practice when performing the identification of unidentified human remains. In the field of missing and unidentified cadavers, it is essential to reach a preliminary generic profile of the unidentified body. This can be obtained only through a multidisciplinary postmortem assessment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the results of an identification casework in which the postmortem collection involved a forensic pathologist, a forensic odontologist, and a forensic biologist, who were able to define the profile of the unidentified person.

In Apulia, one of the 20 regions of Italy with a total of more than four million inhabitants, there are to date 3,548 reported missing persons and 59 unidentified human remains, as highlighted by the Missing Person Association “Penelope Puglia.” In May 2017, an unidentified skeletonized body was found wrapped in dental packaging tape in an abandoned factory in Bari, the capital of the region. The medical examiner appointed by the court was authorized to involve a biologist and a forensic odontologist for a complete postmortem assessment. The anthropological evaluation and the dental autopsy allowed the definition of the generic profile with a specific dental biography, including a dental age estimation using periapical X-ray of the upper and inferior canines. The dental biography was that of a female, aged 55 ( $\pm 5$  years) years old, partially edentulous with only front teeth and one inferior molar, orally neglected, wearing two mobile partial prosthetics, with a high horizontal alveolar bone reabsorption, which resulted in the appearance of long “jagged teeth.”<sup>1,2</sup> The radiological analysis of the jaws revealed infrabony pockets with plausible teeth mobility. The observation of the two partial prosthetics led to the conclusion that they were manufactured seven to eight years previously. Furthermore, the only amalgam restoration was assessed clinically as having been performed approximately five to seven years prior. Dental findings were also recorded in the International Criminal Police Organization (INTERPOL) Unidentified Missing Person form, as the initial nationality of the deceased was not known. A biological DNA sample was collected from the inferior second molar. The condition of the cadaver did not allow for the collection of fingerprints.

Histological findings and a skull Computed Tomography (CT) scan allowed the medical examiner to determine the cause of death as a hemorrhagic stroke, due to several beatings and physical abuse. The forensic dental examination enabled the narrowing of the search to four reported female missing persons, on which the police held some antemortem data. One had been examined for sexual abuse in 2009 and had received a vaginal swab. DNA analysis was performed on this specimen revealing two profiles, one of the victim’s and one of a male abuser. The comparison with the postmortem DNA profile matched with the missing person and all other data was compatible.

This case report confirms the need for always performing a complete dental autopsy in all unidentified human remains cases to reach a speedy identification by narrowing the search of the compatible reported missing persons.

#### Identification, Missing Persons, Dental Autopsy

### G32 Dental Identification of Carbonized Victims in a 2015 Traffic Accident in France

*Gwenola Drogou, DDS\*, Ploemeur 56270, FRANCE; Charles E. Georget, PhD\*, Amboise 37400, FRANCE; Aime Conigliaro, MSc\*, IRCGN, Pontoise 95300, FRANCE*

**Learning Overview:** After attending this presentation, attendees will understand the need for strict protocol implementation before intervening at a disaster site. Attendees will also understand the importance of forensic odontologists being part of the recovery team, especially in cases involving carbonization.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the forensic odontologist's role is not only to collect antemortem and postmortem indices, but that dental protocols are an integral part of the overall process involving the work of other disciplines to obtain an optimized and effective outcome.

A traffic accident occurred in Puisseguin, France, on October 23, 2015, and caused 43 casualties. This accident was the deadliest event in France since the Beaune accident in 1982, which caused 53 deaths, including 46 children. In the Puisseguin case, two vehicles and 51 persons were involved in the accident. A coach with 47 seniors, their driver, and their tour guide began a sightseeing trip. A trailer truck was moving into the left lane during a turn. It was driven by a 31-year-old driver accompanied by his 3-year-old son. These two vehicles caught fire immediately at the moment of collision, causing 43 casualties and injuring eight people, four of them severely.

According to the Land Transports Accidents Bureau of Investigation, once the fire had started in the bus, the Anti-Breaking System (ABS; thermoplastic polymer), polypropylene, polyester, and polyurethane that made up the interior trim of the vehicle began to burn and release highly toxic fumes, which spread very rapidly throughout the vehicle. Within one hour following the accident, L'Institut de Recherche Criminelle de la Gendarmerie Nationale (IRCGN) (The Criminal Research Institute of the French Gendarmerie) was called to the scene to handle this disaster.

A multidisciplinary postmortem team was deployed on the ground to recover the charred victims. Extreme care had to be taken when moving the bodies, placing them in body bags, and then transporting them to the medicolegal institute in Bordeaux as these were all technique-sensitive processes that could have resulted in the loss of critical forensic materials. Photographs were taken to preserve dental data before moving the corpses. All of the heads exhibited a severe degree of carbonization; front, right, and left lateral photographs were taken as a safeguard measure to document as much evidence as possible. This protocol was complemented by placing special bags around the heads to avoid losing any evidence during transportation. Any carbonized remains that had separated from the victims' bodies were sieved to recover any remaining items that may have been forensically interesting.

One forensic dentist from this PM team was sent to the medicolegal institute in Bordeaux to take part in autopsies, dental examinations, and data collecting. An antemortem team was set up at the Criminal Research Institute of the French Gendarmerie in Pontoise near Paris. One forensic pathologist and forensic odontologists got in touch with victims' families to obtain the maximum amount of antemortem data and all the victims were identified when medical and dental data were sufficient. A small antemortem team was also set up in a classroom in a village close to Puisseguin, where families could come to bring in any medical files and X-rays.

This presentation relates the causes and all dental identification techniques established to identify these traffic accident victims. This presentation demonstrates the importance of the strict observance of the selected protocols and the added value of the forensic odontologists' participation in the recovery of the charred victims.

#### Forensic Odontology, Traffic Disaster, Carbonization

### G34 Dental Identification: An Important Thing—The Second Time Around

*Jacqueline S. Reid, DDS\*, Chatham, NJ 07928*

**Learning Overview:** After attending this presentation, attendees will understand the need for dental identification procedures and records maintenance, and how they can assist law enforcement long after the case has been completed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the need for proper identification procedures, report writing, and the long-term maintenance of evidence.

In 2011, Michael Maltese was convicted of killing his parents and burying their bodies in a shallow grave in Beechwood Park, South Brunswick, NJ. In 2015, the Supreme Court of New Jersey affirmed the defendant's convictions for second-degree disturbing, moving, or concealing human remains, fourth-degree tampering with evidence, third-degree hindering apprehension or prosecution, third-degree theft, third-degree fraudulent use of a credit card, and fourth-degree false swearing, and reversed and remanded for retrial the charges of passion provocation manslaughter and first-degree murder.

It was determined that the trial court shall conduct a pretrial hearing to determine whether the physical evidence obtained as a result of the defendant's suppressed statements is admissible under the inevitable discovery exception to the exclusionary rule. Following the inevitable discovery testimonial hearing, the judge ruled that the physical evidence, including the gravesite and autopsy photos were admissible at trial. In 2018, Michael Maltese was retried and found guilty of "passion provocation" manslaughter for both his parents.

The case discussion includes: (1) search techniques for antemortem records; (2) assisting the Medical Examiner (ME) to obtain records; (3) antemortem records review; (4) postmortem examination and data collection; (5) chain of custody; (6) maintenance and digital archiving of dental evidence and case data; (7) report writing techniques; (8) preparing for court; and (9) expert witness testimony .

In October 2008, the ME requested a dental review of photographs of a bitemark on the "pinky" finger of a suspect in custody who confessed to strangling his parents and claimed his father bit him. Upon arrival, the injury photographs provided by the ME were of limited to no value. The ME stated that they could not locate the dental records of the parents and perhaps could look to identify them in some other manner. The suspect/son in custody told the police where the parents were buried. However, it was decided to complete a full dental autopsy, examination, photographs, and radiographs on the parents, nonetheless.

After thoughtful attention and some luck, the search for dental records yielded positive results and a full-mouth series of radiographs for both parents were found. After the comparisons were completed, a positive dental identification was made for Michael and Kathleen Maltese. The dental reports generated were submitted to the ME on November 14, 2008. A subpoena, to be on call to testify, was issued in January 2018. Nearly ten years later, sworn testimony was provided in court on the identification procedures used to determine the identity of the victims found in the grave, at a park in South Brunswick, NJ, on October 24, 2008.

### G35 A Review of Postmortem Dental Radiographic Protocol for Emergency Responders in Individual to Mass Fatality Operations

*Khlea Sumani, DMD\*, Zanesville, OH 43701; Charles E. Berner, DDS, Cleveland, OH 44143*

**Learning Overview:** After attending this presentation, attendees will understand the advantages of implementing a safer dental sensor stabilization technique in conjunction with a sensor holder, to facilitate radiation exposure safety.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the application and use of “at hand” inanimate objects as stabilization devices during the capture of postmortem radiographic images, allowing operators to remove themselves from the field of radiation and thus reduce the risk of radiation exposure to response personnel.

**Background:** Dental radiograph sensor-positioning devices (X-ray sensor holders) are utilized in the office setting or in operating rooms during patient visits. These holders were developed for the routine care of a patient who is compliant and able to assist in the X-ray sensor stabilization process. In an adjunct application, these sensor holders have been employed in morgue settings to assist in the collection of postmortem radiographs.

Frequently during morgue operations, disaster response personnel attempt to use the same in-office devices on human remains to hold the radiograph sensor holder for a proper radiographic image to be obtained. Eighteen radiographs may be taken for a proper dental autopsy in the form of 4 bitewing and 14 periapical radiographs. If vertical or horizontal angulation corrections were made due to lack of anatomic landmarks or incomplete imaging, the operator tasked with sensor placement has often held the position during evaluation of the previous image. The central beam angles may have been corrected and another exposure accomplished. The various paths of the central beam would frequently put the computer terminal operator at risk of downrange exposure. If corrections in sensor placement were necessary, the sensor was adjusted by hand and held for the next exposure and the expected better image.

**Materials and Methods:** Controlled radiographic exposure and image capture of human remains were practiced by a small group of Disaster Mortuary Operational Response Team (DMORT) operators in a training Disaster Portable Morgue Unit (DPMU) setting with human remains. Technique repetition in a coroner’s office, and a later opportunity for training of response personnel with human remains, allowed for additional observations of this behavior change being easily accepted.

**Results:** The repeated effort to remove personnel from the downrange field of exposure was easily accomplished and became the basis for this study being applied to a larger group of responders. All personnel must stay cognizant of the exposure to one another, to stay flexible, and to move away from their station if the central beam would put them at risk of exposure. The use of devices allows the “wet” personnel to clear their hands from the field of radiation while the “clean and dry” data entry operators would step away, which reduces radiation exposure to themselves.

**Odontology, Identification, Mass Fatality**

## G36 A Cemetery Named the Mediterranean Sea: Best Practice in Human Identification

*Francesco Sessa, MS\**, Department of Forensic Pathology, University of Foggia, Foggia 71100, ITALY; *Stefania C. Bello, MD*, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; *Giuseppe Bertozzi, MD*, Department of Forensic Pathology, Foggia 71121, ITALY; *Francesca Maglietta, MD*, Department of Forensic Pathology, Foggia 71122, ITALY; *Emilio Nuzzolese, PhD\**, Dental Team DVI Italia, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the application of best practice when performing the identification of human remains recovered from the sea. There is a significant amount of scientific literature highlighting the importance of having a multidisciplinary approach for unidentified human remains by following Disaster Victim Identification (DVI) standards, yet they are not always applied.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the scientific findings of an identification case in which postmortem and antemortem data are compared to determine whether they belong to the same person. Since 2014, the human identification process has become an important procedure in Italy due to the migratory flows phenomenon and the large number of victims recovered from the Mediterranean Sea.

The European migrant crisis is a term given to a period beginning in 2014 when a rising number of people arrived in the European Union (EU), travelling across the Mediterranean Sea or overland through southeastern Europe. These people included asylum seekers, and also economic migrants.

Thousands of migrants die as a result of shipwrecks when trying to cross the Mediterranean Sea. This has caused the Mediterranean Sea to become a giant cemetery. In December 2014, a ferry boat, which routinely travels from Greece to Italy and vice versa, was set on fire. There were 443 passengers, 56 crew members, and at least 6 clandestine passengers on board. Due to sea conditions, it was not possible to rescue all passengers and, after the rescue, there were 19 missing passengers, 60 injured people, and 9 deaths. Four months later, a corpse in an advanced state of decomposition was recovered near the Tremiti Islands. It was not possible to determine the cause of death or the origin of the corpse. Was it a migrant, an accident, a homicide, or a suicide? Being of unknown origin, a general biological profile was achieved through a dental autopsy, fingerprints, and DNA collection.

One of the most challenging aspects of the human identification process is not the postmortem but the antemortem data collection. To begin gathering antemortem documents and data for identification, there is the need for “presumption of the identity,” which can be offered by the generic profile coming from the dental autopsy. The presumption of the identity was also obtained considering the circumstantial details of the report of the found body and analyzing the list of the missing people. This information was combined with the preliminary findings of the autopsy, such as the cause of death. A dental profile and genetic analysis (DNA and mitochondrial DNA (mtDNA) profiles) were also used to obtain significant data for the human identification process.

In general appearance, the recovered body appeared to be a male. The corpse wore only socks and underpants, and no other personal effects were found. Fingerprints were not practicable as the arms were not present due to sea fauna predation. The head was partially decomposed and the teeth and dental prosthetics were preserved. The histological findings guided the medicolegal analysis to determine that the person died by drowning. Dental X-ray analysis was also performed and was useful in determining the presence of an endodontic technique still used in Middle East European countries (i.e., Greece, Turkey), but no longer used by European clinicians.

Genetic analysis using Short Tandem Repeat (STR) allowed confirmation not only of the sex of the cadaver but also of the statistical distribution of the genetic profile in the population with Random Probability Match. Using mtDNA and an interactive map, it was also possible to obtain a profile for a database query that automatically directed to sampled populations: the haplotypes was R0a1a, the metapopulation was west Eurasian, the continent was Europe, specifically southern Europe, the country was Greece, and the province was Kozani. All data led to the ferry boat accident. A DNA comparison was then performed with the victims' DNA-available profiles. A DNA match was found for one of the missing person's relative's genetic profile; the corpse belonged to the one Grecian missing passenger.

This case report applied the multidisciplinary approach for best practice in human identification. Primary and secondary identifiers, following also DVI standards, could always be applied for the identification of migrant victims of the migratory flow through the Mediterranean Sea.

### Human Identification, Migrants, Dental Identification

## G37 Not Your Typical Forensic Odontology Cases

*John Berketa, PhD\*, University of Adelaide, Norwood, South Australia 5067, AUSTRALIA*

**Learning Overview:** After attending this presentation, attendees have information on various applications or skills of forensic odontology in relation to forensic sciences of which they have been unaware. These skills include evidence retrieval from the oral cavity, radiographic scanning of edentulous areas, and education of the public in the dental care of elderly citizens.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reminding attendees of how forensic odontology may be helpful beyond the traditional roles of restoration comparison in identification work, age estimation, and bitemark analysis. Three casework subject scenarios will be presented.

Regarding the first example, oral examinations conducted during identification work of victims was able to assist pathologists in determining the series of events that may have occurred in two possible homicide cases. Skin found between the teeth did not belong to the deceased in either case and was able to be linked to other suspects. Any material discovered within the oral cavity during a dental identification examination, especially biological material such as hair and skin, could be critical in investigations and need to be photographed *in situ*, recorded for chain of custody reasons, and, following approval from the attending pathologist or medical examiner, removed carefully for matching and/or further testing.

The second scenario suggests that edentulous alveolar arches should always be examined with full radiographic assessment. In a large disaster incident, full dental examination is routine. However, in a single victim case, a triage forensic officer or medical examiner may deem that odontologists may be of no benefit in the identification of an individual due to the edentulous state of the victim, and this process may be overlooked. Often, residual root tips or restorative material could be still present in an individual, which will be evident with dental radiological examination. This information may not be sufficient to confirm the identity of a person and could add further weight to the evidence already present. A casework illustrating this point will be presented.

The third scenario presents a tragic series of events in which a patient died due to denture asphyxiation. In this case, the elderly patient was severely medically compromised, and precautions, obvious to dentists, were not taken. Even though forensic odontology was not involved directly, it highlights the obligation the profession has to educate care workers and law makers regarding dental care and possible legislation.

Odontologists can contribute to the community in many ways, and it is important to keep an open mind for the unexpected ways in which they may assist.

## G38 The Art of Working in Reverse to Resolve a Dental Identification

Mary K. Shields, DMD\*, Louisville, KY 40243; Mark L. Bernstein, DDS, University of Louisville School of Dentistry, Louisville, KY 40292

---

**Learning Overview:** The goal of this presentation is to demonstrate how in dental identification, when efforts in which traditional methods have not produced sufficient antemortem evidence, reconstructive analysis of postmortem dental findings may provide a path to the recovery of additional data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing attendees to recent advances in dental restorative materials so they can understand the importance of knowing differences in their radiographic appearances. This can prove to be a valuable skill when performing a dental identification. Attendees will leave with a better understanding of how to identify modern dental materials radiographically. Modern materials, such as zirconia, porcelain, and lithium disilicate, have a variety of brand names and differ in the way they appear radiographically. Additionally, dental coding in patient charting can be vague regarding dental materials for prosthetics. This can pose a problem when comparing antemortem records and postmortem records.

This presentation will discuss roadblocks that complicated a seemingly straightforward dental identification and will also outline specific triumphs that led to a breakthrough in the identification effort by working backward.

An ideal dental identification of human remains can be simple when complete postmortem specimens having characteristic dental findings can be compared with promptly located and accessioned objective antemortem records mirroring those characteristics.

A family in the suburbs of a Louisville, KY, community notified the police after they stumbled across some bones in their backyard in a washed-out stream bed. A series of twists and turns ensued. Investigators found a backpack upstream with the name of a putative victim. A slow accumulation of antemortem evidence from a variety of sources increasingly supported only a possible identification. Finally, a reversed approach to acquiring antemortem data led to the resolution of the case.

Several considerations impacted the work of the forensic team: (1) recovery of remains (multiple searches); (2) media misreporting (multiple missing persons from the same area); (3) a search for antemortem records, including the family of the putative victim, hospital records, social media sleuthing with a search for smiling photographs, prison records, and working backward (i.e., reconstructive analysis); (4) knowledge of dental materials, specifically, fixed crown and bridge work; (5) sensitive subject matter; and (6) dental laboratory involvement (laboratory prescriptions as part of the dental records).

In cases in which dental identification efforts using only traditional methods have not produced sufficient antemortem evidence, reconstructive analysis of postmortem dental findings may provide a path to the recovery of additional data.

### Dental Identification, Ceramic Crown, Radiographic Analysis

### G39 The Need for a Complete Dental Autopsy of Unidentified Edentulous Human Remains

Emilio Nuzzolese, PhD\*, Dental Team DVI Italia, Bari 70124, ITALY; Mario Torreggianti, DDS\*, Teramo, ITALY; Gina R. Quaglione, MD, UOC Anatomia Patologica, Teramo, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the need for the application of best practices when conducting the identification of missing and unidentified human remains. The scientific literature in the field of human identification highlights the importance of a multidisciplinary approach when conducting a human identification process, including a dental autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the results of an identification casework in which the dental autopsy and dental radiology were beneficial in the postmortem data collection, even in an edentulous individual, for the purpose of narrowing the search of reported missing persons in that geographical area and to establish identity.

In Abruzzo, one of the 20 regions of Italy with a total of more than 1.3 million inhabitants, there are, to date, 505 reported missing persons and 6 unidentified human remains as highlighted by the June 2018 official report of the Italian Ministry of the Interior.

In December 2017, a decomposed unidentified body was found near the river Tronto of Teramo, Italy. The corpse was found with no identifying document or specific personal belongings, except for a pack of cigarettes. The medical examiner diagnosed a gastric perforation as the cause of death, due to the intake of hydrochloric acid. The jar of muriatic acid found near the body led to a verdict of a suicide. After the autopsy, the Penal Court in Teramo appointed two forensic odontologists to complete the postmortem assessment and collect dental data for the purpose of identification. The cadaver was found wearing a complete set of upper and lower dentures. The dental autopsy and 43 periapical X-ray images determined the cadaver as a male between the ages of 55 and 65 years old, totally edentulous with upper and lower dentures, and an osteosynthesis with two plates and screws in the left corner of the mandible. The generic profile was circulated by the Carabinieri Police Agency and was also sent to Penelope Abruzzo, the regional association of missing persons, and to the editorial team of a national television program on missing persons, *Chi l'ha Visto?* (*Have You Seen This Person?*).

In March 2018, the sister of the missing person finally reported the disappearance of her brother, and a presumptive identification was performed through a visual recognition of the decomposed cadaver. The sister confirmed the presence of two dentures and revealed the name of the dentist and the place of the maxillofacial surgery for the treatment of the fractured mandible. The two forensic odontologists were able to establish the identification of the cadaver by comparing the dental and radiological data received from the dentist and the hospital. No DNA comparison was then required.

This case report confirms the need for always performing a complete dental autopsy, including of X-ray imaging, in all unidentified human remains cases, even in edentulous individuals in whom no teeth are clinically visible.

#### Identification, Edentulous, Dental Autopsy

### G40 A Review of Unconventional Points of Dental Identification at the Ontario Forensic Pathology Service: Thinking Outside the Viewbox

Yolanda Nerkowski, BA\*, Ontario Forensic Pathology Service, Toronto, ON M3M 0B1, CANADA; Robert E. Wood, DDS, PhD\*, Ontario Forensic Pathology Service, Toronto, ON M5G 2M9, CANADA; Taylor L. Gardner, BSc\*, Ontario Forensic Pathology Service, Toronto, ON M3M 0B1, CANADA

**Learning Overview:** The goal of this presentation is to demonstrate alternate or less commonly used points of dental identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining the use of unique dental identifiers in dental identification when more traditional points of dental identification are not available in the antemortem or postmortem data set.

The unique characteristics in the development, morphology, and pathology of dentition, coupled with their nearly indestructible quality, make teeth one of the most reliable means for establishing human identification. Additionally, well over half of North Americans are reported to have visited a dental professional in the past year, vastly improving the likelihood that antemortem dental records are available for comparison purposes should the need arise.<sup>1,2</sup> In addition, most people that have seen a dentist have some form of restorative intervention, be it dental restorations, root canal treatments, or extractions of permanent teeth.

The optimal scenario when performing a dental identification would be to have a postmortem data set containing multiple points of identification to compare against a complete antemortem data set, including radiographs. Although this is often the case, there are times when the antemortem or postmortem data set is lacking, either due to poor quality, lack of completeness, or the absence of antemortem records. In the postmortem data set, severe degradation of the body may require dental identification that relies on less traditional points of identification.

Several cases of unconventional points of identification will be discussed in which a positive dental identification was obtained or used to further support a circumstantial identification. One such identification was achieved using a photograph of the decedent's teeth taken antemortem demonstrating a rare feature of the crown in conjunction with other supportive points evident in the photograph, when antemortem dental records were not available. Age stratification was also undertaken to further aid in the establishment of this missing child's identity.

Dentures can prove to be of considerable value in identification as they may contribute to the creation of a biological profile for unidentified human remains. Wear patterns, materials used in the manufacturing, and the overall quality of the dental prosthesis can yield important clues to an unidentified person's habits, age, postmortem interval, or geographical region of origin. Dentures can also be fitted on casts in cases of presumptive identification when these items can be obtained from an individual's dentist. Unfortunately, dental casts are not always available, and a more novel approach must be taken to reveal the utility of a denture in establishing identification. One such case involved an edentulous individual whose identification was made possible by corroboration between the dentist's notes regarding a denture adjustment and an examination of the denture and shade-matching of the appliance.

Finally, several cases with irregular anatomical features or unusual pathoses will be presented in which either peri-mortem destruction or loss of the dentition, or edentulism, has made identification using more commonly used identifiers difficult. These cases include an individual with a unique unilateral nasopalatine duct cyst, a maxillary fracture, and comparison of the left maxillary sinus seen in postmortem Computed Tomography (CT) imaging to antemortem radiographs.

## G41 The Lethal Migrant Sea Route to Italy and the Nigerian Disaster Victim Identification (DVI) Operation

Antonello Crisci, MD, University of Salerno, Salerno 84084, ITALY; Emilio Nuzzolese, PhD\*, Dental Team DVI Italia, Bari 70124, ITALY; Joe Adserias-Garriga, DDS, PhD\*, Texas State University, Forensic Anthropology Department, San Marcos, TX; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY

**Learning Overview:** After attending this presentation, attendees will have a deeper understanding of how victims of migratory flow should be managed, how important teamwork is, and the application of the International Criminal Police Organization (INTERPOL) standards.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the complete rescue, recovery, DVI, and burial operations of 26 bodies drowned in the Mediterranean Sea while migrating to Italy.

On the November 5, 2017, a migrant boat with 375 Nigerian migrants was rescued in the Mediterranean Sea by the Spanish military ship *Cantabria*. Twenty-six Nigerian women and girls were found dead from drowning. The boat with migrants departed from Libya but began sinking near the Italian coast because it was overloaded. Dead bodies were found floating in the water, while survivors clung to partly capsized rubber dinghies. At least 100 bodies are believed to be still missing in the sea.

A DVI operation was established in Salerno, where the *Cantabria* was due to dock. The forensic pathologist appointed by the Penal Court in Salerno promptly set up a team of other forensic pathologists, odontologists, and anthropologists. Personal belongings and all identifying traits (tattoos, scars, and anatomical variants) were recorded during the first preliminary external examination of the dead bodies. Autopsies were conducted at the local cemetery with the goal of diagnosing the cause of death and retrieving all possible data of potential criminal acts, such as torture or violence. Two girls were found to be pregnant, and the cause of death was drowning for the whole group.

Dental autopsies were performed according to INTERPOL standards, with the principal goal of assessing the age of the victims. Age estimation was assessed using Mincer et al., AlQahtani et al., and Carmeriere et al., through the periapical radiographs of canines and third molars, using a portable X-ray hand-held device.<sup>1-4</sup> The age assessment revealed a demography of five minors and 21 adults. Dental examinations and autopsies were completed in three days for the purpose of speeding up the entire operation. Unusual findings will be presented, including a SIM card, ethnical identifying tattoos and scars, and four bitemark-patterned lesions on two of the victims. State funerals were held on November 17, 2017, with a Catholic and Muslim ceremony in the presence of the surviving Nigerian migrants, authorities, and citizens of several nationalities.

Since 1993, the number of migrants whose deaths have been reported is 34,361.<sup>5</sup> In addition, there are migrants whose deaths go undocumented, because they are lost at sea or die in the backs of trucks. These deaths can be described as a humanitarian mass disaster, rather than simply a natural mass disaster. The highest number of deaths occurred in the Mediterranean Sea, considered the most lethal sea route to Italy. From the forensic perspective, humanitarian forensic odontology can offer a strong contribution to migratory flows and illegal migration, reinforcing public health assessment, border control, and identification of the living and the deceased.

### Migrants, Humanitarian Forensic Odontology, Dental Age Estimation

### H1 Stress Evaluation in Indonesian Civil Aviators

*Meta Y. Candra, MSc\**, Faculty of Dentistry Universitas Indonesia, Jakarta 10430, INDONESIA; *Nurtami Soedarsono, PhD*, Faculty of Dentistry Universitas Indonesia, Jakarta, DKI Jakarta 10430, INDONESIA; *Dewi F. Suniarti, PhD*, Faculty of Dentistry Universitas Indonesia, Jakarta 10430, INDONESIA; *Febriana Setiawati, PhD*, Faculty of Dentistry, Jakarta 10430, INDONESIA

---

**Learning Overview:** Flight safety needs to be improved. After attending this presentation, attendees will understand how the work of a civil aviator is a formidable challenge and stress risk. A biological screening to evaluate civil aviators' stresses to minimize the human risk factor will be reported in this presentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging preventive measures to keep civil aviators from being incapacitated and methods to investigate a human risk-factor involvement in an aviation incident. It is important to take notice at this issue and develop early physical and physiological assessments on civil aviators.

Due to the high level of civil aviation incidents in Indonesia from 2010 to 2017, it is necessary to evaluate human factor as one of the main culprits. A civil aviator's stress condition can arise from aviation environments, such as altitude, noise, communication, and vibration. A civil aviator, who operates a short-haul flight in Indonesia (an archipelagic country), will routinely have many flying hours that may turn into a stressor. It was predicted that an aviator's stress is caused by fatigue. The International Civil Aviation Organization (ICAO) uses the Fatigue Severity Scale (FSS) method to measure the level of clinical fatigue in a person by using nine questionnaires with a score of 1 to 7 for the level of fatigue.

This study measured the level of clinical fatigue using the FSS on aviators who do not fly sectors and have a total flight time of less than 6,624 hours, and those who are on a sector flight and have a total flight time of more than 6,624 hours. There are five proteins secreted during stress that can be used as stress biomarkers: cortisol, lysozyme, immunoglobulin A (IgA), chromogranin, and alpha amylase. This study evaluated the stress condition of Indonesian civil aviators using salivary alpha amylase and blood cortisol as biomarkers on both groups.

From this study, it was concluded that stress on civilian aviators can occur because of the high level of fatigue caused by the total number of flying hours that exceed the specified limits. In addition, more than two sector flights within 24 hours also caused aviator fatigue. This fact has been demonstrated by the increased salivary alpha amylase and blood cortisol levels and FSS scores in the aviation group with total flight hours exceeding 6,624 hours and who performed sector flights.

---

### Fatigue, Stress, Civil Aviator

## H2 The Application of Decomposition Scoring Methods to Predict Postmortem Submersion Interval (PMSI) in Human Bodies Recovered From Aquatic Environments: A Comparison Between Freshwater and Salt Water in Italian Areas

Chiara Palazzo, MD\*, Bologna, ITALY; Paolo Fais, PhD, Department of Medical and Surgical Sciences, Unit, Bologna, ITALY; Guido Pelletti, MD, Department of Medical and Surgical Sciences, Bologna, ITALY; Alberto Amadasi, MD, Università di Bologna, Bologna 40126, ITALY; Federica Fersini, Bologna, ITALY; Filippo Pirani, MD, Section of Legal Medicine, Polytechnic University, Ancona, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Adriano Tagliabracci, MD, Section of Legal Medicine, Polytechnic University, Ancona, ITALY; Susi Pelotti, MD, University of Bologna, Bologna 40100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the applicability of aquatic decomposition scoring methods to predict PMSI in human bodies recovered from Italian rivers and the Mediterranean Sea near Italian coasts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by aiding in the estimation of PMSI in submerged corpses in temperate climatic areas.

Determining PMSI may be problematic, since an aquatic environment can affect the rate of postmortem decay. In several studies, performed in northern Europe, PMSI has been estimated through scores that evaluate visual postmortem modification on the head and neck, trunk, and limbs. Based on the scoring system developed by Megyesi et al., Heaton et al., and van Daalen et al. recently developed two new scores to assess aquatic decomposition.<sup>1-3</sup> Basing on the transformative processes observed on head and neck, trunk, and limbs, a Total Aquatic Decomposition Score (TADS) is calculated and related to PMSI. Moreover, since aquatic decomposition is time and temperature dependent, TADS has also been related to Accumulated Degree Day (ADD), which is the sum of average daily temperatures of the body of water, along with the submersion interval.<sup>2-4</sup>

Different environmental conditions and ecosystems influence the rate of decomposition and the relationship between TADS, PMSI, and ADD. Therefore, there is a growing need for systematic studies on human decomposition in aquatic environments.

The goal of this study is to evaluate whether the scores developed by Heaton et al. and van Daalen et al. are suitable in estimating the PMSI in bodies recovered from aquatic environments in a temperate area, namely Italian rivers and the Mediterranean Sea, near the Italian coasts.<sup>2,3</sup>

Both scores were tested on 285 bodies recovered from freshwater and 45 bodies recovered from the sea, in which PMSI was known. The degree of decomposition within the study samples was heterogeneous, varying from no visible changes to almost complete skeletonization. Postmortem decomposition was assessed using photos taken during death scene investigations. Aquatic temperature to calculate ADD was assessed by referring to official weather databases. The scores obtained through the application of the scales were compared with the real PMSI and the related real ADD values. Regression analysis was conducted to evaluate the accuracy of TADS in predicting the PMSI, according to the following logical frame: (1) TADS according to Heaton et al.'s score vs PMSI; (2) TADS according to Heaton et al.'s score vs ADD; (3) TADS according to van Daalen et al.'s score vs PMSI; and (4) TADS according to van Daalen et al.'s score vs ADD.

The correlation between the TADS and PMSI was calculated and a high correlation was observed, especially for van Daalen et al.'s score. The different regression coefficients obtained in relation to the freshwater cases and the salt water cases confirm the influence of the different aquatic environments on the rate of postmortem decay.

According to this study, both scoring methods can be applied to bodies recovered from fresh and salt aquatic environments within the Mediterranean area, taking into consideration the climatic features with periodical temperature variation, to achieve the best accuracy in predicting PMSI.

## H3 Unusual Asphyxial Deaths: Sand, Soil, and Stool

*Diana C. Nointin, MD\**, Maryland Office of the Chief Medical Examiner, Baltimore, PA 21223; *Pamela A. Ferreira, MD*, Columbia, MD 21044; *Carol Allan, MD*, Office of the Chief Medical Examiner, Baltimore, MD 21223; *Zabiullah Ali, MD*, Office of the Chief Medical Examiner, Baltimore, MD 21223; *David R. Fowler, MD*, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to report a series of unusual asphyxial deaths due to the inhalation of foreign material.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the characteristics of asphyxial death caused by the inhalation of foreign material and the need to standardize the classification of asphyxial deaths.

A 30-year-old female was found buried in sand at the beach. The autopsy showed sand in the eyes, ears, nose, sphenoid sinuses, oral cavity, and upper and lower airways. A Computed Tomography (CT) scan showed high-density material in the bronchial tree.

A 26-year-old male who was working at a construction site was witnessed to be buried in soil when the 8-foot hole he was digging collapsed on him. The autopsy showed collections of sand and dirt in the nose, oral cavity, upper and lower airways, esophagus, and stomach.

A 20-year-old male was working in an excavation site repairing a storm drain when the site started to collapse. The autopsy showed collections of mud and dirt in the upper airway, abrasions and contusions of the face, neck, and left arm, and lacerations on the right posterior scalp.

A 48-year-old male (A), an 18-year-old male (B), and a 14-year-old male (C) were found in a manure pit at a dairy farm. All three were working at the farm spreading manure on the fields before they were reported missing. The autopsies showed liquid and semisolid manure in the upper and lower airways and sphenoid sinuses on all three cases. Testing for potential methane gas presence in the lungs was unable to be performed due to impaction of semisolid stool in the airways.

Asphyxia is a broad term used to describe the disruption of oxygen uptake or utilization in cells. Asphyxia can be further subcategorized into suffocation, mechanical asphyxia, strangulation, and drowning.<sup>1</sup> Additionally, the term suffocation is non-specific and encompasses a variety of mechanisms that include smothering, choking, and confined spaces/entrapment/compromised atmosphere, each with its own definition and criteria. Over the past ten years, there were 2,055 deaths attributed to asphyxia at the Maryland Office of the Chief Medical Examiner, including those due to drowning (904 deaths), strangulation/hanging (406 deaths), suffocation (218 deaths), and mechanical asphyxia (143 deaths). The remaining 384 deaths were non-specified, which included the 6 reported cases above. Most of these reported cases showed overlap between categories, including obstruction of the upper airways (smothering) and lower airways (choking) by foreign material, and all likely have impaired respiration due to pressure from being buried or submerged (mechanical asphyxia). In four out of six cases, permeation of material into the sphenoid sinuses was present, which is usually seen in cases of drowning. These cases highlight the apparent complexity of asphyxial deaths and the possible variation of categories in which they may be classified. Although deaths due to inhalation of foreign material are uncommon, they show similar findings at autopsy and likely share the same mechanisms of death. Recognition of these presentations and further exploration of similar cases can aid in structuring a scheme to provide better standardization under the current classification system.

### H4 Strangulation to Stroke: A Fatal Case of Delayed Traumatic Internal Carotid Artery Dissection

*Amber R. Wang, MD\*, Maricopa County Medical Examiner's Office, Phoenix, AZ; Alan C. Wang, MD, Jackson Memorial Hospital, Department of Neurology, Miami, FL 33136; Benjamin Mathis, MD, Miami-Dade County Medical Examiner Department, Miami, FL 33136*

**Learning Overview:** After attending this presentation, attendees will be aware that carotid artery dissection is an uncommon, delayed presentation of strangulation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of an uncommon mechanism of death occurring as a result of neck manipulation and/or trauma. This case stresses the importance of obtaining a thorough history for previous trauma in cases of carotid artery dissection and stroke to properly certify these deaths.

Traumatic carotid artery dissections are uncommon and can be fatal injuries with a delayed onset. The time between neck trauma and neurological signs can be hours to years following the initial injury.

A 32-year-old female presented to the emergency room after being sexually and physically assaulted and strangled. Upon physical examination, she had multiple contusions and lacerations, subconjunctival hemorrhage bilaterally, and a faint ligature mark predominantly around the right side of her neck. A Computed Tomography (CT) of the brain was normal. She was awake and alert. The woman was interviewed by police. Approximately four hours later, she developed an acute left hemiparesis and aphasia. A repeat CT scan of the head showed an infarct in the right middle cerebral artery territory. A Computed Tomography Angiography (CTA) demonstrated a complex dissection of the right internal carotid artery with thrombus extending into the middle cerebral artery. Despite multiple attempts at mechanical thrombectomy and neurosurgical intervention, she was declared brain dead and expired four days later. An autopsy confirmed the cause of death as cerebral infarction due to right internal carotid artery dissection due to ligature strangulation, and the manner was certified as homicide.

Carotid artery dissection is rare but is the most common cause of stroke in people under 45 years of age. It can occur spontaneously or secondary to trauma. Spontaneous dissections are often associated with connective tissue disorders, such as fibromuscular dysplasia. The majority of traumatic carotid artery dissections are due to high-speed motor vehicle accidents, sports, falls, and violent activity. The mechanism by which traumatic carotid artery dissection occurs is hypothesized to be due to stretching of the artery during neck hyperextension, compression against the spinal column during contralateral flexion of the neck, and direct blunt trauma from a blow or other external force. When the dissection occurs, a thrombus may form nearby and result in distal embolism or occlusion.

Cerebral infarction following dissection can be immediate or significantly delayed with respect to the decedent's initial presentation. The interval from neck trauma to onset of neurological symptoms is generally considered to be within 24 hours. However, multiple reports in the literature describe intervals of months and, rarely, even years. Despite medical treatment, including anticoagulation therapy, resulting in a high percentage of spontaneous resolution, a subset of dissections may progress to a chronic stenosis, complete occlusion, or a pseudoaneurysm with risk of rupture. Thus, the association of arterial pathology with the inciting event may be lost due to the delay in presentation.

This case highlights the danger of delayed stroke as a consequence of strangulation, a phenomenon rarely described in the forensic literature. Acquisition of a complete history regarding previous trauma, especially neck pressure or manipulation, is necessary information required for proper certification of deaths related to carotid artery dissection and/or ischemic stroke.

#### Strangulation, Carotid Artery Dissection, Stroke

## H5 A Fatal Case of Candy Aspiration in a Child: Was It a Choking Death?

Giuseppe Davide Albano, MD\*, Foggia 71121, ITALY; Pasquale Malandrino, MD, University of Catania, Catania 95123, ITALY; Massimiliano Esposito, MD, University of Catania, Catania 95123, ITALY; Aldo Liberto, MD, University of Catania, Catania 95123, ITALY; Dario Condorelli, University of Catania, Catania 95100, ITALY; Monica Salerno, MD, PhD, Department of Forensic Pathology, Foggia 71121, ITALY; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY

**Learning Overview:** The goal of this presentation is to describe characteristics, circumstances, radiological, toxicological, and histopathological findings of a singular case of a Foreign Body Aspiration (FBA) death in a child.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the necessity for a complete methodological and multidisciplinary forensic approach by means of autopsy and histopathological examinations to diagnose an FBA-related death.

FBA is still a significant concern in the pediatric population, accounting for thousands of emergency room visits and more than 150 deaths each year in the United States alone.<sup>1</sup> Mortality rates can be relatively high, with some studies reporting a rate of up to 3.4% among patients admitted for FBA.<sup>2</sup> Depending on the location and the degree of airway obstruction, patients can present with signs and symptoms ranging from a non-specific cough to shortness of breath and stridor. In case of distal localization in the tracheobronchial tree, the most common symptoms are unilateral wheeze and decreased breath sounds.<sup>3</sup> Even a small reduction in the size of airway can cause a significant increase in airway resistance; therefore, the consequences of foreign body inhalation could be dramatic.<sup>4</sup> This report describes characteristics, circumstances, radiological, toxicological, and histopathological findings of a singular case of an FBA-related death in a child.

This case regards a 7-year-old child who died at home after a licorice candy ingestion. After the candy ingestion, he started coughing and wheezing and immediately turned cyanotic. His mother attempted resuscitative procedures that were unsuccessful and called the emergency services. At arrival, emergency services attempted tracheostomy without success and decided to transport the child to the closest hospital. During transportation, inside the ambulance, death was pronounced. Recent medical history was positive for an airway infection: cough and mucus were present and he had been treated with antibiotics for five days.

A Computed Tomography (CT) total body scan performed prior to autopsy excluded any traumatic lesion as well as the presence of foreign bodies in the upper airways and the main bronchi.

A complete autopsy was performed two days after death. Cervical and thoracic organs were dissected with Gohn's method (*en bloc*). Inside the trachea and main bronchi a brownish dense material and white foam were observed; in the right bronchus such material was denser. The trachea and main bronchi walls had no lacerations. Macroscopic examination of the brain and abdominal organs was unremarkable. After fixation, the cervical and thoracic organs *en bloc* was examined. Inside a secondary right bronchus, a black, foreign body of hard consistency, which measured 0.5cmx0.4cm, was observed. Histologic examination of all organs was performed using Hematoxylin-Eosin (H&E). An immunohistochemical staining method of lung samples was performed with CD45 and mast-cells antibodies. H&E-stained lung samples revealed acute emphysema, endoalveolar hemorrhagic oedema, as well as thickening of alveolar septa. H&E-stained bronchi and trachea samples revealed thickening of the wall and signs of chronic lymphocytic inflammation. H&E samples of all organs revealed the presence of lymphocytic inflammation. Immunohistochemical staining of lung samples showed a strong positive reaction to CD45 and mast-cells antibodies with signs of degranulation. Routine toxicological analysis was performed and was unremarkable.

In conclusion, the circumstantial data, both macroscopic and microscopic upper airways and lung findings as well as immunohistochemical study, contributed to exclude a choking death. Cause of death was attributed to an acute respiratory failure due to a bronchospastic reaction after a foreign body aspiration in a child with chronic systemic lymphocytic inflammation.

### H6 Lichtenberg Figures in Electrocution Deaths by Evaporative Cooler

*Nilesh K. Tumram, MD\*, Department of Forensic Medicine and Toxicology, Nagpur, Maharashtra 440013, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand that Lichtenberg figures, until now synonymous with lightning strikes, can also occur in electrocution caused by electrical instruments, such as evaporative coolers. This presentation will discuss the possible mechanism of causation of Lichtenberg figures in conditions other than lightning strikes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the occurrence of Lichtenberg figures after electrocution by an evaporative cooler.

In a bizarre accident, three persons of the same family were found electrocuted by the evaporative cooler at their home. The incident happened when a young lady in her 30s, the daughter of an elderly couple, was replacing water in an evaporative cooler. Incidentally, the evaporative cooler was kept running while she was filling it with water. As the water flowed into the evaporative cooler, some spilled on the floor. Though initially everything went smoothly, when the water was spilled on the ground, the lady suddenly screamed for help. Hearing her scream, her mother and father rushed near the evaporative water cooler where their daughter was found lying on the ground and screaming for help. Without any hesitation, the couple went to pull her up, but they also stepped in the pool of water on the floor and started to scream. In the meantime, the neighbors sensed trouble. When the neighbors reached them, they found all three people lying in the pool of water, with the evaporative cooler fallen on one side. The neighbors carefully switched off the mains of the electric source of building, then tried to wake them. However, nobody dared go over the wet floor in fear of themselves being electrocuted too. Someone called the police, who came after some time and found the victims already dead.

The bodies were subjected to a medicolegal autopsy. It was observed that the young lady received superficial burns over her entire back, with blackening and peeling of the skin. There were also abrasions over her chin, right cheek, the right side of her mandible, and the left side of her forehead. There was flattening of the lateral aspect of the left heel, a pattern of reddening tree branching/Lichtenberg figures over the left sole, and the right sole was completely pale. There was cyanosis of the fingernail beds and the internal organs also showed multiple petechial hemorrhages in the lungs and heart.

Interestingly, barring mechanical injuries, there were similar Lichtenberg figure patterns over the soles of the two other victims. Such types of Lichtenberg patterns are common in deaths or accidents by lightning strikes. However, a Lichtenberg figures pattern in electrocution deaths other than lightning is not known per this study's research.

#### **Lichtenberg Figures, Evaporative Cooler, Electrocution**

### H7 Modeling of Inflicted Head Injury by Shaking Trauma in Children—What Can We Learn? Part 1: A Systematic Review of Animal Models

*Marloes E.M. Vester, MD\**, Netherlands Forensic Institute, The Hague, ZH 2497GB, NETHERLANDS; *Rob A.C. Bilo, MD*, Netherlands Forensic Institute, The Hague 2490 AA, NETHERLANDS; *Arjo J. Loeve, PhD*, Delft University of Technology, Delft, Zuid-Holland 2628 CD, NETHERLANDS; *Rick R. Van Rijn, PhD*, Amsterdam UMC, Amsterdam 3544MT, NETHERLANDS; *Jan Peter van Zandwijk, PhD*, Netherlands Forensic Institute, The Hague, Zuid Holland 2497 GB, NETHERLANDS

**Learning Overview:** After attending this presentation, attendees will understand the different forces and their respective injuries in animal studies with lambs and piglets mimicking inflicted head injury without any direct external impact.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a systematic review to address the pathophysiology in order to discuss the forces needed to cause injury in infant animals. These values are important in the interpretation of injury in alleged human abusive head trauma cases.

Injury in infants caused by repetitive acceleration-deceleration trauma (e.g., caused by shaking) in the absence of a direct impact trauma to the outside of the head, other than chin-chest and head-back collisions, is a process better defined as Inflicted Head Injury caused by Shaking Trauma (IHI-ST). IHI-ST, also commonly referred to as Abusive Head Trauma (AHT), can cause brain injury. Yet, the exact pathophysiologic mechanism and its associated thresholds remain unclear. In this systematic review, an overview of animal model studies for shaking injury and their findings on tissue damage will be provided.

A systematic review was performed in MEDLINE® and Scopus® for articles on the simulation of inflicted head injury in animals, up to January 1, 2017. After collection, the studies were independently screened by two researchers for title, abstract, and finally full text, and on methodological quality.

After de-duplicating of the search results, 1,977 articles remained, resulting in 23 articles eligible for full text screening. A total of 12 articles were included after full text screening. Three articles were based on a single study population of 13 lambs, all of one research group. The other 9 articles were separate studies performed in piglets, all by a single second research group.

The 5-to-10-day-old, anesthetized lambs were vigorously shaken by adult humans, resembling human infant shaking, and euthanized after six hours. Overall, the shaken lambs showed injuries of the brain, spinal cord, and eyes. The control animals did not show any relevant abnormalities. Injury was more common and more extensive in the lower weight, younger lambs, who all died prematurely.

In five studies, 3-to-5-day-old piglets received a rapid inertial, non-impact head acceleration in the transverse (axial) plane, while three other articles used accelerations in different planes (transverse, sagittal, or coronal). Lastly, one article reported solely on transverse accelerations as well, yet in 4-week-old piglets. In piglets, it was found that rotation direction was of influence on the neurological and histology results. Tissue strain might be of influence on the injuries found in piglets and lambs. However, the anatomical differences between animals and humans, along with the inconsistent choice of (mostly non-cyclic) rotation directions in the various studies make an adequate comparison between studies and between animals and humans very difficult.

The lamb articles give some information on tissue damage after inflicted head injury. The piglet studies only provide information on consequences of a single plane rotational movement. Generally, with increasing age and weight, there was a decrease of axonal injury and death. Future studies should focus on every single step in the process of a free head movement in all directions, resembling human IHI-SC. In part II of this systematic review, biomechanical models will be evaluated.

#### Closed Head Injuries, Child Abuse, Animal Models

### H8 Modeling of Inflicted Head Injury by Shaking in Children—What Can We Learn? Part 2: Mathematical and Physical Models

*Jan Peter van Zandwijk, PhD\*, Netherlands Forensic Institute, The Hague, Zuid Holland 2497 GB, NETHERLANDS; Arjo J. Loeve, PhD, Delft University of Technology, Delft, Zuid-Holland 2628 CD, NETHERLANDS; Marloes E.M. Vester, MD, Netherlands Forensic Institute, The Hague, ZH 2497GB, NETHERLANDS; Rob A.C. Bilo, MD, Netherlands Forensic Institute, The Hague 2490 AA, NETHERLANDS; Rick R. Van Rijn, PhD, Amsterdam UMC, Amsterdam 3544MT, NETHERLANDS*

**Learning Overview:** After attending this presentation, attendees will: (1) be familiar with the different types of mathematical and physical models that have been used to investigate inflicted head injury by shaking in children, (2) learn about the strengths and limitations of these models and their underlying injury thresholds, and (3) learn how to put into perspective the various claims in the field about inflicted head injury by shaking in children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing medical and legal practitioners who are not biomechanically trained to better put the claims made in the literature into perspective. This is crucial for proper interpretation of injuries in alleged abusive head trauma cases.

Various types of complex biomechanical models have been published in the literature to better understand processes related to Inflicted Head Injury by Shaking in Children (IHI-CS). The wide variety of model types and modelling approaches makes it hard to compare these models to each other and value their—sometimes contradictory—conclusions with respect to the likelihood of pediatric head injury occurring due to shaking. A systematic review was conducted to categorize the available modelling studies and to enable better comparison of these studies.

MEDLINE® and Scopus® were used to find studies applying physical (such as dolls) and mathematical (computer simulation) biomechanical models for shaken induced head injury in children up to January 1, 2017. After de-duplication, the found articles were independently screened by two researchers using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) approach. Data extracted from the papers is represented in a “7-Steps Description” of IHI-CS, addressing the sequence of mechanical events that take place in a child subjected to shaking.

The initial database search yielded 1,977 papers, of which 11 papers on physical models and 23 papers on mathematical models were included after the selection process. In both categories, some models focus on describing gross head kinematics during shaking events, while others address the behavior of internal head and eye structures in various levels of detail.

In the 7-Steps Description, an IHI event is initiated with a shaking motion exerted onto the infant’s torso: the “torso dynamics,” which is the input at Step 1. That motion is transferred by the neck to the head in Step 2 “torso-skull transfer,” which results in the “skull dynamics” at Step 3. In turn, these skull dynamics determine in Step 4 “skull-internal transfer,” how everything inside the skull moves and deforms, resulting in the “internal dynamics” at Step 5. Internal dynamics include loading and deformation of the anatomical elements inside the skull, such as pressure acting on the eyes or strains acting on the bridging veins. The dynamics of internal anatomical elements may lead to damage of these elements if their threshold for material damage is exceeded in Step 6 “injury thresholds,” which then gives rise to “injury” in Step 7.

In virtually all mechanical and mathematical models analyzed, injury thresholds were derived from scaled non-infant data. Studies focusing on head kinematics often used injury thresholds derived from impact studies. Physical modelling studies as well as some mathematical models focusing on head kinematics often conclude that shaking alone cannot produce injury. However, mechanical models containing detailed head anatomy, as well as mathematical models containing a detailed description of structures inside the infant head and eye suggest that shaking events can indeed produce injuries, such as bridging vein rupture and retinal hemorrhaging. Besides this, several of the studies analyzed hinted at the possibility that the injury mechanism during shaking is fundamentally different from that during impact. Mechanical effects in which shaking likely differs from impact include build-up of pressure within the head over multiple shaking cycles, resonance effects, and a slower, but potentially higher, transfer of deformation energy.

Future research focusing on determining injury thresholds for infant biological material is urgently called for. This holds both for macroscopic anatomical data, such as stiffness of the infant neck, as well as for microscopic data, such as the failure stretches of infant bridging veins. Also, possible other injury mechanisms during shaking should be further investigated, because there seem to be clear indications that the currently often-made comparisons of shaking events with impact injury thresholds may not be valid.

#### Closed Head Injuries, Child Abuse, Rigid Body and Finite Element Model

### H9 Chillin' in Hotlanta: A Five-Year Retrospective Study of Hypothermia Deaths in Fulton County, Georgia

Maxwell O. Rollins, MD\*, Fulton County Medical Examiner, Atlanta, GA 30312; Jan M. Gorniak, DO, Fulton County Medical Examiner, Atlanta, GA 30312; Jason Singh, MD, Emory Pathology, Atlanta, GA 30322

**Learning Overview:** The goals of this presentation are to: (1) examine risk factors for hypothermia, and (2) assess anatomic findings of hypothermia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying risk factors for hypothermia that may help the population in preventing hypothermia.

Hypothermia-related deaths are prevalent during the winter in states that have cold climates; however, hypothermia-related deaths also occur in states with milder climates. Close to 800 hypothermia deaths occur each year in the United States. According to the Center for Disease Control and Prevention (CDC), hypothermia is clinically defined as lowering of the core body temperature to less than or equal to 95°F (less than or equal to 35°C). Exposure to cold is responsible for approximately twice the number of deaths annually as is exposure to heat in the United States.

All records of deaths occurring in Fulton County, GA, from 2013 to 2017 in which hypothermia was listed as the cause of death were reviewed. Review of the 47 cases showed that all hypothermia deaths were ruled accidents. There were 41 (87%) male decedents and 6 (13%) female decedents. At least 28 (60%) of the decedents were homeless. Thirty-eight cases (81%) occurred in the outside environment and 9 cases (19%) occurred inside a building. Of the cases that occurred inside ( $n=9$ ), four (44%) occurred in vacant buildings and 5 (55%) occurred in the decedent's own residence. Ethanol was associated with 15 (32%) cases (with ethanol alone or in combination with other drugs), with an ethanol (vitreous or blood) concentration ranging from 74mg/dL to 488mg/dL (.074%–.488%). Of the autopsied cases ( $n=43$ ), grossly, gastric mucosal petechial hemorrhages/hemorrhagic ulcers (Wischnewski spots) were identified in 20 cases (47%).

The year 2014 had the highest number of cases ( $n=18$ , 38%), although surprisingly, no specific correlation is seen with the winter storm that crippled Atlanta for nearly a week beginning January 28, 2014, known colloquially as "Snowmageddon 2014" (in the seven days from 1/28/14 to 2/4/14, there were four cases of hypothermia). It is not known why 2014 had almost 40% of the Fulton county cases over a 5-year period, although per CDC data, nationally in 2014, there were more hypothermia deaths than in the prior 13 years. Understanding risk factors of hypothermia in Fulton County and on a national level is essential for improving prevention efforts.

#### Hypothermia, Weather-Related Death, Drugs of Abuse

### H10 “Hot Deaths”: A Review of Foggia Hyperthermia Cases

*Stefania De Simone, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Francesca Maglietta, MD*, Department of Forensic Pathology, Foggia 71122, ITALY; *Lorenzo Spagnolo, MD*, Department of Forensic Pathology, Foggia 71122, ITALY; *Santina Cantatore, Foggia 71100, ITALY*; *Pietrantonio Ricci, MD, PhD*, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; *Monica Salerno, MD, PhD*, Department of Forensic Pathology, Foggia 71121, ITALY; *Francesco Sessa, MS*, Department of Forensic Pathology, Foggia 71100, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY

**Learning Overview:** The goal of this presentation is to show that in deaths related to hyperthermia, even if caused by different situations, it is possible to reach a diagnosis through the study of some microscopic findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that similar microscopic evidence can be found in heat-related deaths, suggesting the use of these postmortem analyses in similar cases.

Hyperthermia is a condition characterized by an uncontrolled increase in body temperature, which the human body can not dissipate. Exposure to excessive heat usually determines an activation of the hypothalamic thermoregulatory centers, which are activated to favor the dispersion of heat through vasodilatation and sweating. If this does not happen, there is a disruption of the thermoregulation systems, and, therefore, there is rapid multi-organ failure, which leads to death.

This study presents three cases of fatal hyperthermia, analyzed by the Department of Forensic Pathology of Foggia. The first case concerns a 26-year-old Romanian girl, treated for a depressive disorder, who was found immersed in hot water in a bathtub. The toxicological analyses performed on the girl's blood revealed the presence of high concentrations of alcohol. The intake of high doses of alcohol leads to a state of deep lethargy; therefore, the girl, not feeling the excessive heat of the water, in a state of acute intoxication, could not get out of the bathtub. During the crime scene investigation, conducted six hours after the discovery of the corpse, the water temperature was 30°C, while the cadaveric temperature was 43°C.

The second case is that of a 51-year-old man who worked aboard a fishing boat. During a very hot day, around 2:00 p.m., he began to be confused, with garbled speech, until losing consciousness shortly thereafter. Death was attributed to a heat stroke.

The third case is related to a 47-year-old man, a prisoner and ex-drug addict in methadone and neuroleptics therapy, who was found lying on the bed with a high fever while wearing nine wool sweaters. Subsequently, he was transported to the hospital in a comatose state, with a body temperature of 42.8 °C; he died a few hours later.

Presented are three different causes of death related to hyperthermia (immersion of the body in hot water, heat stroke, and intake of neuroleptics), but these all have in common some histological and immunohistochemical findings. Heat Shock Proteins (HSP 27, HSP 70, and HSP 90) were conducted on skin samples; anti-myoglobin antibodies were conducted on kidney and muscle tissue samples. There was widespread poly-visceral stasis. In the brain, edema and acute stasis were documented. The lungs had notable edema, acute stasis, and acute emphysema with septal rupture. The analysis of the skin demonstrated intense positivity to HSP 27 and HSP70. The muscles exhibited plenty of rhabdomyolysis and vacuolization of the muscle fibers. In the muscle and renal sample, tested with the anti-myoglobin antibody, intense positivity was demonstrated. The renal tubules were filled with myoglobin cylinders.

It is common to observe diffuse stasis and acute edema of the brain and the lungs, as well as the cutaneous positivity of HSP 27, HSP 70, and HSP 90. HSPs are proteins that are synthesized especially in response to various forms of cellular stress, such as high temperature, infections, free radicals, and biomechanical forces, to protect proteins from denaturation. In addition, HSP inhibits cell apoptosis induced by various stimuli, including the thermal stimulus, being detected early in case of exposure to heat. The expression of HSPs is related to the time of exposure to heat. Indeed, HSP 27 is the earliest to appear. The positivity to anti-myoglobin antibodies in muscle and the kidneys is also important to detect massive rhabdomyolysis.

#### Heat Shock Proteins, Hyperthermia, Anti-Myoglobin Antibodies

### H11 The Strange Trajectories of Death: Avtomat Kalashnikov—The New Weapon of the Garganic Mafia

Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY; Lorenzo Spagnolo, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Santina Cantatore, Foggia 71100, ITALY; Gianfranco Guccia, Palermo 90145, ITALY; Marcello Rendine, DBA, Department of Forensic Pathology, Foggia 71100, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Irene Riezzo, MD, PhD\*, University of Foggia, Foggia 71100, ITALY

**Learning Overview:** The goal of this presentation is to review wound ballistic evidence that comes from a new murder weapon used by the Garganic Clans (the Apulian Mafia in southern Italy): the Avtomat Kalashnikov (AK). This presentation focuses on macroscopic and histological findings used to distinguish between different weapon injuries, with particular regard to the wounds produced by the AK-47 rifle and AKM-74 missiles.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the need for a different approach to autopsy because of the high-velocity tumbling and fragmentation of AK bullets, describing their unusual trajectories in the body.

In the past few years, the Clans of the Gargano Mafia have radically changed their methods of murder. In fact, the methods of execution were characterized by the propulsion of multiple shots from firearms (shotguns), some of which exploded in the face, serving the double purpose of killing the victim and simultaneously scarring the body that would later be seen by relatives. However, in the past three years, they have changed “the murder tool”: in addition to the usual weapons, the AK is being used. The Garganic Clans use the AK not only for its high-offensive fire potential, but also because it is a symbol of power among the rival clans.

The AK is a gas-fired, selective assault rifle, developed in the Soviet Union, that comes from military scenarios. The original version (AK-47) of this weapon fires the 7.62mmx39mm cartridge with a muzzle velocity of 715m/s. The next version (AKM-74) of this weapon converted the rifle to the intermediate-caliber, high-velocity 5.45mmx39mm cartridge with a muzzle velocity of 900m/s. The different characteristics of these projectiles in comparison with other known firearms (shotguns, handguns), such as mass, caliber, velocity, shape, and material, explains different missile-tissue interaction.

The many and different types of weapons used for the “new” homicides, and the presence of multiple entrance wounds on the victim’s body (average  $\pm 35$ ), forced the use of a different methodological approach to the decedent. This study reports a summary of wound ballistic evidence from nine cases of homicide committed with multiple weapons, including the AK from the Garganic Clan’s wars. At the primary crime scene, ballistic elements were collected. Then, an external regional examination and radiological investigation (X-rays, Multi-Slice Computed Tomography (MSCT)) of the body were performed to detect the bullets.

The gross-examination of the head showed the AK bullets produced shattering of bone. The macroscopic form of the entrance wound of the AK bullet into soft tissues was not constant and depended on the presence of previous interactions with other objects (e.g., car doors). Likewise, the shape of the exit wound was not regular and depended on the injured tissues. When the AK47 bullet passed only through soft tissues, the instability characteristics of the 7.62mmx39mm bullet led to a net via the parenchymatous organs, with holes approximately 1.5cm in diameter. Extremely complex, non-linear, and multiple, spreading intracorporeal trajectories were observed. This phenomenon is due to the destabilization of the bullet during penetration (tumbling phenomenon) and its fragmentation into small and separate parts.

The histological examination of the entry and exit wounds and of the injured organs showed loss of tissue structure, cavitation, vacuolation, few red blood cells, perivascular ring hemorrhages, the presence of passive transport elements (muscular and cutaneous elements in liver), and foreign bodies. These histological findings are different from the lesions produced by low-velocity ammunition.

**THIS ABSTRACT WAS NOT PRESENTED.**

### H13 Retinal Hemorrhages and Spinal Nerve Root Hemorrhages in Pediatric Resuscitated Near-Drownings: Recognizing Ischemia-Reperfusion Injuries

*Anna G. McDonald, MD\**, Wake Forest Baptist Medical Center, Winston Salem, NC 27157; *Nathan S. Shaller, MD*, Wake Forest Baptist Medical Center, Winston Salem, NC 27157; *Patrick E. Lantz, MD*, Wake Forest University, School of Medicine, Winston-Salem, NC 27157-1072

**Learning Overview:** The goal of this presentation is to demonstrate the extent of reperfusion injuries in the eyes, spinal cord, and central nervous system in two pediatric cases of resuscitated, near-drowning events with prolonged resuscitative efforts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how retinal hemorrhages and spinal nerve root hemorrhages are due to hypoxia-ischemia reperfusion injury and are not specific for inflicted trauma.

A complete and thorough autopsy is critical in a subset of accidental pediatric deaths where circumstances are uncertain. Reported here are two resuscitated, near-drowning events in young children who developed fatal hypoxic-ischemic brain injury with herniation, retinal hemorrhages, spinal cord ischemia, and spinal nerve root necrosis and/or hemorrhage. This presentation highlights the necessity of performing a meticulous examination in near-drowning events, including a fundal examination, brain examination, and spinal cord examination to include both nerve roots and dorsal root ganglia.

The first case is a 4-year-old girl who was found submerged in a residential pool at her grandmother's house after being seen one to two minutes prior. Her uncle pulled her from the pool and immediately began cardiopulmonary resuscitation. Emergency Medical Services (EMS) arrived and intubated her prior to her bradycardia and subsequent cardiac arrest with pulseless electrical activity. Resuscitation was performed for approximately one hour prior to the return of spontaneous circulation. Pupils at the time were fixed and dilated, and the child was transferred to a tertiary center where a head Computed Tomography (CT) scan showed diffuse cerebral edema. A CT scan of the chest and abdomen showed sternal fractures (secondary to resuscitation), pulmonary edema, and diffuse dilation of the small bowel. Her condition continued to decline, and she was pronounced brain dead two days after the immersion incident.

The second case is a 7-year-old boy who was found fully submerged in a community pool after being seen playing approximately three to four minutes prior. Video footage later showed the boy jumping in the pool and playing prior to falling beneath the surface of the pool. EMS arrived to find the boy pulseless and performed resuscitative measures for at least 30 minutes prior to the return of spontaneous circulation. On arrival to a tertiary care center, his pupils were asymmetrically dilated and non-reactive. A head CT scan showed diffuse cerebral edema and hypoxic ischemic injury. A CT scan of the chest showed acute non-displaced, bilateral rib fractures (consistent with resuscitation) and lung changes suggestive of aspiration and pulmonary edema. Two brain death examinations were performed prior to pronouncement of death approximately 3.5 days after the near-drowning. Permission was granted for organ procurement.

Autopsy findings for both cases showed diffuse cerebral edema, bilateral aspiration pneumonia, and softening of the spinal cord. The younger child also had bilateral optic nerve sheath hemorrhages. Postmortem monocular indirect ophthalmoscopy revealed retinal hemorrhages in varying numbers, with the younger child having bilateral retinal hemorrhages (10-15 right eye, 50 left eye) and the older having a single hemorrhage. Histologically, the spinal cord and brain of both showed hypoxic-ischemic changes, accompanied by hemorrhage in the lumbar cord of the older child. Sampled spinal nerve roots showed perineural and intraneural necrosis, with associated hemorrhage in the case of the older child. No additional injuries were identified that caused or contributed to the deaths.

Near-drownings with prolonged downtimes and subsequent resuscitation lead to diffuse hypoxic injury of the brain and spinal cord. While no antemortem fundal examinations were performed during the hospitalization, postmortem fundal examination revealed retinal hemorrhages not clinically expected. Meticulous examination of the spinal cord also showed each child had nerve root ischemic changes and hemorrhage, thought by some authors to be specific for a shaking mechanism of injury. These cases highlight the importance of fundal examination and spinal cord examination in the resuscitated pediatric population to detail the extent of the ischemia-reperfusion injuries throughout the nervous system.

## H14 Only the Vagus Nerve: A Pair of Unusual Homicides

Stacey L. Reed, DO\*, Allison Park, PA 15101; Todd M. Luckasevic, DO, Allegheny County Medical Examiner's Office, Pittsburgh, PA 15222; Abdulrezak M. Shakir, MD, Allegheny County Medical Examiner's Office, Pittsburgh, PA 15222; Karl E. Williams, MD, Allegheny County Medical Examiner's Office, Pittsburgh, PA 15222

**Learning Overview:** The goal of this presentation is to increase awareness of an uncommon potential cause of death in the setting of penetrating head and neck trauma without massive injury.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a unique finding at autopsy and encouraging others to consider isolated vagal stimulation or injury as a precipitator of cardiac arrest and death.

The vagus nerve is the longest autonomic nerve in the body, providing parasympathetic control of the heart, lungs, and gastrointestinal tract. Running down the bilateral neck adjacent to the internal carotid arteries, it gives off a branch to the carotid body before entering the thorax and abdomen. Along with the glossopharyngeal nerve, it is responsible for regulating heart rate and blood pressure via the baroreflex, and thus can be implicated in instances of cardiac arrest due to neck trauma.<sup>1,2</sup>

Described here are two deaths in which violent actions (a gunshot and a stabbing) to the head and neck failed to illicit what would be considered “fatal” injuries; in each case, the vagus nerve was the only structure with any demonstrable trauma.

**Materials and Methods:** Case #1 is a 17-year-old African American male found lying in the street for an unknown interval with a gunshot wound to the head. Resuscitation efforts were unsuccessful, and the decedent was brought to the Allegheny County Medical Examiner's Office (ACMEO) as a homicide.

Case #2 is a 59-year-old Caucasian female who was stabbed twice in the neck with a knife by her husband. She was able to run to a neighboring home for help, but as Emergency Medical Services (EMS) was rendering aid, she went into cardiac arrest. Upon arrival at the hospital, emergent laryngoscopy and surgical wound exploration were performed, noting platysmal disruption, but all major vessels were intact. The patient never regained consciousness and after a short hospitalization was brought to the ACMEO as a homicide.

**Results:** Case #1—Examination of the head and neck revealed an indeterminate-range entrance gunshot wound to the right face, with the bullet lacerating only the skin, subcutaneous tissues and muscles of the face, and left lateral neck and contusing the left vagus nerve before exiting the left upper lateral neck. The vertebral bodies, mandible, skull base, and major blood vessels were undamaged.

Case #2—Examination of the head and neck revealed two stab wounds to the right lower anterior neck and left upper anterior neck, both lacerating only the skin, subcutaneous tissues, and muscles of the neck. All major blood vessels were spared; there was hemorrhage surrounding the right vagus nerve. Examination of the cervical spine, vertebral arteries, and spinal cord were unremarkable.

**Discussion:** A literature review for reports of violent deaths with only vagal trauma revealed a case of a screwdriver stab to the neck, which similarly spared all major neck structures, yet resulted in the patient's death.<sup>3</sup> Schrag et al.'s review of Cardioinhibitory Reflex Cardiac Arrest (or CiRCA) deaths found that of 48 potential CiRCA deaths reported between 1881 and 2009, only one death could not potentially be attributed to another cause.<sup>4</sup> While vagal stimulation is known in the anesthesia literature to be a potential cause of cardiac arrest, it is difficult to assign as a cause of death, as there are often many confounding factors.

If a thorough autopsy in a case of violence (e.g., shooting or stabbing) to the head and neck fails to reveal enough vascular, nervous, or bony trauma to account for death, the vagus nerve should be carefully examined for hemorrhage or contusion and considered as the cause of death.

### H15 Unusual Frangible Ammunition Used in a Homicide: A Case Report

*Sandra E. Jones, BS\*, Office of the Chief Medical Examiner, Raleigh, NC 27607; Michelle B. Aurelius, MD, Office of the Chief Medical Examiner, Raleigh, NC 27699-3025; Chad Moose, Rowan County Sheriff's Office, Salisbury, NC 28144*

---

**Learning Overview:** After attending this presentation, attendees will better understand frangible projectiles and how ballistic testing from law enforcement can identify frangible projectiles, confirm the number of gunshot wounds, and complement autopsy findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the need for the forensic pathologist to be familiar with frangible projectiles that are no longer in production as well as how law enforcement ballistic testing can support autopsy findings.

Frangible projectiles for firearms are designed to fragment upon impact. They are mainly used for training purposes and can provide improved safety in some situations by reducing the risk of ricochet and overpenetration of secondary targets. Frangible bullets are made of composites of hybrid materials and can produce atypical injury patterns at autopsy. In addition, the projectile fragmentation can make it difficult to determine the number of gunshot wounds at autopsy, with multiple projectile fragments with their associated multiple wound tracks from a single gunshot wound. The forensic pathologist must be familiar with the evolving firearm and ammunition industry, including knowledge of frangible projectiles that are growing in popularity with manufacturers.

This presentation describes a case of a 62-year-old African American female who was found dead in her home with gunshot wounds of the head. At the scene, law enforcement found three 9mm shell casings. Radiographs showed nine radiopaque projectiles in the head and neck. Two gunshot wound defects were identified on the head. Mild to moderate decomposition with diffuse postmortem softening of the brain and one of the entrance gunshot wounds being atypical (internal and external beveling, no discernible marginal abrasion) made gunshot wound evaluation difficult. Ultimately, two entrance gunshot wounds of the head were identified at autopsy and nine projectile fragments were recovered. Five fragments were spoon-like, convex on one side with a shallow bowl on the other. Two fragments consisted of bases, and the additional two fragments were relatively small. None of the objects appear to have exited.

Law enforcement identified a suspect and it was revealed that Aguila® “IQ” 9mm hollow point ammunition was used during the shooting. The Aguila® “IQ” ammunition has been out of production for approximately a decade. It was produced in Mexico and is not a commonly used projectile. It was designed to break into three or four pieces when it struck a firm surface.

Law enforcement obtained a box of this ammunition and test fired it into a tank of water. Four rounds were test fired, and each round broke into four pieces, resulting in a base and three leaves.

Assessment of the fragments recovered at autopsy and correlation with the law enforcement ballistic findings support that one leaf fragment exited the atypical gunshot wound of the forehead, as supported by a keyhole defect in the skull. The remaining projectile fragments recovered were consistent with the fragments obtained from the decedent, supporting that each frangible projectile fragmented in a similar manner, with three leaves and a round base. The number of fragments found is consistent with two “IQ” ammo projectiles entering the head and one leaf fragment exiting the head.

This case emphasizes the wound interpretation challenges at autopsy that can arise with frangible ammunition as well as the importance of the utilization of firearm ballistics to correlate with wounds.

---

#### Gunshot Wound, Ballistics Testing, Frangible Ammunition

### H16 Plugged, Unplayable Lies: A Case Report of a Novel Suicide by Foreign Body Airway Obstruction

Stacey L. Reed, DO\*, Allison Park, PA 15101; Todd M. Luckasevic, DO, Allegheny County ME, Pittsburgh, PA 15222

**Learning Overview:** The goal of this presentation is to illustrate a novel case of suicide by asphyxiation wherein the decedent intentionally self-occluded the airway by the introduction of multiple foreign objects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the need for thoughtful and thorough scene investigation regarding manner of death in a case that could be interpreted as a likely homicide, as well as by highlighting the inventive nature of suicide enactors.

**Introduction:** Asphyxial deaths by choking and airway obstruction are most often characterized as accidents, such as elderly or inebriated individuals choking on a food bolus, or homicides, as in the case of robbery victims being silenced by gags.<sup>1</sup> Rarely are there reports of intentional self-introduction of foreign objects into the larynx for the purpose of taking one's own life. Such a case is described here.

**Materials and Methods:** The decedent was a 45-year-old Caucasian male found dead one morning in the basement of the home he shared with his mother. There were three strips of white tape measuring 1½ inches wide over the decedent's mouth, and there were multiple additional strips of tape hanging from the side of a nearby table. He was last known to be alive eight hours prior, and there had been no indication of intent for self-harm at that time. The scene showed no sign of a struggle or foul play, and there was no evidence of autoerotic behavior. The decedent had no known psychiatric history or evidence of recent psychosis.

**Results:** At autopsy, the decedent was found to have three soft-sided foam golf balls, each measuring 4cm in diameter, deep in the oral cavity occluding the larynx, with strips of adhesive tape fully covering the mouth. There were healing superficial incised wounds of the bilateral anterior wrists. There was no other evidence of acute trauma or recent violence. The remaining examination was unremarkable. Postmortem toxicology performed on blood was negative. The cause of death was determined to be asphyxiation due to airway obstruction by foreign bodies.

Upon further investigation, it was revealed that the decedent was about to be incarcerated for federal felony charges and had made comments to the effect that he "would not be going to jail." The manner of death was determined to be suicide.

**Discussion:** A literature review for suicidal self-asphyxiation with foreign bodies revealed these cases to be extremely rare, with most decedents choking on paper products or cloth.<sup>2-4</sup> The rarity of suicidal self-asphyxiation is likely due to the act being difficult to complete.<sup>5</sup> Unlike this current case, the actors typically demonstrate some degree of psychosis or have a history of schizophrenia.

Determining the manner of death can be challenging when the cause of death seems violent or unusual. As always, thorough scene investigation is crucial to be able to parse out suicidal intentions from what would otherwise appear to be accidental or even homicidal in nature.

### H17 Death by Fractal Art: A Tale of Beauty and Electrocutation

*Tasha Zemrus Greenberg, MD\**, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919; *Nizam Peerwani, MD*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919; *Stephen P. White*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104

**Learning Overview:** After attending this presentation, attendees will understand the importance of a thorough scene investigation in determining the cause of death in cases of suspected electrocution.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating medical examiners and forensic investigators about the features of deaths by electrocution and, specifically, the dangers involved in fractal art, as well as stressing the necessity of a thorough investigation of the scene to aid in the determination of cause of death.

On March 19, 2018, a 50-year-old male with a history of hypertension and methamphetamine use was found unresponsive in the garage at a private residence. He was taken to a local hospital where he was pronounced. The Tarrant County Medical Examiner's Office was notified of this death by a nurse at the hospital due to suspected electrical burns.

On March 20, 2018, at 11:00 a.m., the forensic investigator met with the decedent's mother. The decedent had been found supine near a homemade wood-burning craft machine plugged into an electrical socket, with a jumper cable clamp near his right hand and another lying across his chest. The mother had received a shock when she tried to remove the device and had thrown it into a trash bag, which was retrieved. The decedent had made the device himself for the hobby of wood burning. No water was seen on the concrete floor near the decedent.

The device was known as a "Lichtenberg Fractal Art wood-burning device," fashioned from a pair of six-foot-long jumper cables that were attached to what appeared to be a transformer out of a microwave oven that had a label stating: "JMOT-N 60A2-61T 120V/60Hz JI YUNG SA CO LTD # 9905111 DANGER HIGH VOLTAGE." The transformer was used to increase the power output to high voltage electricity. The handles of the jumper cables were wrapped in black electrical-type tape, with one of the cable's clamps having a bent/scorched nail in its teeth. The transformer had attachment points that were soldered on, then attached to a section of three-pronged electrical cord marked "14 AWG 12.09mm 105 deg C 300 V VW-1 -- LINETEK—" on the rubberized shielding. The device had been plugged into an older-style toggle switch power strip mounted to a wall. The power strip was found marked "MAX TOTAL RATING 12AMP 125V AC/DC." All the electrical breakers were on, had not tripped, nor had they been reset.

The decedent had been making fractal art for a few months and there were multiple examples in the garage. The art is created by making a circuit in the wood and using a slurry mixture of baking soda mixed with water; the water is used to complete the circuit and the baking soda to control the extent of the burn.

On July 24 2017, as reported in *Woodworking Industry News*, The Safety Committee of the American Association of Woodturners issued a policy against fractal burning, banning it from the American Association of Woodturners (AAW) -sponsored events.<sup>1</sup> This came after it was reported that in May 2017, an experienced woodworker in Walla Walla, WA, was electrocuted while making a picture frame using the Lichtenberg fractal burning technique. The coroner said the process was very dangerous.

Findings at autopsy included pulmonary congestion and edema, cerebral edema, mild fatty metamorphosis of liver, and thermal injuries of the chest with multiple deep troughs with blackened rims across the chest, present in a discontinuous, obliquely oriented line from the right upper to left lower chest. There was burning of the palmar surface of the right index finger extending toward the thenar eminence. There was also a faint area of brown discoloration on the sole of the left foot near the heel, suggestive of burn injury. Toxicology was positive for methamphetamine and amphetamine. The cause of death was ruled high voltage electrocution and the manner of death accident.

This case illustrates not only the danger of the fractal woodworking technique with regard to electrocution, but also the importance of thorough scene investigation to ensure an understanding of the circumstances surrounding the death and to ensure an accurate ruling of cause and manner of death.

**Fractal Art, Electrocutation, Wood Burning**

### H18 Homicidal Violence Against Children in Mississippi: Four Case Reports

*Mark M. LeVaughn, MD\**, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *L.R. Funte, MD*, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *Brent Davis, MD*, Mississippi State State Medical Examiner's Office, Pearl, MS 39208; *Anastasia Holobinko, PhD*, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *Steven A. Symes, PhD*, Mississippi State Medical Examiner's Office, Pearl, MS 39208

---

**Learning Overview:** After attending this presentation, attendees will understand the variation observed in homicidal cases as it pertains to violent crimes against children in the state of Mississippi. According to recent statistical data, Mississippi exhibits the highest infant mortality rate in the United States; however, these mortality rates do not include child deaths resulting from repeated abuse, neglect, or random criminal acts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing four cases of homicide in which the violence or maltreatment was perpetrated against children aged 5 to 13 years by parents or other relatives, non-parents (e.g., acquaintances or partners of relatives), or strangers.

**Case 1:** The partially clothed body of a 5-year-old female was found in an unoccupied mobile home by search teams the day after her abduction from her apartment complex. The postmortem examination revealed evidence of blunt trauma to the face and extremities and penetrating peri-genital injuries indicative of sexual battery. Dependent lividity and regionalized petechiae were consistent with asphyxia due to ligature strangulation (hanging). A male resident/visitor at the complex was eventually arrested and charged with capital murder. He was convicted and sentenced to death.

**Case 2:** A 7-year-old Black male and his mother were reported missing in late 2013. Their overturned and burning car was discovered, and their bodies and that of the child's stepfather were found inside an abandoned house. The juvenile's cause of death was identified as a single shotgun wound of the right forearm into the back with injury to the upper extremity and thoracic region. Authorities believe that the stepfather was killed first, and the child and his mother were subsequently taken to the house and shot. The perpetrator was convicted on two counts of capital murder.

**Case 3:** The decedent was an 11-year-old male who was found unresponsive in the bathroom of his father's and stepmother's home, and subsequently declared dead at the scene. Pertinent findings at autopsy were emaciation with blunt force injuries of the head, neck, torso, and extremities of sufficient severity to cause death. Body weight and organ weights were abnormally low, and subcutaneous adipose tissue and mesenteric fat were scant. The stepmother received a life sentence for second-degree murder; the boy's father was sentenced to 40 years in prison.

**Case 4:** This 13-year-old female and her mother were victims in a domestic murder-suicide carried out by the mother's live-in boyfriend. All three bodies were found at the residence by authorities after efforts to contact them had failed. The child died as a result of a close-range perforating gunshot wounds to the hands and forehead.

---

### Homicide, Children, Child Abuse

### H19 What a Dangerous Place: An Unusual Homicide in the Hospital

Roberto Vaglio, via Napoli n.2, Nardò; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY; Francesca Donno, MD\*, University of Bari, Bari 70121, ITALY

**Learning Overview:** After attending this presentation, attendees will understand patient outcomes resulting from a complex mix of preventable and/or unpreventable factors.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that an absolutely safe place doesn't exist, and autopsy is an essential investigative procedure.

Presented here is a strange case of murder: a hospital—a health care institution providing patient safety—became the setting for an act of lethal aggression.

A 73-year-old woman, confined to bed after a fracture of the femur, suffering from severe Alzheimer's disease and spasticity post cerebral ictus, was admitted to the emergency department with reported episodes of hypotension and bradycardia. After a neurological assessment, the woman was waiting for the diagnostic results in the waiting room. There, from 3:53 a.m. to 3:54 a.m. (when her son, who is assisting her as a caregiver, leaves her for a moment to go to the bathroom), she is the victim of an aggression by another patient (male, 42 years old, repeat offender with psychic disturbances, not in therapy, who had gone to the emergency room for a reported aggression by a known person).

The postmortem examination showed the right temporal region had an excoriated ecchymosis, irregularly oval, with a red-violet color, with small epidermal ridges, with a full thickness discontinuity in its center of the galea capitis, irregularly quadrangular, with dimensions of 2mm x 5mm. The soft tissue wound was next to a hole in the bone of a coarsely roundish shape, with neat margins, regular on the outside, approximately 7mm diameter, flared inside. The described wound, which calls to mind the entrance hole of a single projectile, had a more or less circular shape on the bone that reproduced the shape of the harmful tool. The dura mater presented a wound with morphological characteristics and dimensions compatible with the use of a tool such as a screwdriver, with an approximate diameter of 7mm. There was also a significant presence of small bone fragments in the brain parenchyma, transported inside by the action of the tool.

Penetrating head injuries due to the use of screwdrivers as wounding agents in acts of interpersonal violence are rarely reported events in forensic literature, and the mortality rate is approximately 47.6%.<sup>1</sup>

The cause of death in the present case report was a cardio-respiratory arrest by massive intra-parenchymal hemorrhage, widespread subarachnoid, and bilateral hemispherical subdural (as often happens with unipolar trauma) because of traumatic penetration of the skull.

The thickness of the bone of the victim—not particularly consistent—had facilitated the penetration of the tool and, therefore, the depth of the damage (determined by the introduction of the shaft inside the cerebral parenchyma), different than what has happened after a similar action of the same tool (screwdriver) in well-known cases in the literature.<sup>2</sup>

The autopsy allowed the reconstruction of the dynamics of mortal wounding and of the modality/tools used, even if there were no documented probative-value elements (activated cameras in the waiting room). The probative value of other evidence confirmed the reconstruction. In cases in which technology has its limits (malfunction of the video surveillance system of the waiting room), the integrated evaluation of the acquired elements with the medicolegal investigation can be successful: the compatibility of the injuries found with the use of a rigid tool, as a screwdriver (cut or star pattern), used as a dagger, led to the murderer.

In conclusion, the case presented will demonstrate that the solution is teamwork and an accurate integration of each element of probative value.

#### Hospital Murder, Screwdriver, Penetrating Head Wound

### H20 The “Tin Man”: Another Mafia Homicide

Francesca Donno, MD\*, University of Bari, Bari 70121, ITALY; Alessandro Dell’Erba, PhD, Risk Management Unit, Bari 70124, ITALY; Eloisa Maselli, MD, Bari 70122, ITALY; Roberto Vaglio, via Napoli n.2, Nardò, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance of an accurate “investigation” to interpret Mafia-related crimes. The murders committed and/or commissioned by a criminal organization are characterized both by method used and positioning of the body with a characteristic admonitory significance.<sup>1-3</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as an updated attestation of how the Mafia has preserved its own homicidal modality in the past years; a complete explanation of this will be provided only by careful observation and analysis of present evidence.

A metal-sheet drum covered with branches was found in pine trees close to a metropolitan area in southern Italy. The drum contained a male corpse in a fetal position, covered with stones, soil, concrete, an empty red-colored plastic bottle of hydrochloric acid, and a small “free” rope of approximately 1 meter in length. There was no clothing except for a small piece of fabric around the neck and two dark-colored socks. No identifying features of the face were recognizable. The skin was grayish-black, friable, and inelastic.<sup>4</sup> The hypostases were not visible, and the cadaveric rigidity was artefactual.

The autopsy showed a complex pattern of skeletal lesions, preliminarily demonstrated by total body Computed Tomography (CT) as follows: a fracture with multiple fragments of the lateral wall of the left orbit, disarticulation of the temporal process of the zygomatic bone, depressed, multiple fragment fractures of the left temporal bone, fracture of the lateral wall of the right orbit, and fracture of the maxillary bone with absence of some front teeth (incisors and canines). The mandible was disarticulated from the maxillofacial bones.

There was advanced liquefaction of the tissues of the neck: the head was connected to the trunk only through tendon and slender muscle-cutaneous flaps with dislocation of the anteroposterior axis of about 45° C5 on C4 and C7 on C6. The histological analysis showed some areas of subdural hemorrhage. The study of the other organs and viscera, despite the advanced liquefaction and putrefaction, excluded alternative causes of death.

The described injuries are due to blunt head and maxillofacial trauma. The morphology of the skeletal lesions, particularly in the left temporal region, is typical for the contusive nature of the fractures, produced with an object that probably did not have a large surface (stick, fist, stone, other). The left temporal region, the orbits, and the buccal region presented high-energy fractures caused by a force almost completely perpendicular to the surfaces. The site of the lesions suggests that the victim and the aggressor faced each other.

The analysis of molecular genetics, including the study of the polymorphisms of DNA extracted from the buccal swab of the two presumed sisters of a deceased subject and from the cadaver’s tooth, allowed this study to confirm the sharing of both parents with a probability equal to 99.99999999% (LR=4.21e + 15) with the consequent identification of the “tin-man.”

In conclusion, the case presented will demonstrate that these Mafia-style homicidal methods preserve a timeless symbolism representing a typical mark of belonging.

### H22 An Analysis of Risk Factors Involving All-Terrain Vehicle (ATV) Deaths

Charlene Admissions, BA\*, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Joanne Catania, MS, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Theodore T. Brown, MD, Kalamazoo, MI 49008

**Learning Overview:** After attending this presentation, attendees will better understand the categorized risk factors of ATV-related deaths, including modifiable risk factors that could potentially reduce the mortality rate of ATV-related deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by re-approaching medical examiner investigator reporting on modifiable risk factors relating to ATV deaths, creating a more consistent database for factors that can influence ATV-related deaths.

Each year, there are approximately 650 deaths and 100,000 injuries that involve ATVs.<sup>1</sup> Recognized risk factors of ATV-related accidents and deaths include not wearing a helmet, riding with more than the recommended number of riders, adequate training, driving on paved roads, and young age of the driver.<sup>1</sup> This significant number of ATV-related injuries and deaths warrant an even more detailed investigation of risk factors. This study presents a series of 11 ATV-related deaths in western Michigan where an investigation and/or postmortem examination was performed in order to review the circumstances of individual ATV-related deaths and identify modifiable and non-modifiable risk factors.

Of all ATV-related deaths reviewed, 10 of the 11 decedents were male (91%). The manner of deaths was all accidental (91%), except for one (9%), which was a suicide where a male was found dead in a closed garage with a running ATV. Most commonly, the decedent was the driver (64%), all deaths occurred on ATVs while performing non-work-related activities, and the cause of death was most frequently due to blunt force injuries (64%). Seven decedents (64%) were found ejected from the ATV, two of which were found with the ATV on top of them, which is suggestive that seatbelts were not used. All but two deaths occurred off paved roads, which while this is a United States Consumer Product Safety Commission recommendation, the-off road locations increase the risk of poorer visibility and are potentially more difficult to navigate terrain. In addition, most deaths occurred early in the morning or late in the evening, which is suggestive of decreased visibility as a contributing factor to ATV-related deaths. Of note, the ages of decedents range from 11 years to 82 years (mean age of 39 years) and the majority of cases (55%) had no evidence of alcohol or illicit drugs at the time of death, which is suggestive that age and alcohol/illicit drugs are not strong indicators for increased risk of ATV-related deaths.

This study was most interested in identifying modifiable risk factors of ATV-related deaths, such as use of seatbelts and helmets, in order to reduce ATV-related deaths in the future. While Medical Examiner Investigators (MEI) often included this information in their written report or demonstrated in photographs at the scene, the information provided was not consistent. Therefore, this presentation suggests an additional checklist of specific ATV-related investigative information that could have potential impact in reducing future ATV-related deaths: (1) safety measures of ATV and ATV occupants (seatbelt availability; evidence of seatbelt use; protection around cabin (ex: roof, roll bars, and windshield); evidence of helmet use (if so, location and type of helmet); number of occupants involved in accident; experience and training of driver; known alcohol/drug use of occupants; and significant underlying natural diseases of occupants); (2) circumstances of crash (time; level of visibility; crash location (off-road versus paved road, groomed trail versus ungroomed area); type of crash; location of decedents; and extent of damage to ATV); and (3) ATV-specific information (make; model; horsepower/torque; passenger capacity; and sit versus straddle).

#### ATV, Deaths, Safety

### H23 Delayed Subdural Hematomas in Decedents on Anticoagulation Medication in the County of Santa Clara, California

Michelle A. Jorden, MD, Santa Clara ME, San Jose, CA 95128; Karin E. Wells, BA\*, Aptos, CA 95003

**Learning Overview:** The goal of this presentation is to discuss several delayed subdural hematomas observed in a variety of manners of death at the Santa Clara county medical examiner/coroner's office from 2016 through mid-2018.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how decedents who are on anticoagulants and suffer a head injury do not necessarily present immediately with a subdural hematoma, which was also similar to the cohort not on anticoagulation. This finding underscores that a delayed subdural hematoma in these patients must be considered by the medical examiner as cause and manner of death may be affected.

The medical examiner/coroner's office has observed that decedents taking anticoagulant medication are not immediately presenting with evidence of traumatic brain injury in a variety of manners of death. Anticoagulation therapy is used for a multitude of medical illnesses, and the purported consequences of taking anticoagulation when sustaining a head injury are well established. While anticoagulant medications, such as warfarin, work to block the factors responsible for the coagulation of blood, there have been noticeable delays between injury and the presentation of symptoms of subdural hematoma. This poses a particularly interesting problem for medical examiners when rendering cause and manner of death, as traumatic brain injuries in anticoagulated patients may not always be acute. According to a study conducted by Rust et al., patients on warfarin are 42.5 times more likely to develop a chronic subdural hematoma.<sup>1</sup>

A retrospective search of the Santa Clara county medical examiner/coroner's database was performed for the years 2016 through mid-2018 with key words "subdural hematoma" and/or "blunt head trauma" encompassing all manners of death. The search resulted in 127 cases. The goal was to analyze basic demographics, time of injury to clinical presentation if known, and whether the decedent was on anticoagulation. One hundred five total accidental deaths (85 of which were accidental falls and 20 motor vehicle accidents), six homicides, eight undetermined, and eight natural deaths were identified. Of the 127, 38.5% of the decedents were on an anticoagulant medication, including warfarin, aspirin, clopidogrel, apixaban, rivaroxaban, ticagrelor, and one unknown. The most common anticoagulant medication was warfarin at 55%. The age range for all decedents in this study, whether on anticoagulation or not, was 5 months to 104 years of age, with average age at death being 71 years. The average age of decedents on anticoagulant medication was 81 as opposed to an average age of 65 for those not on anticoagulation. Of the 127 cases, 73% of individuals presented within the first 24 hours (range of minutes to 19 hours), whereas 27% of individuals presented after 24 hours; in these cases, clinical symptoms were more apparent (headache, vomiting, sleeping). In 77 cases in which exact time intervals from injury to clinical presentation were known, the average was 1.8 days.

The greatest percentage of deaths (68.5%) were related to accidental falls relating to traumatic head injuries. Of the 49 decedents on anticoagulant medications, 48 experienced an accidental fall; the average age at death for these decedents was 81 years. Of the 47 decedents who experienced falls while on anticoagulants, the average time from injury to clinical presentation among these decedents was 2.5 days. The reported timeframe corresponds with that presented by Volans, whose clinical study found that patients presented with complaints of headache up to three days after experiencing a fall.<sup>2</sup> There were an additional nine decedents for whom specific times to clinical presentation were not captured. Also of interest were three decedents who experienced a fall and had negative Computed Tomography (CT) scans initially; however, scans in the following days demonstrated subdural hematomas.

Of the six homicide cases, one decedent was taking anticoagulant medication and suffered craniocerebral injuries due to blunt head trauma. Four of the six homicide cases had thin subdural hematomas documented in addition to craniocerebral injuries, and all were pronounced deceased at scene.

Research on the delayed presentation of subdural hematomas in patients taking anticoagulant medication is limited, particularly from the perspective of the medical examiner.

### H24 Forensic Analysis in Mass Disasters: Were Gunpowder Explosions in a Fireworks Factory an Accident or a Terrorist Bombing?

*Francesca Tarantino, MD, Bari 70124, ITALY; Maricla Marrone, MD, Bari 70124, ITALY; Valentina Ronco, MD\*, Section of Legal Medicine D.I.M., Bari 70124, ITALY; Paola Corsignano Carrieri, Section of Legal Medicine D.I.M., Ballistic Centre, Bari 70124, ITALY; Stefania Lonero Baldassarra, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY; Francesco Vinci, MD, Bari 70124, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand more about the relevant role of forensic investigation and genetic analysis for the reconstruction of prior and consequential events in mass disasters.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing through an unfortunate event that explosions and/or bombings remain the most common deliberate cause of disasters involving large numbers of casualties, especially as an instrument of terrorism.

To address the problem to the maximum benefit of mass disaster victims, organization must be developed in classifying corpses, obtaining biological samples, and identifying people. The goal of this study is to evaluate the impact of different approaches to victims and to fulfill a valid protocol for their identification, which may gain importance in the resolution of forensic cases.

Reported here is the case of a fireworks factory in which combustible chemicals caused explosions and fires with consequent destruction of the factory and the death of all the workers. Four of ten victims had a meaningful Total Burn Surface Area (TBSA) of 99% and the last ones died in the hospital from cardiovascular collapse resulting from severe hypovolemic shock and sepsis. Two victims died from carbonization and the other four workers had carbonization associated with fractures of limbs (lower > upper), lacerations, amputations, decapitation, and massive body trauma resulting from explosions. The bodies of seven victims showed prominent traumatic changes that made it impossible to do individual identification, particularly for the mangled corpses and some that had extensive limb amputations and/or decapitation. A team performed autopsies and created a protocol to obtain biological samples (bones, blood, teeth, muscles). The forensic pathologists contacted the families of the alleged victims and each of them gave a blood sample collected for comparing DNA. The geneticist, using the method of extraction and gene amplification, obtained the DNA from bones, teeth, muscles, or blood samples taken from the victims, then compared with the those extracted from blood samples of the relatives; electropherograms showed at least one allele for each genetic marker of the Combined DNA Index System in common between the victims and the families, thus allowing the certain identity of everyone involved in the event. Therefore, it was possible to correlate the human remains to a specific person, then recompose the extensively traumatized body. After establishing the identity of all workers, it was possible to determine their position in the environment at the time of the occurrence of fires and explosions and, in this way, also identify the exact place of the first explosive event, which then, as a chain reaction, involved all the factory buildings containing gunpowder.

The results of the different forensic analyses (autopsies, genetic investigations, and traumatological ones) have made it possible to validate a scientific method useful in all mass disasters, even when it is difficult to do any type of anthropological investigation or forensic odontology. The reported case demonstrates how an accidental catastrophic event can be easily confused with a terrorist attack, the latter event not difficult to achieve especially, in the wake of current international events. Therefore, it is essential that in all events involving a large number of people, there is a highly specialized team in forensic fields that can easily recognize the nature of the traumatic event and direct further investigations useful to understanding the detrimental dynamics of mass disasters.

### H25 Small RNA Sequencing and Real-Time Quantitative Polymerase Chain Reaction (RT-qPCR) Validation of Forensically Relevant Body Fluids

Karly L. Johannsen\*, University of New Haven, West Haven, CT 06516; Claire Glynn, PhD, Forensic Science Department, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to inform attendees of several microRNAs (miRNAs) discovered via next generation sequencing that have the potential to be discriminatory for the identification of forensically relevant body fluids, including venous blood, semen, saliva, vaginal fluid, and menstrual blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the methodology of using next generation sequencing to discover known and potentially novel miRNAs that are specific to forensically relevant body fluids. Additionally, the forensic science community will have the opportunity to learn more about the validation of next generation sequencing results via RT-qPCR.

Body fluid identification is an important aspect of forensic investigations as it can assist with the reconstruction of a crime scene and can refute and/or support witness statements. Currently, there is no universal method for body fluid identification. Each body fluid has several tests, both presumptive and confirmatory. Additionally, there are no reliable confirmatory tests for the identification of menstrual blood and vaginal fluid. This causes body fluid identification to be a time-consuming process that can be highly destructive to an unknown body fluid sample. A universal method for body fluid identification that is sensitive, specific, efficient, and minimally destructive is necessary.

In recent years, miRNAs have been heralded as novel biomarkers for the identification of body fluids. They represent an ideal candidate for this purpose as they are remarkably stable, require minimal starting material, and can be co-extracted with DNA, thereby providing both body fluid identification and person identification simultaneously. Several published studies have reported various lists of miRNAs that show potential for the identification of particular body fluids. However, there is little agreement across the studies of which miRNAs are suitable, and few studies included menstrual blood and vaginal material. In addition, all miRNAs reported to date are shown to be differentially expressed across all body fluids, with none yet reported to be uniquely expressed in one body fluid. With the advent of Next Generation Sequencing (NGS), it is now possible to sequence all forensically relevant body fluids for both known and novel miRNAs, with the expressed interest to identify panels of miRNAs for each body fluid, ideally with several that are uniquely expressed in a particular body fluid.

The first goal of this study was to sequence a range of forensically relevant body fluids to identify known miRNAs and potentially discover novel miRNAs that are specific to venous blood, semen, saliva, menstrual blood, and vaginal fluid. The second goal of this study was to select panels of miRNAs, based upon the sequencing data, for RT-qPCR validation, that show promise for body fluid identification.

Following Institutional Review Board (IRB) approval, venous blood ( $n=10$ ), semen ( $n=5$ ), saliva ( $n=10$ ), menstrual blood ( $n=10$ ), and vaginal fluid ( $n=10$ ) was collected from volunteers with informed written consent. Each body fluid was extracted using the miRNeasy® miRNA isolation kit, following the manufacturer's protocol. Liquid fluids (venous blood, semen, saliva) were extracted using 500µL of each. Menstrual blood and vaginal material were collected on sterile cotton swabs and were therefore extracted directly from the swabs. Following miRNA isolation, the extracts were stored at -20°C until required. Four quantification methods were utilized, including the NanoDrop™ One<sup>C</sup> UV-Vis Spectrophotometer, the Qubit® 3 Fluorometer using the RNA HS Assay kit, and the Agilent® 2100 Bioanalyzer using both the Small RNA kit and the Nano 6000 kit. The concentration of each sample was obtained, and the integrity of the samples were analyzed in the form of the RNA Integrity Number (RIN). Samples were then prepared for sequencing using the TruSeq® Small RNA library preparation protocol. The prepared samples were then sequenced using the MiSeq® FGx platform. The sequencing data was analyzed using the Illumina® BaseSpace small RNA app. Several miRNAs were chosen for further RT-qPCR validation, based on their potential applicability for body fluid identification. The results of this study contribute greatly to the growing body of knowledge for the eventual implementation of miRNAs for body fluid identification.

### H26 A Forensic Volatolomic Approach: A Step Forward in the Characterization of Wound Pathogens

Shawna F. Gallegos\*, Lubbock, TX 79410; Paola A. Prada, PhD, Texas Tech University, Lubbock, TX 79416; Kendra P. Rumbaugh, PhD, Texas Tech University Health Sciences Center, Lubbock, TX 79430

**Learning Overview:** After attending this presentation, attendees will better understand the Volatile Organic Compounds (VOCs) emitted by chronic wound pathogens, both *in vitro* and *in vivo*.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an enhanced understanding of VOCs emitted by wound pathogens and how they can be analyzed to better understand the etiological causes of wound infections. Enhanced and early diagnosis of organisms colonizing a wound are critical to effective treatment and prevention of chronicity. Diagnosis by detecting and identifying VOCs could provide physicians with more rapid and sensitive knowledge of the organisms present in the wound and therefore expedite treatment to prevent complications.

With ongoing conflicts engaging military personnel, there has been a substantial increase in combat-related injury with high rates of morbidity and mortality. Chronic wounds have considerable effects on the patient, both physically and psychologically, as treatment is painful, the wound is slow to heal, and often leads to amputation to prevent sepsis and death. Treatment costs are also substantial, accumulating upward of \$3 billion annually. The persistence of the chronic wound and the related costs is contributed to by microbes that colonize the wound, many of which are highly resistant to antibiotics, creating additional challenges to treatment. These microbes often form biofilms—bacteria encased in their own Extracellular Polymeric Substances (EPS), which compound the healing problem. Biofilms, especially those in the wound environment, are generally polymicrobial with relationships that vary from symbiotic to highly competitive. Diagnosis relies upon standard culture methods to identify the organisms present in the wound. However, some microbes are difficult to culture or may not be present at quantifiable levels, posing additional challenges to effective treatment.

Individual species of microbes have specific molecular makeups, including specific VOCs that are also thought to be unique to each organism. *Pseudomonas aeruginosa* and *Staphylococcus aureus* are two of the most common chronic wound pathogens and are highly multidrug resistant. Utilizing Solid-Phase Microextraction (SPME) and Gas Chromatography/Mass Spectrometry (GC/MS), this study used an *in vivo* model to compare VOCs present in the chronic wound environment to those present *in vitro*. While the number of identified volatile compounds were reduced *in vivo*, these compounds were still comparable to the *in vitro* baseline. Interestingly, in the dual species infection, the dominant compounds belonged to *P. aeruginosa* with lower levels to *S. aureus*. While relationships between organisms in a chronic wound vary from symbiotic to highly competitive, the detected volatile patterns indicate that even at low levels, pathogen VOC profiles vary between species, both qualitatively and semi-quantitatively. This method could lead to the identification of bacterial species present in acute and chronic wound infections without the time needed for standard cultures, as well as overcome limitations with regard to complex and difficult-to-culture organisms.

#### Volatolomics, Solid-Phase Microextraction (SPME), Pathogens

**H27 WITHDRAWN**

## H28 Evaluating Bioinformatic Pipeline Performance for Forensic Microbiome Analysis

Sierra Kaszubinski, BS\*, Michigan State University, East Lansing, MI 48824; Jennifer L. Pechal, PhD, Michigan State University, East Lansing, MI 48824; Heather R. Jordan, PhD, Mississippi State University, Mississippi, MS 39762; Carl J. Schmidt, MD, Wayne County Medical Examiner's Office, University of Michigan, Detroit, MI 48207; M. Eric Benbow, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will understand how available bioinformatic pipelines are applied to forensic microbiology and postmortem microbiome research. Attendees will see that downstream output of multiple pipelines differs based on statistical evaluation, including taxon abundance, diversity metrics, and machine learning model building.

**Impact on the Forensic Science Community:** This presentation will impact the forensic scientific community by informing bioinformatic analysis for further forensic microbiology research and future casework.

While recent research suggests excellent potential for microbial community use in forensics, additional foundational work is needed before forensic microbiology can be applied in the criminal justice system. Downstream bioinformatic analysis needs to be optimized of forensic microbiological data created by high-throughput sequencing platforms in research and case work.<sup>1</sup> To accomplish this goal, a better understanding of performance among bioinformatic pipelines is needed to reveal potentially significant differences in downstream analysis and data interpretation. The ultimate outcome of such evaluation will be the identification of analytical pipelines optimized for use in forensic microbiology.

One aspect of forensic microbiology is examining the human microbiome, which consists of 10-100 trillion microbial cells per person.<sup>2</sup> The composition of these microbial communities can be specific to groups of living individuals and varies by area of the body (e.g., gut vs. skin).<sup>2</sup> Current research on forensic microbiology includes human microbial fingerprinting and estimating time since death using the postmortem microbiome.<sup>3</sup> Advances in sequencing technology have made studying microbes at the genomic level much more affordable. Large-scale microbial identification can be accomplished using 16S rRNA gene sequences obtained from targeted amplicon high-throughput sequencing. These microbial taxon identifications provide a microbiome profile that has potential use in forensics.

Despite increasing research in the use of microbiomes in forensics, there is still a limited understanding of the human postmortem microbiome beyond studies that take place in controlled anthropological facilities.<sup>4</sup> One of the first studies to investigate large-scale ( $n=188$  cases) postmortem microbial changes using high-throughput sequencing and statistical analyses during decomposition revealed dynamic changes for the postmortem microbiome.<sup>5</sup> This research was the largest dataset to provide empirical evidence that microbial communities of the eyes, ears, nose, mouth, and rectum could predict time since death during routine death investigation using high-throughput technology and *in silico* computational tools.<sup>5</sup>

*In silico* tools are needed to analyze forensic microbiology data. For bioinformatic analysis, raw data files undergo a series of transformations using executable command line software known as pipelines.<sup>6</sup> Pipelines most commonly cited are QIIME, mothur, and MG-RAST.<sup>7</sup> Current literature is not sufficient to justify which pipeline would be most useful in analyzing forensic microbial data. Previous studies comparing pipelines either used simulated data, small sample sizes ( $n<40$ ) composed of the same sample type (i.e., human gut microbial data), or *in silico* data.<sup>7-12</sup> Studies analyzing samples of limited sample type and number do not extrapolate to forensic microbiology studies, which often included swabs from multiple body sites.<sup>4,5,13</sup>

Two anatomic areas, the mouth and rectum, were selected from the large and variable dataset from Pechal et al. to quantitatively evaluate each pipeline.<sup>5</sup> Random subsamples were made from the dataset to include 30 cases, 60 cases, 120 cases, and 188 cases. Microbial sequence reads were analyzed with QIIME2 (2017.8), mothur (v.1.39.5), and MG-RAST (4.0.2). The reference database (SILVA) and operational taxonomic unit generation (*de novo*) were controlled. Phylum and family level taxon were used for comparison and revealed a significant difference ( $p < 0.01$ ) in the number of unclassified reads between pipelines. MG-RAST also had fewer taxa present at 1% relative abundance than mothur or QIIME2. The number and identity of taxa shared between anatomic areas, or core taxa, was distinct among pipelines. Alpha diversity metrics, including Shannon and Inverse Simpson diversity indices, were compared among the pipeline outputs. Alpha diversity metrics were significantly different ( $p < 0.01$ ) between MG-RAST and the other pipelines. The pipelines were also compared using random forest, a machine learning algorithm. While predicting anatomic area, the error rates for the model were relatively similar, predicting the correct anatomic area about 95% of the time. Yet, important predictor taxa differed among pipelines. Overall, mothur and QIIME2 had similar results, while MG-RAST was distinct. QIIME2 and mothur can be systematically used for further forensic microbiome analysis.

### Forensic Microbiology, Postmortem Microbiome, Bioinformatics

### H29 Investigating Commercially Available MicroRNA Extraction Kits for Use With Forensically Relevant Body Fluids

*Autumn T. Muise\**, West Haven, CT 06516; *Karly L. Johannsen*, University of New Haven, West Haven, CT 06516; *Claire Glynn, PhD*, Forensic Science Department, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to inform attendees of a variety of commercially available microRNA (miRNA) extraction kits and their use with forensically relevant body fluids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the various methods available for miRNA extraction, a variety of methods for quantifying miRNA extracts, and the optimal method for use with forensically relevant body fluids from those tested in this study.

While current research is highlighting the potential of miRNAs for body fluid identification, little research has been performed to investigate the best method for extracting the miRNA content from forensically relevant body fluids. There are more than a dozen commercially available miRNA/RNA extraction kits, with new kits regularly being released onto the market. However, all miRNA extraction kits currently available have been designed for use with pristine clinical laboratory samples, such as cell cultures, primary tissues, plasma/serum, etc. A kit designed specifically for use with forensic samples—venous blood, semen, saliva, menstrual blood, and vaginal material—is not yet commercially available. Therefore, an investigation of some of the currently available, and widely reported, miRNA extraction kits is warranted for use with forensically relevant body fluids. The goal of this research was to select four commercially available miRNA extraction kits, and to assess their ability to extract the miRNA content from forensically relevant body fluids in sufficient quantity and quality for downstream analyses.

Following Institutional Review Board (IRB) approval, body fluids were collected from volunteers with written informed consent. Venous blood was collected by a licensed phlebotomist into EDTA vials. Semen and saliva were collected into sterile conical tubes. Menstrual blood and vaginal material were collected using sterile cotton swabs. All samples were stored at -20°C until extractions were performed.

The miRNeasy Mini Kit (Qiagen®), PureLink® miRNA Isolation Kit (Invitrogen™), magMAX™ mirVana™ Total RNA Isolation Kit (Applied Biosystems®) and High Pure miRNA Isolation Kit (Roche) were the chosen kits in this study. Each miRNA isolation was performed according to the manufacturer's protocol. Following miRNA isolation, the extracts were stored at -20°C until quantitation was performed. The extracts were quantified using the NanoDrop™ One UV/Vis spectrophotometer (Thermo Scientific™), Qubit® 3.0 fluorometer (Invitrogen™), with the RNA HS assay kit, and the Agilent® Bioanalyzer 2100 (Applied Biosystems®) with the small RNA chips. As each kit has a different final elution volume, all results were converted from ng/μL to total RNA (ng) obtained.

Quantifiable amounts of miRNA were collected from all samples. The results generated using the NanoDrop™ One UV/Vis Spectrophotometer showed the miRNeasy kit to be the optimal kit in the majority of the bodily fluids, with yields ranging from 2,844-6,279ng total, except for vaginal material, in which magMAX™ mirVana™ Total RNA isolation Kit yielded higher results. The results were verified using the Qubit® 3.0 Fluorometer. This quantification method further confirmed that the miRNeasy was the superior kit; however, the Qubit® showed that the High Pure Isolation Kit was preferred for the extraction of vaginal material. Agilent's® Bioanalyzer 2100 quantified the miRNA concentration in extracts that held promising results from the Qubit®. Qiagen's® miRNeasy Mini Kit's miRNA concentration values were present for all five of the bodily fluids. miRNeasy's miRNA concentration ranged from 487-12,749ng total. The use of three separate quantification methods did not consistently give the same amounts.

Qiagen's® miRNeasy Mini Kit was overall the optimal kit in extracting miRNA from forensically relevant bodily fluids, with the exception of High Pure miRNA Isolation Kit, yielding higher results in the extraction of vaginal material. Although the miRNeasy is slightly more expensive than the High Pure, the quantity of miRNA eluted is greater, thus offsetting the costs.

These results in the extraction of miRNA using commercially available kits were successful and will aid the forensic science community in future casework.

#### MicroRNA, Extraction, Body Fluids

### H30 Postmortem Submersion Interval (PMSI) Estimation From the Microbiome of Bone in a Freshwater Lake Across 4,750 Accumulated Degree Days (ADD)

Claire M. Cartozzo, MS\*, Virginia Commonwealth University, Richmond, VA 23220; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how changes in microbial communities across ADD can be used to predict the long-term PMSI for skeletal remains recovered from a freshwater lake.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing proof of concept concerning a novel area of research, the use of microbial succession on skeletal remains submerged in a freshwater lake to predict PMSI.

Aquatic decomposition, the process of remains progressing from submerged fresh remains, to remains floating in a stage of decay, and finally sunken remains, varies due to water temperature, salinity, depth, current, scavengers, three-dimensional movement, and other extrinsic factors. Being able to estimate time since death, or in the case of water-related incidents the postmortem submersion interval (PMSI), is pertinent to Medicolegal Death Investigations, as it assists in identifying remains, corroborating eye witness statements, and narrowing suspect pools. Because microorganisms are present throughout decomposition, researchers proposed that their succession pattern, like insects, could be used to estimate PMI.<sup>1</sup> Recent studies by Dickson et al. and Benbow et al. have demonstrated that bacterial communities in aquatic environments can be a useful tool for estimating PMSI due to advancements in metagenomic approaches (e.g., next-generation sequencing and pipeline analysis software).<sup>2,3</sup> Unfortunately, these studies were performed with small sample sizes ( $n \leq 3$ ), a short sampling period (21–42 days), repeated sampling and disturbance of the same remains. In addition, the focus of these studies was not on microbial community structure of skeletal remains, which is addressed by this research.

In this study, fresh pig (*Sus scrofa*) bones ( $N=100$  rib and  $N=100$  scapula samples) were obtained from a butcher. From November 2016 to June 2018, bones were placed in cages attached to a flotation device and submerged in Henley's Lake (White Hall, VA 38° 05' 11.7"N, 78° 41' 02.8" W). Water temperature was recorded hourly using waterproof loggers. Every 250 ADD, five scapulae, five ribs, and 500ml of water were collected and stored at either -80°C or 4°C until processed. Bone samples were cut and ground into a powder using liquid nitrogen in a mortar and pestle; meanwhile, water samples were filtered on 0.22µm filters. DNA was extracted and purified using ChargeSwitch® gDNA Plant Kit and DNeasy PowerClean® Pro Cleanup Kit, if necessary. Following parameters set forth by Kozich et al., extracted samples were used to carry out sequencing-by-synthesis of microbial 16S rDNA variable region 4 using Illumina's® MiSeq® 2X300 paired-end sequencing.<sup>4</sup> The resulting data were analyzed via MiSeq® SOP mothur version 1.36.1.<sup>5</sup>

According to preliminary data encompassing baseline through collection 5 (0–1,250 ADD), Analysis of Molecular Variance (AMOVA) indicate a significant difference in the bacterial structure between sample types, specifically rib-scapula, ( $p < 0.0002$ ), rib-water ( $p < 0.0002$ ), and scapula-water ( $p < 0.0002$ ). For each sample type, phylum and family level changes were observed across ADD. In addition, rib ( $R^2=0.48$ ) and scapula ( $R^2=0.64$ ) samples demonstrated a positive relationship between Shannon species diversity and logADD, whereas the water samples showed a negative relationship ( $R^2=0.48$ ). Similar differences and trends are expected with the remaining 13 collections.

### H31 The Mouse Thanatobiome and Postmortem Interval (PMI) Estimation

Molly B. Still\*, Emporia, KS 66801; Scott S. Crupper, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** The goal of this presentation is to offer an alternative method for determining the PMI using the thanatobiome as examining changes in microbial succession patterns may satisfy this objective.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping to address current problems in PMI estimation and showing how thanatobiome data may offer an alternative. Although the thanatobiome is a relatively new field of study, data acquired may offer an alternative to PMI determination.

Determining an accurate PMI in a death investigation is a critical piece of information needed to gain a thorough understanding of the circumstances surrounding a death. While different methods are available to forensic investigators, each has its own set of limitations that decrease its accuracy. Microbes are ubiquitous and play a significant role in decomposition. The thanatobiome is a term used to describe the microbes that colonize internal organs postmortem. Since there is dramatic shifting in microbial communities within a deceased host, these unique microbial signatures may be utilized by forensic investigators to establish a PMI.

Previous PMI studies have employed animal models, such as swine and rodents, since it is easier to control the PMI and obtain multiple replicates as compared to human cadavers. To gain a better understanding into the use of the thanatobiome for PMI studies, this study utilized a mouse model system to examine microbial succession patterns in the liver postmortem. Mice were sacrificed by CO<sub>2</sub> asphyxiation and placed at room temperature in sealed containers that allowed air flow. In total, mice were separated into four groups: a control group (0-day postmortem), and 7-, 15-, and 21-day postmortem groups. At the indicated PMI, livers were removed and stored at -80 C. Total DNA was isolated from each liver sample using a Zymo Research Fungal/Bacterial DNA MiniPrep kit according to the manufacturer's recommendations. Subsequently, the V3 hypervariable region of the 16S rRNA gene was amplified and sequenced on an Illumina® MiSeq® platform. The results indicate *Clostridium* species dominated in all three PMI groups, whereas *Lactobacillus* species accounted for only a small proportion of the total thanatobiome. However, in two of the 21-day PMI mice where the total percentage of *Clostridium* species was significantly lower, *Lactobacillus* species accounted for most of the genera identified. Noteworthy is the fact that putrefaction in the 21-day postmortem mice had progressed to a level that significantly liquefied and made the liver difficult to recognize and harvest. Furthermore, the Shannon Species Diversity Index, which measures species richness, significantly increased from approximately .021 in the control groups to 0.78–2.4 in the 7- to 21-day PMI groups, illustrating that decomposition is a process mediated by a wide variety of microbes. In total, results obtained agree with previous human cadaver thanatobiome studies that have noted a “*Clostridium* Postmortem Effect.”

#### Thanatobiome, PMI, Clostridium

## H32 Postmortem Hair Microbiome and Its Forensic Applications

Denise Wohlfahrt, BS\*, Virginia Commonwealth University, Richmond, VA 23284; Kailey Babcock\*, Richmond, VA 23220; Courtney Hutchens, BS, Virginia Commonwealth University, Richmond, VA 23284; Vadim Mesli, MD, Institut Médico Légal/Forensic Institute, Nord 59037, FRANCE; Erwan Le Garff, MD, Institut Médico Légal/Forensic Institute, Nord 59037, FRANCE; Valéry C. Hedouin, MD, PhD, Hauts De France 59037, FRANCE; Xavier Demondion, MD, PhD, Laboratoire D'anatomie, Nord 59000, FRANCE; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will better understand bacteria associated with human hair samples collected after death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping forensic scientists find new ways for analysis of hair evidence during death investigation.

Human hair is often encountered at crime scenes. However, those hairs most often found don't often contain nuclear DNA needed for the current human DNA workflow. This survey of the microbiome associated with human hair can aid researchers in determining whether hair can be useful in Postmortem Interval (PMI) estimation as well as in determining whether the area from which the hair is collected is important. This analysis was performed as part of an ongoing investigation into the microbiome of hair samples. Previous research has shown that in living humans, bacteria associated with scalp hair are significantly different from those bacteria associated with pubic hair in both sexes. We also know that bacteria associated with pubic hair of males are significantly different than those bacteria associated with pubic hair of females. One question that remains unanswered is how hair microbiome is affected after death, and whether the scalp hair microbiome changes depending on the area of the scalp it is collected from. To understand this, scalp and pubic hair samples were collected from ten human cadavers from the United States (Office of the Chief Medical Examiner, Richmond, VA) and from 25 human cadavers from Europe (Medicolegal Institute of Paris, France). For the European population, scalp hair samples were collected from frontal, occipital, left and right parietal, and vertex regions of the scalp, whereas for the American population, scalp hair samples were collected from a single location. Pubic hair samples were collected from a single location in the pubic area in both populations. All samples were stored at -80°C. DNA was extracted from approximately one inch of finely cut hair samples using the Tridico et al. method with the addition of zirconium bead beating.<sup>1</sup> Samples were then amplified using dual-index 16SrDNA MiSeq<sup>®</sup> sequencing using the protocol as described by Kozich et al.<sup>2</sup> Sequences were then analyzed using mothur version 1.39.4, and statistical analysis was performed using R version 3.4.0.<sup>3,4</sup>

Preliminary results indicate that the bacterial structures associated with scalp hair are significantly different from those associated with pubic samples. The majority of bacteria found in scalp and pubic hair samples belong to the phyla Cyanobacteria, Proteobacteria, Spirochaetes, and BRC1, varying only in their relative abundances. When comparing the genera, pubic hair samples show much higher relative abundance of *Staphylococcus*, where scalp hair showed a higher relative abundance of *Selenomonas*, *Vagococcus*, and *Streptococcus*. However, initial tests did not indicate significant variation between male and female pubic or scalp hair samples. As the majority of samples were obtained from Caucasian donors, no determination was made on whether race impacted the microbiome of hair samples.

In conclusion, this ongoing study provides information on the bacterial communities associated with hair samples collected from human remains. This information will help provide better understanding of the usefulness and utility of hair associated microbial communities in forensic investigations.

### H33 Forensic Microbiology: An Analysis of a Series of Cases

*Elvira Ventura Spagnolo, MD\*, University of Palermo, Palermo 90127, ITALY; Cristina Mondello, MD\*, Department BIOMORF, University of Messina, Messina 98123, ITALY; Salvatore Rocuzzo, Caltagirone 95041, ITALY; Francesco Daleo, MD, Department of Clinical and Experimental Medicine, Messina, ITALY; Stefania Zerbo, MD, Via Del Vespro, 127, Palermo 90100, ITALY; Antonina Argo, Palermo, Europe 90100, ITALY*

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the importance of microbiology for forensic investigations and the importance in creating a standardized protocol to improve its practical application.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting how forensic microbiology could be a useful tool to determine the cause and manner of death, especially in difficult forensic cases such as sudden unexpected death or death due to nosocomial infections.

Postmortem microbiology is a relatively novel research field with great potential concerning forensic field applications. Nevertheless, an effort is needed to solve actual controversies on the correct interpretation and statistical significance of a postmortem cultural result. To this end, a multidisciplinary approach would be useful. A large part of the issue is relative to the lack of standard procedures for the collection and analysis of samples. Relying on the studies so far produced, a correct approach requires: correct storage of the body at 4°C to prevent bacterial translocation; collection of samples within 24h and 48h from death prior to evisceration of the body; the use of appropriate collection media; sterilization of the surfaces of the body sites chosen using, for example, a hot spatula or iron; the use of sterile tools (e.g., sterile needles); and immediate transfer of the samples collected to the microbiology laboratory.

According to the Human Microbiome Project (HMP), a healthy human body contains ten times more microbes than human cells. Microbial communities colonize different organs of the body, playing fundamental roles both in human health and disease. Despite the vast scientific knowledge on the role of microbial communities in a living body, little is known at present about microbial changes occurring after death.

The study investigated 35 autopsies performed by the standard techniques in which cardiac and femoral blood, pericardial fluid, pleural fluid, urine, pieces of lung, spleen, and liver were obtained. The sampling was conducted according to the rules of asepsis indicated by Riedel et al. and according to the procedures issued by the European Congress of Clinical Microbiology & Infectious Diseases (ESCMID) Study Group for Forensic and Postmortem Microbiology (ESGFOR) study group to exclude contamination or postmortal translocation of microbes.<sup>1</sup>

The microbiological results showed positivity for both ubiquitous and multi drug resistance microorganisms (such as *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, and *Acinetobacter baumannii*). These results provided data to confirm infections diagnosed during care assistance and, in particular, to assess the responsible microbes in cases without pre-mortem microbiological analysis. It was also observed that in cases of health care-related infections, the microorganisms presence were found in all the examined samples (biological fluids and body tissues), supporting the clinical diagnosis of a severe septic state. Obviously, the interpretation of these results must be integrated by circumstantial, clinical, autopsy, and histological findings. Moreover, it is important to critically analyze the microbiological results considering possible bacterial contamination and a general effort is thus needed to obtain standardized protocols to demonstrate the real potential of this recent research field.

### H34 Calliphoridae of Forensic Importance of Campeche, Mexico

*Carolina Núñez-Vázquez, PhD\*, Carolina Núñez Vazquez, Merida, Yucatán 97168, MEXICO*

---

**Learning Overview:** The goal of this presentation is to help attendees better understand the diversity of species of Calliphorids of forensic importance in Campeche, Mexico.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data not previously generated in Mexico.

The objective of this study is to know the diversity of species of Calliphorids that can be found in the locality of Campeche, Mexico, with the purpose of this information forming part of a national database as part of a larger project of georeferencing and seasonality of insects of forensic importance in Mexico. This database will serve as a reference for forensic investigators, experts, scientific researchers, or students since, in Mexico, forensic entomology is little known and therefore little applied in the legal system. One of the basic needs for the development and implementation of forensic entomology in the country is that the presence, distribution, and seasonality of the insect species that may be involved in a forensic case must be known. Knowing the presence or absence of these insects at different seasons of the year can help to establish the season in which the death occurred; knowing the distribution of insects can help in investigations that involve relocation of corpses, origin of some drugs, location of a suspect in the scene, and locating where a vehicle has traveled, among others.

The site that was chosen to conduct the insect collection is the town of Pucnachen in the state of Campeche, located in southeast Mexico. This region has an altitude of 5 meters above sea level, the soils are rocky with little organic matter, has a semi-flat surface, and few elevations that reach 2.5 meters in height. Its climate is mostly warm-subhumid and rainy during the summer. The average annual temperature is 27.1°C and has vegetation belonging to the low deciduous forest.

The insect collection took place in March and April. Six traps baited with pork and alcohol as a method of preservation of insects were used. The traps were placed on trees at a height of 2 meters to prevent other scavengers, such as dogs, from destroying them and were separated at a distance of 30 meters. The traps were monitored every week for eight weeks. All collected insects were transferred to the laboratory for identification and preservation. Currently, this work is in development, so results are preliminary, and the collection work will be replicated in other seasons. The information generated will be part of the database for future reference.

---

#### **Forensic Entomology, Pucnachen, Calliphoridae**

### H35 Development of the Discrimination Procedures Between Nasal Secretion and Saliva by Real-Time Reverse Transcription Polymerase Chain Reaction (rRT-PCR) and Indirect Enzyme-Linked Immunosorbent Assay (ELISA)

Tomoko Akutsu, PhD\*, National Research Institute of Police Science, Kashiwa, Chiba 277-0882, JAPAN; Ken Watanabe, National Research Institute of Police Science, Kashiwa, Chiba 277-0882, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the applicability of rRT-PCR and ELISA procedures on nasal secretion- and saliva-characteristic markers for the discrimination of these body fluids through analysis of specificities and sensitivities of these procedures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing reliable information on the source of human DNA through the identification of body fluids, which are often left at crime scenes but are difficult to distinguish from each other.

In forensic casework, nasal secretions could be a good source of DNA for the identification of individuals. There are, however, few procedures to identify nasal secretions. Further, saliva that is often left at crime scenes could prove sexual assault. However, presumptive and confirmative tests for saliva on the basis of  $\alpha$ -amylase can cross-react with other body fluids, such as nasal secretions. In previous studies on messenger RNA (mRNA) - based identification of body fluids, some nasal secretion- and/or saliva-characteristic genes have been reported; however, end point detection of these genes may be difficult to discriminate from each other because of their insufficient specificity and detectability. In addition, there are no reports of protein marker(s) for the identification of nasal secretions. Furthermore, ELISA detection of Statherin (STATH), commonly used as a saliva marker, cross-reacted with nasal secretions.

Therefore, the goal of this study was to develop more specific procedure(s) for discrimination between nasal secretions and saliva for forensic purposes. Candidate molecules for the identification of nasal secretion (bactericidal permeability increasing protein fold containing family A member 1 ((BPIFA1), STATH) and saliva (STATH, histatin 3 (HTN3)), and proline-rich protein HaeIII subfamily 2 (PRH2)) were selected, and RT-PCR and indirect ELISA procedures were developed to determine these mRNA and protein expression levels quantitatively.

Expression levels of candidate genes were determined in various body fluids and discrimination criteria for nasal secretions and saliva were determined based on quantitative results of multiple markers. In addition, a flowchart to discriminate among nasal secretions, saliva, and other body fluids was proposed and evaluated on various forensic samples. Similarly, the specificity and sensitivity of ELISA detection of candidate proteins were determined using various body fluids, and a positive threshold value was set for each candidate marker. Then, applicability of ELISA procedures to the forensic casework was investigated using simulated casework samples.

As a result of real-time RT-PCR analysis, BPIFA1 was highly but incompletely expressed in nasal secretions and expressed in semen and vaginal fluids in trace levels. STATH was expressed in almost all the nasal secretion and saliva samples but not detected in other body fluids analyzed in this study. HTN3 was specifically expressed in saliva samples as reported previously. Unexpectedly, only a few saliva samples showed positive results in RT-PCR analysis for PRH2 though it was reported as a specific protein marker for saliva. Using determined discrimination criteria and the proposed flowchart, nasal secretions and saliva were successfully discriminated among various body fluids analyzed in this study.

The results of ELISA analysis showed that BPIFA1 was specific to nasal secretions. Besides, STATH was detected in both nasal secretion and saliva samples in accordance with previous reports and results of gene expression analysis. PRH2 was specifically detected in most saliva samples despite low gene expression levels in saliva. Development of ELISA detection of HTN3 was not achieved because suitable antibodies were not found in this study.

In conclusion, for the discrimination of nasal secretions and saliva among various body fluids, BPIFA1, STATH, and HTN3 could be effective markers for RT-PCR. On the other hand, BPIFA1, STATH, and PRH2 could be useful as protein markers for ELISA. Suitable procedures could be selected depending on the sample condition and sample type because environmental tolerance between mRNA and protein was thought to be different.

#### Nasal Secretion, Saliva, Body Fluid Identification

### H36 The Estimation of Postmortem Submersion Interval (PMSI): Are Nails' Ultrastructure of Any Help?

*Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Ilenia G. Tredici, PhD, CISRiC, University of Pavia, Pavia I27100, ITALY; Elena Mercuri\*, Pavia 27100, ITALY; Chiara Siodambro\*, Pavia 27100, ITALY; Matteo Moretti, MD, University of Pavia, Pavia 27100, ITALY; Luisa Andrello, MD, Bellinzona, Canton Ticino 6500, SWITZERLAND; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Giovanni Fassina, Pavia, Lombardia 27100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY*

**Learning Overview:** The goal of this presentation is to provide new tools for the estimation of the PMSI in bodies recovered in freshwater.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing a scarcely investigated issue that can provide helpful information regarding the circumstances and time of the death.

Forensic pathologists face numerous challenges when dealing with corpses submerged for several days. In such cases, the pathologist encounters many difficulties in determining the time since death, as the submersion deeply alters the postmortem phenomena. Therefore, it is of great interest to be able to assess how long the corpse remained in water, regardless of the PMI. This data can be helpful to reconstruct the circumstances of the death. Several approaches have so far been proposed for the PMSI estimation. Methods involving the growth of biofilms, such as algal, bacterial, fungal, and protozoan species, have been reported in the literature with encouraging results. Another tested method used to estimate the PMSI involves measuring the degree of decomposition of the recovered human remains. In the present study, a novel approach was tested, consisting of examining the microscopic structure and the ultrastructure of the nail plate, experimentally submersed in freshwater. The structure of the nail unit has been well described in literature. The nail plate is the completely keratinized part of the nail unit and it is made up of three different layers that are well-bonded together. Nail matrix produces the nail plate that includes an average of 196 cell layers that are distributed among three tightly bound layers. Given its very low permeability to water, due essentially to the chemical composition of the nail containing residual lipids, the penetration of water into the nail plate is likely to be slow. These characteristics lead to the hypothesis that the changes in the nail structure due to submersion in water develop gradually, going through different stages.

To observe these modifications, the nail plate of the hallux was removed from five cadavers during forensic autopsies. Each nail was experimentally kept in freshwater at room temperature for defined time intervals: 3, 6, 9, 12, and 24 days. As a negative control, a dry hallux nail, removed as well from a cadaver, was used. As positive controls, the hallux nails of two cadavers pulled from the water, respectively, after 9 and 24 days, were examined. Each nail was formalin fixed for 24 hours, then dehydrated in a graded series of ethanols (60%, 80%, 95%, 100%). Then, after drying, each nail was longitudinally divided into two parts, to expose the internal structure of the nail, rather than the external surface. Each sample, previously carbon-coated using Cressington carbon coater 208c, was examined with a Scanning Electron Microscopy (SEM) Tescan® Mira3XMU, operated at 20kV.

The results showed that a relevant different pattern can be observed for each experimental submersion interval. High-power views indicate that the nails not submerged or submerged for the shortest interval (3 days) show a compact structure, with regularly aligned keratin fibers. After 6 days, some cracks are observed, and they appear considerably more extended after 9 days; after 12 days of submersion, the nail plate is characterized by the apposition of exogenous material, such as diatoms. After 24 days of submersion, the structure is totally altered, with extensive discontinuities and it is no longer possible to distinguish the different layers of keratin, which appear to be compacted and amorphous.

Such results suggest the usefulness of the ultrastructural observation of the nails using the SEM in the evaluation of the PMSI in bodies recovered in freshwater. Indeed, the observed changes seem to follow a gradual process. The characteristics pointed out in this presentation, even though they must be validated and confirmed by more research, appear promising and may be extremely useful in the forensic practice.

#### Scanning Electron Microscopy, Nail, Postmortem Submersion Interval

### H37 Intentional Body Dismemberment: A Difficult Path for the Forensic Pathologist in the Search for Truth

Aniello Maiese, *Sapienza University of Rome, Rome 00185, ITALY*; Alessandra De Matteis, *University Sapienza of Roma, Rome 00100, ITALY*; Matteo Scopetti, MD\*, *Sapienza University of Rome, Rome, ITALY*; Alessandro Santurro, MD, *Sapienza, University of Rome, Rome 00161, ITALY*; Vittorio Gatto, MD, *Sapienza University of Rome, Roma 00185, ITALY*; Mariantonia Di Sanzo, MD, *Rome, ITALY*; Luigi Cipolloni, MD, PhD, *Rome 00161, ITALY*; Massimiliano dell'Aquila, MD, *Sapienza University, Department of Anatomy, Rome, Lazio 00169, ITALY*

**Learning Overview:** After attending this presentation, attendees will better understand the importance of a systematic approach to intentional body dismemberment cases, based on radiological, autoptical, genetic, histological, immunohistochemical, and toxicological investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of the most recent cases of dismemberment that occurred in Italy in the past eight years.

The term “dismemberment” is used to indicate the detachment of the limbs and/or the head from the trunk at the level of the respective joints, or the subdivision of the thorax, the abdomen or the limbs into the respective segments. Three cases of intentional body dismemberment by another individual have been analyzed at the Morgue – Umberto I General Hospital/Sapienza University of Rome to determine the identity of the victim, the causes of death, and the wound vital reaction. The identity of the victim had been ascertained during the crime scene investigation, conducted by data and photographic recovery, and subsequently confirmed by the genetic exam, which also allowed confirmation of the assignment of all the body parts to the same subject.

In one case, dismemberment of the lower limbs has been performed. In the second, both the upper limbs and the lower limbs had been detached as well as an evisceration of the thoracic and abdominal organs. In the last case, the corpse had been dismembered meticulously, so much so that it was difficult to even identify the various anatomical segments during the crime scene investigation.

In all cases, a preliminary radiological study by a total-body Postmortem Computed Tomography (PMCT) was conducted and subsequently a complete autopsy exam was performed; on the tissue samples taken at autopsy, a classic histological exam with hematoxylin/eosin and an immunohistochemical study with IL-15, CD-15, and triptase were performed in order to evaluate the wound vitality at the incised planes. Finally, with gas chromatography, toxicological tests were conducted on the biological fluids (central and peripheral blood, urine, and vitreous humor) to identify exogenous substances.

From these investigations, it was possible to identify the cause of death: in two cases, it was by violent mechanical asphyxiation perpetrated by strangulation, while in the other, it was attributed to a sharp-force injury penetrating the abdomen. Histological and immunohistochemical results have shown that the depletion had occurred postmortem in all three cases; the toxicological investigations, on the other hand, yielded positive results for exogenous substances (heroin) in one case, but not in such a concentration as to determine the death.

In all the examined cases, the dismemberment followed the murder of the victim. This practice is in fact usually performed to make the body more easily concealable; in all three cases, the perpetrator of the crime had hidden the remains of the body in plastic bags, suitcases, or similar containers to hide them. Another detail common to all cases is the accidental finding of the remains by pedestrians who passed through the area, showing that the meticulousness performed in fragmenting the victim was not applied to the concealment of the bodies.

### H38 Buried Secrets: A Multidisciplinary Approach to Solving a Half-Century-Old Homicide

*Elizabeth M. Sepulveda, BA\*, Islip, NY 11751; Ruth E. Kohlmeier, MD, Suffolk County Office of the Medical Examiner, Hauppauge, NY 11788-0099*

---

**Learning Overview:** After attending this presentation, attendees will understand how law enforcement and the different forensic specialties interact, the importance of teamwork in solving cold cases, and what an impact police investigations and forensic sciences can have on the surviving family members and loved ones of the deceased.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing how a team of investigators and forensic scientists worked together to solve a half-century-old homicide.

In early October 1966, a Long Island woman disappeared, leaving behind her 11-year-old daughter. She was last seen getting into her boyfriend's vehicle and was never seen alive again. In an era of hushed mouths and limited investigative resources, the mystery and scandal surrounding this woman's departure remained unknown until March 2018. It was a reporter with the *Suffolk Times* who took an interest and began to dig deeper, which led to a guilt-ridden widow's confessions being told. Law enforcement agencies, including the New York State Police, the Southold Police Department, and the Suffolk County Police Department investigated further and eventually interviewed the boyfriend's ex-wife. She described to police how her husband had placed this woman in a burlap sack and then buried her in a grave he had dug in the basement of their home in eastern Long Island.

After three attempts at locating this missing woman, in March 2018, the remains were found in the basement of the boyfriend's house approximately six feet below the surface. In addition, two .38 caliber projectiles were also recovered from the grave. The forensic anthropologist stated there was near complete recovery of the skeleton and described the remains as being that of a Caucasian female, 22 to 50 years of age, and approximately 5 feet 6 inches in height. There was no trauma identified. Although there were no antemortem dental records available, the forensic dentist was able to conduct a survey and noted a moderate amount of restoration. The restoration material was then analyzed by a colleague, and it was noted that the material was in use in the 1960s. The morgue supervisor, along with a deputy medical examiner and firearms examiner with the Suffolk County Medical Examiner's office, examined the recovered clothing and noted defects on the front of various articles of clothing that were consistent with gunshot wounds. Finally, the woman was positively identified via DNA using exemplars from the decedent's daughter and brother.

This case exemplified extraordinary teamwork, which led to the discovery, identification, and cause of death of a woman who had been missing since 1966. This case also demonstrates the impact law enforcement investigations and forensic science can have on the surviving family members and loved ones of the deceased.

---

#### Homicide, Cold Case, Forensic

### H39 Suicides Among the Young: A Ten-Year (2007–2017) Retrospective Analysis of Suicides Under the Age of 18 in Metro Detroit

Vera Mendes-Kramer, MA\*, White Lake, MI 48383; Lynette Desjarlais, BA\*, Wayne State University, Detroit, MI; LokMan Sung, MD, Detroit, MI 48207; David Moons, MD, PhD, Detroit, MI 48207; Leigh Hlavaty, MD, Wayne County Medical Examiner's Office, Detroit, MI 48207; Avneesh Gupta, MD\*, University of Michigan, Ann Arbor, MI 48109

**Learning Overview:** After attending this presentation, attendees will understand the growing trends of suicide-related deaths within adolescence during a ten-year period in the Wayne County Medical Examiner's Office, and how they correlate with those found at the national level.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing child suicide prevention and the need for increased therapy and follow-up, as evidenced by child suicide data reviewed by the Wayne County Medical Examiner's Office.

The United States has seen suicide rates steadily increase within the past 30 years, with suicide currently being the tenth-leading cause of death nationally and the second cause of death among youths 10-17 years of age.<sup>1,2</sup> To assess Michigan trends in suicidal youth, the Wayne County Medical Examiner's Office conducted a retrospective study of suicides in the Metro Detroit area from 2007 to 2011, and again from 2012 to 2017.

A total of 2,513 suicide cases were reported for all age groups between the years 2007 and 2017, of which 103 suicides fell within the 0-17 age group, comprising 4% of the total number of suicides. The number of suicides in youths, ages 0-17 years, has increased by 39.5% in the last 5 years in comparison with the previous 5 years. The data gathered for the two comparison periods observed the highest numbers of suicide taking place between 16 to 17 years of age and recorded the youngest suicide at the age of 7 years ( $n=1$ ).

In addition to age, data was collected for gender, suicidal method, reported bullying, medical conditions, indication of previous suicide attempts, the type of note left, and toxicology findings for the two five-year periods. The rate of suicide is 3.5 times more prevalent in males than females; 70% of suicides are attributed to males and 30% to females in the overall gender distribution. A comparison between 2007–2011 and 2012–2017 in suicide by gender also attributed a higher number to males in both groups, with a 20% increase in the last five-year period.

The number of suicide deaths by method was compared to national trends and, contrary to national data where firearms hold the place for leading suicide method over suffocation/hanging and drugs for all age groups, at Wayne County, hanging was the chosen method for the 2007–2017 period with 66% of attributed deaths, followed by firearms with 21%, drugs with 7%, multiple injuries with 5%, and drowning with 1%.<sup>3</sup> Though deaths attributed to firearms increased from 16% to 25% in the past five years, the method of hanging, though decreased from 72% in 2007–2011 to 61% in 2012–2017, is still leading the suicide death by method of choice.

Bullying is a multifaceted developmental issue that stems from issues forming or holding relationships that manifest into aggression in peak ages of 9-15 and increase the likelihood of self-inflicted harm in those that participate in or are victims of bullying.<sup>4,5</sup> This study found that the second-largest age distribution occurred in ages 13-15 ( $n=42$ ), which aligns itself with the idea that bullying may predispose children to self-harm.<sup>6</sup>

The number of prior suicide attempts increased from 19% in 2007–2011 to 27% in 2012–2017. Of the 103 suicide cases recorded, 23% ( $n=24$ ) presented with at least one prior attempt, and 23 of the 24 cases reported decedents suffering from depression at the time of demise.

Twenty-five percent of the suicide victims of this study left a suicide note behind, either paper-based, verbal, or in social media. The type of note left changed over the years, particularly the increase in social media notes, from non-existent in 2007–2011 to 8% in 2012–2017.

This study highlights the veer from the national trends in suicide deaths by methods and recognizes new developments that merit mention and for which further research is recommended: the impact bullying has on increasing suicides in youths, the number of prior suicide attempts, and the type of suicide notes left behind.

#### Suicide, Young, Bullying

## H40 Difficult Suicide Cases: A Case-Based Approach

Wendy M. Gunther, MD\*, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046; Michael Alan Hays, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** The goal of this presentation is to review cases of suicide with conflicting manner-of-death indicators from scene, history, and autopsy, as well as compare case-based methods of differentiating difficult suicides from homicides or accidents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) providing a case-based approach to the analysis of difficult suicides; (2) analyzing conflicting manner-of-death indicators by scene, history, and autopsy findings; and (3) suggesting alternate testing and extended scene investigation for difficult suicides.

Differentiating cases of suicide from homicides or accidents is not always straightforward. Factors that may complicate determination of a suicidal manner include unclear history, scene investigation findings that do not point clearly to suicidal intent, and autopsy findings, including unusual or atypical drugs or injuries.<sup>1</sup> Deliberate self-harm can be difficult to determine in drowning and overdose deaths, which may result in assignment of an undetermined manner; this may contribute to undercounting of suicides in vital data.<sup>2</sup> Unclear history, scene indications, and autopsy findings may contribute to medical examiner/coroner difficulties with families who do not accept the manner of suicide.

Difficult suicide cases are likely to lack a clear history of suicidal ideation, medical records of psychiatric illness/depression, or reported motive for committing suicide. Hanging suicides may create family suspicion depending on their understanding of the degree of suspension required to result in death. A problematic history may include involvement of another person. If this person is a romantic partner whose behavior is deemed suspicious by the family, additional investigation and autopsy maneuvers may be indicated to indict or clear the alleged assailant. Difficulties may be encountered when death occurs during a struggle between two people over a weapon.

This review of difficult suicide cases from the Tidewater, VA, Office of the Chief Medical Examiner (OCME) experience includes cases with unclear histories, complicated scene investigations, and atypical injuries. Difficult history findings in this series include lack of a note or a texted warning, atypical drug abuse in overdose deaths, and behavior before death atypical for suicide, such as celebrating at a bar, going to the beauty parlor, or caring for small children without other arrangements to provide for them. Additional history/scene investigation factors include romantic partners who fled the scene or insisted on hospitalization for emotional distress prior to a police interview.

Difficulties in scene investigation may include decomposition artifacts, premises that are not secure, a body under water, unclear suicide notes or suicide notes that appear to have been written after death, and scenes that have been altered prior to investigation; these may require extended investigation. Complicated scenes reported in this case series include struggle over a gun, allegedly running from the home prior to being found unresponsive in a ditch, discovery of a decomposed missing person in a marshy area, and intraoral gunshot wound while in handcuffs during the process of arrest.

Atypical injuries may present difficulties in determining manner. These include gunshot wounds that are not hard contact, gunshot wounds or sharp force injuries in unusual locations, multiple gunshot wounds or sharp force injuries, and poisoning with unusual drugs. Atypical injuries reported in this case series include a tangential gunshot wound with stippling, sharp force injury to the wrists without tendon or vascular involvement, and drowning with unexplained internal neck injuries.

Ancillary studies that may be useful to clarify cases like these include gunshot residue testing for the decedent and the alleged assailant, blood spatter analysis at the scene, extended toxicologic analysis, and extension of the scene investigation to correlate it with autopsy findings. This series of cases from the Tidewater, VA, experience illustrates an approach to difficult suicides that may be useful to the medical examiner/coroner.

## H41 A Broad Demographic Analysis of Chronic Ethanol Deaths and Sequelae From Two Different Medical Examiner Offices

Anastasiya Haponyuk, BSc, University of New Mexico School of Medicine, Albuquerque, NM 87122; Sarah Lathrop, DVM, PhD, Albuquerque, NM 87111; Lori A. Proe, DO, Office of the Medical Investigator, Albuquerque, NM 87102; Daniel W. Dye, MD, Jefferson County Coroner/Medical Examiner Office, Birmingham, AL 35233; Matthew D. Cain, MD\*, Office of the Medical Investigator, Albuquerque, NM 87102

**Learning Overview:** After attending this presentation, attendees will understand the demographics of chronic ethanol-related deaths in New Mexico and Jefferson County, AL.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting trends associated with chronic ethanol deaths across racially and ethnically diverse populations.

**Background:** Mortality due to cirrhosis in the United States has increased substantially over the past two decades. Liver disease caused by chronic ethanol abuse has fueled this increase and has disproportionately affected younger people.<sup>1</sup> Ethanol-related mortality, particularly liver disease caused by ethanol, has disproportionately affected American Indian populations.<sup>2</sup>

New Mexico's population is 2,103,586 and is comprised of 8.6% American Indian/Alaska Native, 1.7% Asian/Pacific Islander, 2.2% Black/African American, 48.5% Hispanic, and 39% non-Hispanic White. In the United States as a whole, 0.8% of the population is American Indian/Alaska Native.<sup>3</sup> Ethanol-related mortality rates in New Mexico have historically been highest among American Indians and, while ethanol-related mortality declined among non-Hispanic Whites in New Mexico over recent decades, it has remained high in American Indian populations.<sup>4</sup>

**Purpose:** The intent of this study is to compare ethanol-related deaths in New Mexico to those in Jefferson County, AL, by examining data from the medical examiners' offices in both locations. Jefferson County's population is estimated at 659,197, with 53.2% non-Hispanic Whites, 43.4% Black/African American, 0.3% American Indian/Alaska Native, 3.9% Hispanic, and 1.8% Asian/Pacific Islander.<sup>5</sup> By comparing ethanol-related mortality between these racially diverse populations, this study will identify demographic trends, particularly related to the ages at which people succumb to complications of ethanol abuse, and will also examine autopsy findings indicating an ethanol-related death.

**Methods:** To examine a diverse population, five years of data were retrieved from the New Mexico Office of the Medical Investigator (OMI) and Jefferson County Coroner/Medical Examiner (JCCMO) databases. Cases included natural deaths directly related to chronic ethanol abuse. Analysis of chronic ethanol abuse-related diagnoses used only cases with autopsy verified findings.

Analysis was performed using Statistical Analysis Software (SAS). This study analyzed continuous variables with a Wilcoxon rank-sum test, compared categorical variables using either a chi-square test or Fisher exact test. The significance level was 0.05.

**Results:** Given the racial and ethnic differences between these two offices, an initial control comparison using White and Black chronic ethanol-related deaths indicated no significant difference. The mean age at death from chronic ethanol abuse increased between 2013 and 2018 at both OMI and JCCMO, with a mean age at death of 47.4 years in 2013 and 56.5 years in 2018. Age at death among autopsied cases was lower in New Mexico (47.2 years  $p < 0.007$ ) compared to Jefferson county (51.3 years), possibly due to the younger age at which American Indians died from chronic ethanol abuse (45.3 years,  $p < 0.0001$ ). Regarding sex, women died significantly younger than men ( $p < 0.0001$ ), and this can be explained by the disproportionate number of American Indian females dying young from chronic ethanol abuse (39.4 years).

Autopsy findings demonstrated American Indians had a younger mean age at diagnosis of cirrhosis (42.5 years,  $p < 0.0026$ ), steatosis (42.1 years,  $p < 0.0026$ ), cardiomyopathy (38.7 years,  $p < 0.0016$ ), and jaundice (37.3-year,  $p < 0.01$ ) compared to the rest of the population. Additionally, American Indians comprised a high proportion of cases with varices and cardiomyopathy (35%, and 31%, respectively).

Despite comprising only 8.6% of New Mexico's population, American Indians made up 21.5% of chronic ethanol abuse cases analyzed. Furthermore, American Indian females represented 29% of the female deaths. These dramatic results suggest that factors leading to ethanol abuse and early death within the American Indian population need further investigation.

### H42 A Review of Manner of Death in Denver's Homeless Population (2016–2018)

Shauna Kumar\*, Denver Office of the Medical Examiner, Denver, CO 80204; Meredith A. Frank, MD, Denver Office of the Medical Examiner, Denver, CO 80204; James Louis Caruso, MD, Denver Office of the Medical Examiner, Denver, CO 80204

**Learning Overview:** After attending this presentation, attendees will understand the trends of manner and manner subtypes of death in the homeless population of Denver, CO.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing emerging trends of various causes involving specific drug types, natural disease processes, and multifactorial related deaths in Denver's homeless.

In 2016, 10,550 individuals experienced homelessness in Colorado.<sup>1</sup> The state experienced the third-largest percent increase in homelessness nationally between 2015 and 2016. Homeless individuals are at a greater risk for illness and death than the general population. The experience of being homeless has been found to be an independent risk factor for mortality.<sup>2</sup> Studies show that homeless persons report difficulty accessing health care and experience low rates of outpatient care.<sup>3</sup> Harsh living conditions, such as sleeping outdoors in extreme weather and crowded shelters, increase the risks of exposure to disease, violence, and poor access to proper nutrition. These factors further limit an individual's ability to obtain health care and medications, preventing them from managing health issues. Furthermore, a state of homelessness can result in the exacerbation or development of behavioral health problems.

The Denver Office of the Medical Examiner (DOME) investigates deaths in the City and County of Denver and is responsible for the certification of death. It is involved with the investigation of more than 2,000 deaths and performs approximately 800 autopsies annually. Board-certified forensic pathologists are charged with the examination of a body to determine the cause, manner, and mechanism of death as well as documentation of any injuries or diseases. In this jurisdiction, deaths are categorized by manner, which consist of natural, accident, suicide, homicide, undetermined, and are further subcategorized by cause.

The DOME maintains a searchable database of all deaths occurring in Denver County that are reported to the office. The database was queried for deaths from 2016 to July 2018 in known cases of homeless persons. Specific details of each case were examined, including age, race, and gender of the decedent, as well as place of injury, place of death, any contributing factors, manner, and final cause of death. In cases in which toxicology studies are performed, the specific drug or drugs detected are identified. Toxicological testing is performed primarily on samples of postmortem peripheral blood with occasional substitution of heart or cavity blood. Additional toxicologic studies are performed on urine or antemortem specimens in some cases. Toxicological testing was performed according to internal laboratory protocols with appropriate controls at National Medical Services, Inc, Willow Grove, PA, by means of High Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS).

The total number of homeless deaths in Denver within the specified time was 230. Of those, 114 were accidental (10 traffic related), 80 were natural, 15 were suicide, 11 were homicide, and 10 were undetermined. The total number of homeless deaths in 2016 was 79. Thirty-seven were accidental (4 traffic related), 26 were natural, 5 were suicide, 4 were homicide, and 7 were undetermined. The total in 2017 was 103. Fifty-three were accidental (5 traffic related), 36 were natural, 7 were suicide, 6 were homicide, and 1 was undetermined. The total from January 2018 to July 2018 was 48. Twenty-four were accidental (1 traffic related), 18 were natural, 3 were suicide, 1 was a homicide, and 2 were undetermined. Emerging trends in all three years included deaths ruled as accidental ( $n=104$ , 45%) or natural ( $n=80$ , 34%) as the most common manners. Approximately 50% of the accidental deaths were due to intoxication, showing detection of heroin, cocaine, and methamphetamine or a combination of illicit drugs in combination with prescription drugs or ethanol. Among natural deaths, heart disease with various contributing factors was the most common cause of death at approximately 40%. The majority of cases examined were complete autopsies; however, ( $n=20$ , 8.7%) of these were external examinations only.

### H43 Mississippi Organ and Tissue Recovery: A Collaborative Success Story

*Mark M. LeVaughn, MD\**, Office of the Chief Medical Examiner, Pearl, MS 39208; *Anastasia Holobinko, PhD*, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *Taylor Phillips*, Mississippi Organ Recovery Agency, Flowood, MS 39232; *Carrie Deese, BS*, Mississippi Organ Recovery Agency, Flowood, MS 39232; *Kevin Stump, BS*, Mississippi Organ Recovery Agency, Flowood, MS 39232

---

**Learning Overview:** After attending this presentation, attendees will better understand organ and tissue recovery rates and trends in a state with a mixed death investigation system (i.e., coroner and medical examiner).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the history of organ and tissue recovery in Mississippi and providing the results of collaborative efforts on recovery rates.

Prior to 2011, the recovery rate of organs and tissues from coroner death investigations throughout the state of Mississippi was extremely low. The abysmal recovery rate was due to a statewide lack of knowledge and education among the county coroners, combined with a lack of cooperation from the non-board-certified pathologists who performed the autopsy examinations. Denials were frequently attributed to interference from the pathologists, who informed the county coroners that organ and tissue recovery would hinder or preclude their ability to determine the cause and manner of death of the potential donor patient. This flawed practice continued throughout the state for nearly 30 years.

In 2011, the Mississippi Department of Public Safety implemented a State Medical Examiner's System and began hiring only board-certified forensic pathologists. Soon thereafter, the State Medical Examiner's Office established communications with the Mississippi Organ Recovery Agency (MORA). The two agencies developed a relationship patterned after the guidelines set forth in the corresponding position paper (National Association of Medical Examiners 2014). The collaboration led to the establishment of a Medical Examiner Referral Process and an on-scene referral process to assist the coroner with potential referrals of patients who would not likely be transported to the hospital or State Medical Examiner's Office.

MORA is one of 58 federally designated organ procurement organizations. The agency utilizes iTransplant<sup>SM</sup>, a web-based clinical management and communications software system that is widely available on hand-held and other electronic devices. The donation and transplantation platform provides rapid information gathering and exchange between multiple agencies including the medical examiner's office.

Over the past several years, the State Medical Examiner's Office and MORA have combined their efforts to educate and train the county coroners regarding the importance of organ and tissue recovery. These efforts have demonstrated to our local coroners and district attorneys that organ and tissue recovery essentially has no negative effect on the determination of cause or manner of death of a potential donor patient. As a result of collaborative efforts and coroner education, MORA has observed nearly a 10% increase in patient referrals in addition to a significant decrease in cases declined by the coroner. It is expected that the recovery rate will continue to increase.

---

#### Organ Recovery, Tissue Recovery, Collaborative Effort

### H44 A Death Investigation of Mining Fatalities: The Utah Experience

*Kacy Krehbiel, MD\**, Utah Office of the Medical Examiner, Taylorsville, UT 84129; *Joseph Pestaner, MD*, Utah Office of the Medical Examiner, Taylorsville, UT 84129; *Erik D. Christensen, MD*, Utah Office of the Medical Examiner, Taylorsville, UT 84129

**Learning Overview:** After attending this presentation, attendees will: (1) understand the importance of a thorough death investigation in mining fatalities, (2) be able to describe the impact that autopsy findings have in the subsequent enforcement of safety rules and regulations, and (3) be familiar with the role of outside regulatory agencies in the investigation of these deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by detailing the complexities of the investigation of mining fatalities and highlighting the importance of investigative and autopsy findings in the subsequent regulatory consequences concerning these deaths, as illustrated by a recent case study at the Utah Office of the Medical Examiner (OME).

Mining deaths in the United States, which has active mines in all 50 states, have decreased since the passage of the Federal Mine Safety & Health Act of 1977. This strict liability statute establishes that mine operators may be assessed fines, civil penalties, or even imprisonment for violations of health or safety standards. The number of mining fatalities in the state of Utah has likewise decreased over time, with only one mining disaster (defined as greater than five deaths in an incident) in the new millennium. Death investigation plays a vital role in the investigation and subsequent enforcement of safety rules and regulations. All mining fatalities since 2001 in Utah were reviewed to better understand the investigative challenges in such cases.

Since 2001, there have been 24 mining deaths in Utah that were investigated by the Mine Safety and Health Administration (MSHA), 18 of which were investigated by the Utah OME. The six cases not investigated by the Utah OME were individuals whose bodies were not recovered following the Crandall Canyon Mining disaster of August 2007, in which nine individuals were killed in two separate collapses at this underground coal mine. Investigative issues, such as uncertainty regarding jurisdictional authority, can occur, with overlap between cases falling under the jurisdiction of the MSHA and the Occupational Safety and Health Administration (OSHA). The Utah OME has jurisdiction for all such deaths and works with whichever government agency leads the investigation.

Correlation of autopsy findings with the scene investigation is critical, as exemplified in a recent case at the Utah OME. A 56-year-old male sustained a fatal head injury while installing discharge chutes on the screen deck of a gravel sifter. Witnesses saw the decedent fall backward, but nobody could state what exactly had happened. MSHA's preliminary conclusion, as published in the initial fatality alert report on its website, was that the suspended chute shifted, striking the decedent. This preliminary conclusion was made prior to their review of the autopsy findings. The autopsy revealed significant head injury with two separate significant impact sites that supported an alternative hypothesis, namely that the head was pinched or compressed between two objects. Through subsequent collaboration with MSHA, it was determined that the decedent had most likely been working underneath the suspended chute, in violation of applicable regulations, when his head became pinched between the chute assembly and the surrounding steel structures.

In the investigation of mining fatalities, a thorough understanding of the circumstances surrounding death and correlation with the findings at autopsy is critical. Forensic pathologists should be aware of the role their findings play in the investigation and subsequent regulatory enforcement concerning these deaths.

#### **Mining, Fatal, Investigation**

## H45 Trends in the Certification of Choking-Related Deaths

Joshua Vandeburgh\*, Kalamazoo, MI 49007; Abigail Jacqueline Grande, MPH, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Amanda O. Fisher-Hubbard, MD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be more familiar with trends in the certification of choking-related deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying risk factors and/or other significant conditions that may contribute to choking-related deaths for complete, accurate death certification.

According to the National Center for Injury Prevention and Control, suffocation, including choking, was the fourth-leading cause of unintentional injury death in 2016.<sup>1</sup> A review of the literature reveals varied etiologies for unintentional death by choking/asphyxiation. Among those greater than 65 years of age, dementia, Parkinson's disease, and pneumonitis were often associated with death by choking on food.<sup>2</sup> In adults, choking is also associated with a variety of conditions, including alcohol intoxication, poor dentition, and dysphagia due to mental illness.<sup>3-5</sup> Although it may seem obvious that individuals with certain conditions, temporary or otherwise, would be more susceptible to choking, it is unclear how these are captured on the death certificate.

The goal of this study is to discern trends in the certification of choking-related deaths, particularly related to risk factors or other conditions that may have made individuals more susceptible to choking. The hypothesis is two-fold: the majority of decedents that die of choking will have a risk factor or contributing cause listed on the death certificate, and/or the decedents will be at the extremes of age.

This study used an electronic database of cases investigated by a medical examiner's office serving multiple counties in Michigan. A search was conducted for "chok\*" in *Part I* and in the *Injury Description* section of the death certificate. The search also included deaths that were categorized as "Asphyxia" with the cause of asphyxia listed as "food/drink." Cases that listed a *Part II* on the death certificate were noted. In addition, *Part I* of the death certificate was surveyed for choking risk factors, including toxicities and neurological disorders.

A total of 71 cases were identified, five of which were incorrectly categorized and one of which had an incomplete death certificate. The remaining 65 decedents ranged in age from 3 to 95 years, with mean and median ages of 62 and 64 years, respectively. Of these cases, the manner of death was certified as accidental in 62 cases; one death was certified as indeterminate due to a family's objection to an autopsy and two deaths were certified as natural. Food or drink was implicated in 57 cases (88%), while an object/other material was implicated in four cases (6%); the causative agent was not specified in four cases (6%). Of the 65 cases, 38 death certificates (58%) documented information in *Part II* and nine (14%) had possible risk factors for choking listed in *Part I b, c, or d*. The majority of *Part II* conditions included neurological/neurodegenerative diseases (17 cases, 45%), while a minority included toxicities (five cases, 13%); in 16 cases (42%), the conditions listed in *Part II* were unrelated to neurological disorders or toxicities. In 8 out of the 65 cases, a neurologic or toxicologic risk factor was listed in *Part I (a, b, c, or d)*. In one case, the medical examiner listed the same risk factor in *Part Ib* and *Part II*.

To summarize, only 30 decedents (46%) had a choking risk factor listed in the cause of death section of the death certificate (*Part I* and/or *II*). These decedents ranged widely in age, although most were 60 years of age or older. To conclude, the way in which choking-related deaths are certified lacks standardization.

### H46 Cremation Clearance by the Medical Examiner: What Is the Best Method?

*James R. Gill, MD\**, Office of the Chief Medical Examiner, State of Connecticut, Farmington, CT 06032; *Maura DeJoseph, DO*, Office of the Chief Medical Examiner, State of Connecticut, Farmington, CT 06032; *Holly Olko, MA*, Office of the Chief Medical Examiner, State of Connecticut, Farmington, CT 06032

**Learning Overview:** The goal of this presentation is to provide objective data from a single statewide medical examiner system to aid in the determination of whether a physical inspection of a decedent helps detect more unnatural, unreported deaths than just a review of the death certificate/medical records during the process of cremation clearance by the Medical Examiner/Coroner (ME/C).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an evidence-based approach to assessing remains for cremation approval by ME/C jurisdictions.

Numerous jurisdictions require the ME/C to investigate decedents that are to be cremated. Since cremation involves the irreversible destruction of the body, a forensic investigation helps ensure that a previously unreported or undetected unnatural death (homicide, accident, or suicide) is not missed. The process of “clearing” these deaths varies by jurisdiction and ranges from reviewing the death certificate to a physical inspection of the body. With the increasing numbers of cremations and staffing challenges to meet this increased workload, it would be useful to know if one method of cremation investigation is superior to another. The goal of this study is to assess if physical inspection detects more unnatural, unreported deaths than a medicolegal investigation without inspection.

In Connecticut, only an ME can certify homicides, suicides, and accidents. All these known or suspected deaths, as well as all cremation dispositions, must be reported to the Office of the Chief Medical Examiner (OCME). All deaths reported by a funeral home to the OCME for cremation clearance in 2012 and 2016 were reviewed. This review compared the rates of subsequent amendments of the death certificates following two different investigative methodologies performed in each year.

In 2012, physical inspection was the investigative protocol for cremation review. There were 10,367 requests for cremation on non-ME deaths. All but one involved the standard protocol of an OCME-trained medicolegal death investigator performing physical inspections of the remains at funeral homes around the state and reviewing the corresponding death certificate.

In 2016, the cremation clearance protocol was changed to no longer require an inspection of the body but rather a review of the death certificate and other pertinent investigative information as needed. This additional information included a review of the medical records and/or discussions with the family, treating physicians, and or police. In 2016, there were 11,906 of these investigations.

Of the 10,367 reviewed deaths in 2012, there were 86 deaths (0.83%) in which the investigation with physical inspection resulted in an amendment to the cause and/or manner of death (82 accidents, 3 natural deaths, and 1 undetermined). Of the 11,906 reviewed deaths in 2016, there were 153 (1.28%) that required amendment to the cause and/or manner of death (107 accidents, 2 delayed homicides, 2 suicides, 8 therapeutic complications, and 34 natural). The accidents included hip fractures, subdural hematomas, and choking deaths. For the detection of accidents, there was no statistically significant difference between the two groups (chi-square  $\chi^2=0.8119$ ,  $p=.367552$ ). In 2012, four of these 86 decedents had subsequent autopsies at the OCME (3 accidents, 1 natural). In 2016, there were 12 that subsequently underwent autopsy (5 naturals, 5 accidents, and 2 homicides).

For cremation investigations, the manpower and costs of performing physical inspections do not appear justified given the similar detection rates for unnatural deaths among the two groups. Review of the death certificate and associated records without physical inspection detects a comparable number of unnatural deaths as does an investigation with inspection. Without any forensic review of cremations, some ME/C deaths are missed and therefore not properly investigated and certified. Since approximately 30% of deaths in Connecticut do not undergo cremation and do not receive any forensic scrutiny, it is likely that there are unreported ME/C deaths in this non-cremation group.

#### Cremation, Medical Examiner, Investigation

### H47 The Native American Graves Protection and Repatriation Act's (NAGPRA's) Broader Impact: Assessing NAGPRA Implementation Within the Medicolegal System

Megan K. Kleeschulte, MA\*, University of Tennessee, Knoxville, TN 37909

**Learning Overview:** The goal of this presentation is to explore the state of NAGPRA implementation within Medical Examiner/Coroner (ME/C) offices. In doing so, the objective of this research is to aid the medicolegal community in understanding how the law applies to a medicolegal context as well what protocols need to be implemented to be compliant with the law.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees of their responsibility to acknowledge that NAGPRA is a federal law and therefore must be followed, as well as that compliance with NAGPRA indicates that ME/C offices, and those working within them, recognize the rights of Native Americans as well as their own role in ensuring those rights are not ignored or violated.

Passed in 1990, NAGPRA was the culmination of efforts by Native Americans, anthropologists, scientists, museum workers, and politicians to provide a legal process for tribes to claim the remains of their ancestors. Section 43 CFR § 10.9 of the law states that universities and museums must prepare an inventory of the items within their possession and return human remains at the request of a lineal descendent, Indian tribe, or Native Hawaiian organization by 1995. An examination of the qualifications that designate a museum for NAGPRA purposes reveals that ME/C offices fall under this definition and are therefore subject to NAGPRA's stipulations and consequences for noncompliance.

As NAGPRA implementation has not been explored or discussed in a medicolegal context to date, a national survey of medicolegal practitioners was distributed to collect data on practitioners' familiarity with the law as well as the presence of disposition protocol for non-forensically significant Native American remains. The survey responses totaled a range of 55–915 cases that are determined to consist of non-forensic, Native American remains each year (this accounts for only a percentage of the total ME/C system). However, the results also indicated that only 44.3% of the survey respondents are familiar with NAGPRA. Additionally, 34.1% of the survey respondents reported that they have an official protocol for the disposition of non-forensic, Native American remains. However, when asked to provide a description of that protocol, not a single response included NAGPRA-compliant disposition procedures. These results indicate that despite the national attention that NAGPRA has received, that law has not succeeded in widespread knowledge and acceptance among the medicolegal practitioners to whom it directly applies.

In order to provide medicolegal practitioners with the knowledge necessary to operate in a compliant manner, and to avoid the fines associated with noncompliance, this research discusses the sections and stipulations of the law that apply to the medicolegal community as well as what NAGPRA-compliant protocol for the disposition of non-forensic Native American remains should consist of. The benefit of the implementation of compliant protocol is two-fold, as it provides a legal mechanism for ME/C offices to transfer these remains out of their control or jurisdiction, avoiding becoming a permanent repository; and acknowledges both the human and civil rights of Native Americans to claim the remains of their ancestors as well as practitioners' roles in ensuring these rights are not violated or ignored.

#### NAGPRA, Implementation, ME/C Office

### H48 Next-of-Kin—May I? Providing Information to an Organ/Tissue Procurement Organization (O/TPO) on Out-of-Hospital Deaths

*Jan M. Gorniak, DO\*, Fulton County Medical Examiner, Atlanta, GA 30312; Charles M. Gammill, BA\*, Lifelink of Georgia, Norcross, GA 30071*

**Learning Overview:** The goal of this presentation is to discuss referring out-of-hospital deaths to an O/TPO. After attending this presentation, attendees will be able to gain consent, if needed, from Next-Of-Kin (NOK) to provide information to an O/TPO.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by possibly increasing the number of life-saving tissues in the community.

Medical Examiners/Coroners are crucial in the donation process. By referring all out-of-hospital deaths to an O/TPO, they can ensure that many citizens in their community are given the opportunity to leave a legacy through the gift of donation. Because the majority of suitable donors fall under medical examiner/coroner jurisdiction, their role in referring out-of-hospital deaths and releasing tissue for donation is one of the most important components in the transplantation process.

Per the Official Code of Georgia Annotated (O.C.G.A) § 44-5-159.2, "... a medical examiner shall release to the procurement organization the name, contact information, and available medical and social history of a decedent whose body is under the jurisdiction of the medical examiner." In 2009, the Fulton County Medical Examiner's Office requested an official opinion from the Fulton County Attorney, specifically, "Is there anything in the law that prohibits us from providing the next-of-kin information to the tissue recovery agency?" The opinion received stated, "Fulton County Medical Examiner **cannot** provide next-of-kin information to the procurement organization that **has not** requested the information." This means that on out-of-hospital deaths, the Fulton County Medical Examiner's Office could not refer cases to the O/TPO.

According to the National Association of Medical Examiners Position Paper, Medical Examiner Release of Organs and Tissues for Transplantation, medical examiners/coroners should have "a goal of 100% referral of out of hospital deaths investigated by medical examiner/coroner offices where last known alive time is within 24 hours." With the county attorney opinion, the Fulton County Medical Examiner's Office was not able to obtain that goal. In November 2016, recognizing the loss of potential donors, the Fulton County Medical Examiner's Office requested a review of the original opinion, specifically asking if the "law prohibits Fulton County Medical Examiner's Office from providing the next-of-kin information to an organ procurement agency such as LifeLink of Georgia®." The current opinion is that "Fulton County Medical Examiner's Office is not prohibited from providing next-of-kin information to LifeLink of Georgia® so long as the next of kin has given their consent prior to releasing this information."

On November 15, 2017, after revising the Organ and Tissue Procurement Standard of Operating Procedure and training medicolegal death investigators, Fulton County Medical Examiner's Office began referring out-of-hospital deaths to LifeLink of Georgia®. Between November 15, 2017, and April 30, 2018, Fulton County Medical Examiner's Office medicolegal death investigators responded to 561 scenes and received next-of-kin consent to share their information in 135 (24%) cases.

#### Donation, Referral, Deaths

### H49 A Novel Adaptation of Electronic Health Records (EHR) for Medical Examiner Use

*Carley J. Holmes\**, Flint, MI 48532; *Kaila Jakubczak, BS*, Hurley Medical Center, Flint, MI 48503; *Brian C. Hunter, MD*, Flint, MI 48502

**Learning Overview:** After attending this presentation, attendees will understand a new way of integrating public health information with clinical information while improving the efficiency of a Medical Examiner's Office (MEO). Epic is an EHR system capable of combining two different health platforms (patient care and postmortem care), providing information sharing capabilities, computer-generated reports, and improved ease of documentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new information management source for medical examiners that improves access to clinical health information and by exploring the capabilities Epic has to offer the medical examiner community.

Epic is an integrated information management system that can be manipulated to accommodate user's workflow, thereby allowing for improved efficiency in all areas of an MEO: report generation times, processing efficiency, and distribution tracking. The development of a medical examiner module within the Epic system allows for secure sharing of data between clinical care teams and the MEO, both locally and nationally (Epic is widely used throughout the country). Epic's security features limit information sharing to only that which is deemed permissible and appropriate by the involved clinical care system and the involved MEO.

The Genesee County Medical Examiner's Office (GCMEO) in Flint, MI, partnered with Hurley Medical Center, Flint's Level One Trauma Center, to create the first medical examiner/morgue module within Epic, the electronic health record system used by Hurley. The GCMEO had two main objectives when choosing to use Epic: (1) improve the efficiency of the office as a whole, and (2) more seamlessly integrate autopsy data and clinical care information.

There are three main ways Epic can improve efficiency: (1) automatic report generation, (2) specialized notes, and (3) all-in-one storage. The automatic report generation feature can be used as a tool for the National Association of Medical Examiners (NAME) accreditation by pulling together specific information, such as cause of death or manner of death, within a user-specified time range. Specialized notes can be created based on job type (e.g., medical examiner investigators, pathology assistants, medical examiners, etc.); additionally, case reports/notes can be automatically generated based on entered information. Epic provides an all-in-one storage for cases including, but not limited to, images, notes/reports, and past medical history/previous encounters with physicians.

There are three main ways Epic is able to integrate public health information with clinical information: (1) MEO access to clinical health information, (2) clinical physician access to certain MEO information (if permitted), and (3) automatic report generation based on information provided from the MEO. Clinical health information already in Epic for a patient is readily available. Clinical health information may include demographics, diagnoses, surgical history, current medications, lab results, imaging, and encounter notes. Clinical physicians, such as emergency department providers, may be given clearance to view information obtained from performed autopsies on certain patients; case-specific information, such as a trauma report, can be provided in a quick manner through report generation and Epic access. Automatic reports can be generated from the clinical information and the MEO information entered into the system. General information, such as age, sex, and the amount/type of causes of death and manners of death, can be generated for a user-specified time span. Generated reports can be produced from a combination of different information.

In order to quantify efficiency, medical examiner report turnaround time was analyzed from two different time periods: before Epic and with Epic. Additionally, Epic allows for an additional service, a scribe, to aid in report generation at the time of autopsy; therefore, report turnaround time was also analyzed from a period without Epic and a scribe and with Epic and a scribe. It was concluded that report turnaround time was improved (decreased case completion time) with the use of Epic and showed further improvement with the use of Epic and a scribe. Epic provides both enhanced functionality/efficiency and information integration.

#### Electronic Health Records, Medical Examiner, Integration

### H50 Mass Disaster Management and Disaster Victim Identification (DVI) Activities in the 2016 Central Italy Earthquake

Luigi Cipolloni, MD, PhD, Rome 00161, ITALY; Benedetta Baldari\*, Rome, ITALY; Mariantonia Di Sanzo, MD, Rome, ITALY; Livia Besi, Rome, ITALY; Matteo Scopetti, MD, Sapienza University of Rome, Rome, ITALY; Alessia Quattrocchi, Rome, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the management and identification process of victims after the 6.0 earthquake that struck Amatrice, Italy, on August 24, 2016.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an effective protocol based on the elaboration of an algorithm for the management of dead bodies and on the systematic acquisition of data during corpse processing.

The management of a mass disaster requires a series of fundamental steps concerning the designation of a collection area, transfer, examination, and storage of dead bodies, *in situ* identification, and the return of bodies to relatives for burial. On August 24, 2016, following the earthquake that struck central Italy, a team of forensic pathologists from Sapienza University of Rome were entrusted with managing the disaster.

Upon arrival in Amatrice, a suitable site for the establishment of a collection center was identified. The collection center was divided into an acceptance area, an examination area, and an information center comprising the antemortem section, postmortem data entry, and administrative support. Subsequently, the forensic team developed a cadaver management algorithm based on the World Health Organization guidelines and coordinated, with the local authorities, the transfer of the bodies to the designated center. Upon acceptance, each corpse was attributed an identification number using pre-numbered tags attached to the body and body bag. Each body was then assigned to examiners for data collection. The examiner's team was composed of forensic pathologists and police officers from the Carabinieri scientific investigation division and the scientific police. At least four examiners were assigned to each body to conduct a systematic examination. Findings were documented through compiling data collection forms and taking photos of the body, clothing, accessories, and other personal items. Only identified bodies were sent to be buried in Amatrice cemetery or in other places for non-residents. The bodies without identification were momentarily placed in refrigerated tents awaiting identification. In cases in which identification did not occur within a reasonable time, burial was ordered for hygienic and health reasons after fingerprints collection and DNA sampling.

From August 24–28, 2016, 244 bodies were received at the collection center. Most of the 244 bodies examined were complete bodies (235, 96.3%), while in a few cases, the bodies were dismembered (9, 3, 7%), with the loss of anatomic parts such as the head, ears, limbs, feet, and fingers. Sex was recognizable in all 244 bodies with a male- (98, 40%) to-female (146, 60%) ratio of 1.48.

The causes of death of the 244 subjects examined were classified, according to the *International Classification of Disease, 10<sup>th</sup> Edition (ICD-10)* Lists for Tabulating Mortality Statistics, into crushed chest (124, 51%), confinement or entrapment in a low-oxygen environment (66, 27%), fractures involving multiple body regions (27, 11%), fractures of the skull and facial bones (20, 8%), and fractures of the cervical spine (7, 3%).

Most of the bodies (227, 93%) were directly identified through clothes, personal effects, marks, photographs, and comparison between antemortem and postmortem data. In a minority of cases (17, 7%) it was necessary to take samples for DNA analysis. At the end of the operations, all the deceased had been identified and returned to relatives.

Identification of mass disasters victims is a complex activity because of the emergency conditions in which the operations take place and the conditions of conservation in which the bodies are found. In this context, the role of forensic pathologist assumes extreme importance in the coordination of the multidisciplinary team involved in the post-disaster management of victims. The experience proposed demonstrates, albeit in a small-scale context, that a standardized protocol focused on identification is highly effective, reducing the use of more advanced methods.

#### Mass Disaster, Earthquake, Identification

## H51 Acute Myocarditis Following PD-1 Inhibitor (Nivolumab) Treatment for Lung Carcinoma

Peter Houston, MD, Charleston, SC; Angelina I. Phillips, MD\*, Medical University of South Carolina, Charleston, SC 29425

**Learning Overview:** After attending this presentation, attendees will: (1) understand the pathophysiology of Immune Checkpoint Inhibitors (ICIs), (2) become aware of myocarditis as a severe immune-related adverse event, and (3) include immunomodulatory treatments in the differential diagnosis of acute myocarditis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the increasing need to include ICIs in the differential diagnosis of acute myocarditis when evaluating a patient's anticancer regimens.

Nivolumab is a monoclonal PDL-1 inhibitor in the class of ICIs used in the treatment of several malignancies, including non-small cell lung cancer, renal cancer, and melanoma.<sup>1,3</sup> Common reported treatment-related adverse events of immunomodulators include fatigue, decreased appetite, rash, diarrhea, and arthralgia, including treatment-related autoimmune effects in sites such as skin, kidney, lungs, brain, endocrine organs, gastrointestinal tract, and, more recently described, cardiovascular system.<sup>1,2,4</sup> Over-expression of inhibitory checkpoint molecules, such as Programmed cell Death Ligand 1 (PDL-1) allows cancer cells to prevent the body's natural immune response from activating CD8 T-cells, allowing the cancer cells to proliferate, escaping cytotoxic cell mediated death.<sup>2</sup> ICIs work by blocking PDL-1, which allows the CD8 T-cells to become active and kill cancer cells, although not without some notable side effects. Severe cases of immune-related adverse events have been well documented. Of these, approximately 0.06% to 0.27% of patients can experience immune-related myocarditis that can lead to arrhythmias, heart failure, and death due to cardiogenic shock.<sup>2</sup>

This presentation describes a fatal case of fulminant myocarditis after treatment with nivolumab in a 76-year-old man with metastatic lung adenocarcinoma. The patient presented with chest discomfort while at the infusion clinic; he reported experiencing some nausea and vomiting, shortness of breath, and dizziness approximately five days prior. Examination revealed atypical Electrocardiogram (EKG) findings, including ventricular tachycardia with apparent Atrioventricular (AV) dissociation and S-T segment elevations concerning for S-T-Elevation Myocardial Infarction (STEMI) with serum troponin elevations suggestive of a myocardial infarction; the patient died within one day of admission. Postmortem examination was requested by the clinical team with suspicion of metastasis to the AV node due to EKG findings.

At autopsy, the gross examination of the heart was unremarkable except for evidence of coronary atherosclerosis and focal pallor in the interventricular septum. Histologic examination revealed a fulminant myocarditis with infiltration of the myocardium by lymphocytes, numerous neutrophils and eosinophils associated with marked myocyte necrosis, and interspersed large atypical appearing cells. The large atypical cells were concerning for metastatic tumor; however, immunohistochemical workup ruled out carcinoma. Infective myocarditis workup performed at the Center for Disease Control could not identify a specific infectious etiology. Ruling out the presence of metastatic tumor and common infectious causes, the final diagnosis favored the immune check point inhibitor treatment as the etiology of the fulminant myocarditis.

Multiple immune checkpoint inhibitors are on the market for use in the anticancer regimens of a variety of cancer types, which has markedly increased the number of patients receiving these therapies. This report adds to the cases of acute myocarditis presenting after PD-1 inhibitor treatment and highlights the need to consider a broader differential in myocarditis presenting in patients with cancers treated by immunomodulators.

### H53 Madelung's Disease: A Rare and Benign Life-Threatening Condition

*Helena D. Corro, MD\**, Portuguese National Institute of Legal Medicine, Coimbra, Beira Litoral 3000, PORTUGAL; *Carla Carreira, Largo da Sé Nova, Coimbra, PORTUGAL*; *Rosa H. Gouveia, PhD, Portuguese National Institute of Legal Medicine, Coimbra 3000-213, PORTUGAL*; *Ana S. Coelho, MSc, National Institute of Legal Medicine, Coimbra, PORTUGAL*; *Joao E.S. Pinheiro, PhD, MD, Instituto Nac Medicina Legal e Ciências Forenses, Coimbra 3000-213, PORTUGAL*; *Francisco Corte-Real, PhD, Center Branch, Coimbra, PORTUGAL*

**Learning Overview:** After attending this presentation, attendees will understand about a rare and benign condition called Madelung's Disease, which can mimic head and neck malignancy and add an asphyxial component to the cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing this rare disorder of unknown etiology, also called Launois-Bensaude Syndrome and Multiple Symmetric Lipomatosis, and provide tools for its diagnosis. The forensic implications to the cause of death are also relevant.

Madelung's disease is characterized by a prominent and symmetric deposition of non-encapsulated adipose tissue, preferentially on the upper region of the body. Symptoms depend on the affected body area. With only 200-300 cases described worldwide until 2015 and an incidence of 1/250,000, it is more frequently observed in middle-aged men with Mediterranean ancestry, strongly associated to chronic alcoholism. Forensically, the excess of fat accumulation around the neck is the most striking feature, because it may compress the aero-digestive tract, and/or the lipomatosis aggregates may undergo malignant transformation. In such cases, surgical excision or liposuction with removal of the entire lesion could be attempted.

Reported here is a case of a 48-year-old man with a history of heavy alcoholism, oligophrenia, and Madelung's Disease admitted to a mental health department for alcohol detoxification and posterior surgical treatment, who died suddenly when sleeping. The patient exhibited a good general condition, BMI of 28.7, and large adipose neoformations on the submandibular, cervical, supraclavicular regions, and upper arms. The patient had previously been submitted to surgery for this disorder.

The autopsy showed, apart from the above-mentioned external lesions, an enlarged amount of anomalous deposition of adipose tissue surrounding the aero-digestive tract with compression of laryngeal structures, although still permeable. Anatomico-pathological examination revealed benign subcutaneous and soft tissue lipomatosis that compressed and deformed the local structures, affecting their natural functions (as shown by marked distention of alveolar spaces and pulmonary infection). Toxicology was negative for alcohol, revealed anti-epileptic, neuroleptic, and benzodiazepines in therapeutic concentrations. The cause of death was acute bronchopneumonia with a probable contribution of the cervical lipomatosis to respiratory compromise.

Forensic pathologists should be aware of the characteristic appearance of this unique and rare disorder, scarcely described in forensic literature, as an important clue to recognize associated risk factors, such as alcoholism, hyperglycemia, hyperlipidemia, diabetes, and polyneuropathy. It is also important to evaluate, for each case, its role in an eventual asphyxial death.

#### **Madelung's Disease, Multiple Symmetric Lipomatosis, Asphyxial Deaths**

### H54 Disseminated Miliary Staphylococcal Infection: A Case of Pyomyositis and Bacterial Myocarditis in a Prisoner

Ariana Pape, BA\*, Norfolk, VA 23508; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will be able to: (1) recognize the signs and symptoms of disseminated staphylococcal infection, (2) differentiate bacterial from fungal meningitis, and (3) familiarize themselves with the tissues most likely to be invaded by disseminated staphylococcus aureus.

**Impact on the Forensic Science Community:** This presentation will impact attendees by: (1) increasing clinical suspicion of disseminated pyomyositis in severe sepsis of unclear source, and (2) suggest alternate testing beyond routine culture and radiology, such as investigation of the heart and skeletal muscle by biopsy, ultrasound, and magnetic resonance imaging.

Fatalities due to disseminated staphylococcal infection are relatively rare. Most staphylococcal infections do not disseminate and are focused in a specific area of the body. Here is reported a case of a 39-year-old male prisoner who died of disseminated miliary staphylococcal infection. He had a history of chronic drug addiction with repeated overdoses and had previously been treated in the hospital for an overdose two months before imprisonment. He became ill in jail after the first ten days of imprisonment, spent three days in the medical isolation ward, and was transferred to the hospital for lethargy, confusion, and tachycardia with decreasing blood pressure. After a negative drug screen, the differential diagnosis on admission was focused on severe sepsis of unclear origin. Meningitis was suspected to be due to cryptococcal infection, due to a positive India ink test, but that was later ruled out due to antigen testing. He was also diagnosed with a urinary tract infection, sepsis, and pneumonia, all due to methicillin-resistant *Staphylococcus aureus*. He died in the hospital before the origin of the meningitis was able to be determined.

On autopsy, external examination showed petechial hemorrhages and severe jaundice. The petechial hemorrhages were in the sclerae, oral mucosa, and skin and corresponded to a markedly reduced platelet count due to diffuse intravascular coagulation. Internal examination identified disseminated pustules in a miliary pattern throughout skeletal muscle and the myocardium, along with bilateral consolidated pneumonia, hepatomegaly, splenomegaly, and splenic infarcts. The disseminated miliary pustules were found in the pectoral, abdominal, and strap muscles, myocardium, lungs, tongue, and jejunal wall. Several of the pustules had abscess cavities, and the lungs were the most severely affected. The Cerebrospinal Fluid (CSF) gram stain demonstrated innumerable gram-positive cocci without fungal organisms; multiple blood and urine cultures grew *Staphylococcus aureus*. The cause of death was determined to be disseminated miliary staphylococcal infection despite appropriate antibiotic therapy.

The literature includes one report of eight autopsy cases of fatal pyomyositis due to *Staphylococcus aureus* infection.<sup>1</sup> Six out of the eight cases involved recent trauma to the area of infection, and the pustules were most frequently found in the trunk, shoulder girdle, and thigh muscles. Besides the pyomyositis, cirrhosis and fatty liver were the most frequent autopsy finding, and death was due to sepsis in all cases. This case confirmed the skeletal muscle pattern of pyomyositis and adds cardiac involvement; there was no recent trauma. A second case report on *Staphylococcus aureus* myocarditis, reporting a 44-year-old male on methotrexate who was diagnosed with *Staphylococcus aureus* myocarditis associated with a left ventricular apical thrombus, noted that it is seen most frequently in immunocompromised persons.<sup>2</sup> That patient was treated with antibiotics and made a complete recovery. The case presented here was reportedly HIV negative and had no known immunosuppression; his disseminated miliary staphylococcal infection with pyomyositis and cardiac involvement was not suspected prior to autopsy.

### H55 Deaths Due to Cardiomyopathy of Unknown Etiology in Children and Young Adults

*Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Ponni Arunkumar, MD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Steven M. White, MD, PhD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

**Learning Overview:** After attending this presentation, attendees will better understand the autopsy findings of deaths due to cardiomyopathy of unknown etiology in children and young adults in the Cook County Medical Examiner's Office in Chicago, IL.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating cases of sudden, unexpected death in which the hearts were abnormal (either grossly or microscopically), but there was no known underlying etiology for the cardiomyopathy.

Cardiomyopathies are a heterogeneous group of diseases of the heart muscle that can lead to heart failure, cardiac arrhythmia, and sudden death. Although there are many etiologies for cardiomyopathies, they typically manifest as an enlarged heart or a heart with normal weight with microscopic pathology (fibrosis, inflammation, etc.). Since cardiomyopathy is not a specific diagnosis, this study has attempted to determine the underlying etiologies in our population. Diseases such as hypertension, obesity, chronic alcoholism, and genetic abnormalities can all cause cardiomyopathies and have similar gross and microscopic findings. This project focused on cases of cardiomyopathies in which no underlying etiology could be found through medical history or autopsy.

The files of the Cook County Medical Examiner's Office in Chicago, IL, were searched for cases of subjects between 1 and 40 years of age with "cardiomyopathy" as a cause of death, from January 2013 to June 2018. Cases were reviewed for age, sex, race, cause and manner of death, medical history, and autopsy findings.

In total, 140 cases were identified: 116 cases (83%) with cardiomyopathy due to hypertensive cardiovascular disease, 1 case with cardiomyopathy due to obesity, 1 case with cardiomyopathy due to chronic alcoholism, 2 cases with cardiomyopathy due to alcoholism and obesity in combination, and 20 cases (14%) with an unknown etiology, which is the group examined for this study.

Regarding the 20 cases with a cardiomyopathy of unknown etiology, 16 were males and 4 females; 15 were African American and 5 Caucasian. Ages ranged between 14 and 40 years old: two decedents were <20 years old, eight ranged between 21-30 years, and ten ranged between 31-40 years. The manner of death was determined to be natural in all cases.

Cardiomegaly was present in 16 out of 20 decedents (80%) with heart weights ranging between 376 grams and 840 grams. Additional gross pathological changes were present in 15 out of 20 cases (75%), consisting mostly of dilated ventricles, hypertrophic ventricles, and myocardial scarring.

All 20 cases showed microscopic pathology consisting of the following changes: fibrosis (17 cases), cardiac myocyte hypertrophy (13 cases), interstitial chronic inflammation (10 cases), and interstitial adipose tissue (5 cases). In 4 out of 20 cases (20%), there were no gross pathological changes, but histology showed one or more of the above-listed abnormalities.

Regarding medical history, 10 out of 20 cases had other associated diseases, with the most common being obesity, asthma, and fatty liver. Obesity was present in 6 out of 20 cases (BMI ranged between 32 kg/m<sup>2</sup> and 35.3kg/m<sup>2</sup>). In cases in which obesity was considered as the etiology of cardiomyopathy, BMI ranged between 40kg/m<sup>2</sup> and 46kg/m<sup>2</sup>.

Genetic testing is being offered to decedents' families to search for an underlying etiology and counsel families. To date, this study has results from 3 out of 20 cases. So far, no pathogenic mutations have been identified. Genetic variants of uncertain significance have been identified, including missense variants of genes PRKAG2, DOLK, DMD, NEBL, PDLIM3, and DSG2. At this point, it is unclear how these variants may contribute to the development of cardiomyopathies. Therefore, in all the autopsy reports, it was recommended that first-degree (immediate) family members undergo cardiovascular screening and possible genetic evaluation by experienced cardiologists and geneticists to diagnose and prevent sudden death in surviving family members.

This study shows that in children and young adults, there are a significant number of decedents with cardiomyopathy with no known etiology after a complete autopsy and review of medical records. In some cases, the heart may appear grossly normal and show only microscopic evidence of pathology. Screening for cardiovascular disease and possible genetic testing should be performed in immediate family members of a child or young adult dying from a cardiomyopathy of unknown etiology.

#### Cardiomyopathy of Unknown Etiology, Sudden Death, Genetic Testing

### H56 Alveolar Capillary Dysplasia With Misalignment of the Pulmonary Veins: Histopathology and Applicability to Autopsy

Rhonda M. Mittenzwei, MD\*, Duke University Health System, Durham, NC 27710; Elizabeth Pavlisko, MD, Duke University Medical Center, Durham, NC 27710; Laura Hale, MD, PhD, Duke University Medical Center, Durham, NC 27710

**Learning Overview:** After attending this presentation, attendees will be able to: (1) identify the pathognomonic histologic features of a rare lung development disorder, Alveolar Capillary Dysplasia with Misalignment of the Pulmonary Veins (ACD-MPV); and (2) recognize its clinical presentation and understand confirmatory testing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by elucidating a rare disease process that may present as unexplained cardiopulmonary arrest in an infant and providing diagnostic criteria that can help make a diagnosis.

Herein, a case of ACD-MPV is presented in which this diagnosis was not initially suspected clinically. The patient presented with respiratory failure within hours of birth, with subsequent development of pulmonary hypertension refractory to treatment. He received near-constant ventilator support and was put on Extracorporeal Membrane Oxygenation (ECMO) twice during his three weeks of life. Several hours after his second ECMO decannulation, he acutely decompensated with systemic hypotension and pulmonary hypertension requiring the use of vasopressors and fluid resuscitation. Infection was suspected clinically due to a rising white blood cell count in the context of hypotension, but all cultures were negative. The patient's ultimate demise was precipitated by an acute hypoxic event; his family opted to have an autopsy performed. Gross autopsy findings included left pulmonary artery stenosis with ostial stenosis, pulmonary trunk dilation, and right ventricular hypertrophy. Light microscopy revealed a decreased number of pulmonary capillaries and increased distance from alveolar epithelium in conjunction with pulmonary veins and pulmonary arteries in the same adventitial sheath. Genetic testing performed on the patient identified a c.691\_698delGCGGCGGC frameshift mutation in the *FOXF1* gene.

ACD-MPV is a rare but generally fatal developmental disorder of pulmonary vasculature. Genetic variations of the *FOXF1* gene, including heterozygous point mutations, deletions, and mutations of an upstream enhancer region have been identified in patients with ACD-MPV, and mutations in *FOXF1* have been shown to cause similar pulmonary vascular abnormalities in mice. However, pedigree analysis suggests that mutations in other still unknown gene(s) may also result in ACD-MPV. The initial presentation of this disorder typically involves neonatal respiratory distress and pulmonary hypertension, both of which are refractory to supportive measures. Respiratory distress typically occurs within 24–48 hours after birth and may be accompanied by central cyanosis and tachypnea. The clinical presentation may be exacerbated by a concomitant hypoplastic left heart. The *FOXF1* gene is also involved in gastrointestinal tract development, and malrotation or intestinal atresia may be identified alongside lung abnormalities. Rarely, genitourinary malformations are identified.

Histopathology is considered the gold standard for diagnosis of ACD-MPV. Tissue may be collected via a lung biopsy, if tolerated, but is often collected at the time of autopsy. Five histopathologic findings are diagnostic of ACD-MPV: immature lobular development; decreased number of pulmonary capillaries located away from alveolar epithelium; thickened alveolar septa; arteriolar and arterial changes, including medial hypertrophy and muscularization; and malposition of pulmonary veins within the same adventitial sheath as pulmonary arteries. In up to 30% of cases, lymphangiectasis may also be identified.

This case report highlights the importance of autopsy in elucidating a disease process that was not initially suspected clinically. It is important for pediatric critical care teams to include ACD-MPV in the differential diagnosis of patients with severe and refractory respiratory failure and pulmonary hypertension. Definitive diagnosis can be made by lung biopsy, if tolerated. Identification of an inactivating *FOXF1* mutation can confirm the diagnosis, but absence of such a mutation cannot definitively rule out ACD-MPV. Prompt antemortem diagnosis may allow the development of treatments that can prolong survival, as no effective treatments for ACD-MPV exist currently, and may assist families in coping with their child's prognosis. In the broader context of forensic autopsies, the diagnosis of ACD-MPV may be identified histopathologically within the context of an otherwise unexplained cardiopulmonary failure in a term neonate.

### H57 Exacerbation of Traumatic Brain Injury in the Presence of Diabetes Mellitus: An Experimental Study of Mice

*Kazuhiko Kibayashi, MD\*, Tokyo Women's Medical University, Tokyo 162-8666, JAPAN*

**Learning Overview:** After attending this presentation, attendees will understand the relationships between pre-existing natural diseases and traumatic injuries and the possible exacerbation of injuries after experiencing trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing evidence that diabetes mellitus is a possible condition that contributes to death due to Traumatic Brain Injury (TBI).

TBI can occur as a result of falls, traffic accidents, and blows. An assessment of severity is required to determine the prognosis and elucidating cause of death. It is known that age is a risk factor for TBI. Elderly people sometimes have diabetes mellitus as a pre-existing co-morbid disease. Diagnosis of a coexisting or pre-existing condition that contributes to underlying cause of death is required in completing the cause-of-death statement. It was supposed that TBI is exacerbated by pre-existing diabetes mellitus due to microcirculation dysfunction and prolonged inflammation. This study investigated the change in brain function and extent of brain contusion after TBI in diabetic and non-diabetic mice.

Ten-week-old male KKAY (type 2 diabetic) and C57BL/6J (non-diabetic) mice were used in this study. A Controlled Cortical Impact (CCI) device was used to induce TBI in each mouse (CCI model). Sham-operated (craniotomy without impact) and naive (did not undergo any operation) animals were used as controls. This study measured the volume of brain contusion using Magnetic Resonance (MR) imaging, which was performed using the Bruker® Icon 1T MR imaging system. This study then assessed changes in nerve function using the Neurological Severity Score (NSS) for motor function and cognitive deficits, learning and memory using the Morris Water Maze (MWM), depression/helplessness using the Forced Swim Test (FST), and motor function using Beam Walking (BW). These experiments were performed from 1 to 112 days after surgery ( $n=4-10$  per timepoint for each group).

Brain contusion was produced in the ipsilateral cerebral cortex of the diabetic and the non-diabetic mice. Compared with those in the non-diabetic mice, the diabetic mice had significantly higher volumes of brain contusion based on the MR imaging and significantly greater deterioration in NSSs after TBI. There were no significant differences in MWM, FST, or BW performances between the diabetic and non-diabetic mice. The results of this present study suggest that pre-existing diabetes is a factor that worsens TBI. Exacerbation of TBI should be monitored in patients with diabetes mellitus. This experimental study also suggests that coexisting diabetes mellitus is a condition that contributes to death due to TBI.

#### **Cause of Death, Diabetes Mellitus, Traumatic Brain Injury**

### H58 Primary Cardiac Tumor as a Cause of Sudden Death: A Report of a Rare Case of Atrial Lipoma

*Stefano D'Errico, MD, PhD, Department of Legal Medicine, Lucca 55100, ITALY; Diana Bonuccelli, MD, Department of Legal Medicine, Lucca, ITALY; Alberto Mandoli, MD, Department of Legal Medicine, Lucca, ITALY; Massimo Martelloni, MD, Department of Legal Medicine, Lucca, ITALY; Francesca Maglietta, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY*

**Learning Overview:** The goal of this presentation is to present the case of a sudden undiagnosed cardiac lipoma of the right atrium.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing fatal cardiac rhythm disturbances caused by an atrial tumor infiltrating the free wall of the right atrium and the role of primary cardiac tumors as a cause of sudden death.

Primary tumors of the heart are rare, and the incidence varies between 0.0017 and 0.19% in unselected autopsy studies. Among these, more than 70% are benign, mainly myxomas. Other benign tumors are lipoma, papillary fibroelastoma, rhabdomyoma, and fibroma. It is extremely rare, with a reported incidence of approximately 10%–19% among primary tumors of the heart and pericardium. Histopathologically, cardiac lipoma can be classified into two types: lipomatous hypertrophy of the interatrial septum and true lipoma. Approximately 50% of cardiac lipomas arise subendocardially, 25% subepicardially, and 25% from the myocardium. The most common chambers involved are left ventricle and right atrium with a prevalence between 40–60 years of age without sex predominance and extremely variable in size. Patients with cardiac lipoma are usually asymptomatic and discovered incidentally; symptoms reported are fatigue, dyspnea, palpitation, syncope, and even chest pain, which are frequently a result of coronary artery or cardiac conductive system involvement. Tumors in the subepicardial region can create a mass effect on nearby structures. They can cause angina if they compress the coronary arteries, or they can reduce systolic function by compressing on the left ventricle. Tumors in the myocardium can infiltrate the electrical circuit and be a nidus for arrhythmogenesis. Depending on the chamber involved and the size of the mass, they can cause obstruction of flow and congestive heart failure.

Cases of sudden unexpected death attributed to myocardial tumors have been poorly described in forensic and clinical literature; in these cases, cardiac neoplasms cause atrioventricular or intraventricular conduction disorders, which are manifested by arrhythmias, interfering in the cardiac dynamic and leading to sudden death. It has been calculated that 0.0025% of all cardiovascular deaths may be sudden death caused by primary cardiac lesions and 0.01%–0.005% of all sudden deaths could be due to primary cardiac tumors and 0.06% of cardiovascular deaths among the 0 to 34-year-old population may be the result of sudden death caused by a primary intracardiac tumor. These data indicate that primary cardiac lesions are uncommon, yet potentially lethal. Owing to the rarity of these lesions, it seems likely that many practicing autopsy pathologists will never encounter a primary cardiac lesion. It is also expected that several primary cardiac tumors causing sudden death will be missed each year because an autopsy is not performed.

**Case Report:** Presented here is the case of a 67-year-old man who was found unconscious at home and immediately taken to the emergency department of the local hospital. He had a history of hyperthyroidism and hyperlipidemia. One hour after recovery, clinical conditions improved, he was without pain and oriented (GCS 15); normal cardiac function was recorded at Electrocardiogram (ECG), and neurological examination was unremarkable. Two hours after recovery, he suddenly and unexpectedly died. A hospital autopsy was performed the day after death. External examination was unremarkable. Gross examination revealed an encapsulated tumor (40mm x 30mm x 30mm) in the external layer of the right atrium free wall. The section showed a yellowish and elastic solid mass. The heart was normal in size and shape and the coronary arteries were unremarkable. A heart examination was performed according to the inflow-outflow method; no further pathological findings were attributable to the heart except for the presence in the subendocardial wall of the right atrium of three yellowish nodular buttons 1cm in diameter. Mild pulmonary edema was also recorded, with white foam on the main bronchi. The histologic study was completed using formalin-fixed paraffin embedded tissue sectioned at 4mm and stained with hematoxylin–eosin. Microscopic findings were suggestive for a right atrial lipoma infiltrating through the atrium wall with mild intracardiac involvement. The diagnosis was confirmed by immunostaining that revealed immunopositivity for S100. Based on morphological and microscopic findings, a sudden arrhythmogenic cardiac death related to an atrial rhabdomyoma was diagnosed.

### H60 Massive Portal Vein Thrombosis as a Rare Cause of Unexpected Death in a Non-Cirrhotic Patient

*Stefano D'Errico, MD, PhD, Department of Legal Medicine, Lucca 55100, ITALY; Sara Niballi, MD, Department of Legal Medicine, Lucca, ITALY; Giuseppe Davide Albano, MD\*, Foggia 71121, ITALY; Massimiliano Esposito, MD, University of Catania, Catania 95123, ITALY; Marco Conti, MD, Department of Legal Medicine, Lucca, ITALY*

**Learning Overview:** The goal of this presentation is to present the case of an unexpected death in a non-cirrhotic patient with acute abdominal pain of recent onset due to a massive Portal Vein Thrombosis (PVT).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that a common presenting symptom, such as abdominal pain, in a young, healthy adult can be a manifestation of a rare diagnosis such as PVT, supporting the relevance of the hospital autopsy as an instrument of audit in the practice of emergency medicine.

PVT as the etiology of abdominal pain in an otherwise healthy young adult is an uncommon occurrence and is capable of leading to serious adverse short- and long-term events in the affected patients. While the occlusion of the extrahepatic portal and splenic vein can provoke complications mainly related to portal hypertension, mesenteric vein obstruction shows a high rate of complications and mortality due to intestinal infarction. The occurrence of this condition is probably underestimated given the fact that the clinical appearance can vary from asymptomatic patients incidentally diagnosed to patients with severe complications. The underlying cause of PVT includes malignancy, chronic liver diseases, local inflammatory processes, systemic disorders, including myeloproliferative disorders, and thrombophilia.

In a high percentage of patients, two or more risk factors are present. In population studies, the cohort of patients with occlusion in the portal tributary system can be divided into three similarly large subcohorts of major etiologies: malignant thrombosis mainly due to gastrointestinal, hepatobiliary, or pancreatic cancer; chronic liver diseases, especially liver cirrhosis with portal hypertension; and non-malignant, non-cirrhotic PVT. While the underlying disease determines the natural history and outcome of patients in the case of malignant thrombosis, the two other groups of patients are characterized by an outcome influenced by PVT. Furthermore non-malignant, non-cirrhotic PVT has often been described as an entity of its own, leading to non-cirrhotic portal hypertension, which represents more of a consequence than a complication of another disease. It has been estimated that in non-cirrhotic PVT patients, thrombophilic states account for approximately 40% to 60% of PVT cases, and local factors are thought to be the causative factor in 10% to 50%. In about one-third of patients, the etiology is unknown. The site, extent, chronicity, and course of thrombosis determine clinical presentation as well as complications in affected patients. While partial PVT is usually discovered incidentally by routine diagnostics and remains clinically silent, the complete occlusion of the vein (90%–100% of the lumen) is associated with abdominal and/or lumbar pain characterized by sudden onset or progressive development over the course of a few days. Acute and complete thrombosis is usually associated with intestinal congestion and occasionally with non-sanguineous diarrhea. The most feared complication is intestinal infarction with a mortality of 20%–60%, leading to extended resections with a high risk of postoperative complications. In contrast to intestinal congestion, infarction often presents with persistent pain, hemochezia, guarding, contractures, ascites, or multiorgan failure with metabolic acidosis. This complication is usually found when the mesenteric veins are involved.

**Case Report:** A 61-year-old man reached the emergency department of the local hospital complaining of onset of acute abdominal pain for two days. Hypotension (80/60mmHg) and bradycardia (55bpm) were detected when he suddenly collapsed. Resuscitation maneuvers were attempted, unsuccessfully. Hospital autopsy was performed the day after death to investigate cause of death. Diffuse mesenteric ischemia was observed due to massive PVT extended to splenic and mesenteric veins. Liver was increased in volume (32cm x 20cm x 10cm), non-cirrhotic, with mild steatosis. Histological assessment of thrombus samples with immunohistochemistry was also performed to establish chronological stage. Audit and mortality and morbidity review with clinicians was performed after postmortem investigation.

### H62 Asbestos Fiber Burden in the Lungs of the Deceased From Asbestos-Related Diseases (ARD): An Epidemiological Study and Scanning Microscope/Energy Dispersive Spectroscopy (SEM/EDS) Analysis

Silvia D. Visona, MD\*, University of Pavia, Pavia 21100, ITALY; Silvana Capella, PhD, University of Torino, Torino, ITALY; Elena Belluso, University of Torino, Department of Earth Sciences, Torino 10125, ITALY; Simona Villani, PhD, Department of Public Health, Experimental, and Forensic Medicine, Pavia, Lombardia 27100, ITALY; Federica Manzoni, University of Pavia, Pavia 27100, ITALY; Yao Chen, MD, University of Pavia, Pavia 27100, ITALY; Giorgio Ardissino, MD, Department of Forensic Medicine, Pavia, ITALY; Francesca Russo, Pavia, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY

**Learning Overview:** The goal of this presentation is to investigate a large series of deaths due to ARD, through an extensive epidemiological study and, in a smaller group of individuals, by assessing the fiber burden in the subjects' lungs using SEM/EDS to clarify the role of asbestos in causing human diseases, primarily mesothelioma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing novel insights regarding the impact of asbestos on human health using biological samples collected during forensic autopsies.

ARDs are often brought to the forensic pathologist's attention due to the high mortality of mesothelioma and lung cancer and to the complex legal implications, related to the responsibility of the manufacturers. Even though the use of asbestos has been banned in the United States, as well as in most European countries, the widespread production and use of asbestos have caused unprecedented human suffering and still represents a major public health problem all over the world. Note that in many countries, the mining and use of asbestos is still allowed (e.g., Canada, Russia, China). The latent onset of disease from exposure has led to a catastrophic epidemic and a continuing onslaught because of people being exposed decades ago. Despite the relationship between asbestos and mesothelioma, lung cancer, and asbestosis being well documented, many issues concerning the etiopathogenesis of ARD, especially mesothelioma, are still debated. For example, the role of fiber type and dimension (length and thickness), the importance of exposure dose, and the dose-response effect are still questioned.

This retrospective study included 188 subjects who died from ARDs (mesothelioma, lung cancer, and asbestosis) during 2000–2017 in the area around Broni, Italy, where an important asbestos cement factory had been active from 1932 until 1993. A forensic autopsy was performed in each case, during which the entire lungs were collected and formalin-fixed. The main objective consisted in analyzing the records, including the clinical files, the autopsy, and the histological report, investigating the type of exposure to asbestos (occupational, neighborhood, household), the survival time since the diagnosis, the latency time, and the relationship to cigarette smoking.

Then, a smaller group was carefully selected, including 40 subjects, subgrouped as follows: ten males who died from mesothelioma and had occupational exposure; ten males who died from mesothelioma and had only neighborhood exposure; ten females who died from mesothelioma and had only neighborhood exposure; and, finally, ten males with occupational exposure who died from asbestosis. For these subgroups, an SEM/EDS analysis was performed on the lung samples collected during the autopsy.<sup>1</sup> The main endpoints consisted in detecting the lung fiber burden, the dimensions, and the mineralogic species of each detected fiber.

The statistical analysis performed on the whole sample showed that there was a significant relationship between the cause of death and the type of exposure. Interesting and significative differences were reported between the different kinds of exposure (occupational, neighborhood, and household) analyzed for the different pathological pictures (mesothelioma, asbestosis, and lung cancer). A significant association was observed between smoke and neighborhood exposure ( $p=0.026$ ). Moreover, among the mesothelioma patients, the survival time was shorter in the subjects with a neighborhood or household exposure. Regarding the SEM/EDS results, interesting differences, in terms of mineralogic species and fiber dimension, were observed between the four groups.

In conclusion, this study provided interesting and novel data about the role of different doses and types of asbestos in causing human pathologies and its interaction with other factors. The present data appear to support the hypothesis that even an exposure to a very small amount of asbestos (due to, for example, a neighborhood exposure) can cause mesothelioma in hypersusceptible subjects.

## H64 A Rare Case of Sudden Death From Hereditary Hemorrhagic Telangiectasia (HHT)

Heather M. O'Connor, DO\*, Medical University of South Carolina, Charleston, SC 29425; Ellen C. Riemer, MD, JD, Medical University of South Carolina, Department of Pathology, Charleston, SC 29425

**Learning Overview:** The goal of this presentation is to report on a rare case of sudden death from HHT.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing features of HHT, since many cases are undiagnosed and may present as sudden death. In previously undiagnosed cases, clinical and/or genetic testing of at-risk family members could be lifesaving.

Reported here is a rare case of sudden death due to HHT in a 66-year-old female with a history of high output heart failure and pulmonary hypertension. At autopsy, multiple Arteriovenous Malformations (AVMs) were throughout the lungs and liver. Additional AVMs were identified on the epicardial surface of the right atrium. Secondary effects of the disease identified at autopsy included cirrhosis of the liver and marked biventricular dilatation of the heart.

HHT is an autosomal dominant disorder with variable penetrance in which agenesis of capillaries results in a direct connection between veins and arteries, known as telangiectasias in mucocutaneous sites and AVMs in visceral organs.<sup>1-4</sup> HHT is associated with multiple gene mutations; the two most common are ENG (endoglin) and ACVRL1/ALK1 (activin receptor like kinase 1), with fewer than 5% of cases having mutations in SMAD4 or GDF2. All of these genes are part of the Transforming Growth Factor Beta (TFG-B) superfamily of regulatory proteins that play various fundamental roles in cellular function, including cell survival, proliferation, and differentiation. Mutations in any of these genes leads to malfunction of this signaling pathway and results in abnormal angiogenesis.<sup>5</sup>

The visceral organs most frequently involved include the lungs, brain, gastrointestinal tract, urinary tract, and liver. Approximately half of all affected individuals have lung involvement, resulting in an anatomical right-to-left shunt, the major consequence of which is impairment of gas exchange leading to local and systemic hypoxemia.<sup>2</sup> Another serious potential consequence of pulmonary AVMs is paradoxical emboli, which can lead to strokes and brain abscesses.<sup>5-6</sup> Although the majority of HHT cases have hepatic involvement, fewer than 10% of these are symptomatic.<sup>3,7</sup> Symptomatic cases often lead to high output heart failure and have a higher risk of portal hypertension, cirrhosis, and encephalopathy.<sup>7</sup>

Those affected by HHT can have a near-normal life expectancy with early initiation of treatment and monitoring.<sup>1</sup> When a case is diagnosed at autopsy, it can lead to identification of at-risk family members who can benefit from appropriate screening and treatment through clinical evaluation and possibly genetic testing.

### HHT, Arteriovenous Malformations, Endoglin

### H65 Silicosis: Medicolegal Implications of Diagnosis

*Brandon J. Bukovitz, BS\*, University of Wisconsin School of Medicine and Public Health, Madison, WI 53705; Jonathan G. Meiman, MD, Madison, WI; Henry A. Anderson, MD, Wisconsin Department of Health Services, Madison, WI 53703; Erin G. Brooks, MD, University of Wisconsin Hospital and Clinics, Madison, WI 53705*

**Learning Overview:** After attending the presentation, attendees will: (1) be able to recognize and diagnose silicosis at autopsy; and (2) gain a better understanding of the legal ramifications of diagnosis for the patient and the patient's family, including the potential need for expert medical testimony in a court of law.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the diagnostic and death certification accuracy of forensic pathologists, as well as potentially better facilitating compensation for the family of the deceased.

**Introduction:** Despite well-publicized sources of occupational hazard and available means to minimize exposure to harmful particles, silicosis continues to threaten industrial workers in the United States. Although the incidence of hospitalizations and fatalities related to silicosis appear to be declining, recent data suggests that many cases may go unreported. Nationally, Wisconsin has one of the highest incidences of silicosis. Wisconsin has had an occupational disease surveillance program since 1983 and required reporting of outbreaks of occupational disease and toxic substance related diseases, but as of July 1, 2018, reporting statutes were revised to explicitly require reporting of silicosis and several other occupational and environmental diseases. It is hoped this will improve silicosis morbidity/mortality reporting, and detailed investigations can advance understanding of the disease. This study reviews Wisconsin silicosis incidence, compensation, and mortality data—including autopsy results—from the prior 14 years.

**Methods:** A retrospective search of the University of Wisconsin Hospital and Clinics (UWHC) electronic pathology databases was conducted for autopsy cases in which chronic silicosis was diagnosed. Cases were retrieved from the years 2003–2018 utilizing the search term “silicosis.” Additionally, statewide silicosis epidemiologic morbidity/mortality data was provided by the Wisconsin Department of Health Services (W-DHS) for the years 2003–2017, as well as information regarding Wisconsin workman's compensation and employer liability. A literature search utilizing the term “silicosis” and article review was conducted.

**Results:** Between 2003 and 2017, three cases of silicosis were confirmed via UWHC autopsy. All three were men (mean age: 69 years.) Comorbidities included hypertension, coronary artery disease, smoking, and pneumonia. Pertinent histologic findings included collagenous anthracotic nodules, interstitial fibrosis, and refractile foreign bodies. In two cases, silicosis was found to have caused or contributed significantly to death. Overall in Wisconsin, the age-adjusted rate of hospitalizations attributable to silicosis declined between 2003 and 2017 but remains substantially higher than the national average (e.g., 10.1 hospitalizations per million Wisconsin residents in 2010 vs. 1.2 hospitalizations per million residents nationally in 2010, the most recent year in which official reports are comparable). The age-adjusted death rate from silicosis per million residents likewise remains significantly higher in Wisconsin than the national average (i.e., 1.1 deaths per million Wisconsin residents in 2010 vs. 0.4 deaths nationally). A diagnosis of silicosis typically entitles individuals to worker's compensation to cover medical costs associated with their condition. In Wisconsin, the employer may also be required to pay compensatory damages up to \$100,000; this amount may exceed \$100,000 if the employer is found to be non-compliant with Occupational Safety and Health Administration (OSHA) regulations.

**Conclusion:** Historically, Wisconsin has had many foundries, ceramic companies, and industrial complexes where occupational exposure to silica dust is high; this may account for the relatively high silicosis hospitalizations and mortality in Wisconsin as compared to national averages. A diagnosis of silicosis should be carefully weighed by the pathologist in any patient with pulmonary fibrosis and suspicious occupational history, since it carries substantial implications for worker's compensation, compensatory losses, and employer liability.

### Silicosis, Pneumoconiosis, Occupational Lung Disease

### H66 Pulmonary Alveolar Microlithiasis: A Case of Sudden Death

Adrienne E. Sauder, MD\*, Broward County Office of Medical Examiner, Fort Lauderdale, FL 33312; Marlon Osbourne, MD, Broward County Office of Medical Examiner, Fort Lauderdale, FL 33312; Craig T. Mallak, JD, MD, Fort Lauderdale, FL 33312

**Learning Overview:** After attending this presentation, attendees will better understand Pulmonary Alveolar Microlithiasis (PAM), a rare hereditary lung disease, and its histology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing attendees' understanding of PAM and the role of histology in cases of sudden death with non-specific autopsy findings.

**Introduction:** PAM is a rare autosomal recessive disorder characterized by intra-alveolar accumulations of calcium phosphate that eventually impedes gas exchange. It is caused by mutations to the type IIb sodium-phosphate gene cotransporter (SLC34A2) responsible for phosphate homeostasis found on type II pneumocytes.<sup>1</sup> The inability to transport the phosphorus ions out of the alveoli leads to the microlith formation. Most people with PAM have a sibling with the disease. Symptoms usually appear in the third or fourth decade. Patients with PAM are usually asymptomatic in early stages. As the disease progresses, symptoms include dyspnea, dry cough, chest pain, and cor pulmonale. Diagnosis is usually made by imaging or lung biopsy. Chest radiograph would have the "sandstorm" appearance of the diffuse opacifications of both lungs.<sup>2</sup> Histologically, these intra-alveolar accumulations are round to oval concentric laminated microliths. The only effective treatment is a lung transplant.<sup>3</sup>

**Materials and Method:** The decedent was a 32-year-old woman with a history of diabetes and alcohol abuse. She was not taking any medications. She had an episode of vomiting the morning of her death but was feeling better around dinnertime the same day. She was found unresponsive shortly thereafter and was taken to the hospital and was not revived.

**Results:** At autopsy, the lungs were firm and non-compliant. The right lung weighed 1,280 grams and the left lung 1,200 grams. The pleural surface was smooth and shiny. The cut surface was gritty, firm, and consolidated. There was honeycombing of the parenchyma. Microscopic examination of decalcified lung showed lamellated calcium microliths filling most of the alveoli, with no fibrosis or inflammation. All other organs were within normal parameters. Toxicology was performed and was negative.

**Discussion:** This case highlights the importance of histology in correlating non-specific gross findings with microscopic findings. This is an unusual case because the decedent did not know she had PAM, and her death was earlier than most cases reported in the literature. The lack of fibrosis and cor pulmonale findings could indicate a rapid progression, even though it is a disease known for its slow and progressive course. Establishing the diagnosis after death has significance because it allows siblings to be tested and monitored for the disease.

### H67 Tau and Neurofilament Light Proteins in Cerebrospinal Fluid as Biomarkers of the Time of Death

Pierre-Antoine Peyron, MD\*, Département de Médecine Légale, Montpellier 34295, FRANCE; Sylvain Lehmann, PhD, Laboratory of Biochemistry - Clinical Proteomic, Montpellier 34295, FRANCE; Constance Delaby, PhD, Laboratory of Biochemistry - Clinical Proteomic, Montpellier 34295, FRANCE; Eric Baccino, MD, Hôpital Lapeyronie, Montpellier, Cedex 5 34295, FRANCE; Christophe Hirtz, PhD, Laboratory of Biochemistry - Clinical Proteomic, Montpellier 34295, FRANCE

**Learning Overview:** The goal of this presentation is to present an exploratory, cross-sectional study aimed at identifying two new biomarkers of the time of death by means of thanatochemistry.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of how thanatochemistry may help in more precise and reliable estimation of the Postmortem Interval (PMI), thanks to the most recent technological developments in this field.

**Background:** One of the most important and challenging tasks in forensic medicine is the accurate determination of the PMI. Different methods have been proposed, but they all lack precision and reliability. Recent developments in biochemical techniques may provide the opportunity to assist in more precise estimation of the time of death. The study of postmortem chemical changes in closed compartment body fluids such as vitreous humor and Cerebrospinal Fluid (CSF) has shown promise. In the present study, two major proteins of the central nervous system (Tau and Neurofilament Light (NFL) proteins) were investigated in CSF as potential biomarkers of the time of death.

**Objectives:** The main objective of the study was to assess the correlation between the concentrations of Tau and NFL in CSF and the PMI. The secondary objectives were: (1) to determine the inter-individual variability of the concentrations of Tau and NFL for a same PMI; (2) to determine the kinetics of these concentrations over time; and (3) to determine the variability of these concentrations according to the sampling site (lumbar vs. sub-occipital).

**Materials and Methods:** This study was reviewed and approved by the Ethics Committee of the University Hospital of Montpellier, France. Postmortem CSF samples were collected from 100 adult cadavers whose time of death was precisely known, at the mortuary of the University Hospital of Montpellier, France. Individuals with neurological disorders and head trauma were excluded from the study. CSF samples were removed by cisternal and lumbar punctures at different time intervals. Two mL of CSF were obtained at each tap in clean, sterile polypropylene tubes, using a 18G lumbar puncture needle. The cadavers were divided into four groups according to the PMI ( $n=25$  in each group). The samples were taken 0h–6h (group A), 6h–12h (group B), 12h–18h (group C), and 18h–24h (group D) after death. Additionally, CSF samples were collected every 3h from ten cadavers during the first 15h postmortem. All cadavers were kept at room temperature ( $+20^{\circ}\text{C}\pm 2^{\circ}\text{C}$ ) during sample collection. CSF samples were transferred in ice to the laboratory where they were centrifuged for 10min ( $+4^{\circ}\text{C}$ , 1,000g). The clear supernatant was divided into aliquots, then stored at  $-80^{\circ}\text{C}$  until analysis. The rectal and tympanic temperatures at the time of CSF collection were measured using a probe thermometer, and *rigor* and *livor mortis* were assessed.

Concentrations of total Tau and NFL in CSF were measured by conventional and ultrasensitive digital immunoassays, respectively. Total protein concentration was determined using a bicinchoninic acid protein assay.

The correlation coefficient between the concentrations of Tau and NFL in CSF and the PMI was calculated in each case. The inter-individual variability was assessed by measuring the Standard Deviation (SD) of the mean concentrations of Tau and NFL in each group. Linear regression analysis (adjusted for confounders) was used in assessing whether concentrations of Tau and NFL were dependent on the PMI. Paired Student's *t*-test was used to assess the variability of Tau and NFL concentrations depending on the site of CSF collection.

**Results pending.**

**Conclusion:** Thanks to this exploratory study, it will be possible to know if Tau and NFL proteins can be considered as potential CSF biomarkers of the time of death and if further research is needed to confirm these preliminary results.

### H68 An Uncommon Fatal Ruptured Pseudoaneurysm of the Brachial Artery in an Injected Drug Abuser

Silvia Trotta\*, Bari 70124, ITALY; Antonella Sorrentino, MD, Istituto Medicina Legale, Bari 70124, ITALY; Giuseppe Bertozzi, MD, Department of Forensic Pathology, Foggia 71121, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY; Biagio Solarino, PhD\*, Università degli Studi di Bari, Bari 70125, ITALY

**Learning Overview:** After attending this presentation, attendees will understand a rare case of fatal ruptured pseudoaneurysm of the brachial artery occurring just before heroin self-injection in a chronic drug abuser.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stressing the importance of scene investigation, autopsy findings, and toxicology results to determine the cause and manner of death in chronic drug abusers.

Intravenous (IV) drug abusers are a population at risk for pseudoaneurysm, an aneurysmal sac with a single layer of fibrous tissue and blood clots present in its wall. In IV drug abusers, this occurs due to traumatic damage by the repeated injections and infections and mostly involves femoral arteries.<sup>1,2</sup>

A 41-year-old man with a previous history of heroin-cocaine abuse presented twice to the hospital emergency room with a painful and swollen arm. The first time, with a clinical suspicion of thrombophlebitis, he refused a surgical consultation and was then discharged with a prescription for anticoagulant therapy. Two days later, he returned to the hospital, and a venous doppler was recommended but the man never did it. Ten days later, he died in his flat in a pool of blood, with an empty syringe and a pre-filled syringe beneath his body; traces of cocaine powder were found in the apartment. At autopsy, there were numerous circular scars on the surface of his arms and legs. A swelling in the right antecubital fossa with a central 3.5cm x 2.6cm defect, exposition of vascular tissue, and clotted blood on the surface was observed. Accurate postmortem examination with a right forearm incision demonstrated a pseudoaneurysm of the right brachial artery with a 1cm x 0.4cm tear on its anterior wall.

Other findings on internal examination included an edematous brain, edematous and anthracotic lungs, and diffuse lymphadenopathy. The section of the pulmonary artery showed scarce blood, as well as in the vena cava; there was no blood in the aorta. Microscopic examination of the vascular wound samples confirmed layers of fibrin-hematic tissue with infiltration of acute inflammatory cells into the surrounding skin specimen. General drug screening by Gas Chromatography/Mass Spectrometry (GC/MS) on the blood sample provided negative results for opiate derivatives, revealing instead the presence of cocaine, opioids, and methadone in the urine sample.

According to medicolegal, histological, and toxicological findings, the cause of death was ruled as hemorrhagic shock due to spontaneous rupture of brachial artery pseudoaneurysm in a chronic drug abuser. Given these results, a direct correlation with acute drug intoxication was excluded. In this presentation, the uncommon role that the intent to self-administer a drug just before vascular rupture could have on the manner of death will be discussed.

### H69 A Fatal Idiopathic Spontaneous Intraperitoneal Hemorrhage (ISIH) (Spontaneous Hemoperitoneum) in a 56-Year-Old Male With Cirrhosis

Gregory M. Dickinson, MD\*, Montefiore Medical Center, Bronx, NY 10467; Hannah C. Jarvis, MRCS\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Jacob Steinberg, MD, Montefiore Medical Center, Bronx, NY 10467

**Learning Overview:** After attending this presentation, attendees will better understand the signs, symptoms, risks, and findings associated with ISIH.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the difficulties of evaluating a spontaneous intraperitoneal hemorrhage for both clinicians and forensic pathologists and highlight the likely associations to be aware of for improving diagnostic accuracy.

A 56-year-old man with a history of chronic alcohol abuse collapsed at work and was brought to the emergency department. Despite resuscitative efforts, he remained hypotensive and tachycardic. His hemoglobin dropped from 8.9g/dL to 2.1g/dL (reference range 14.0g/dL–17.4g/dL) over the course of several hours. Additionally, the patient's prothrombin time was >200 seconds (reference range: 26.1–33.8 seconds) and his partial thromboplastin time was 24.5 with an International Normalized Ratio (INR) of 2.4 (reference range: 0.9–1.2, respectively). An abdominal Computed Tomography (CT) scan revealed abdominopelvic hemorrhagic ascites without active extravasation. Multiple blood products were transfused, but without any clinical improvement, and the patient died.

At autopsy, the abdomen was distended with a fluid wave. There was 3.5 liters of blood in the peritoneal cavity. Despite a thorough search, the source of the hemorrhage could not be identified. The patient also had hepatomegaly (2,750 grams) with nodular and fatty changes. On histology, the liver showed steatosis and fibrosis, consistent with cirrhosis. The manner of death was natural, and the cause of death was complications of coagulopathy due to severe liver disease.

Peritoneal hemorrhage may be secondary to aneurysmal rupture, solid organ malignancy, inflammatory erosive processes, or trauma. The cause may also be idiopathic.<sup>1</sup> Trauma and non-malignant gynecological conditions account for greater than 90% of peritoneal hemorrhages. The major cause in women is ruptured ectopic pregnancy, and the major cause in men is post-traumatic rupture of the liver or spleen.<sup>2</sup> Non-traumatic peritoneal hemorrhage is a rare condition. ISIH was first reported by Barber in 1909. The term “abdominal apoplexy” was coined by Green and Powers in 1931 as a comparison to its cerebral counterpart of historical significance.<sup>1</sup> ISIH is a diagnosis of exclusion after aortic dissection, ruptured aortic aneurysm, malignancy, gynecologic lesions (ectopic pregnancy), traumatic injury, or other obvious sources of hemorrhage are ruled out. It is thought to be caused by a spontaneous rupture of the smaller abdominal arteries or veins, especially at branch points where small aneurysms may form.<sup>3</sup> Approximately 30% of cases have no identifiable cause.<sup>4</sup> Likely risk factors include arteriosclerosis, essential hypertension, portal hypertension, and liver cirrhosis.<sup>1,4</sup> The exact pathophysiology is unknown but likely represents weakness of the tunica media, which predisposes the vessel to rupture in the face of abrupt increases in pressure. Spontaneous hemorrhage may also be associated with inflammatory and necrotizing processes, such as polyarteritis nodosa and rheumatoid arthritis. Venous rupture is thought to be associated with portal hypertension.<sup>1,3</sup> There is a male predominance, and the majority of cases present between and 50 and 60 years of age.<sup>1,4</sup>

### H70 A Case Report on the Death of a 20-Year-Old Female Due to Complications of Minimally Invasive Transcatheter Atrial Septal Defect (ASD) Closure

Jan Ynav T. Quiz\*, University of Tennessee Health Science Center, Memphis, TN 38163; Marco Ross, MD, West Tennessee Regional Forensic Center, Memphis, TN 38105; Erica Curry, MD, Collierville, TN 38017

**Learning Overview:** After attending this presentation, attendees will better understand: (1) the fatal complication of cardiac erosion in transcatheter closure of ASDs, (2) corresponding risk factors, and (3) possible methods for its prevention.

**Impact on the Forensic Science Community:** The presentation will impact the forensic science community by raising awareness of sudden death following transcatheter closure of ASD in adults.

ASD is one of the most common congenital heart defects presenting in adulthood. Although small defects may be asymptomatic and not require therapy, closure is usually indicated for larger defects with significant shunts, evidence of volume overload, or in patients at high risk for life-threatening complications.<sup>1</sup> Among obstetric patients, it has been determined that those with unrepaired ASD had a higher risk for pre-eclampsia, small-for-gestational age birth weight, and fetal mortality compared to those with repaired ASDs.<sup>2</sup> The common closure procedures involve open-heart surgery and transcatheter closure. Transcatheter closure, now commonly performed with the AMPLATZER™ Septal Occluder (ASO), was determined to be as effective and yet safer than cardiopulmonary bypass and surgical repair as it avoids their associated risks (e.g., infection); however, this approach does carry a risk for a rare but serious and potentially fatal complication—cardiac erosion.<sup>3,4</sup>

This study describes the case of a 20-year-old woman with a 2.1-cm ASD who underwent transcatheter closure of the ASD postpartum using the ASO and expired two weeks later. Postmortem examination revealed significant hemopericardium due to full-thickness right atrial erosion caused by the rim of the ASO.

A medical literature review indicates several relative risk factors associated with cardiac erosion, mainly deficiency of any rim, device >5mm larger than ASD diameter, and lesser weight:device-size ratio. Median onset of cardiac erosion was determined to be about two weeks.<sup>5</sup> The case described here had a deficient anterior rim, and cardiac erosion occurred two weeks post-procedure. More frequent follow-up echocardiograms may allow for early clinical detection of erosion, which can be successfully repaired with no further complications.<sup>6</sup>

In conclusion, transcatheter closure of ASDs by the ASO is relatively safe and effective compared to open-heart surgical repair. However, cardiac erosion by the ASO is a rare but potentially fatal complication. Early clinical recognition of this complication, possibly using more frequent post-procedure follow-up echocardiography, is essential and can result in successful surgical repair.

## H71 Alcoholic Hepatomegaly: A Case Report and Review of the Literature

Ashley M. Luebbbers, MS\*, Eastern Virginia Medical School, Norfolk, VA 23507; Wendy M. Gunther, MD, OCME, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will be familiar with the pathologic features of alcoholic hepatitis and fatal alcoholic liver disease, in the absence of variceal bleeding, and will review the etiology of fulminant jaundice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by assisting in the recognition of fatal and non-fatal features of acute and chronic alcoholism, in particular hepatomegaly and alcoholic hepatitis, in the absence of ascites or esophageal variceal bleeding.

Excessive, prolonged alcohol intake has been shown to cause a variety of hepatic changes, including steatosis, inflammation, and fibrosis; inflammation may result in the development of alcoholic hepatitis in persons with a genetic predisposition.<sup>1</sup> Sequelae include resolution, hepatomegaly, cirrhosis, and/or progression to hepatocellular carcinoma. A host of systemic complications may include hiccups, abdominal pain, splenomegaly with thrombocytopenia, and portal hypertension leading to ascites and esophageal varices. Alcoholic liver damage may be recognized at gross autopsy from hepatomegaly, liver friability due to steatohepatitis, micronodular or macronodular cirrhosis, and jaundice. Although death is commonly due to variceal rupture and gastrointestinal bleeding, it may occur from alcoholic hepatitis alone.

**Case History:** A 36-year-old Caucasian male with a long-standing history of alcohol abuse was found dead in a supine position on the floor next to his bed, surrounded by empty alcohol bottles. Eight months earlier, he had presented to the emergency room with complaints of hiccups and right upper quadrant pain. He denied recent alcohol intake despite an odor of alcohol detected by emergency room personnel; the laboratory reported a blood alcohol concentration of 0.34g/dl. The patient's family stated that he was still drinking heavily on a regular basis. He admitted to consuming upward of 25 ounces (over 700g) of vodka per week. His liver panel results were consistent with liver damage (bilirubin 4.7mg/dL [direct 2.7mg/dL], AST 339 U/L, ALT 76 U/L, alkaline phosphatase 76 U/L) with thrombocytopenia (platelets 65K/uL). Despite impaired liver function, his albumin was normal at 4.1g/dL, and he did not have ascites; his kidney function appeared normal, without evidence for hepatorenal syndrome. An ultrasound examination showed hepatomegaly and fatty infiltration, characteristic indicators of alcoholic liver damage.<sup>2</sup> He was admitted to the hospital for a week with a diagnosis of alcoholic hepatitis, placed on withdrawal precautions, and subsequently discharged with a recommendation to abstain from alcohol. There was no further medical contact before he was found dead in his room.

At autopsy, he showed head-to-foot jaundice, including scleral icterus, and multiple purple contusions consistent with thrombocytopenia. The liver showed profound hepatomegaly (4475g/9.845lbs), about three times the normal weight, and measured 35cm x 26.5cm x 12cm, with both extreme steatosis and micronodular cirrhosis. Aspiration of the gallbladder resulted in 110cc of sludgy bile, although the biliary tree was patent. His spleen, at 582g, was also enlarged to about three times its normal weight. There was no ascites. Esophageal varices were unruptured, with no blood in the gastric pouch. Death was ascribed to fulminant liver failure, due to recurrent alcoholic hepatitis.

**Discussion:** The amount of alcohol intake required to initiate liver failure is approximately 100g-200g per day.<sup>3</sup> In this case, he admitted to an alcohol intake of 700 grams per day. Although this patient was only 36 years old at the time of death (below the average presenting age of 53 years for alcoholic hepatitis), he showed signs of fulminant liver failure superimposed on hepatic cirrhosis and recurrent alcoholic hepatitis. Acute fulminant jaundice may be due to alcoholic hepatitis, hepatotropic viruses, ischemic injury, drugs and toxins (e.g., acetaminophen, anticonvulsants, poisonous mushrooms), and unusual entities such as autoimmune hepatitis. He had no history of exposure to viral agents or hepatotoxic drugs (acetaminophen could not be ruled out). Although he never developed ascites or variceal bleeding, which are common causes of death from alcoholic cirrhosis, his autopsy findings correlated to his presenting symptoms on his prior hospital admission. His fatal liver disease resulted from many of the systemic alterations that have been described in association with alcoholic hepatitis.

### H72 A Ruptured Infective Aneurysm Presenting as an Acute Subdural Hematoma: A Case of Sudden Death in a Drug Addict With Previously Undiagnosed Bacterial Endocarditis

Michael Alan Hays, MD\*, Tidewater Office of the Chief Medical Examiner, Norfolk, VA 23510

**Learning Overview:** After attending this presentation, attendees will recognize the risk factors for infective aneurysm, familiarize themselves with an unusual presentation of aneurysmal rupture, and recognize causes of non-traumatic subdural hemorrhage.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing clinical suspicion of non-traumatic subdural hemorrhage and suggesting alternate diagnostic modalities beyond routine radiology, where indicated.

Acute Subdural Hematomas (SDHs) are most commonly caused by blunt impact trauma to the head. Non-traumatic (or “spontaneous”) SDH is a rare condition. Known causes of non-traumatic SDH include ruptured cerebral aneurysm. Such cases typically manifest as a combination of subdural and subarachnoid hemorrhage. Presentation of a ruptured aneurysm as an isolated subdural hematoma is exceptionally rare.

Here is reported the case of a 25-year-old female patient who died of a ruptured infective aneurysm that appeared as a pure SDH on clinical imaging. Her medical history included chronic intravenous drug abuse and infection with HIV and hepatitis C. She was discovered unresponsive and nude from the waist down inside a known drug house, was transported to a nearby hospital, and was subsequently transferred to a tertiary referral center. An initial urine drug screen was negative, and no significant traumatic injuries were noted on physical examination. A Computed Tomography (CT) scan of the head revealed a right-sided subdural hematoma measuring up to 1.8cm in thickness, with associated right-to-left midline shift of 1.5cm and herniation of the cingulate gyrus. Emergency craniectomy for evacuation was performed. She subsequently developed a high fever and blood cultures grew positive for Methicillin-Resistant *Staphylococcus aureus* (MRSA). Antibiotic coverage was initiated, and hospital workup revealed endocarditis. She followed a downward course and ultimately died on hospital day seven.

At autopsy, external examination showed a chronically ill-appearing female with no external injuries apart from scattered, small scabs and track marks. Internal examination confirmed the presence of bacterial endocarditis of the mitral valve with associated abscesses of the myocardium, spleen, and kidney. Neuropathological examination of the brain confirmed the presence of subdural hemorrhage and revealed a 2.7cm lesion of the right parieto-occipital cortex, with minimal associated subarachnoid hemorrhage. Microscopic examination of the lesion demonstrated features consistent with a ruptured infective aneurysm. Multiple smaller lesions consistent with septic emboli were identified elsewhere in the cortex, predominantly in the distribution of the right middle cerebral artery. Secondary neuropathological findings included cerebral edema, marked hypoxic-ischemic change, uncal herniation, and infarction of the midbrain.

Non-traumatic SDH is a relatively rare occurrence and has a high risk of mortality. Accurate diagnosis of the underlying cause is critical to effective medical decision making, and possible etiologies include aneurysmal rupture. A recent review of the literature identified no more than eight cases of pure acute SDH due to rupture of a cortical middle cerebral artery aneurysm, as seen in the present case.<sup>1</sup> The case presented here is remarkable in that the circumstances of discovery and initial clinical presentation were suggestive of a non-natural death, including the possibility of a blunt trauma homicide. Patients presenting with acute subdural hemorrhage with no clear etiology necessitate thorough clinical and radiographic evaluation to determine the cause of bleeding.

### H73 Sudden Death (SD) in Adults With Congenital Heart Disease (CHD): A Retrospective Review of Cases in the Cook County Medical Examiner's Office

*Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Steven M. White, MD, PhD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Ponni Arunkumar, MD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

**Learning Overview:** After attending this presentation, attendees will better understand the causes of SD in adults with diagnosed and undiagnosed CHD in Cook County, IL.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the anatomic defects (simple or complex, single or multiple) and the medical history in adult CHD cases in a medical examiner's population.

CHD in adults is associated with a high rate of SD, despite improved life expectancy because of better surgical and interventional therapies. Most congenital heart defects are repaired in childhood; however, there may be less severe defects that go undiagnosed, resulting in SD in adulthood. The annual incidence of SD in the entire adult CHD population is relatively low, but because the CHD population is growing and aging, the risk profile for SD may have changed.

The electronic database of the Cook County Medical Examiner's Office in Chicago, IL, was examined using the keyword "congenital," searching for cases of CHD as a primary or contributory cause of death, in the period between July 2008 and July 2018. Cases were reviewed for age, sex, race, cause and manner of death, medical history, type of congenital heart disease, and gross and microscopic cardiac findings. Only subjects between 18 and 99 years of age were included in this study.

A total of 84,820 deaths were reported in the studied period in the Cook County Medical Examiner's Office. Of these, there were 15 cases (0.02%) of adult CHD identified, including 14 natural deaths and 1 accidental death. The age ranged between 21 and 62 years. Seven subjects were Caucasian, six African-American, one Hispanic, and one Asian. The male/female ratio was 2.7/1. A complete autopsy was performed in 14 out of 15 cases with consultation with a cardiac pathologist requested in 7 cases.

Of the 14 hearts examine, 12 hearts were enlarged, 8 were dilated, and 9 showed hypertrophy. Simple cardiac defects were observed in 7 cases (50%): 2 cases with isolated Atrial Septal Defects (ASD); 2 cases with isolated Ventricular Septal Defects (VSD); 1 case with VSD combined with pulmonary stenosis, 1 case of bicuspid aortic valve, and 1 case of congenital anomaly of the left coronary ostium. Complex defects were observed in 7 cases (50%): 2 tetralogies of Fallot, 1 Ebstein's anomaly, 1 double outlet right ventricle, 1 transposition of the great vessels alone, 1 transposition of great vessels combined with tricuspid atresia, and 1 Total Anomalous Pulmonary Venous Return (TAPVR).

Diagnosis of CHD was known in 12 cases out of 15 (80%) and, among these, 11 subjects had undergone prior (single or multiple) surgical repair. In 13 out of 15 cases, CHD was the primary cause of death, while it was a contributory cause in 2 cases. Toxicological analyses were negative in 14 out of 15 cases, while in 1 case the subject was found to be positive for a non-toxic level of ethanol.

Despite the limited number of cases, CHDs were very heterogeneous and SDs were more common in adult males (73%). Almost all the CHDs were previously known. The three unknown CHD cases consisted of valvular diseases or coronary defect, which could explain the absence of clinical signs and, therefore, the lack of diagnoses. It is questionable whether these minor abnormalities can cause SD, but in the absence of other potentially lethal pathology at autopsy, they may be used as a cause of death.

In 11 out of the 12 cases (92%) with a known diagnosis of CHD, surgical correction was performed in childhood and 3 of them required additional surgical interventions in adulthood. Since subjects suffering from these complex CHD may require multiple surgical corrections during their lifetimes, there could be misinterpretation of the original cardiac defect at autopsy because of the distortion of the usual anatomy due to the surgeries. It is important for the forensic pathologist to be trained in recognizing CHDs and the surgical procedures used to treat them. When the diagnosis is not clear, the forensic pathologist should request a consultation with a cardiac pathologist experienced in CHD.

#### Congenital Heart Disease, Adult Cardiac Pathology, Sudden Death

### H74 Strangulated and Incarcerated Internal Hernia: A Rare Complication of Meckel's Diverticulum

*Mark A. Giffen, Jr., DO\*, Jamestown, NC 27282; Lauren E. Dvorscak, MD, New Mexico Office of the Medical Investigator, Albuquerque, NM 87131*

**Learning Overview:** The goal of this presentation is to highlight a rare, potentially fatal complication of Meckel's diverticulum.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how to better recognize potentially fatal complications of Meckel's diverticulum.

Meckel's diverticulum is the most common congenital gastrointestinal abnormality, occurring in between 1%–4% of the population. The diverticulum is a remnant of the embryonic vitelline duct which fails to involute, resulting in a true diverticulum of the small intestine. The embryonic vitelline duct is supplied with blood by the vitelline artery, most commonly supplied from what will become the superior mesenteric artery. This blood supply can also fail to involute or partially involute, resulting in a mesodiverticular band that is most commonly attached to the ileal mesentery.

Most people with Meckel's diverticula are asymptomatic and the diverticulum is found incidentally during another procedure or at autopsy. It is estimated that between 4%–6% of individuals with these diverticula will present with gastrointestinal pathology, most commonly Small Bowel Obstruction (SBO). The causes of SBO vary, but most commonly include volvulus, adhesions, hernias, and intussusception. These complications are more commonly documented in adults and older children.

Meckel's diverticula are difficult to diagnose and their complications typically mimic generic SBO symptoms, including nausea, vomiting, abdominal pain, and abdominal distention, making antemortem diagnosis difficult. If left untreated, they carry a high risk of morbidity and mortality. SBO is even more difficult to diagnose in small children due to the non-specific symptoms and their inability to verbalize their complaints. These complications should be recognized, especially in cases of SD in children with non-specific gastrointestinal symptoms as they can be easily missed during autopsy without careful dissection and a high degree of suspicion.

This presentation will highlight the case of a 17-month-old infant who developed vomiting and decreased oral intake with rapid progression to death within 24 hours of symptom onset. Postmortem, non-contrast computed tomography revealed non-specific intestinal and mesenteric edema with a small amount of free fluid in the abdomen. At the time of autopsy, an internal hernia containing the majority of the small bowel was identified. The hernia contents were contained between the mesentery of a Meckel's diverticulum and a mesodiverticular band attached to the mesentery and retroperitoneal tissues adjacent to the ileocecal valve. The large length of herniated bowel resulted in incarceration with compression of the mesentery and vascular pedicle of the contained small intestine, causing ischemia and strangulation.

### H75 Spontaneous Uterine Rupture as a Complication of Placenta Previa and Percreta

*Mark A. Giffen, Jr., DO\*, Jamestown, NC 27282; Lauren E. Dvorscak, MD, New Mexico Office of the Medical Investigator, Albuquerque, NM 87131*

**Learning Overview:** After attending this presentation, attendees will be able to describe abnormal placental implantation and the potential complications that can occur and be able to recognize the findings of uterine rupture on postmortem, non-contrast computed tomography.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a rare, potentially fatal complication of abnormally invasive placental implantation during pregnancy.

Abnormally invasive placental implantation, also known as placenta accreta, is a rare complication of pregnancy with significant morbidity and mortality. Placenta accreta occurs when the normal decidua basalis fails to form (or only partially forms), and the chorionic villi directly invade into the myometrium. Placenta increta occurs when the chorionic villi invade through at least half the thickness of the myometrium. The most severe form of placenta accreta, placenta percreta, occurs when the chorionic villi invade through the entire thickness of the myometrium. Complications of placenta accreta are life-threatening and may include retained placental components after delivery, severe postpartum hemorrhage, and postpartum infections. Additionally, depending on the invasiveness through the myometrial wall, severe complications such as uterine rupture may occur. Without medical/surgical intervention, uterine rupture as a consequence of placenta accreta may cause severe hemorrhage and rapid fatality.

In addition to placenta accreta, placenta previa is a rare but well-recognized complication in pregnancy. Placenta previa occurs when the placenta implants within the lower uterine segment instead of the uterine fundus or body. This may result in the placenta partially or completely overlying the uterine cervix, which can lead to both maternal and fetal morbidity and mortality.

Myometrial damage is increasing in frequency with Cesarean births, which places women at greater risk for the development of both placenta accreta and previa. Placenta previa and placenta accreta have additional risk factors in common, including scarring from prior surgical intervention or curettage and congenital uterine abnormalities, which often results in them occurring together. Furthermore, the lower uterine segment is prone to placenta accreta because of a thinner endometrial component compared to the uterine fundus or body.

Reported here is the case of a 32-year-old woman who was found collapsed on the floor of her apartment. She was known to abuse both depressant and stimulant drugs and it was suspected that she had succumbed to the toxic effects of illicit substances. No external traumatic injuries were present. Her previous surgical history was significant for two prior Cesarean deliveries. Full body, non-contrast computed tomography revealed an intrauterine, third-trimester pregnancy and a large volume of fluid within the abdomen. It remains unknown if the decedent was aware of the pregnancy or had any prenatal care.

At autopsy, 3.5L of liquid and clotted blood was present within the peritoneal cavity. The anterior and right lateral lower uterine wall was visibly ruptured, with placental tissue extruding through a 6cm defect. An intrauterine, female fetus of a 30-36 weeks gestational age, without gross developmental abnormality, was confirmed. The placenta was implanted in the lower uterine segment and completely covered the internal os of the uterine cervix. Approximately one-quarter of the placental disc had invaded entirely through the myometrium and was covered only by a thin layer of uterine serosa with focal rupture. The area of invasion corresponded with an anterior uterine scar, consistent with prior Cesarean section. Toxicology analysis of postmortem femoral blood samples revealed the presence of methamphetamine, which likely contributed to the development of uterine rupture and massive hemoperitoneum due to increased intravascular pressure adjacent to the thin uterine serosa.

### H76 A Ten-Year Retrospective Study of Risk Factors Associated With Deaths Due to Pulmonary Emboli in Washington, DC

Breanna M. Cuchara, MFS\*, Manassas, VA 20110; Francisco J. Diaz, MD, Washington DC Office of the Medical Examiner, Washington, DC 20024; Sasha Breland, MD, Washington, DC 20024

**Learning Overview:** After attending this presentation, attendees will be acquainted with the risk factors of pulmonary emboli and be familiar with potential new risk factors based upon a ten-year review of pulmonary emboli cases that were investigated at the Washington, DC, Office of the Chief Medical Examiner (OCME).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness and diagnosis of pulmonary emboli based upon the recognition of additional risk factors, therefore potentially decreasing the number of deaths that occur yearly from this preventable disease process.

Pulmonary emboli are thrombi that obstruct the pulmonary arteries and most commonly originate from blood clots that form in the deep veins of the extremities. Common and established risk factors include decreased mobility, pregnancy, obesity, and genetic predisposition. Potential new risk factors will also be looked at, such as drug abuse and decedents who are intellectually delayed. Although detectable and treatable, according to recent CDC data, it is estimated that 60,000–100,000 Americans die each year from pulmonary emboli.<sup>1</sup>

In 2006, the DC OCME investigated 879 natural deaths, of which there were two deaths that were caused by pulmonary emboli.<sup>2</sup> In 2015, four decedents died from a pulmonary embolism out of 477 natural deaths.<sup>3</sup> During this ten-year review, it was found that 43.9% ( $n=40$ ) of the decedents that died from pulmonary emboli were females, while 56% were males ( $n=90$ ). It was discovered that 92% of the decedents were African American and 8% were Caucasian.

During this study, the most common risk factors were examined. Obesity, with the average body mass index of 33.2, was mostly seen in this population. New risk factors were also revealed. It was found that 12% ( $n=11$ ) of the decedents had a history of drug abuse. Crack/cocaine ( $n=5$ ) and alcohol abuse ( $n=4$ ) were most commonly seen among these decedents. Interestingly, there was only one case where drug intoxication was officially listed as a contribution to the decedent's cause of death (acute cocaine intoxication followed by prolonged hospitalization and pulmonary emboli). Therefore, this evidence may or may not support a correlation between pulmonary emboli and drug abuse, but it proves that a certain population may be at risk. Other risk factors that came out of this study were intellectual disabilities ( $n=3$ ), fetal alcohol syndrome ( $n=1$ ), autoimmune diseases ( $n=3$ ), and inability to ambulate ( $n=5$ ).

The OCME has a responsibility to report its data to the public and health care agencies to prevent further deaths from occurring. Although this study resulted in small numbers, new risk factors were revealed. People with drug abuse history or who are intellectually disabled have an increased chance of developing pulmonary emboli. If their intellectual and physical disability prevents ambulation, then their chances will increase further. Analyzing data and promoting discussions about this subject allow agencies to create programs that can reach out to at-risk populations. This research warrants an investigation to ascertain the correlation between drug abuse and the risk for pulmonary emboli.

### H78 A Case of Necrotizing Pneumonia From a Marijuana Water Pipe: A Recreational Experience Gone Wrong

Drake Ryan Thrasher, BS\*, Birmingham, AL 35205; Deanna A. Oleske, MD, District 23 Medical Examiner's Office, St. Augustine, FL 32095

**Learning Overview:** After attending this presentation, attendees will better understand the potential complications that can result from habitual marijuana consumption via a water pipe or “bong” and similarly used devices for inhaled marijuana usage.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing a rare association between rapidly fatal bacterial necrotizing pneumonia and habitual marijuana use with water pipes. This presentation will also add to the knowledge of those conducting medicolegal death investigations and forensic autopsies in cases of sudden deaths in young persons with no medical history and drug history limited to marijuana usage.

A 34-year-old White female with only a known history of chronic marijuana use, was complaining of flu-like symptoms (vomiting, chills, and fever) for two days prior to death. The decedent was found obtunded and in cardiac arrest when Emergency Medical Services (EMS) arrived. The decedent was successfully resuscitated, transported to the hospital, and immediately intubated due to respiratory failure. She presented with multi-organ system failure, lactic acidosis due to prolonged downtime, and a clinical suspicion of Disseminated Intravascular Coagulopathy (DIC). A chest radiograph was performed with comment limited to endotracheal tube position. Limited point of care testing revealed a critical anemic state with markedly decreased hemoglobin levels (5.4g/dl). Influenza A/B screens were negative. No other clinical workup was performed due to the grave prognosis, and the decedent expired approximately four hours post-admittance. Further investigation revealed that the decedent preferred a water pipe or “bong” when using marijuana.

At autopsy, the decedent had a diffuse vesicular rash with petechial hemorrhages over the conjunctivae and chest. Cloudy effusions were in the pleural cavities. The lungs were heavy (lung combined weight: 2,910 grams) and consolidated. The pulmonary parenchyma of both lungs was diffusely necrotic and purulent. Other notable gross findings included an enlarged liver with diffuse steatosis, petechial hemorrhages over the pleural surfaces, epicardial surface, and renal calyces.

Postmortem blood and lung tissue cultures were obtained and submitted. Microbiology results showed growth of an isolated bacterial species (*Streptococcus pneumoniae*) in both submitted lung and blood specimens. Postmortem toxicology testing was significant for common marijuana metabolites, indicating chronic usage.

Histopathological examination of the lungs revealed diffuse areas of dense neutrophilic inflammation with alveolar septal destruction and perivascular infiltration. Additionally, the lungs were diffusely involved with large clusters of pigmented macrophages within the alveolar air spaces and septae. Microscopic examination of the skin from the chest showed sub-epidermal blister with thrombi in the dermal blood vessels. Microthrombi and fragmented red blood cells (schistocytes) were identified in the kidney. The liver showed diffuse hepatosteatosis with thin strands of fibrosis.

The manner of death was natural, and the cause of death was Thrombotic Thrombocytopenic Purpura (TTP) due to Necrotizing Pneumonia due to *Streptococcus pneumoniae* bacteremia, with marijuana abuse listed as a contributing factor.

A review of the medical literature shows few case reports demonstrating a possible correlation between necrotizing pneumonia or related conditions and marijuana usage with a water pipe.<sup>1-3</sup> However, this is the first reported case of *Streptococcus pneumoniae* as the causative bacteria species of necrotizing pneumonia presenting with TTP.

The purpose of this case study is to present evidence to the medical community of potential complications of habitual marijuana usage in the hopes of preventing unfortunate circumstances such as this one, as well as to make the forensic community aware of this unique but known complication to better assist in determining cause and manner of death.

### H79 Sudden Death in a Case of Hiatal Hernia Mimicking a Bochdalek Hernia

*Vittorio Gatto, MD\*, Sapienza University of Rome, Roma 00185, ITALY; Alessia Quattrocchi, Rome, ITALY; Valentina Fazio, Rome, ITALY; Matteo Scopetti, MD, Sapienza University of Rome, Rome, ITALY; Alessandro Santurro, MD, Sapienza - University of Rome, Rome (RM) 00161, ITALY; Mariantonia Di Sanzo, MD, Rome, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will understand the forensic problems related to a fatal case of a giant hiatal hernia in an older patient. Particularly, a complete forensic approach by means of clinical data collection, autopsy, microscopic, and toxicological investigation led to the conclusion that the cause of death was a cardiac compression resulting in electromechanical dissociation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as an example that can help identify a cause of sudden death potentially underdiagnosed. This study provides information regarding a rare occurrence reported through the clinical history and the results of the forensic investigation, providing an in-depth and complete point of view.

A 72-year-old man who had no relationship with his family was found dead in a farmhouse near Rome, Italy. The inspection of the place of death and the external examination of the body by police officers strengthened the hypothesis of a natural death. For this reason, a diagnostic autopsy was performed on the body.

The circumstantial data collected before autopsy, in particular the patient's medical history, suggested that the subject was suffering from a condition of gastroesophageal reflux, but no references to other pathologies have been found. In addition, a toxicological screening test was conducted that gave a negative result.

At the inspection of the thorax, marked emphysema of the right lung was found and the left pleural cavity appeared to be occupied by a voluminous mass that was determined as a subatelectasia of the left lung. Opening of the pericardial sac revealed a condition of adhesive pericarditis. Microbiological samples were also taken, with negative results, and the histological study of the pericardium confirmed the irritative condition.

In examination of the abdominal cavity, the omentum, the transverse colon, the stomach, and the pancreas were absent, with an evident dislocation to the left lobe of the liver. After the mass wall was opened, all the omental apron, the stomach, the transverse colon, and part of the pancreas were detected inside. After a cautious removal of the hernial content, it was evident that the hernial gate was represented by the diaphragmatic hiatus, in absence of congenital alterations of the diaphragm.

This case reports how a giant hiatal hernia that simulates a Bochdalek hernia can lead to sudden death by multiple mechanisms. Compression of the heart can induce the development of cardiac arrhythmias or, as is also shown in this case report, lead to the development of irritative pericarditis. This case demonstrates how a mild pathology, if neglected, can lead to sudden death.

---

#### Hiatal Hernia, Sudden Death, Case Report

### H80 Death Due to External Compression of the Trachea in a Case of Multinodular Hemorrhagic Goiter

*Massimiliano dell'Aquila, MD\**, Sapienza University, Department of Anatomy, Rome, Lazio 00169, ITALY; *Alessandra De Matteis*, University Sapienza of Roma, Rome 00100, ITALY; *Alessandro Santurro, MD*, Sapienza - University of Rome, Rome (RM) 00161, ITALY; *Vittorio Gatto, MD*, Sapienza University of Rome, Roma 00185, ITALY; *Matteo Scopetti, MD*, Sapienza University of Rome, Rome, ITALY; *Aniello Maiese*, Sapienza University of Rome, Rome 00185, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the main mechanisms responsible for external compression of the trachea in a case of intra-thyroid bleeding.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting an extremely rare case of asphyxia due to a massive intra-thyroid hemorrhage with an acute external compression of the trachea.

An 81-year-old White female (142cm height and 45kg weight) with a history of multinodular goiter for about 40 years, following the onset of a clinical condition characterized by acute respiratory failure, was transported to the emergency room by ambulance, where the death was ascertained within a few hours after admission.

A recent cardiologic examination in the clinical records reported, in the absence of risk factors for cardiovascular diseases, a sinus tachycardia with a heart rate of 131bpm (beats per minute), a negative objectivity for signs of cardio-circulatory failures, a blood pressure of 120/80mmHg, and a modest exertional dyspnea. At laboratory analysis, Thyroid-Stimulating Hormone (TSH) 0.01 microUI/mL, FT3 (free triiodothyronine) 4.76pg/mL, and Free Thyroxine (FT4) 2.33ng/mL were found, pointing out a hyperthyroidism pattern, attributable to a Basedow's goiter.

At the autopsy, the thyroid presented a weight of 1,510g and showed a much-increased consistency with an irregular and frankly hemorrhagic appearance, compatible with the development of an extensive hemorrhage within a massive multinodular goiter. An extensive hemorrhagic infiltration of mediastinal soft tissues and a tracheomalacia due to compression and dislocation determined by the bulky thyroid mass were also detected.

The microscopic examination confirmed the presence of a wide hemorrhagic area extended to the perithyroidal soft tissues and showed the presence, in sub-pleural location, of intra-alveolar accumulation of erythrocytes and of amorphous eosinophilic material in the alveolar spaces. Blood congestion in pulmonary vessels was also evident, with diffused atelectasis and emphysema.

The microscopic and macroscopic findings suggested the cause of death was a mechanical asphyxia, not attributable to external agents. The goiter (overly bulky if related with the weight-height ratio of the patient) was complicated by the development of intra-thyroid and intra-capsular multiple hemorrhages, involving perithyroidal tissues and the upper mediastinum, and causing an acute swelling of the gland and an external compression of the trachea, leading to the subject's death.

Conclusively, the case herein described has been never reported in the international scientific literature and offers meaningful insights on the mechanisms underlying death in the event of sudden massive bleeding within the thyroid, resulting in a significant swelling of the gland, with external compression of the trachea and the development of an acute asphyxia.

#### Multinodular Goiter, Intra-Thyroid Hemorrhage, Asphyxia

### H81 Cryptococcal Central Nervous System (CNS) Disease in a Large Urban Forensic Population

Jonee Taylor, MD\*, Office of the Chief Medical Examiner, New York, NY; Rebecca Folkerth, MD, PhD, Office of the Chief Medical Examiner, New York, NY 10016

**Learning Overview:** The goals of this presentation are to: (1) alert attendees to the continued presence of CNS Cryptococcal disease in a forensic population in New York City, a relatively resource-abundant setting during the era of Highly Active Retroviral Therapy (HAART); and (2) provide an overview of organism burden, degree of inflammation, and neuroanatomic localization in CNS Cryptococcal disease, and correlation with the type of immune compromise and other demographic factors.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reminding practitioners that CNS Cryptococcal infection is still noted in a relatively resource-abundant urban forensic setting, even during the era of HAART.

**Background:** Despite the introduction and now widespread availability of HAART, fatal opportunistic infections are still a major problem, especially in the developing world. For example, in 2016, >1 million deaths occurred worldwide from AIDS-related illness, and as many as 15%–20% were attributed to meningitis due to *Cryptococcus* species. In contrast to hospital-based autopsy practice, which focuses on patients already in the health care system (and has limited autopsy volume), forensic practice involves high numbers of unattended deaths, very often among vulnerable or underserved populations. Thus, forensic autopsies, particularly in a large, diverse urban setting, can contribute to a public health surveillance function by highlighting underappreciated trends. The goal of this study was to characterize all cases with autopsy evidence of Cryptococcal CNS infection from the office of the Chief Medical Examiner in the City of New York, during the HAART era.

**Methods:** This study screened its database of cases referred for neuropathology consultation from 2004 to 2014 for decedents diagnosed with Cryptococcal disease and identified 14 cases. (For reference, during this period, 10,916 cases were referred for neuropathology evaluation, of which 313 were decedents with HIV/AIDS.) Microscopic sections included frontal lobe, thalamus, basal ganglia, hippocampus, midbrain, pons, medulla, and cerebellum, stained with hematoxylin and eosin. A variable combination of standard ancillary stains, including methenamine silver, periodic acid-Schiff, and mucicarmine, was used in 11 cases. Neuropathology reports on all, and microscopic slides on 9, were reviewed to semi-quantitatively evaluate: (1) organism burden (scale of 1 [rare or sparse], 2 [moderate numbers], and 3 [numerous]); (2) degree of inflammation (0 [none], 1 [sparse], and 2 [robust, including granuloma formation]); and (3) anatomic location (leptomeninges; perivascular space; and parenchyma). Additionally, demographic features were recorded.

**Results:** Among the 14 cases, 8 were female and 6 male, ranging in age from 20 to 74 years. A majority ( $n=11$ ) were born in the United States, and 2 were born in Haiti; the country of origin for one was unknown. There were 9 Black decedents, 4 Hispanic, and 1 White. Of the 14 cases, 11 carried the diagnosis of HIV/AIDS, and 3 were immune-compromised due to other medical illness. Macroscopically, leptomeningeal opacification was noted in 12, particularly over the cerebellum. Histologically, 12 cases had leptomeningeal involvement, 9 had perivascular, and 9 had parenchymal (most cases had more than one pattern). The organism burden was high in 3, moderate in 7, and sparse in 2. In 2 cases, Cryptococcal meningitis was noted as a premortem diagnosis; however, no inflammation or organisms were seen on microscopy. The degree of inflammation was sparse in 7, and robust in 5, including granuloma formation in 3. The neuroanatomic site most frequently affected was the cerebellum ( $n=8$ ), followed by brainstem ( $n=6$ ), and diencephalon ( $n=5$ ). Of note, one case, with a clinical history of blindness, showed histologic involvement of the optic nerve. Only the non-HIV cases demonstrated granulomatous inflammation, including multinucleated giant cell formation engulfing Cryptococcal organisms.

**Limitations:** The numbers of cases are small and likely reflect selection bias, as not all brains were referred for neuropathology consultation. Sampling bias likely prevented postmortem confirmation of a premortem diagnosis of CNS Cryptococcal disease in a minority of cases.

**Conclusion:** *Cryptococcus*, as an opportunistic fungal infection of the immune-compromised, showed a spectrum of CNS involvement regarding distribution of organisms and host response. Of note, only the HIV-negative immune-compromised individuals were able to mount a granulomatous response. It is further pointed out that, even during the HAART era in our relatively resource-abundant forensic setting, CNS Cryptococcal disease is still a significant finding. If anything, this experience likely underrepresents the true incidence of Cryptococcal disease among the large diverse urban population. This study emphasizes the role of neuropathologic evaluation of immune-compromised decedents for public health surveillance of this fatal complication.

### H82 A Review of Shellfish Illnesses and Deaths in Mississippi

Mark M. LeVaughn, MD\*, Mississippi State Medical Examiner's Office, Pearl, MS 39208; Brent Davis, MD, Mississippi State Medical Examiner's Office, Pearl, MS 39208; L.R. Funte, MD, Mississippi State Medical Examiner's Office, Pearl, MS 39208; Anastasia Holobinko, PhD, Mississippi State Medical Examiner's Office, Pearl, MS 39208; Steven A. Symes, PhD, Mississippi State Medical Examiner's Office, Pearl, MS 39208

**Learning Overview:** After attending this presentation, attendees will better understand the epidemiology and spectrum of illnesses and deaths caused by the consumption of, or direct contact with, shellfish from the Gulf Coast region of Mississippi.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the results of clinical reviews and autopsy findings of shellfish disease and death over a period of five years. Risk factors, history of exposure, source and types of organisms, and autopsy findings will be discussed.

The family *Vibrionaceae* consists of eight genera of bacteria, not all of which are pathogenic to humans. Infection caused by pathogenic species of *Vibrionaceae* result in two separate types of illness (i.e., cholera and vibriosis) in humans. Cholera was first reported in the United States in 1832. Of the more than 200 serotypes, only types 01 and 139 are referred to as the cause of cholera. On average, seven cases are reported annually in the United States. Vibriosis is caused by infection with any of the remaining serotypes representing pathogenic species of *Vibrionaceae*. There are approximately 80,000 cases reported annually in the United States with 300 deaths.

Vibrios were recognized as an important pathogen in the 1970s. The Cholera and other Vibrio Illness Surveillance System (COVIS) was initiated in 1988 by the Centers for Disease Control and Prevention (CDC), the Food and Drug Administration (FDA), and the states of Florida, Alabama, Mississippi, Louisiana, and Texas. Over the past five years, 46 cases of Vibrio infection have been reported in the state of Mississippi by the State Health Department and State Medical Examiner's Office. Fifteen of these cases were caused by *Vibrio vulnificus*; four were fatal.

*Vibrio vulnificus* is a halophilic (salt-requiring), gram-negative, and naturally occurring bacterium commonly found in warm marine environments. It causes disease in humans via consumption of contaminated shellfish or by contamination of an open skin wound by seawater. Ingestion results in vomiting, diarrhea, and abdominal pain. Skin infection results in ulceration, hemorrhagic bullae, and necrosis. In both types of contamination, the infection can progress to bacteremia and result in sepsis and death. Persons with pre-existing medical conditions are 80 times more likely to develop bacteremia. Patients who develop bacteremia have a mortality rate of approximately 50%.

**Case Study:** A 57-year-old male was reportedly stuck by the barbed fin of a salt water catfish while on a fishing boat out in the Gulf. When the decedent reported feeling ill, the Coast Guard was summoned, and the decedent was transported to the hospital. His condition declined; resuscitation efforts were unsuccessful. At autopsy, evidence of systemic epidemolysis was present. Petechiae and purpura were present on the torso and extremities. Based on the decedent's case history, postmortem examination, and microbiology cultures, the death was ruled accidental due to complications of *Vibrio vulnificus*.

#### Vibrionaceae, Vibriosis, Gulf Coast

### H83 A Fatal Dental Extraction: A Case of Ceftriaxone-Induced Anaphylactic Shock in an Inmate

*Massimiliano Esposito, MD, University of Catania, Catania 95123, ITALY; Federico Patanè, MD, Catania 95123, ITALY; Francesco Amico, MD, Medicina Legale, Catania 95123, ITALY; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY; Aldo Liberto, MD, University of Catania, Catania 95123, ITALY; Giuseppe Davide Albano, MD, Foggia 71121, ITALY; Angelo Montana, MD\*, University of Catania, Catania, ITALY*

**Learning Overview:** The goal of this presentation is to underline the role of immunohistochemical technique and to estimate serum concentration of mast cell tryptase as a specific marker to determine the cause of death during suspected anaphylactic shock.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of an accurate anamnesis and to give the patient a detailed explanation of the risks of procedures and the possibility of Ceftriaxone (CTR<sub>X</sub>) anaphylaxis. It is important to conduct an exhaustive immunohistochemical study, with anti-tryptase antibodies and measuring allergen-specific IgE in blood samples from the corpse to indicate sensitivity to certain allergens in order to obtain a reliable postmortem diagnosis.

CTR<sub>X</sub> is a third-generation cephalosporin commonly used for bacterial infections. The incidence of CTR<sub>X</sub>-related hypersensitivity skin reactions is between 1% and 3%, whereas anaphylaxis is rare. Although CTR<sub>X</sub> is a frequently used antibiotic, only a few cases of anaphylaxis in response to the first dose of CTR<sub>X</sub> have been reported. A case of anaphylactic shock after a single dose of CTR<sub>X</sub> without previous exposure to the drug is presented. Signs and symptoms of anaphylaxis are variable and can range from mild skin lesions to fatal reactions. It is generally quite difficult to prevent anaphylaxis, although effective advanced life support and postresuscitation care may improve survival.

The following case concerns a sudden death due to intramuscularly administered CTR<sub>X</sub> after a dental extraction in an inmate. Physicians did not collect an accurate anamnesis and did not offer a detailed explanation about the risks of this drug before injection, about any procedures offered, and precautionary measures before and during the dental extraction.

**Case Report:** A 35-year-old male convict with a medical history of allergic asthma, celiac disease, and known food-induced allergies for fish, fresh milk, peanuts, hazelnuts, walnuts, apples, kiwis, and peaches underwent a dental extraction with intramuscular CTR<sub>X</sub> administration. A few minutes after CTR<sub>X</sub> administration, he suddenly collapsed. Advanced life support with intramuscular adrenaline and resuscitation maneuvers were unsuccessful. Postmortem examination was unremarkable. At the autopsy, gross examination showed mild cerebral edema and white foam in the main bronchi. Lungs were normal in shape, increased in volume and weight, and exhibited small subplurular petechiae. Histological examination revealed polivisceral stasis and mild cerebral edema. Myocardial interstitial edema was also detected. An immunohistochemical technique was used to estimate the mast-cell population using the anti-tryptase antibody as a mast-cell specific marker. A considerable number of degranulating mast cells with extracellular tryptase-positive material were observed. Histological and immunohistochemical (CD4, CD15, CD68, CD20, CD3, CD8, and CD45) investigation of brain specimens revealed a diffuse cerebral edema. Lung samples showed subpleural and interstitial hemorrhage, intra-alveolar and diffuse interstitial edema, and acute stasis. The analysis of other organs was unremarkable. The goal was to detect IgE specific for CTR<sub>X</sub>. A serum concentration of mast cell tryptase from femoral blood was 41.4 µg/l. The laboratory tryptase enzyme immunoassay on blood revealed a tryptase concentration of 136.50 mcg/L (n.v. 0.00–15.00 mcg/L), greater than the cut-off value of 45 µg/l for the diagnosis of anaphylactic shock. The death was attributed to an anaphylactic shock due to CTR<sub>X</sub>, after his very first dose.

#### Ceftriaxone, Anaphylactic Shock, Dental Extraction

### H84 An Intrapericardial Rupture of an Aortic Aneurysm in the Anatomic Aortic Arch Variant: A Multidisciplinary Approach

*Enrica Calabrese, MD\*, University of Ferrara, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Raffaella Marino, MD, University of Ferrara, Ferrara 44121, ITALY; Letizia Alfieri, MD, University of Ferrara, Ferrara 44121, ITALY; Erica Bacchio, MD, University of Ferrara, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Ferrara 44121, ITALY; Paolo Frisoni, MD, University of Ferrara, Ferrara 44121, ITALY; Francesca Gualandi, MD, University of Ferrara, Ferrara 44121, ITALY; Matteo Fabbri, MSc, University of Ferrara, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY*

**Learning Overview:** The goal of this presentation is to present a multidisciplinary approach to a case of an unexpected sudden death due to rupture of an aortic arch aneurysm associated with an atypical aortic arch branching variant incidentally detected during autopsy. To clarify the cause of death, to perform the postmortem genetic analysis and a systematic evaluation of decedent's family members, different professional experts, such as forensic pathologists, clinical geneticists, and general practitioners, were involved.

**Impact on the Forensic Science Community:** Little is known in the literature about non-syndromic familial Thoracic Aortic Aneurysms (TAAs); therefore, this presentation will impact the forensic science community by providing a methodical approach in those cases of sudden/unexpected death occurring in asymptomatic individuals with a postmortem diagnosis of Thoracic Aortic Disease (TAD).

According to the literature, aortic arch variants (i.e., variations in the aortic arch vessel branching pattern) are currently viewed as a marker or risk factor for TAD. Furthermore, about 20% of patients with TAA show a family history of similar disease, indicating an underlying significant genetic component. TAAs are usually asymptomatic until acute dissection or aortic rupture occurs; therefore, they often remain undiagnosed until fatal consequences.

A 53-year-old man, who worked as a carpenter, with a negative past medical history, suddenly collapsed at his workplace due to a cardiac arrest. Cardiopulmonary resuscitation maneuvers were immediately performed but were unsuccessful. He was declared dead by medical personnel 25 minutes after the beginning of the cardiopulmonary resuscitation. Before autopsy, the victim's past medical history, circumstances surrounding the sudden death, and the family's medical history were evaluated in collaboration with the general practitioner. The autopsy, performed two days after death, showed no sign of injury, except for traces of emergency medical care procedures. The most striking macroscopic feature was represented by cardiac tamponade, due to the rupture of a saccular aortic arch aneurysm (7.5cm x 8cm), at the site of a complex atheromatous plaque. It was 3cm in thickness, made of several layers of degenerative material. The autopsy also revealed the presence of an aortic arch variant with a two-vessel branching pattern: the first branch was a common origin of the brachiocephalic trunk and left common carotid artery, and the second one was the left subclavian artery. A histological examination was performed, including microscopic evaluation of the site aneurysm rupture and atheromatous plaque samples.

Since the current aortic arch variants associated with the presence of aortic arch aneurysm could be related to the presence of gene mutations that show an autosomal dominant-codominant inheritance with incomplete penetrance, a genetic evaluation of a cluster of most frequently involved mutations was performed, including FBN1, TGFBR1, TGFBR2, COL3A1, ACTA2, MYH11.

These findings suggest that a methodological approach, which involves collective efforts from general practitioners, forensic pathologists, and clinical geneticists, is essential in cases like this, not only to define the cause of death but also to perform postmortem genetic analysis in order to understand the pathophysiology involved in the genetics of aortic aneurysms and a systematic genetic counselling that could reveal disease-causing mutation and potentially prevent further deaths.

#### Sudden Unexpected Death, Aortic Arch Variants, Thoracic Aortic Aneurysm

### H85 An Interesting Case of a Pregnant Female With Systemic Calcification and Thromboemboli

Tasha Zemrus Greenberg, MD\*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919; Joshua Smith, BS, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104

**Learning Overview:** After attending this presentation, attendees will gain awareness of an interesting case of systemic calcification in a pregnant female examined at the Tarrant County Medical Examiner's Office.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating medical examiners about possible etiologies of systemic calcification as seen in a pregnant female with no known medical history who died as a result of pulmonary thromboemboli.

On February 3, 2018, a complete autopsy was performed on a 37-year-old White female who was found unresponsive in the bedroom at a private residence. She had no known medical history except for being approximately six months pregnant with recent complaints of feeling ill with cough and vomiting. She had not had any pre-natal care and had only used an unknown walk-in clinic for minor complaints. Reportedly, marijuana pipes were found in the residence, though she had no history of substance abuse.

The autopsy was significant for an intrauterine pregnancy with placenta previa. The fetus was male with no congenital anomalies, consistent with 4–5 months gestational age by weights and measurements. The uterus showed a large fundic leiomyoma, 18cm x 18cm x 15cm, as well as multiple additional smaller leiomyomata throughout the myometrium. There was a 14cm x 10cm x 6cm left ovarian chocolate cyst with a 6cm x 3cm x 2cm lobulated tumor in the wall that corresponded to decidualized tissue on histology. Decidualized tissue was also identified in the left fallopian tube that appeared distorted and markedly thickened grossly.

In the left lower lobe of the lung, there was a large thromboembolus. The kidneys were enlarged and pale, weighing 345gms each. Numerous vascular thrombi in varying stages of organization were noted bilaterally in the hilum and throughout the parenchyma. The right thyroid was nodular, scarred, and calcified. A 5mm right adrenal cortical adenoma was present. There was a 10cm x 7cm x 6cm thin-walled cyst on the right pericardium containing serous fluid. A small posterior left parietal osteoma was present.

On histologic examination, there were diffuse vascular calcifications in multiple organs, including the heart, liver, and spleen. The lungs showed calcification of the bronchial basement membranes, and there was calcification of the mucosal basement membranes in the stomach and pancreas. In the liver, there was calcification of the sinusoidal lining. In the heart, there was also calcification of individual myocytes. The thyroid nodule was consistent with a papillary carcinoma. Multiple additional small organizing thromboemboli were identified on histology throughout the lungs.

Review of the literature identified the differential diagnosis of diffuse vascular calcification to be very wide, including common and rare disorders ranging from premature atherosclerosis, diabetes, parathyroid disorders, chronic kidney disease, uremia, systemic lupus erythematosus, hyperphosphatemia, pseudoxanthoma elasticum, Marfan's syndrome, liver disease, and hyperparathyroidism.<sup>1</sup> The patterns of vascular calcifications vary among these conditions; however, none of them have been reported to have cardiac myocyte or hepatic sinusoid calcifications. A case report of acute fatty liver of pregnancy developing massive intrahepatic calcification indicates that it is usually associated with infectious, vascular, or neoplastic lesions in the liver.<sup>2</sup> In pregnancy, it has been reported to be associated with HELLP syndrome.<sup>2</sup> Cardiac fibroblasts can adopt an osteoblast cell-like fate contributing to heart muscle calcification.<sup>3</sup> No reports of a case with the constellation of findings in this death were found. A similar picture can be seen in idiopathic infantile arterial calcinosis. No reports of a case with the constellation of findings in this death were found.

In summary, this is an interesting case of diffuse systemic calcification of unknown etiology in a pregnant woman who died as a result of pulmonary thromboemboli and had thrombi in the kidneys. The association is uncertain and her death, in the absence of the thromboemboli, certainly could have been attributed to the cardiac myocyte calcification and an arrhythmia.

### H86 Carbohydrates That Kill: Death From Refeeding Syndrome?

*Carolyn E. Lemieux, MD\*, London, ON N5X 3L1, CANADA; Vickie Willoughby, DO, Travis County Medical Examiner's Office, Austin, TX 78787; Keith Pinckard, MD, PhD, Travis County Medical Examiner's Office, Austin, TX 78701*

**Learning Overview:** After attending this presentation, attendees will: (1) be able to define refeeding syndrome, (2) understand the cellular mechanisms and metabolic changes associated with refeeding syndrome, and (3) have developed an awareness of the risk factors and special populations in whom refeeding syndrome may be a factor in causing sudden death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and forensic pathology communities by raising awareness of refeeding syndrome, a paradoxical differential diagnosis of sudden death in malnourished persons that can present for forensic autopsy. Knowledge of refeeding syndrome in these cases is important for death investigators and forensic pathologists to ascertain a complete clinical history, correlate autopsy features, and order appropriate laboratory testing.

Two cases with possible refeeding syndrome were identified at the Travis County Medical Examiner's Office. A 21-year-old male visited the United States from Mexico. Upon arriving, family was concerned at his emaciated appearance and took him for a large meal. Shortly after eating, he began vomiting and experiencing constipation. His symptoms persisted for 24–36 hours before he was witnessed to collapse and succumb to a presumed illness. At autopsy his Body Mass Index (BMI, measured in  $\text{kg}/\text{m}^2$ ) was  $14.5 \text{ kg}/\text{m}^2$ . His stomach and small and large bowel were empty. Vitreous analysis demonstrated hypernatremia consistent with dehydration and his recent history of emesis. Toxicology was negative for alcohols, illicit and prescription medications. In the second case, a 26-year-old male with a history of anorexia nervosa and prior inpatient and outpatient recovery treatment was found deceased in his residence. At autopsy his BMI was  $14.8 \text{ kg}/\text{m}^2$ . Internal examination demonstrated fluid within the chest cavities and lower extremity edema. Toxicology showed therapeutic level of citalopram. Vitreous analysis demonstrated low levels of sodium; however, the potassium concentration was slightly increased.

Refeeding syndrome is a relatively unknown entity that paradoxically potentiates sudden death in malnourished persons subsequently receiving oral, enteral, or parental nourishment. Earliest descriptions of refeeding syndrome were presented during the last century when emaciated prisoners of war clinically described as having marasmus or kwashiorkor were refeed. Progressive knowledge of anabolic and catabolic states of metabolism, nutritional requirements, and electrolyte physiology has provided an understanding of the cellular mechanisms that underlie refeeding syndrome and supported the development of treatment protocols for gradually increasing nutritional intake.

Currently, however, there are challenges in recognizing refeeding syndrome due to the diversity of predisposing risk factors and populations affected, and variable electrolyte disturbances and their subsequent systemic effects. Predisposing risk factors for malnourishment may include malabsorption, infectious disease, eating disorders, low socioeconomic status, cachexia associated with malignancy, advanced age, and post-surgical patients, particular bariatric surgery patients. Electrolyte shifts may demonstrate combinations of hypophosphatemia, hypokalemia, hypomagnesemia, alterations of glucose, lipid, and thiamine, and changes in sodium and water excretion that can cause dehydration or extracellular fluid compartment expansion and edema. Symptoms leading to possible death may incorporate single or multiple bodily systems, including cardiovascular (arrhythmia, hypotension, heart failure), endocrine (hyperglycemia), gastrointestinal (vomiting, constipation, paralytic ileus, diarrhea), hematological (hemolysis, leukocyte dysfunction), neurological (delirium, seizures), renal (metabolic acidosis or alkalosis, acute tubular necrosis), respiratory (hypoventilation, pulmonary edema, respiratory drive failure), and musculoskeletal (rhabdomyolysis, ataxia, diaphragm weakness, muscle cramps, osteomalacia). Malnourished persons with refeeding syndrome can be evaluated in hospital for the aforementioned symptoms and underlying electrolyte abnormalities with a diagnostic battery of testing. However, such methods and diagnostic certainty are not available postmortem.

#### Refeeding Syndrome, Eating Disorder, Anorexia

### **H87 A Very Affordable Postmortem Computed Tomography (PMCT) Angiography Kit: A Feasibility Study Using an Immersion Pump and 3D-Printed Parts**

*Wolf Schweitzer\**, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*; *Markus Enders, Präparator, Zurich Institute of Forensic Medicine, University, Zurich 8057, SWITZERLAND*; *Dominic Gascho, Universitat Zurich, Zurich CH-8057, SWITZERLAND*; *Michael Thali, MD\**, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*

---

**Learning Overview:** After attending the presentation, attendees will better understand that it is not difficult to assemble all parts required for PMCT angiography (PMCTA) using parts from a normal hardware store and from pre-designed 3D models that they can get 3D-printed or print themselves.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a very low cost PMCTA kit (except contrast agent).

**Introduction:** A frequent objection to using PMCTA is the associated extreme costs. In that context, this study has not only identified a small immersion pump to be very affordable, but found it to also achieve better vascular filling than a heart lung machine. Using that pump as the core item, this study developed a PMCTA kit containing all materials needed (with the exception of contrast agent admixture).

**Methods and Materials:** This study developed a parts list made of items available at hardware stores and built the remaining items using 3D design and 3D printing. The kit contains a pump as well as a variable power supply. It contains a silicone tube to attach to a small immersion pump. The tube is fixed to the pump by use of a press-fit cylinder. The tube, at its other end, attaches to a femoral catheter. To make a distinction between the venous and arterial access line easier, red and blue colors may be used for 3D printing. The silicone tube and attached pump are kept in place with a spring clamp and a 3D-printed tube clamp fixture that allows for fast tube slide-in or slide-out. Last but not least, the kit contains two vascular tourniquet sets containing a stylet, an occlusion tube, and a quick-release clamp. These are required to fix the femoral catheter, once in position, to the femoral vessel into which it is inserted. The femoral catheter model appeared to be particularly difficult to design for flawless 3D printing using a standard PLA printer. This study employed Finite Element Analysis (FEM) to examine design issues in relation to repeatedly experienced breaks of earlier models. The kit was tested in an adult PMCTA. Its total cost is around 120 Swiss Francs (CHF) for all devices and parts and 170 CHF if a durable case is included.

**Results:** Vascular filling of the arteries contained scalp arteries; excellent filling also of intracranial arteries and upper extremities past the elbow. Vascular filling of the veins extends also past the Torcular herophili with a full staining of the superior sagittal sinus. Images will be presented.

### H88 The Detection of Insect Stains From Four Species of Necrophagous Flies on Household Materials Using Immunoassays

David B. Rivers, PhD\*, Loyola University Maryland, Baltimore, MD 21210; Gregory Cavanagh, BS, Loyola University Maryland, Baltimore, MD 21210; Valerie Greisman, BS, Loyola University Maryland, Baltimore, MD 21210; Rebecca Brogan, PhD, Loyola University Maryland, Baltimore, MD 21210; Andrew Schoeffield, PhD, Loyola University Maryland, Baltimore, MD 21210

**Learning Overview:** After attending this presentation, attendees will understand how insect stains can be differentiated from human body fluid stains using a confirmatory immunoassay.

**Impact on the Forensic Science Community:** The presentation will impact the forensic science community by describing a new method for identification of insect stains found at crime scenes that can be reliably used to distinguish insect contaminants from body fluid evidence.

Any interaction between an insect with a corpse or associated exuded body fluids has the potential to create trace evidence in the form of insect stains. In many instances, the chief culprits producing the contaminates are several species of necrophagous Diptera that feed on a wide range of human tissues. By definition, only one type of insect artifact is officially recognized by bloodstain pattern analysts: insect stains. The Scientific Working Group for Bloodstain Pattern Analysis (SWGSTAIN) has defined insect stains as those bloodstains produced as a result of insect activity.<sup>1</sup> This definition leaves open the possibility of producing insect stains by two methods: insect modification of existing bloodstains or the creation of new stains. It is the latter that is most frequently cited by forensic entomologists, since both regurgitation and fecal elimination can yield insect stains containing human blood. The reality is that necrophagous flies can produce stains or artifacts as a result of feeding on several types of fluids (e.g., blood, saliva, semen, vaginal fluids, decomposition fluids), which yield artifacts that vary widely in terms of shape, color, and size.<sup>2-4</sup> Additionally, deposition of artifacts is not restricted to just foraging adults, as post-feeding larvae and newly emerged adults have the potential to contaminate crime scenes with unique artifacts.

Despite claims that fly artifacts can be detected based on morphological features, alternate lighting, and presumptive chemical tests, few species have been tested by the reported methods for discernment and none have proven to be consistently reliable in distinguishing insect stains from human body stains.<sup>5,6</sup> In an effort to overcome deficiencies in current methods used for identification of insect stains, an immunoassay has been developed that utilizes polyclonal antisera (termed anti-md3) based on a unique cathepsin D-like proteinase found in some cyclorhaphous Diptera.<sup>7</sup> The confirmatory immunoassay (dot blot) recognizes insect stains that contain fly digestive enzyme, specifically fly regurgitate and defecatory or fecal stains.

In this study, artifacts produced by four species of necrophagous flies (*Protophormia terraenovae*, *Calliphora vicina*, *Cynomya cadaverina*, and *Sarcophaga bullata*) were examined using the confirmatory immunoassay to determine if insect stains could be distinguished from a range of human body fluids (e.g., blood, semen, urine, saliva, and feces). Adult flies were fed *ad libitum* human blood, semen, urine, feces, or saliva for 24h at 25°C and permitted to deposit artifacts on a range of household materials: ceramic tile, carpet (plush), t-shirt (cotton), wood block, and unfinished drywall. A lift technique was developed that permitted transfer of fly artifacts from the test materials to filter paper (Whatman #4 110 mm Ø) for dot blot analyses.

Artifact transfers were confirmed visually and with an Alternate Light Source (ALS) using a 450nm emission filter and an orange contrast filter. All species readily deposited artifacts on all test household materials regardless of diet consumed. Despite differences in texture and porosity of the household materials, artifacts of all species transferred to saturated filter paper (Dulbecco's PBS) with apparent equal efficiency based on visual inspection. With all fly species, anti-md3 sera bound to artifacts produced after feeding on semen, blood, feces, urine, and saliva. Binding appeared proportional to the size of the artifact transferred during the lifts. By contrast, none of the human fluids tested positive in the immunoassays nor did lifts from household materials not exposed to flies. There was no evidence of false positives with any of the fly species tested, regardless of diet consumed. Similarly, there was also no indication of false negatives with any of the dot blot assays. However, flies did deposit artifacts not derived from the digestive tract on the test materials that, as expected, did not yield positive reactions with the immunoassay. Such artifacts generally cannot be visually distinguished from regurgitate and defecatory stains and thus can yield results perceived as false negatives.

These observations suggest that immunoassays using anti-md3 sera coupled with a simple lift technique can be used effectively as a confirmatory assay to distinguish fly regurgitate and fecal stains from human body fluids. The new method overcomes the limitations of current techniques and can be performed reliably by anyone properly trained without the need of a forensic expert for consultation.

### H89 Diurnal Oviposition Timing by Blow Flies (Diptera: Calliphoridae) in Different-Aged Carrion

Kristi Bugajski, PhD\*, Valparaiso, IN 46383

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the timing of blow fly oviposition in relation to sunrise and how the age of the carrion affects this timing. Species composition and ambient factors will also be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how the timing of blow fly oviposition in relation to sunrise greatly affects accuracy in estimating the Postmortem Interval (PMI).

Blow flies (Diptera: Calliphoridae) are among the first insects to oviposit (lay eggs) on carrion.<sup>1</sup> The timing of blow fly oviposition is critical for determining a PMI estimation, which is the time that has passed between death and corpse discovery.<sup>2</sup> The objective of this investigation was to gain more information about the timing of blow fly oviposition so that a more accurate PMI can be calculated. Past research in the lab has shown that blow fly oviposition occurs an average of 4.75 hours after sunrise in Northwest Indiana. This research expanded on previous studies by using carrion that had been thawing for different amounts of time to simulate different ages of carrion. To see if there was a difference in the timing of oviposition related to the age of the carrion, three piglets were thawed for approximately 15 hours (“new pigs”), and three piglets were thawed for approximately 55 hours (“old pigs”). The six piglets were then placed in a remote, wooded area one hour after sunrise. The piglets were checked once an hour until oviposition occurred, and it was recorded whether flies and eggs were present each hour. The research was repeated six times in the fall of 2017. Egg masses were collected and reared to the third larval instar stage for identification using taxonomic keys.<sup>3</sup>

The timing of oviposition, in hours after sunrise, was analyzed with respect to temperature, humidity, and light intensity. There was no significant difference found in the timing of oviposition between treatments. ( $t=120$ ,  $df=27$ ,  $P=.441$ ). Oviposition occurred an average of 3.9 hours after sunrise in new and old pigs. The species composition varied by date and between new and old pigs. The most common flies found ovipositing were Diptera: Calliphoridae, *Phormia regina* (Meigen) and Diptera: Calliphoridae, *Lucilia coeruleiviridis* (Macquart). *Calliphora vomitoria* (L.) were only collected on new pigs and were absent on old pigs. *Phormia regina* (Meigen) oviposited on new pigs with the same, or higher, frequency than on old pigs, which is the opposite of what was expected. There were record high temperatures in September 2017 (34°C), and this could account for the slightly early oviposition timing found in this experiment (3.9 hours after sunrise). After three years of research, it was found that the average timing of oviposition in Northwest Indiana is 4.4 hours after sunrise in the fall months. This research has importance in both the scientific and forensic communities, as a more accurate PMI can strengthen the validity of a forensic investigation.

**H90 WITHDRAWN**

## H91 Transcriptional Markers of Sex Determination for Forensic Entomology

Michelle Jonika\*, Magnolia, TX 77354; Ashleigh M. Faris, PhD, Texas A&M AgriLife Research, Corpus Christi, TX 78406; Carl E. Hjelman, PhD, Texas A&M University Department of Entomology, College Station, TX 77843; Aaron M. Tarone, PhD, Texas A&M University Department of Entomology, College Station, TX 77843

**Learning Overview:** After attending this presentation, attendees will understand how genetic markers can be used to predict the sex of blow fly species of forensic importance, which can aide in determining more accurate Postmortem Interval (PMI) estimates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying genes that can be used for a transcriptional approach to sex identification in blow fly species of forensic importance: *Lucilia sericata* (Diptera: Calliphoridae) (Meigen), *Cochliomyia macellaria* (Diptera: Calliphoridae) (Fabricius), and *Chrysomya rufifacies* (Diptera: Calliphoridae) (Macquart).

Indication of sex when identifying insects from human remains is important for death investigations in forensic science. The age and sex of insects is integral for PMI estimates when assumptions for certain conditions can be met.<sup>1</sup> In forensic entomology, species-specific data is gathered for development rate under different temperature conditions.<sup>2</sup> This data can then be applied to case samples and a minimum PMI can be determined utilizing the known data sets.<sup>1</sup> Within these estimates, there can be error in not considering differences in development times between males and females of blow fly species. Currently, only adult specimens can be identified for sex by sight identification, while immature forms have no standardized method for sex identification.<sup>3</sup> This can lead to inaccuracies in PMI estimates as this difference in development time is not being considered in the estimates. The objective of this research is to create an assay that will address the issue of sex identification in immature blow fly forms that can be applied to forensic casework, yielding more accurate PMI estimates.

Three species, *Lucilia sericata* (Meigen) (Diptera: Calliphoridae), *Cochliomyia macellaria* (Fabricius) (Diptera: Calliphoridae), and *Chrysomya rufifacies* (Macquart) (Diptera: Calliphoridae) were selected for this study. These species are all prominent within the state of Texas and have varying importance in widespread fields of entomology, such as veterinary entomology for myiasis of sheep, use in medical entomology for wound debridement therapy, and importance in forensic entomology, as they are all commonly found at remains recovery scenes.<sup>3</sup> Developmental differences between males and females within these species can be attributed to sexual dimorphism.<sup>4,5</sup> Within the sex determination pathway, differential splicing plays an important role.<sup>4,5</sup> It occurs during gene expression and will give rise to sex-specific phenotypes.<sup>4,5</sup> For this project, two genes of importance within the sex determination pathway—*transformer* (*tra*) and *doublesex* (*dsx*)—were targeted for analyses.<sup>4,5</sup> For the analyses, whole RNA was extracted and converted to cDNA. Then gradient Polymerase Chain Reaction (PCR) was used to determine the best annealing temperature for the selected primer sets and splicing products were visualized with gel visualization. Products and negative controls were confirmed with quantitative PCR (qPCR).

Currently, three distinct assays have been created that can identify the sex of immature forms within the selected blow fly species. Using accepted methodology within the field, these assays were created to target the *tra* sequence in *C. macellaria* and *L. sericata* and the *dsx* sequence in *C. rufifacies*. In addition to the assays created, an identification and error rate for this assay were determined to align with the need for known error rates within the field of forensic science. The assays will help advance forensic entomology by allowing for more accurate postmortem interval estimates in death investigations.

The application of this work can be seen in other projects as well. Currently, there is known gene expression data for *L. sericata*, as well as in progress gene expression data for *C. macellaria* and *C. rufifacies*.<sup>6</sup> With the help of this assay, we can determine whether gene expression has bias in the sexes and the amount of expression each sex may see. This assay can also be useful outside of forensic use in veterinary and ecological applications, such as for sex-specific biological control and better understanding sex-specific traits that may arise in species.<sup>7</sup> With this assay, not only will the field of forensic entomology benefit, but many other fields of entomology as well.<sup>7-9</sup>

### H92 An Investigation of Volatile Profiles of Specific Human Organs During Decomposition

Lena M. Dubois, MSc\*, University of Liège, Liège 4000, BELGIUM; Pierre-Hugues Stefanuto, PhD, University of Liège, Liège 4000, BELGIUM; Katelynn A. Perrault, PhD, Chaminade University of Honolulu, Honolulu, HI 96816; Jean-François M. Focant, PhD, University of Liège, Liège 4000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will understand which Volatile Organic Compounds (VOCs) are released from specific human organs, as well as their trends over time as organs decompose.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential of decomposition VOC profiling for postmortem examinations and its value as a tool to improve postmortem interval estimation and/or the determination of antemortem conditions.

The human body is made up of multiple complex biological systems. Despite great advances in science and technology, understanding how these systems are linked together and their influence on each other remains a complex task. Death involves the shutdown of these systems, initiating a sequence of events that breaks the body down into its smallest components; these processes are influenced by intrinsic factors such as diet, age, or gender and extrinsic factors such as temperature or humidity. Comprehensive knowledge of human decomposition processes would allow advancements to be made in many crucial forensic applications, including the determination of the postmortem interval or the examination of physical conditions prior to death, which can help to reconstruct antemortem events.

Comprehensive Gas Chromatography coupled to Time-Of-Flight/Mass Spectrometry (GCxGC-TOF/MS) is commonly used to study complex mixtures of VOCs from biological specimens. The objective of this research was to determine the VOCs present during the decomposition of human tissues, along with their respective postmortem trends over time using GCxGC-TOF/MS. Previous research has been largely focused on the analysis of VOCs produced by whole animal or human cadavers. However, this study aimed to identify whether the VOCs produced as a result of decomposition differ between specific organs within a body and, further, to determine the extent of variation between organs in different individuals. The study design allowed for intra- and inter-cadaver comparison for each organ sampled. Heart, lung, liver, kidney, and blood were collected from five bodies. The headspace was monitored during the decomposition process. Tissues were split into replicate glass jars and the headspace was sampled by dynamic pumping onto sorbent tubes that were further thermally desorbed onto a GCxGC-TOF/MS system. Due to the number of cadavers, organs, replicates, and time points analyzed, a large amount of data was obtained, leading to challenges in the integration, interpretation, and representation of the results. To monitor the temporal changes in VOC profiles, multivariate statistical methods, such as Principal Components Analysis (PCA) and Hierarchical Cluster Analysis (HCA) were applied to the dataset to evaluate trends and differences in subgroups.

The first approach was an intra-cadaver approach, where the profile from each organ was compared within a single body for all measured time points. The second approach consisted of an inter-cadaver comparison, where the VOC profiles for a single organ were compared between different bodies at each time point. The intra-cadaver analyses demonstrated that all organs from one body followed a similar trend, despite distinct differences at each time point. Examining the temporal trends, some cadavers exhibited similar trends; however, it was challenging to determine global trends across samples from all bodies. The inter-cadaver analysis focused on the comparison of the different tissues types from the five bodies at selected time points. Distinctive VOCs for each tissue for each time point could be determined. Furthermore, differences were demonstrated for the compounds produced from each organ, which is likely related to their composition based on the different functions they perform within the body. Differences observed in the VOC profiles between the analyzed bodies could range from the individual diet and lifestyle to the cause of death, as all these aspects have an impact on taphonomic processes.

This research is significant because it is the first study monitoring a high number of human tissues during decomposition. The increased number of samples and the use of technical replicates allowed a high quality of analytical data and an assessment of variance for inter- and intra-cadaveric samples. This will provide a foundational basis for the future implementation of VOC profiling from cadavers in forensic casework.

#### Decomposition, Volatile Organic Compounds (VOCs), Human Organs

### H93 An Investigation of the Decomposition Odor Profile Produced by Postmortem Microbes

Terezie Cernosek, Chaminade University of Honolulu, Honolulu, HI 96816; Kevin E. Eckert, MS, Honolulu Police Department, Honolulu, HI 96813; David O. Carter, PhD, Chaminade University of Honolulu, Honolulu, HI 96816; Katelynn A. Perrault, PhD\*, Chaminade University of Honolulu, Honolulu, HI 96816

**Learning Overview:** After attending this presentation, attendees will understand the importance of building a reference library of Volatile Organic Compounds (VOCs) produced by postmortem microbes, as well as the general trends associated with VOC evolution from three postmortem microbial species.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the correlation between results of VOC profiling and the postmortem microbial clock, which may improve postmortem interval estimation and/or search and recovery procedures.

VOCs are the category of decomposition byproducts that comprise the odor associated with decomposing remains. While there have been substantial leaps forward in recent years toward characterizing this odor under various conditions (e.g., postmortem interval, geographical region, season), there exists a large gap in knowledge of the underlying mechanisms that produce these VOCs. A decomposing body is a complex resource of biotic and abiotic components, meaning that volatile by-products cannot always have their exact sources established. Substantial information has become available regarding the microbial community that exists on decomposing bodies, which may provide insight into the sources of critical VOCs released throughout decomposition. As VOCs are now being more closely investigated with hopes of improving cadaver-detection dog practices and introducing complementary portable sensor approaches, it is increasingly important to understand the relation of VOC production in relation to the postmortem microbial community.

The purpose of this study was to investigate VOC emissions from bacteria collected from decomposing remains using Solid-Phase Microextraction Arrow combined with Gas Chromatography/Mass Spectrometry (SPME Arrow-GC/MS). Three postmortem bacterial species (*Bacillus subtilis*, *Ignatzschineria indica*, and *I. urei*) were cultured in headspace vials on standard nutrient agar at 24°C and monitored over a period of five days. The hypothesis was that these species would release VOCs that have been previously identified in decomposition odor in temporal trends throughout their growth cycle.

The results of this work indicated that each species monitored in this study exhibits a specific VOC profile. In addition, VOCs monitored over time exhibited temporal trends; some compounds trended upward in abundance whereas others trended downward, depending on the compound and species of bacteria. SPME Arrow was effective and reproducible in producing bacterial VOC profiles. *I. urei* was the only major producer of dimethyl disulfide, a key decomposition VOC previously identified in all decomposition odor studies. Other compounds of interest included various alcohols, ketones, aldehydes, and aromatics.

This research is significant because it is the first primary study that links decomposition odor with postmortem microbial community. The trends developed in this study will assist in developing more accurate portable sensor arrays for decomposition odor, as well as understanding the dynamics and variability of VOC production in previous literature. Future work on additional postmortem bacterial species and with more advanced chromatographic technology will assist in building a VOC database that can be accessed in future approaches profiling VOCs from whole cadaver decomposition in postmortem examination scenarios.

### H94 Estimating Postmortem Interval (PMI) Using Microbial Succession in Human Cadaver Rib Bones

Heather L. Deel\*, Fort Collins, CO 80525; Aerial D. Belk, MS, Colorado State University, Fort Collins, CO 80525; Aaron M. Lynne, PhD, Huntsville, TX 77341; Sibyl R. Bucheli, PhD, Sam Houston State University, Huntsville, TX 77340; Zech Xu Zhenjiang, MS, University of California San Diego, La Jolla, CA 92093; Franklin E. Damann, PhD, DPAA CIL, Offutt Air Force Base, NE 68113; David O. Carter, PhD, Chaminade University of Honolulu, Honolulu, HI 96816; Rob Knight, PhD, University of California San Diego, La Jolla, CA 92093-0763; Jessica L. Metcalf, PhD, Colorado State University, Fort Collins, CO 80523-1171

**Learning Overview:** After attending this presentation, attendees will understand microbial decomposition of human cadavers, how microbiome technologies can be used to estimate the PMI, and how microbial invasion into human rib bones during decomposition may be developed into a novel form of physical evidence for estimating PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of novel microbiome tools that may be useful in investigations of unattended death scenes, in which PMI is unknown.

In crime scene investigations, estimating the PMI is critical for validating alibis and, in some cases, identifying the deceased. Although there are multiple methods to estimate PMI, there are few tools that are accurate after the first two weeks of decomposition. Therefore, a new tool for estimating PMI on the scale of weeks to months is needed. Microbes are major drivers of decomposition that could serve as evidence of microbial succession in a similar way across bodies during decomposition. Previous research has demonstrated that microbiome data collected from both mouse models and human bodies can be used to create an accurate “microbial clock of death.” This study hypothesized that the invasion of microbes into bone is likely a slow process and tracking the succession of microbes into bones after death may provide accurate estimates of PMI for longer timeframes of decomposition.

To test this hypothesis, rib bones from six human bodies were collected, beginning at approximately three months after death. For each body, one rib was collected every three weeks for a total of 48 sampled ribs. Research was conducted at the Southeast Texas Applied Forensic Science Facility, an anthropological research center in Huntsville, TX. After sample collection, samples were shipped to Colorado State University, where each of the rib samples were processed by excising a portion of the bone with a Dremel® drill, cleaning the newly excised piece with bleach and Ultraviolet (UV) irradiation, then pulverizing it into a fine powder. Each of the bone powders were demineralized, then DNA was extracted using the DNEasy® Powersoil Isolation Kit following the Earth Microbiome Project standard protocols. The bacterial microbiome in each sample was then characterized using 16S ribosomal RNA (rRNA) amplicon sequencing on the Illumina® MiSeq® platform at the University of California, San Diego. Data analysis using Quantitative Insights Into Microbial Ecology revealed that similar microbes invade the rib bones during decomposition. This study discovered that PMI could be estimated within approximately one month over a decomposition period of nine months by constructing a random forest regression model using 16S rRNA data. These results are promising because the error of the model (~4 weeks) cannot be more accurate than the sampling frequency (~3 weeks). Therefore, this initial study demonstrates that utilizing the invasion of microbes into bone may be useful for estimating PMI on a longer timescale, and the model may be improved with studies that include more frequent sampling.

#### Bone, Microbiome, Postmortem Interval

### H95 Investigating Italian Criminal Cases' Postmortem Microbiome Signatures

Gulnaz T. Javan, PhD\*, Alabama State University, Montgomery, AL 36104; Holly L. Lutz, University of Chicago, Chicago, IL 60637-1508; Sheree J. Finley, PhD, Alabama State University, Montgomery, AL 36104; Neil Gottel, BSc, University of Chicago, Chicago, IL 60637; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY; Jack A. Gilbert, PhD, University of Chicago, Chicago, IL

**Learning Overview:** After attending this presentation, attendees will understand how to use postmortem microbial diversity of reproductive organs, spleen, etc. from Italian cadavers with times of death up to 15 days to aid in the correlation of time and manner of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing statistically significant next generation sequencing data that may realistically support crime scene investigation findings (homicide, suicide, etc.).

There is active microbial life in the human body after death throughout the stages of human decomposition, and reproductive organs are among the last internal organs to deteriorate. The role that microbes play during decomposition may provide critical data that is potentially useful for the determination of the time or manner of death. Previous thanatomicrobiome studies using corpses from the United States and Finland established statistically significant differences in microbial signatures between two geographical locations. However, the impact of microorganisms on human decomposition in Italian corpses has yet to be fully elucidated for death investigations. In the present study, 16S ribosomal RNA (rRNA) gene amplicon sequencing of DNA extracts was performed using 40 Italian cadavers' internal organs. The samples were obtained from the University of Pavia's Department of Public Health, Experimental and Forensic Medicine. The tissues were collected from between 1-5 internal body sites, namely brain, heart, liver, spleen, and reproductive organs. It was hypothesized that the microbiome profiles associated with decaying reproductive organs maintain signatures that are indicative of the time and manner of death. This study tested the hypothesis by surveying Italian cadavers with postmortem intervals between 24 hours and 15 days with causes of death of homicide, suicide, natural, and accident. All cases were Caucasian with the exception of two, who were of South American nationality. The ages of the cases at the time of death ranged from 16 to 89 years old.

Results of these studies showed that 16S rRNA gene amplicons demonstrated alpha diversity of microbial communities and were significantly different between organ types. For example, the alpha diversity of prostate- and uterus-associated microbial communities was significantly greater than ( $p < 0.005$ ; Kruskal-Wallis) heart and liver. Microbial beta diversity was weakly, but significantly, correlated ( $p < 0.001$ ; ADONIS) between gender ( $R^2=0.031$ ), Body Mass Index (BMI) ( $R^2=0.053$ ), manner of death ( $R^2=0.073$ ), and postmortem interval ( $R^2=0.04$ ). Spleen, liver, heart, and brain microbial diversities were significantly enriched in the cyanobacterial class 4C0d-2. Furthermore, prostate and uterus samples were depauperate for this class, but were dominated by *Bacilli*, *Betaproteobacteria*, *Gammaproteobacteria*, and *Clostridia*.

In conclusion, the postmortem microbial diversity in cadaver organ tissues was analyzed by high-throughput next generation, 16S rRNA amplicon sequencing techniques. This rapidly developing technique is likely to provide several discoveries in DNA casework. This study confirmed that the alpha and beta diversities varied significantly among internal organ tissues. The significant enrichment of specific bacteria show correlations to several factors, particularly gender, BMI, and postmortem interval, which may provide insight into several aspects of medicolegal death investigations. This data will be used to build statistical models to generate a predictive environment whereby the microbiome of these internal tissue samples can be used to predict the time and manner of death for a given corpse.

#### Cadaver Internal Organs, 16S rRNA, Thanatomicrobiome

### H96 The Application of Eukaryotic Community Succession on Porcine Remains for Postmortem Interval (PMI) Estimation

Luisa Forger, MS\*, Dumfries, VA 22026; Michael Shane Woolf, MS, Charlottesville, VA 22903; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA 23284; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how changes in the structure of eukaryotic communities found on decomposing remains may aid in the estimation of PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a novel area of research that uses eukaryotic communities to provide a useful alternative to traditional PMI estimation techniques by employing next generation sequencing and statistical modeling. Furthermore, this study explores the use of eukaryotic communities for such estimations, an underresearched area.

Determining time since death is an essential component of forensic investigations to complete victim timelines, eliminate suspects, and corroborate the testimonies of those involved. Current techniques for estimating PMI involve observing the physical appearance of remains against known time-/temperature-related changes to calculate a time frame. Recent studies on porcine, murine, and human models have shown that the succession of the microbial community of remains can be used as an alternative method to estimate time since death.<sup>1-5</sup> However, these studies had insufficient replicates, were performed in a laboratory setting, or could not provide long-term estimations. The goal of this study was to combat these issues by performing a better-replicated ( $N=6$ ) field study on a porcine model over an extended period (two months, or 1,703 Accumulated Degree Days (ADD)) and to characterize the eukaryote community of decomposing remains, a topic that is underresearched.

Skin microbial samples were collected from the torso of each set of remains every day during the first week, on alternate days during the second week, and once a week for the remainder of the 60-day period. The eukaryote community of each sample was determined using 18S recombinant DNA (rDNA) MiSeq<sup>®</sup> sequencing. Sequence data were analyzed in the mothur pipeline (v1.39.5) and subsequent statistical analyses were performed in R (v3.4.3). The relative abundance of eukaryote taxa across time points and an Analysis of Molecular Variance (AMOVA) indicated similarities between sequential ADD, but significant differences in the eukaryote communities as different stages of decay were reached. At Level 5 (Family), fresh remains (0–57 ADD) were characterized by the combined presence of *Trichostomatia* (12.1%), *Saccharomycetaceae* (5.6%), *Rhabditida* (18.9%), and *Trichosporonaceae* (11.0%). During bloat and active decay (87–209 ADD), *Diptera* (86.4%) was the most abundant family. At the advanced decay stage (267–448 ADD), *Rhabditida* (34.3%) was predominant, but *Coleoptera* (19.3%) also appeared toward the end of this stage. Dry/skeletal remains (734–1,703 ADD) were dominated by the combined presence of *Dipodascaceae* (33.3%), *Trichosporonaceae* (18.9%), *Debaryomycetaceae* (32.3%), and *Sporidiobolaceae* (8.8%). A random forest model generated using Level 5 taxa for the first 15 days of decomposition (0–448 ADD) explained 84.65% of the variability observed with a Root Mean Square Error (RMSE) of 58.6 ADD (approximately 2 days). Another model generated using Level 5 taxa from all collection times explained 89.51% of the variability observed with an RMSE of 178.1 ADD (approximately 6.6 days). Both models show improvement over those generated using only bacterial community succession data and highlight the importance of the microbial eukaryote community throughout the process of decomposition.

In conclusion, this study will impact the attendees by increasing their understanding of methodologies currently in place and their awareness of emerging forensic techniques for PMI estimation. It will also provide recommendations on how investigators may better approach crime scenes to preserve and collect evidence for use in necrobiome sequencing. Finally, the presentation will highlight how the application of next generation sequencing may change the way that postmortem interval is determined by providing a supplemental technique to traditional estimation methods.

### H97 iFly: Mobile Software for Recording Data From a Carrion Source or Death Scene

*Trevor I. Stamper, PhD\*, Purdue University, West Lafayette, IN 47907*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the capabilities of iFly, a new mobile application for recording data from carrion or death scenes, with a focus on forensic entomological specimen collection and Total Body Score (TBS) estimation. Decomposition scenes rich in entomological material present numerous data recording and preservation challenges. Because of this, most entomologists construct their own “scene data sheets” to record what they consider to be necessary data. iFly was created to provide a flexible digital platform for recording this data from the scene and for sharing data between users in a standard format.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how a mobile application for forensic entomological and TBS data collection can assist in research projects or cases.

iFly integrates a customizable scene documentation system, device enabled “hidden” photography, remote weather station data acquisition, a proof-of-concept built-in visual key system, and precise annotation of sampling location for multiple types of instrumentation (temperature, humidity, wind speed, light level, invertebrate samplings, etc.). Three standard models—domestic pig, human male, and human female—come pre-built into iFly. These standard models allow for concise annotations that reflect the underlying anatomical body locations unique to each model. Tagging samples to the underlying anatomical position on the body allows for the automated acquisition of body location along with specimen or feature documentation—creating the potential to move forensic entomology further into the “big data” future of data analysis. To facilitate this, a MATLAB® utility was created to allow for the customized creation of new body outlines (which would then need to be curated by the iFly team). iFly allows the user to create their own environmental parameters for data sampling and allows the user to compute decedent TBS from the in-application evaluation of photo evidence, as well as the opportunity to identify some entomological specimens using a proof-of-concept built-in visual key.

Cases can be organized around any number of single- or mixed-model assemblages using the default models in iFly. Each model can then be tracked through any number of sampling events. This allows for complicated research set-ups, multiple victim events, or the precise collection of data for carrion ecology student projects at user-defined time increments. Scene data collection layouts can be formatted as a template to conform to pre-established standard operating procedures, allowing for many users to record the same data. iFly allows for the first-ever routine data exchange between carrion ecology or vertebrate decomposition researchers. Individual screens can be exported as .csv files, or the entire case can be exported for peer-to-peer transfer of cases on iFly enabled devices. Photographs imported or taken within iFly are protected from the normal iPad® camera roll, meaning they cannot be accessed from any other app on the device.

---

## H98 International Associations of the Postmortem Microbiome

Jennifer L. Pechal, PhD\*, Michigan State University, East Lansing, MI 48824; Carl J. Schmidt, MD, Wayne County Medical Examiner's Office, University of Michigan, Detroit, MI 48207; Heather R. Jordan, PhD, Mississippi State University, Mississippi State, MS 39762; M. Eric Benbow, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will better understand which metadata has the most impact on structuring a human postmortem microbiome dataset from a multi-country study.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight as to how regularly collected case metadata, such as sex, age, body mass index, manner of death, or country, influenced the human postmortem microbiome.

The use of high-throughput sequencing and advanced statistical modeling to characterize the postmortem microbiome during death investigations has experienced a recent surge. This presentation will describe the human microbiome associations from samples collected during routine death investigations across four countries.

Samples were collected during routine death investigations from four medical examiner's offices (or the international equivalent) located in: Salzburg, Austria; Lille, France; Naples Italy; and Wayne County, Detroit, MI, United States. The individuality of the death circumstances and death investigation protocols within each country is key to acquiring a broad survey of samples from non-targeted case demographic or circumstances of death.

Microbial samples were collected in 2014–2017 from a total of 242 cases. Each case needed to meet the following criteria for inclusion in this dataset: (1) adult ( $\geq 18$  years old), and (2) known circumstances of death. To collect the microbial communities, sterile DNA-free cotton-tipped swabs were individually rubbed against the external surfaces of three anatomic locations (mouth, nose, and rectum) as part of the office's established death investigation protocol. Individual swabs were extracted under aseptic conditions using a commercially available kit with a modified protocol, and the resulting DNA was quantified using commercially available kits for a fluorometer and a microchannel-based automated electrophoresis system. Targeted amplicon (16S ribosomal RNA (rRNA) V4 gene region) high-throughput sequencing was performed on individual sample libraries using a 2x250 base pair, paired-end approach. Samples were processed using an open-source bioinformatic pipeline and statistical analyses, including machine learning algorithms, to identify significant associations among the targeted gene amplicon sequences (microbiome) and case metadata from four countries located in North America and Europe.

Microbial analyses results confirmed distinct postmortem microbiome signatures based on anatomic location and estimated postmortem interval, as previously shown.<sup>1</sup> Alpha-diversity differences (e.g., observed species, taxon diversity) were distinguished among anatomic location postmortem microbial communities. Visualization of these differences were clearly seen in principal coordinate analyses based on phylogenetic similarity (abundance weighted UniFrac distances), demonstrating strong intra-anatomical location similarity. Samples were partitioned based on these anatomic location differences for subsequent analyses. Supervised machine learning analyses classified metadata sources based on sequence variant community composition. Bacterial species within Firmicutes were the most important features for all metadata tested structuring this dataset.

In conclusion, this dataset further highlights the spatial and temporal variability of the human postmortem microbiome across an international, large-scale survey of death investigation. Potential pan-microbial signatures of forensic importance, including ubiquitous bacterial species, were identified within this dataset. There is a tremendous need for pathologists and researchers to continue to work together to identify robust microbial signatures that could be routinely used to inform questions of interest during death investigation across the globe. Additional sample collection, processing, and modeling is imperative to validate the models developed from individual datasets, such as this one, to confirm or identify additional postmortem microbial biomarkers.

### H99 The Composition and Shifts of Soil Bacterial and Fungal Communities Following Cadaver (*Sus Scrofa* Domesticus) and Plant Litter (*Quercus Robur*) Burial

Chawki Bisker, MSc\*, Teesside University, Middlesbrough, North Yorkshire TS1 4PS, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand how soil bacterial and fungal communities change during carcass decomposition and the potential exploitation of this phenomenon to estimate time since death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an insight into the shifts in soil bacterial and fungal communities up to 24 months after piglets' burial in contrast with oak leaves decomposition. Furthermore, it suggests the use of soil bacterial and fungal communities to assess time since death and locate clandestine graves.

The scientific community's growing interest in cadaver decomposition in soil is reflected by the increasing numbers of publications on this topic. Nevertheless, there is still a gap in the knowledge about some key processes, such as human decomposition, soil microbial communities associated with the different decomposition stages, their role and effect on decomposition, and their value as a forensic tool.<sup>1</sup>

This study aims to expand the knowledge base of subsurface decomposition within a forensic context by comparing soil microbial communities associated with the decomposition of mammalian surrogates (*Sus scrofa* domesticus) and plant litter (*Quercus robur*) in a natural setting.

The experimental design consisted of three piglet (*Sus scrofa* domesticus) burials, three plant litter (*Quercus robur*) burials and three soil-only burials (controls). The subsurface decomposition experiment was conducted in a natural setting in secure land in North East England (North Yorkshire, United Kingdom).

Soil pH, soil temperature, atmospheric temperature, and precipitation were monitored, and the associated soils profiled for shifts in bacterial communities by Denaturing Gradient Gel Electrophoresis (DGGE) and high throughput sequencing using 16s ribosomal RNA (rRNA) gene-specific primers. Soil fungal communities were monitored by DGGE using 18s rRNA gene specific primers. Soil samples were collected at regular intervals over a 24-month period. The different treatments were sampled monthly during the first year, then every two months until the end of the study. Sampling was performed at 50cm–60cm deep, without disturbing the buried material. At each time point, four soil samples were collected from around each treatment using a soil corer and combined into a 25ml sterile universal tube, then transported to the laboratory, on ice, and stored at -20°C until required.

The ecological indices calculated after DGGE and data obtained from 16s rRNA high-throughput sequencing allowed a profiling of the soil bacterial and fungal communities at each time point. The results have shown a direct relationship between seasonal temperature changes and shifts in microbial activity, together with exploitable shift patterns with the potential to be used for the estimation of time since death.

Soil microbial communities can be of great value for time-since-death/-burial estimations due to their recognized potential to facilitate higher accuracy by complementing the existing tools.<sup>2</sup> Nevertheless, more research is needed to understand the microbial communities' dynamics in different deposition conditions and their interactions with soil, the cadaver, and its inherent microbiome.

### H100 A Field Study on the Effects of Morphine on the Carrion Decomposition Process and Dipteran Larvae Development

Abigail J. Props, MS\*, Lafayette, IN 47904

**Learning Overview:** After attending this presentation, attendees will learn how morphine affects Dipteran larvae development and carrion decomposition process from a field study in comparison to laboratory research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by looking at morphine effects on carrion decomposition and Dipteran larvae development outside of a controlled laboratory setting.

Laboratory studies have shown that toxicants, in general, can influence the growth and development of maggots.<sup>1-3</sup> These were in controlled environments with fly eggs of specific species being placed on the food source and an infinite food source, in some studies. With taking the research to the field, verification of the laboratory research results can be achieved. Throughout the beginning stages of the blow fly life cycle, larvae are feeding on tissue around the natural orifices and any trauma-created openings. Because not all organs and tissues will have the same concentration of morphine, not all tissue will affect the larvae the same. Lower levels of concentration will result in little to no effect on the growth and development of the Diptera larvae, while tissues with higher levels, such as the liver, are more likely to affect their growth and development.

Current research has shown that morphine has a negative effect on the growth and development of the blow fly larvae—the same effect it has on humans.<sup>3</sup> Morphine can also have a stimulating effect on the growth and development of flesh fly larvae, the opposite effect it has on blow fly larvae and humans.<sup>4</sup> This possible increase/decrease will directly affect the postmortem interval estimation, causing it to be over- or underestimated. Examining these processes will help determine if morphine will affect the postmortem estimation.

This field study looked at the effects of morphine on the growth and development of maggots, colonization rate, and carrion decomposition rate. Five pigs were injected with morphine along with five control pigs being punctured with a needle for five days prior to being euthanized. All ten pigs were allowed to decompose as naturally as possible, in an open field with no vegetation coverage with open exposure to solar radiation. Dipteran larvae were collected in a way that would be comparable to collections at a crime scene. The initial decomposition rate appeared to be faster among the treated pigs as compared to the control pigs but was not significantly different. The larval lengths of individuals belonging to forensically important family, Diptera: Calliphoridae, were not significantly different between the treated and control pigs, in any instars on days three, six, and ten.

### H101 Building a Microbial Model to Estimate the Postmortem Interval (PMI) Using Data Collected During the Spring Season at Three Anthropological Facilities

*Ariel D. Belk, MS\**, Colorado State University, Fort Collins, CO 80525; *Heather L. Deel*, Fort Collins, CO 80525; *Zech Xu Zhenjiang, MS*, University of California San Diego, La Jolla, CA 92093; *David O. Carter, PhD*, Chaminade University of Honolulu, Honolulu, HI 96816; *Sibyl R. Bucheli, PhD*, Sam Houston State University, Huntsville, TX 77340; *Aaron M. Lynne, PhD*, Huntsville, TX 77341; *Melissa A. Connor, PhD*, Colorado Mesa University, Grand Junction, CO 81501-3122; *Dawnie W. Steadman, PhD*, University of Tennessee, Knoxville, TN 37996; *Giovanna M. Vidoli, PhD*, University of Tennessee, Knoxville, TN 37996; *Rob Knight, PhD*, University of California San Diego, La Jolla, CA 92093-0763; *Jessica L. Metcalf, PhD*, Colorado State University, Fort Collins, CO 80523-1171

**Learning Overview:** After attending this presentation, attendees will understand the changes to microbial community structure that occur after death in human cadavers and how this information can be applied to create predictive models estimating the PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a novel tool for criminal investigation in cases of unattended death scenes in active and advanced decay.

PMI is crucial for criminal investigation. When known, this metric allows investigators to identify suspects and validate alibis. However, most tools designed for estimating PMI are no longer useful after 48 hours. In these cases of late discovery, the microbes associated with the remains may serve as physical evidence that can be used to estimate the PMI. The communities of microbes and their associated genes, known as the microbiome, have been shown to change in a repeatable manner on decomposing mammalian tissue, therefore providing a microbial clock that can capture the length of the decomposition period. The objectives of this experiment were to: (1) determine if the microbiome changes similarly in different geographic and environmental regions; and (2) use machine learning techniques to build a predictive model of PMI that can be used as a tool in forensic investigation.

Three anthropological research facilities, located in distinct geographic regions in the United States (Colorado Mesa University (CMU), Sam Houston State University (SHSU), University of Tennessee Knoxville (UTK)) were used for this study. Three donated human cadavers were placed at each facility ( $n=9$ ) in the spring of 2016. Skin and soil swabs were collected daily from each body for 21 days of decomposition. DNA was extracted from these samples, and 16S and 18S ribosomal RNA (rRNA) microbial gene amplicons sequenced. Data were then processed to evaluate changes in microbial diversity over time and between locations, and feature information was used to train machine learning models to predict PMI from microbial composition.

Each facility had a distinct microbial signature, primarily driven by the soil composition. As decomposition progressed, the soil came to cluster more closely with the skin samples, likely due to translocation from the cadaver to the soil. The primary phyla found at all sampling points was Proteobacteria, although the relative abundance of Firmicutes increased as decomposition progressed. The changes in microbial diversity and taxonomy that occurred over the 21-day decomposition period differed enough to be included in PMI modeling using machine learning. Overall, in a model built using data from all facilities, the microbiome data could be used to predict the PMI within 3-4 days. Prediction errors from models generated for each facility were similar, with samples predicting PMI within 2-4 days. Each model was also tested across facilities; models trained within a single facility were used to predict PMI at each of the other two facilities. On average, these cross-facility testing errors were within 4.5-6.5 days. The higher error is likely due to temperature ranges in testing sets that were beyond those in the training sets.

Overall, this study confirmed the concept proposed in previous research that the microbiome associated with decomposing mammalian tissue varies in a clock-like pattern. Furthermore, this was then applied to generate predictive models to estimate PMI. These models were accurate, and in future study can be improved by the addition of higher sample numbers and perhaps a longer sampling period. Future work will also include similar results from the summer, fall, and winter seasons to build a fully generalizable model.

### H103 Scanning Electron Microscopy (SEM) in the Identification of Fly Artifacts (FAs): A Preliminary Qualitative Study

Guido Pelletti, MD, Department of Medical and Surgical Sciences, Unit, Bologna, ITALY; Paolo Fais, PhD, Department of Medical and Surgical Sciences, Unit, Bologna, ITALY; Alberto Amadasi, MD\*, Università di Bologna, Bologna 40126, ITALY; Chiara Palazzo, MD, Bologna, ITALY; Maria Carla Mazzotti, MD, Department of Medical and Surgical Sciences, Unit, Bologna, ITALY; Laura Ingrà, PhD, Department of Biomedical and Neuromotor Sciences, Bologna, ITALY; Desiree Martini, PhD, Department of Biomedical and Neuromotor Sciences, Bologna, ITALY; Susi Pelotti, MD, University of Bologna, Bologna 40100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand that SEM is a useful and promising tool to assist in the differential diagnosis between FAs and unaltered bloodstains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing a key aspect of bloodstain pattern analysis, since many techniques have been applied for the differential diagnosis between bloodstains and FAs, but most of them rely on the experience and opinion of the analyst rather than on standardized and reproducible methods. Morphological analysis through SEM may provide reliable objective parameters to daily forensic casework.

Bloodstain Pattern Analysis (BPA) has a key role in crime scene investigation. After deposition, bloodstains can be altered by diverse forces, some of which are related with the crime, while others may act as confounding factors, such as the stains produced by insect activity, which are commonly referred to as FAs. Flies can produce FAs in different manners: by contact, by regurgitation, and by defecation. Differential diagnosis between FAs and bloodstains is sometimes cumbersome, especially in cases of small stains (0.1cm–0.3cm). Several techniques and methods of analysis have been used to differentiate between unaltered bloodstains and FA, such as visual macro-microscopic and contextual analysis, heme-based presumptive tests and immunological confirmatory tests. However, these techniques mostly rely on the experience and opinion of the analyst rather than on standardized and reproducible methodology.

The present survey aimed at testing the potential utility of SEM for distinguishing bloodstains from FA produced by *Sarcophaga carnaria* under experimental conditions.

One hundred adults of *Sarcophaga carnaria* were placed in a scaled-down room analog with free access to 50ml of fresh human blood and were free to deposit fly artifacts on five different surfaces (two porous and three non-porous types of paper) for 48 hours. Experimentally produced bloodstains were used as controls. FAs and controls were compared through visual analysis (color, shape, tail, edges) and SEM analysis (surface, deposits, presence of red blood cells) analysis.

Visual analysis allowed the identification of two types of FAs. Type 1FAs (FAs1) showed brownish color with no or short tails and resembled the controls, while Type 2FAs (FAs2) showed yellow-brownish color with longer and curved tails, being easily distinguishable from controls and FAs1. SEM analysis allowed the distinguishing between controls and FAs through the identification of red blood cells on the surface of the controls, which were absent in both types of FAs. Other distinctive morphological features were observed: (1) FAs1 showed luminescent deposits on the surface, which were absent on controls and FAs2; and (2) FAs2 showed irregular/glomerular surfaces, while controls and FAs1 showed flat or cratered surfaces.

Based on these features, the detection through SEM of red blood cells on the surface of the controls was the key element for the differentiation between FAs and bloodstains, since red blood cells were present in all controls and absent in all FAs. Other features can be considered to confirm the differential diagnosis, such as the presence of luminescent deposits and the morphological features of the surface of the spot.

Therefore, SEM analysis demonstrated to be a useful tool for the distinction between FAs and unaltered bloodstains, since it allowed identification of some objective morphological features that do not rely on subjective evaluation. In the future, this technique could be used for the differentiation of FAs and bloodstains deposited by different species on other types of surfaces to assess the potentialities of this technique in real forensic scenarios.

### H104 Forensic Imaging in Two Cases of Survived Car Surfing in Zurich, Switzerland

*Michela Lanfranchi\**, Zurich Institute of Forensic Medicine, Zurich 8057, SWITZERLAND; *Michael Thali, MD\**, Universitat Zurich, Zurich CH-8057, SWITZERLAND; *Wolf Schweitzer\**, Universitat Zurich, Zurich CH-8057, SWITZERLAND

**Learning Overview:** The goal of this presentation is to demonstrate the use of clinical Computed Tomography (CT) in forensic reconstruction of car surfing and in the differentiation of the presented injuries in the overall context containing different possibilities for injury causation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enabling attendees to appreciate the power of dedicated forensically reconstructed CT images based on clinical CT images in conjunction of conventional photographic documentation in the specific context of car surfing.

**Proposition:** That clinical CT is highly relevant in the forensic reconstruction of survived car surfing victims.

**Introduction:** Car surfing describes the ride that a person experiences or performs when holding onto the outside of a passenger car, which is not legally approved on public roads. The discrimination of injuries as consequence of car surfing appear to be of particular legal, and therefore forensic relevance, not only because of injury severity but also the risk that has to be considered and assessed. With the insight and experience of the Virtopsy project, which now overlooks a time span of 25 years with forensic Postmortem Computed Tomography (PMCT), applying that knowledge based on forensic postmortem imaging to clinical cases is an increasing focus in forensic medicine.

**Cases:** This case series contains two cases of car surfing that were investigated by this study. In both cases, forensic physicians from the Zurich Institute of Forensic Medicine performed a physical examination of the victim with a forensic scientist. The examination was supplemented with a retrospectively added forensic assessment of high-resolution CT images that had been acquired in the respective emergency departments where the victims had been admitted.

**Results:** The two unrelated cases both featured male car surfers in their early thirties, found riding on the hood of a car. Both car rides appeared to have been escalations of a preceding verbal and physical argument. In the first case, forensic examination was performed approximately six hours after the event. The driver of the car was an enraged taxi driver, and the car surfing ride was alleged to have reached up to 125kmph (77mph). In the second case, forensic examination took place 13 hours after the event. There, the driver was an allegedly petrified escort girl, in which the driving speed was not known but the glass of the windshield had sustained fractures. In both cases, the individuals were severely injured after they had fallen off the hood. They had to be brought to the local hospital emergency departments. In the first case, with the head, torso, and extremities injured, the most severe trauma was to the feet, with a very significantly abraded left great toe. Two lacerations on the head had to be surgically treated with stitches. The second case featured several fractures to the skull, and the clinical course was primarily defined by the severe blunt head trauma. There also were abrasions to the upper extremities typical for finger nails. Forensic questions into both cases contained differentiation between injuries sustained from a physical fight, from those sustained while car surfing, from those sustained as consequence of falling from the car.

**Conclusions:** In both cases, CT imaging was relevant from a forensic point of view for event reconstruction. The victim in the first case sustained a relatively serious toe injury and two lacerations of the head that required surgical repair. In particular, the second case benefited both from extensive visualization of the skull fracture patterns that were interpreted and with comparison against the forensic photographs of the car. In this presentation, both cases will be presented with extensive images of both CT and ancillary photography.

#### Virtopsy, Car Surfing, Forensic Imaging

### H105 Postmortem Computed Tomography (PMCT) Versus the Skeletal Survey in Children: A Pathology-Proven Study

*Esther L. Van De Mortel, MSc, Master's Programme in Forensic Science, Faculty of Amsterdam, Noord-Holland, NETHERLANDS; Judith Fronczek, MD, PhD, Department of Forensic Medicine, Netherlands Forensic Institute, The Hague 2497 GB, NETHERLANDS; Simon G.F. Robben, MD, PhD, Department of Radiology, Maastricht University Med, Maastricht 6229 HX, NETHERLANDS; Rick R. Van Rijn, PhD\*, Amsterdam UMC, Amsterdam 3544MT, NETHERLANDS*

**Learning Overview:** After attending this presentation, attendees will understand the value of skeletal surveys and PMCT in deceased children with respect to the detection of fractures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing a potential new approach to postmortem pediatric imaging in cases of suspected physical abuse.

Annually, between 118,000 and 180,000 children in the Netherlands are exposed to some form of abuse. Of these children, 18% are physically abused. It has been shown that child abuse not only has short-term but also long-term effects on the (mental) health of a child. Therefore, it is important to detect child abuse as early as possible to protect the health of the child and to prevent further injuries, of which death is the most extreme outcome. To do this, non-accidental injuries should be recognized correctly by the physician and an imaging technique should be available to accurately detect abuse-related injuries. In children under the age of 3 years, a skeletal survey is a mandatory procedure in the work-up of suspected physical abuse. This skeletal survey consists of a predefined set of Conventional Radiographs (CR) as defined by the Royal College of Radiologists and the Society and College of Radiographers.

In recent years, several studies in adults have shown that Computed Tomography (CT) has a higher sensitivity for rib fractures and skull fractures, for example. However, it is not clear if this is true for children as well, or if CT has the ability to detect small metaphyseal corner fractures.

The goal of this research was to determine whether it was possible to (partly) replace the skeletal survey by PMCT. For this determination, deceased children younger than five years referred to the Netherlands Forensic Institute for a forensic autopsy in whom both a skeletal survey and a PMCT scan were obtained were included in this study. Included cases were retrospectively reviewed by an experienced pediatric radiologist. The fracture patterns on CR and CT were scored and evaluated. Out of 55 eligible cases, fractures were observed in 24 cases (16 boys (mean age: 3.25 months, age range: 1–8 months) and 8 girls (mean age: 3.25 months, age range: 0–13 months). Radiology findings were compared to full autopsy reports.

CR and CT were concordant in 36 cases and non-concordant in 19 cases. It was shown that CT detects significantly more rib fractures compared to CR or autopsy ( $p=0.01$  and  $p=0.004$ , respectively). Also, CT detected more skull fractures compared to CR. In contrast, CR had a higher sensitivity compared to PMCT (e.g., metaphyseal corner fractures), where PMCT missed two out of three fractures. Autopsy was superior in detecting basilar skull base fractures ( $N=5$ ), which all were missed by CT and CR.

These results suggest that radiographs of the thorax and skull can be excluded from the skeletal survey in a postmortem setting. However, it is shown that PMCT cannot completely replace the skeletal survey, as clinically relevant metaphyseal corner fractures were missed on CT. Based on these findings, it is suggested that a whole body PMCT with additional radiographs of the joints, hands, and feet may be a viable option in a forensic postmortem setting.

#### Child Abuse, Fractures, Radiology

### H106 Upper Versus Lower Limb Pediatric Fracture Healing: A Radiographic Study of Time Since Injury (TSI)

Diana L. Messer, MS\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickham, HI; Brent H. Adler, MD, Nationwide Children's Hospital, Columbus, OH 43205; Farah W. Brink, MD, Nationwide Children's Hospital, Columbus, OH 43205; Huiyun Xiang, MD, PhD, Nationwide Children's Hospital, Columbus, OH 43205; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH 43210

**Learning Overview:** After attending this presentation, attendees will understand the influence of fracture location on pediatric fracture healing and its potential impact, in both forensic and clinical contexts, for radiographic methods of TSI estimation, particularly in cases of child physical abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting that not only should future TSI methods be specific to fracture location, but that the utility of methods derived from pooled bone samples may be inaccurate and inappropriate for use in a forensic or clinical setting. Improved TSI methods may lead to more accurate identification of child physical abuse that can inform decision-making regarding child protection.

The relationship of fracture location to healing is vastly understudied and its potential impact on TSI estimates remains largely unknown. As a result, timelines of pediatric fracture healing are often based on pooled samples of skeletal elements, which may not provide accurate results if healing rates differ significantly by location. Malone et al. suggest differences in healing between fractures of the radius and tibia, but whether this applies to all bones of the upper and lower limb remains unknown, and few, if any, existing methods take fracture location into account.<sup>1</sup>

This study assesses radiographic features of fracture healing in a modern pediatric sample of accidental fractures to evaluate whether fracture location (upper vs. lower limb) significantly influences rate of fracture healing.

Four hundred ninety-eight skeletal fractures (>1,355 radiographs) at Nationwide Children's Hospital in Columbus, OH, were evaluated for features of fracture healing, specifically fracture margin definition, Subperiosteal New Bone Formation (SPNBF), and callus formation. Features of SPNBF and callus were recorded for presence, thickness, matrix, and character based on modified parameters set by Walters et al.<sup>2</sup>

Independence and goodness of fit frequency tests were used to evaluate the relationship between fracture age and levels of SPNBF, callus formation, and fracture margin definition. Analysis of covariance tests were conducted to control for patient age, which has been demonstrated to affect fracture healing.<sup>3</sup>

Results of this study demonstrate that limb location significantly affects SPNBF thickness ( $p < 0.001$ ), with SPNBF occurring earlier in upper limb fractures. In addition, SPNBF thickness that was greater than 75% of the original bone shaft width only occurred in upper limb fractures. Limb location also significantly affects SPNBF character ( $p < 0.05$ ), with single-layered and multi-layered SPNBF occurring earlier in upper limb fractures. Further, limb location significantly affects callus thickness ( $p = 0.002$ ), with callus formation appearing thicker earlier, and lasting for a shorter duration, in upper limb fractures.

### H107 Virtopsy in Clinical Forensic Medicine: A Trauma Case Series With Clinical Emergency Computed Tomography (CT) Reconstruction Details

Eddie Surer, MD\*, Zurich Institute of Forensic Medicine, University, Zurich 8057, SWITZERLAND; Michael Thali, MD\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Rosa M. Martinez, MD\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Valeria Hofer\*, University of Zurich, Zuerich CH-8057, SWITZERLAND; Michela Lanfranchi\*, Zurich Institute of Forensic Medicine, Zurich 8057, SWITZERLAND; Wolf Schweitzer\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND

**Learning Overview:** The goal of this presentation is to explain in detail how image quality and resolution of clinical emergency CT images serves to solve forensically relevant questions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how good emergency CT data is considering forensic analysis of even relatively small survived injuries.

**Introduction:** Emergency CT images have a therapeutic focus, and axial images have been the mainstay of their interpretation. That data has been regarded as inadequate for forensic questions as reconstructive forensic approaches also heavily employ Multiplanar Reconstruction (MPR), and 3D techniques demand sufficient resolution also of the third dimension (z-axis, slice distance). This case series provides examples of the forensic use of that data.<sup>1</sup>

**Cases:** Case 1 features blunt head trauma of a bicycle rider found with a nose bleed and visible facial injuries but no bicycle. The forensic question was to discriminate between blows against head and a fall. Case 2 features a sternal stab wound with the forensic question of why, as there were more than 20 mostly very superficial stab wounds allegedly delivered by a single person, there was no other fracture. Case 3 features a firearm injury to the head with the forensic question why the bullet exited with deformation, seeing as there was a straight line from entrance (right neck) to exit (left eye) that did not contain thick bone. Case 4 features multiple stab wounds to head and torso with questions as to how deep and how close to vital structures they were. CT scan details were accessed through Digital Imaging and Communications in Medicine (DICOM) -header tags.

**Results:** Resolution of clinical emergency CT scans was 0.35mm to 0.46mm inplane (x/y) and 0.5mm to 0.7mm (z) for head scans and 0.88mm to 0.97mm (x/y) with 1mm to 1.5mm (z) for thorax and abdomen scans. Anisotropy (percentage: z relative to x/y) was 141%±36%. The time required to acquire data to reconstruct a head CT at maximal z-resolution of 0.5mm was 26 seconds, not that different from a head scan with less z-resolution (such as 0.7mm), where the longest duration in this case series was 33 seconds. Thorax CT scans took 6 to 10 seconds with substantially larger image thicknesses.

In Case 1, burst fracture lines, some of them quite thin, showed a combined burst and impression fracture system to the face typical for severe blunt trauma, such as riding a bicycle into a street sign at relatively high speed, matching the victim's statement. In Case 2, features of both a sternal foramen and sharp force injury to the bone could be discriminated, explaining why a relatively superficial stab wound injury pattern was not a contradiction to a perforated sternum. In Case 3, the bullet track also containing a ricochet area at the orbital rim of the left eye containing a subtle hairline fracture could be visualized in detail. In Case 4, all deep stab injuries could be reconstructed to answer regarding their depth and proximity to vital structures.

**Discussion:** Clinical emergency CT uses similar machines as those used for Postmortem CT (PMCT), so they have no intrinsically lower data quality. In all these cases, visualizations were achieved that answered the forensic questions not only with plausibility but with confidence. While resolution of CT scanners generally is sufficient for many forensically relevant injuries, even limited resolution or quality of radiological images has been shown to be relevant in the context of forensic medicine in the past.<sup>2,3</sup>

### H108 My Darkest Hour: Bringing a Consumer LED Torch Light Into Forensic Macrophotography Through 3D-Design of a Lamp Mount for a Consumer Point-and-Shoot Camera

Wolf Schweitzer\*, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*; Valeria Hofer\*, *University of Zurich, Zuerich CH-8057, SWITZERLAND*; Rosa M. Martinez, MD\*, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*; Michael Thali, MD\*, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*

---

**Learning Overview:** After attending this presentation, attendees will understand how a mounted Light-Emitting Diode (LED) can result in great forensic macroscopy photos with a point-and-shoot consumer camera.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how extremely affordable materials (3D-printed lamp mount, LED torchlight) can cause massive quality improvements in forensic macrophotography.

Macrophotography contains an application domain with an extremely limited parameter space circled by sensor size, aperture, exposure time, and International Organization for Standardization (ISO) number. This study pragmatically asks how to proceed to achieve cost-effective equipment for around ten assistant doctors of a medicolegal institute to perform optimal hand-held “action” shots on death scenes or event scenes or during clinical forensic medicine examinations. The benchmark lesion is the single conjunctival pinpoint hemorrhage as encountered after strangulation.

**Analysis, Methods, and Materials:** High aperture numbers (i.e., small opening) promise great depth-of-field and not only reduce but also diffract light, which lowers image quality, particularly on small sensors. Reduced light is remedied with higher ISO numbers that increase visual noise. Increasing exposure time risks motion blur. Despite optimizing these parameters, image quality remains severely restricted. This study fitted an LED lamp (CREE-XML-T6, ~\$2 USD) on a 3D-designed hot-shoe fitted mount with an interlocking joint (3D-printed PLA ~\$1.50 USD, screw assembly ~\$2.20 USD) on the consumer camera (Canon® G16, modified firmware to read out scene illumination in  $L=cd/m^2$ ), yielding a total cost of the LED lamp including Mount (LEDMNT) of ~\$4.20 USD (not counting batteries). This study compared images in realistic settings photographed: (1) with no extra light; (2) using LEDMNT; and (3) the integrated as well as a hot-shoe mounted Canon® Speedlite 270EXII flashlight.

**Results:** A first series of 20 photos of skin injuries photographed postmortem at normal autopsy room ceiling light showed that luminance measured on the sensor at a medium range ( $28cd/m^2$ – $60cd/m^2$ ) dropped to  $2cd/m^2$ – $10cd/m^2$  for close range macro photos with no extra light source (1). Using the LEDMNT (2) values of  $90cd/m^2$ – $500cd/m^2$  were achieved while flashlight (3) caused significant shadows in close-range macro photos. The image quality improved drastically after installing the LEDMNT.

**Discussion:** It is not a new insight that more light can improve photographs. However, this contribution is not theoretic but practical and represents an extremely affordable and practical approach to a very relevant problem.

#### Virtopsy, Forensic Macro-Photography, 3D Printing

### H109 Role of Postmortem Computed Tomography (PMCT) as a Triage Tool Between External Inspection and Full Autopsy

Vasiliki Chatzaraki, MD\*, Institute of Forensic Medicine Zurich, Zurich CH-8057, SWITZERLAND; Jakob Heimer, MD, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Michael Thali, MD, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Wolf Schweitzer\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND

**Learning Overview:** The goal of this presentation is to show the current advantages and weaknesses of PMCT usage in the forensic pathologist's routine. As imaging has been expanded around the world as a supplement to conventional autopsy, it is important to consider the strengths as well as the limitations and pitfalls.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the strengths of PMCT regarding determining the cause and manner of death and excluding or indicating signs of violence. However, there are also limitations in PMCT usage, which may be solved by increasing the quality of image acquisition and doing more research in the field. Combining imaging with toxicological analysis and biopsies is also recommended.

**Objectives:** In forensic medicine, PMCT and PMCT Angiography (PMCTA) assist in determining cause and manner of death, providing significant information regarding specific forensic questions.<sup>1-3</sup> After the external examination of a body, PMCT appears to be a valuable tool for imaging-based decision making, whether or not conducting an autopsy is necessary. The role of PMCT has become increasingly interesting as a method to improve decision making rather than a one-stop solution for all forensic morphological postmortem issues. Its costs can be significantly lower than those of a conventional autopsy, and the information gained can be significant. Its relevance is dependent on the specific forensic question; however, that forensic question is always case dependent. With that, not all that is visually apparent on PMCT also forensically solves every case. Within that domain of application, a series of ten cases is presented to qualitatively highlight the advantages and remaining problems of the current PMCT usage.

**Materials:** Due to their relevance for the question of decision making, a deliberate and manually selected case series of ten PMCT examinations was selected from the Institute of Forensic Medicine Zurich's database (time range 2014 to 2017). All cases had been admitted to the Institute following a forensic death scene investigation for further examination and assistance in judicial decision making. In five of the cases, a forensic autopsy was conducted after imaging. One case underwent PMCTA in addition to unenhanced PMCT. In one case, a CT-guided lung biopsy was performed. In eight cases, toxicological analyses of body fluids (qualitative toxicological screening within PMCT triage or quantitative after collecting blood and urine during autopsy) were conducted. Time interval between death and PMCT was 14.9h±12.8h (range: 3h to 48h). All case protocols were evaluated for the final manner and cause of death.

**Results-Conclusion:** Five cases were released after imaging without conducting an autopsy as PMCT-PMCTA alone or combined with toxicological screening or lung biopsy confirmed a cause and manner of death and/or excluded third-party involvement/malpractice or ensured identity, answering the relevant forensic questions required. In one case, PMCT revealed a large number of tablets in the stomach, supporting the already-assumed cause and manner of death; however, toxicological analysis did not match the drug suspected according to scene inspection. In another case, PMCT failed to reveal laryngeal fractures indicating violence and possible homicide. In the other two cases, PMCT indicated infectious disease without being able to confirm a microbiological diagnosis; however, it warned the pathologists to protect their health during autopsy.

PMCT can satisfactorily answer the leading forensic questions of some cases alone, like the validation of the victim's identity, the exclusion of third party violence, and the presence of foreign bodies and determine the cause and manner of death. Thus, a conventional medicolegal autopsy can be avoided as all relevant forensic questions are answered, which is also time and cost consuming. However, reliable evaluation of relevant head and cervical trauma, strangulation, infection and sepsis, metabolic disorders, intoxication, and neuroreflex deaths keeps evading a purely PMCT-based approach.<sup>4,5</sup>

### H110 Postmortem Fetal Angiography: A Tool for Better Understanding Congenital Vascular Malformations

*Jessica Vanhaebost\**, Brussels, BELGIUM; *Xavier De Spiegeleire, Bac*, Cliniques Universitaires saint-Luc, Brussels 1200, BELGIUM; *Gregory Schmit, MD*, Service de Médecine Légale, Brussels 1200, BELGIUM; *Catherine Behets, PhD*, Université Catholique de Louvain - Pole of Morphol, Brussels 1200, BELGIUM; *Emmanuel Coche, PhD*, Cliniques Universitaires Saint-luc, Brussels 1200, BELGIUM

---

**Learning Overview:** The goal of this presentation is to adapt postmortem angiography to a small-caliber vascular system, as found in the fetus, and to evaluate the feasibility of the fetal postmortem angiography in a routine clinical examination. After attending this presentation, attendees will understand the feasibility and impact of the intravascular injection of contrast medium to detect vascular malformations. Preliminary results will be shown and discussed with attendees.

**Impact on the Forensic Science Community:** Few articles have been published on this topic or how to handle this type of forensic question. The injection technique, involving an oily contrast agent dedicated to postmortem examination using a multislice Computed Tomography (CT) scan has seemingly never before been performed in a fetus. Therefore, this presentation will impact the forensic science community by providing a methodological approach to this medicolegal issue. This method will also impact the forensic community in cases of untimely intra-uterine death, which raises questions about the obstetric management of pregnancy and may lead to complaints from parents.

**Method and Material:** In order to demonstrate feasibility, ten fetuses (fresh and frozen) were investigated by whole-body postmortem CT scanner with the following parameters: slice thickness: 0.4 mm; field of view: 25cm, 80kV, and 168mAs, using a multislice CT scan (Definition 40) in single-energy mode, without and after intravascular injection (very low flow) of contrast medium dedicated to postmortem examination (Angiofil®) by umbilical or transcardiac injection under ultrasound control. The images were reconstructed on a workstation using a dedicated software.

**Results:** The results show the feasibility of injection and opacification of the entire fetal vascular system without any tissue extravasation in a very important postmortem delay (up to two years after death) by umbilical vessels. The amount of contrast agent necessary to opacify the entire vascular system is approximately 15mL. The time required to obtain an access route for the injection was essentially dependent on the state of preservation of the fetus. Arteries and veins of large caliber and infra-millimeter vessels could be visualized during the CT examinations.

**Conclusion:** This study demonstrates the feasibility of postmortem angiography of the fetus and its ability to opacify very small visceral vascular structures on multi-slice CT. Further investigations, especially autopsy, are needed to compare the findings side-by-side and understand the clinical and medicolegal implications of such imaging.

---

### Fetal, Angiography, Vascular Malformation

### H111 The Value of Craniocervical Magnetic Resonance Imaging (MRI) Following Non-Fatal Strangulation

Jakob Heimer, MD\*, *Universitat Zurich, Zuerich CH-8057, SWITZERLAND*; Carlo Tappero, *Institute of Forensic Medicine, Zurich, SWITZERLAND*; Dominic Gascho, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*; Patricia Flach, PD, *Kantonsspital St. Gallen, St. Gallen, SWITZERLAND*; Thomas Ruder, PD, *Northland District Health Board, Whangarei, NEW ZEALAND*; Michael Thali, MD, *Universitat Zurich, Zurich CH-8057, SWITZERLAND*; Sabine Franckenberg, MD, *Diagnostic and Interventional Radiology, Zurich 8091, SWITZERLAND*

**Learning Overview:** After attending this presentation, attendees will be updated on the current state of magnetic resonance imaging following non-fatal strangulation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing a well-founded idea of when MRI following non-fatal strangulation is worth logistic and financial efforts.

**Introduction:** Manual strangulation is a form of assault frequently encountered in the context of domestic violence targeted against women. Manual strangulation results in a wide range of health impairments, including death. At the same time, external findings are often absent or scarce. To reveal possible internal injuries not observable in external documentation, MRI was introduced to the forensic examination of strangulation survivors a decade ago. Both Yen et al. and Christe et al. described various findings related to the assault, and suggested MRI to be a worthwhile asset in the medicolegal investigation.<sup>1,2</sup> The University of Zurich has offered MRI to every victim of manual strangulation since 2011. Based on a database of 114 completed MRI examinations at the time, this study present results on the value of craniocervical MRI following manual strangulation.

**Methodology:** All cases were routinely examined including a full documentation of case history and photographic documentation of external findings. Cases were then invited to undergo craniocervical MRI and were issued a gratification card for free transport to the clinical examination center. MRI was conducted as fast as possible with dedicated sequences. Radiologic images were evaluated by a clinical radiologist and a forensic radiologist. Case data was grouped into external findings (hematoma, abrasions, swelling), subjective findings (localized pain, difficulty swallowing and/or breathing, loss of urine and/or feces, loss of consciousness) and MRI findings (sub-cutaneous, intramuscular, and peri-laryngeal fluid accumulations, lymph node hemorrhage).

**Results:** The case group consisted of 94 women and 24 men with a mean age of 32.5 years. The most prevalent methods of attack were both-handed (41.1%) and one-handed (41.2%), followed by chokeholds (12.3%), and manual ligature strangulation (4.4%). More men than women were victims of chokeholds. Visible external findings were present in 106 (93%) cases. Subjective findings were reported by 95 cases (83.3%). MRI yielded positive findings in 49 (43%) cases, with a total number of 75 radiologic findings. In 7 cases, MRI was positive while no external findings were delimitable. MRI findings of (peri-)laryngeal structures were significantly associated with reported difficulty swallowing and chokeholds. In only one case did cranial MRI yield a positive result, but an association with the assault could not be safely established.

**Discussion:** The additional value of craniocervical MRI in victims of non-fatal strangulation is limited to victims of severe attacks and reported subjective symptoms, when no or few external findings are delimitable. For a low sensitivity-reproduction of superficial fluid accumulations, logistical and financial efforts of MRI appear not to be justified. The stark contrast to the number of findings of previous studies calls for a common definition and standardization of radiological findings. The acquisition of cranial MRI is not feasible, unless it is routinely indicated by the presence of neurological symptoms.

### H112 Evaluation of Arterial Injuries Using Contrast and Conventional X-Rays: A Practical Method for the Assessment of Arterial Injuries in Forensic Settings

*Nikki Mourtzinou, DO\**, Office of Chief Medical Examiner, Baltimore, MD 21204; *Zabiullah Ali, MD*, Office of Chief Medical Examiner, Baltimore, MD 21223; *David R. Fowler, MD*, Office of Chief Medical Examiner, Baltimore, MD 21223

---

**Learning Overview:** After attending this presentation, attendees will understand the utility of using contrast injection and conventional radiography to identify and diagnose vascular injury in a routine autopsy setting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a practical and inexpensive method to identify vascular injuries during autopsy.

Postmortem vascular visualization, using various contrast agents, has been in use since the 17<sup>th</sup> and 18<sup>th</sup> centuries to study vascular anatomy. With advances in radiology, Multidetector Computed Tomography (MDCT) has been increasingly used for vascular and soft tissue imaging in forensic settings. The use of MDCT angiography is more common in European countries, but due to excessive costs, only a handful of medical examiner offices in the United States are equipped with MDCT. As a result, most medical examiner offices continue to use conventional radiography to aid in the assessment of vascular pathology in forensic settings. At the Office of the Chief Medical Examiner (OCME) for the State of Maryland, MDCT is available and has proven a useful tool in the assessment of traumatic injury at autopsy, although time constraints and/or staff training impedes the practical use of MDCT on a consistent basis. This study performed targeted arterial angiography as an adjunct to routine autopsy using conventional radiography. In forensic autopsies, identification and dissection of vascular regions can prove critical in determining a cause of death, but in many cases, access to these regions can prove time consuming, invasive, and at times, impossible. A goal of this study was to evaluate these hard-to-access vascular regions that remain cumbersome for forensic pathologists, especially in a busy metropolitan office. Another objective of this study was to concentrate on the practical and logistic aspects of visualizing the vascular anatomy and associated trauma, which could be used daily in a busy medical examiner's office.

Although numerous different contrast media are available for use in clinical and postmortem angiography, this study achieved excellent results using a water-soluble, barium-based contrast agent that is easily obtainable with minimal cost implications. To achieve better imaging quality, the vessels were flushed prior to contrast injection using tap water to remove any air bubbles or postmortem clots. There was no difference between using saline or regular tap water for flushing of the vessels.

Study cases were selected based on the likely presence of visualizing vascular trauma and included gunshot wounds, stab wounds, and motor vehicle/pedestrian injuries. In some cases, visualization of vascular injury was well-correlated with subtle gross autopsy findings that may otherwise have been overlooked. This study demonstrates that using contrast injection combined with conventional radiography provides medical examiners with an additional and inexpensive tool for assessing vascular injuries and associated trauma during autopsy.

---

**Contrast Agent, Conventional X-Rays, Vascular Injuries**

### H113 The Needle in the Haystack: Histology of Postmortem Computed Tomography (CT) -Guided Biopsies Versus Autopsy-Derived Tissue

*Bartholomeus G.H. Latten, MSc\*, Nederlands Forensisch Instituut, Den Haag, Zuid Holland 2497 GB, NETHERLANDS; Frans Bakers, Maastricht University Medical Centre, Maastricht, Limburg 6229HX, NETHERLANDS; Paul Hofman, PhD, Maastricht University Medical Center, Maastricht 6202 AZ, NETHERLANDS; Axel zur Hausen, MD, PhD, Maastricht University Medical Centre, Maastricht, Limburg 6229 HX, NETHERLANDS; Bela Kubat, PhD, Nederlands Forensisch Instituut, Den Haag, Zuid Holland 2497GB, NETHERLANDS*

**Learning Overview:** The goal of this presentation is to make a critical statement concerning the inferiority of histological examination of postmortem CT-guided biopsies in comparison to tissue derived during the classic autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the limitations of postmortem imaging/minimal invasive autopsy and raising reasonable doubts concerning new non-validated techniques.

**Objective:** During the last decade, autopsies have been declining worldwide, whereas non-invasive methods have been proposed as an alternative for the classic autopsy. Some of these methods add needle biopsies to imaging techniques to provide an alternative to histological examination of autopsy-derived tissue. The goal of this study was to investigate the representativeness of the histology of CT-guided postmortem needle biopsies in comparison to autopsy derived tissue from the same organ.

**Method:** Consent of next of kin was obtained from relatives of the deceased within the department of Internal Medicine to perform an autopsy, postmortem CT, and CT-guided needle biopsies. The lungs and the liver were routinely sampled with CT-guided postmortem biopsies and during the autopsy. In addition, optionally extra CT-guided biopsies of lesions reported on the CT were sampled. The biopsy and the autopsy reports were independently reported and retrospectively coded according to the Nationwide Network and Registry of Histo- and Cytopathology in the Netherlands (PALGA). Three pathologists with an interest in autopsy pathology and three physicians of the department of internal medicine separately and independently interpreted all histological results in relation to the cause of death as formulated in the autopsy report. Fleiss's Kappa was calculated, and a consensus grade was defined.

**Results:** Fleiss's Kappa showed substantial agreement in both lungs and moderate agreement in the liver. Of the 60 included cases, 43% of the CT-guided postmortem biopsies in the left lung and 30% in the right lung showed false negative findings, primarily concerning a bronchopneumonia. In contrast, 91% of the liver biopsies showed concordant results; however, only 22% of these concerned a major diagnosis related to the cause of death. The positive predictive value of the biopsies of the left lung, right lung, and the liver were, respectively, 86.8%, 88.9%, and 100%. The negative predictive values of these biopsies were 34.3%, 50% and 92.7%, respectively.

**Conclusion:** CT-guided postmortem biopsies of the lungs have a mediocre predictive value. Due to a low prevalence of relevant findings, the overall usefulness of biopsies of the liver is limited. Conventional autopsy should still be preferred to biopsy-based postmortem examination. Postmortem biopsies are only an alternative if consent for an autopsy cannot be obtained.

#### Biopsies, Autopsy, Histology

### H114 Deep Learning on Volumetric Radiologic Imaging Datasets for Forensic Pathology Investigations

*Summer J. Decker, PhD\*, University of South Florida, Tampa, FL 33606; Lars C. Ebert, PhD\*, University of Zurich, Zurich CH-8057, SWITZERLAND; Jonathan M. Ford, PhD, University of South Florida, Tampa, FL 33606-3571; Akos Dobay, PhD, University of Zurich, Zurich CH-8057, SWITZERLAND; Natalie L. Adolphi, PhD, Center for Forensic Imaging, Albuquerque, NM 87131; Kurt B. Nolte, MD, Office of Medical Investigator, Albuquerque, NM 87131-0001*

---

**Learning Overview:** After attending this presentation, attendees will understand: (1) the concepts of Artificial Intelligence (AI) and Deep Learning (DL), (2) the hardware and software needs, (3) the potential impact of automated analysis on Postmortem Computed Tomography (PMCT) imaging, and (4) the greater role AI algorithms such as DL will play for forensic pathology in the future.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential utility of DL as an automated triage tool for PMCT.

Traditionally, Forensic Pathologists (FP) perform an external examination, then document internal pathologies via the autopsy. Imaging modalities, such as PMCT, can establish the cause of death in certain types of cases and better elucidate specific traumas. Postmortem medical imaging also has the added value of helping with teaching, expert witness demonstration, quality control, and telemedical consultation. The flexibility of medical imaging can assist an already-overtaxed Medical Examiner (ME) system as either a tool for triaging cases or supplementing the autopsy process. The growing opioid crisis in the United States has dramatically increased the number of autopsies needed and threatens National Association of Medical Examiners (NAME) accreditation compliance for many offices based on excessive workload. Pathologists attempting to accommodate these expanded caseloads without adequate support can become fatigued and prone to error.

While PMCT can significantly reduce the burden on offices, FPs still may not have adequate time to search for more routine but tedious findings, such as the thorough detection of bone fractures or volume estimation of organs. To further reduce time and costs for interpreting images generated, assistance systems for image reading are required. Current advances in clinical radiology are being made toward adopting DL for patient care. Studies are showing the impact of DL in areas such as the identification of lung nodules and automated brain tumor segmentation. Similar studies must be undertaken to enable use of this technology with respect to forensics. As postmortem scans have unique findings that do not occur in images from living patients, existing DL techniques will require some modifications. Postmortem imaging datasets tend to be larger, have a greater number of images and different scanning protocols, detect different pathologies and artifacts in addition to other complications, such as decomposition and extensive polytrauma.

Clinical radiology has already made significant headway in leveraging DL as a triage and first-pass diagnostic tool. However, medicolegal postmortem scanning has unique requirements and, consequently, specific algorithms need to be created. This presentation will demonstrate the use and potential value of DL in analyzing, screening, and triaging PMCT scans to evaluate its potential as a forensic tool. This presentation will provide examples of how a DL workflow is set up as well as representative examples of how DL can tackle specific forensic pathology problems.

As forensic pathologists in the United States continue to adopt advanced radiologic imaging, tools such as DL need to be in place to improve the overall throughput of the medicolegal death investigative process. AI and DL have the potential to address the diagnostic questions facing forensic pathologists in the United States and worldwide.

---

#### Forensic Pathology, Deep Learning, Radiologic Imaging

### H115 Simulation-Based Learning in Forensic Medicine: The Use of 3D Photogrammetry

*Vadim Mesli, MD\**, Institut Medico Legal, Lille Cedex, Nord 59037, FRANCE; *Erwan Le Garff, MD*, Institut Médico-Légal/Forensic Institute, Lille Cedex, Nord 59037, FRANCE; *Vincent Deffaux*, Universite de Lille, Lille 59000, FRANCE; *Elodie Marchand, MD*, Universite de Lille, Lille 59000, FRANCE; *Anne A. Becart, DDS, PhD*, Service De Medecine Legale, Lille 59000, FRANCE; *Valéry C. Hedouin, MD, PhD*, Lille, Hauts De France 59037, FRANCE; *Didier Gosset, MD, PhD*, Institut de Medecine Legale, Lille 59045, FRANCE

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the potential applications of 3D photogrammetry in the field of forensic medicine teaching.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing useful insights and practical examples about 3D photogrammetry technology in a simulation-based teaching context.

Simulation-based learning in medicine concerns educational activities that use an artificial representation of a real-world medical situation. It allows the students to acquire different skills in a safe environment, contrary to in a real-life experience. This methodology is commonly used in various disciplines, such as aviation or economics. It was recently developed in a dematerialized format in the medical field but is not widely used in forensic medicine.

3D photogrammetry is a technology that makes it possible to create a 3D digital model of an object. It is based on the recording and interpretation of photographic images taken from different points of view, to obtain spatial data of the object. 3D photogrammetry was used in different fields, such as engineering, archaeology, or architecture, and was also developed in a wide variety of medical applications. The recent progress of this technology and its algorithms currently enable a large-scale use at low financial costs. This work presents potential applications of 3D photogrammetry at different stages of forensic medicine education.

The detail quality concerning the study of a body, an injury, or a pathological condition is particularly important in forensic medicine courses. Photographs are commonly used for that purpose; however, they are limited by the quality of the image, the perception of colors, the lighting, and the two-dimensional format. Video footages could also be used but are restrained in terms of interactivity with the students. The examination of real bodies could provide the best conditions, but the accessibility to the bodies for pedagogic purposes would be an issue regarding the number of students. 3D photogrammetry enables a capture of a whole organ, injury, or even a whole body in three dimensions, with good image quality. It also allows a good interactivity with the user thanks to its suitability for a touchscreen. The key features of 3D photogrammetry make it a powerful, low-cost, and user-friendly tool to improve teaching to a small or large group of students and for remote learning.

During this presentation, the use of real organs and bodies modeled in 3D with a photogrammetry software will be displayed for first, second, and third cycles of studies, post-graduation, and continuing education courses.

### Photogrammetry, Education, Simulation

### **H116 Anatomical Distribution and Autopsy Features of Gunshot Injuries to Discriminate Between Homicides and Suicides: A Five-Year Retrospective Study From the Onondaga County Medical Examiner's Office**

*Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Robert Stoppacher, MD*, Syracuse, NY 13210

---

**Learning Overview:** After attending this presentation, attendees will better understand the most common features of fatal gunshot wounds encountered in homicides and suicides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the most common body regions affected by gunshot wounds and the relevant autopsy features, showing their relationship with the manner of death.

Firearm-related injuries are commonly encountered by forensic pathologists worldwide. In these fatalities, a careful evaluation of all the evidence is mandatory to prevent wrong conclusions concerning the manner of death. The analysis of the location of the gunshot wounds can be useful to understand the circumstances of death. This study will provide data to support an association between a specific wound location and the manner of death.

The files of the Onondaga County Medical Examiner's Office were searched for deaths due to gunshot wounds between January 2012 and December 2016. Only cases in which gunshot wounds were the primary cause of death and in which a clear and reliable manner of death was reported were included in the study. Undetermined deaths were not considered as part of study population. The investigative report, the autopsy report, and postmortem toxicological studies were reviewed in each case. The following parameters were recorded from the files: manner of death, gender, race and age, firearms and bullets type (if available), number and sites of entrance and exit wounds, shooting distance, internal bullet pathway, blood drugs and/or alcohol concentration, and investigative narratives. The obtained data were then subcategorized as to the manner of death (suicide, homicide, and accident). The information detected on the autopsy report was used to create a graphic reconstruction of the anatomical distribution of the gunshot wounds on the body surface.

A total of 5,231 accepted cases in the studied period were found in the Onondaga County Medical Examiner's Office database, including 626 suicides, 208 homicides, and 2,275 accidents. Of these, 347 deaths due to gunshot wounds were identified and were then subcategorized based on the manner of death, showing: 238 suicides (~69%), 108 homicides (~31%), and 1 accident (<1%). A thorough discussion of the results, including graphical models showing the most common location of the injuries, and demographic data will be presented.

This study will illustrate distinct differences in suicidal and homicidal wounds that should be considered while investigating gunshot wounds related deaths. The autopsy findings, together with the scene findings, the investigative report, and the medical history of the victim, can help determine a reliable manner of death.

### **H117 The Value of Elevated Transaminases, Lipase, and Amylase in Children for Predicting Abdominal Injury After Blunt Abdominal Trauma: Is Laboratory Screening Valuable for Recognizing Physical Child Abuse? A Literature Review**

*Daniel H. Hoekstra, MD, Faculty of Medicine, University of Amsterdam, Amsterdam 1105 AZ, NETHERLANDS; Joost G. Daams, MA, Medical Library, Amsterdam University Medical Center, Amsterdam 1105 AZ, NETHERLANDS; Wouter A. Karst, MD, Department of Forensic Medicine, Netherlands Foren, The Hague 2497 GB, NETHERLANDS; Rick R. Van Rijn, PhD\*, Amsterdam University Medical Center, Amsterdam 3544MT, NETHERLANDS*

**Learning Overview:** After attending this presentation, attendees will understand the value of liver and pancreas enzyme analysis in screening cases of suspected physical child abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the evidence, or lack thereof, behind liver and pancreas enzyme analysis in screening cases of suspected physical child abuse.

Recognition of abdominal injuries after blunt abdominal trauma due to physical child abuse at the emergency department can be very difficult, as the clinical history and physical examination can be deceitful. In several studies, it has been suggested that laboratory screening is useful with respect to liver and pancreas trauma.

The goal of this systematic review is to examine the predictive value of transaminases, amylase, and lipase as a screening tool for abdominal injury in cases of suspected physical abuse.

With the help of a clinical librarian, a search strategy with a focus on the predictive value of different cut-off values of transaminases, amylase, and lipase in predicting abdominal injury or liver injury, confirmed by Computed Tomography (CT), Magnetic Resonance Imaging (MRI), autopsy, or surgical exploration, was designed. Using this strategy, literature was searched in MEDLINE® and EMBASE®. Inclusion criteria were studies in which the participants were children (0–18 years old) presenting at the hospital with suspected blunt abdominal trauma due to physical child abuse or other trauma mechanisms. Studies also had to mention a cut-off value for the laboratory studies. Exclusion criteria were studies in participants older than 18 years, studies relating to penetrating abdominal trauma, and articles written in a non-western language.

A three-stage on-line selection process was used for data extraction using Covidence. Out of 4,287 papers, 15 relevant studies were identified. Data were extracted, and quality assessment was conducted with the usage of QUADAS-2. All data were summarized in an overview table. In all articles, abdominal CT scan was either the only reference test or part of a subset of reference tests. Only in two articles was it reported that the radiologists were blinded for other information when interpreting the CT scan. In the other studies in which abdominal CT scan was part of a subset of reference tests, the other reference standards were also acknowledged gold standards for this research question.

There was a significant variation in reported cut-off levels and, thus, predictive value of transaminases, amylase, and lipase in children with blunt abdominal trauma. With respect to transaminases, it was shown that were significantly higher values in cases of more severe liver injury. This was in contrast to amylase and lipase in which neither initial nor peak levels were significant predictors of a specific grade of pancreatic injury.

Limitations of the literature search were the low number of articles concerning this topic that were useful for answering the research question. Furthermore, all but two articles were retrospective or observational prospectives with an inherent higher risk of bias due to case selection or selective exclusion.

Concluding, this systematic review showed a range of cut-off values used as a threshold in laboratory screening tools for blunt abdominal trauma in children, suspected of physical child abuse, who present at the emergency department. A prospective multicenter study is needed to validate appropriate cut-off values for transaminases, amylase, and lipase. Within these, the study designs should also pay attention to the risk of radiation exposure, cost-effectiveness, timing of laboratory screening, and implementation in daily clinical practice.

#### **Child Abuse, Abdominal Trauma, Screening**

### H118 Optic Nerve Hemorrhage: A Sensitive or Specific Marker of Trauma?

Melissa M. Blessing, DO\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Merrill O. Hines III, MD, Houston, TX 77054; Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Glenn D. Sandberg, MD, Harris County Institute of Forensic Sciences, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will: (1) better understand the optic nerve and nerve sheath anatomy, including histological differences between the Intracranial (IC) and Intraorbital (IO) components; (2) describe how to easily expose and sample the optic nerve during autopsy; (3) describe mechanisms of injury that lead to hemorrhage in one or both optic nerve compartments; and (4) determine when histological review of these components may help to elucidate the cause and manner of death in adult and pediatric autopsies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the utility of gross and histological examination of the optic nerve as it relates to the mechanism of injury and, ultimately, the cause and manner of death.

Optic nerve evaluation is a crucial component of the pediatric autopsy when abusive head trauma is suspected. Initial studies and current literature emphasize the presence or absence of Optic Nerve Sheath Hemorrhage (ONSH)—typically subdural—as an indicator of trauma.<sup>1</sup> While often associated with abusive head trauma, ONSH can be seen in non-traumatic settings and thus is non-specific.<sup>2,3</sup> Additionally, the majority of literature on this subject does not distinguish between Subdural Hemorrhage (SDH) and Subarachnoid Hemorrhage (SAH). This pilot study examines the characteristics of Optic Nerve Hemorrhage (ONH) to better elucidate IO ONH as a sensitive and/or specific marker of trauma. The IC and IO subdural potential spaces are non-contiguous; however, the subarachnoid space is connected. This pilot, therefore, also attempts to discover the frequency of SAH extension between the IC and IO compartments and elucidate the role of Cerebrospinal Fluid (CSF) flow in the movement of SAH under traumatic and non-traumatic circumstances.

Medical examiner cases with gross evidence of SAH with and without SDH were collected over the one-month pilot portion of this ongoing study. Bilateral segments of IC optic nerve were sampled anterior to the optic chiasm. The orbits were unroofed using an autopsy saw along the medial, lateral, and anterior margins of the anterior cranial fossa followed by removal of cut bone and orbital periosteum. The exposed IO portion of the optic nerves was sampled without removal of the globe. Cases with grossly evident ocular injuries were excluded. All specimens were fixed in formalin, processed in the usual manner, and evaluated with hematoxylin and eosin. The presence or absence of gross and microscopic SDH and SAH was recorded and reviewed in conjunction with autopsy photographs and reports.

Nine cases with SAH hemorrhage were collected during the one-month period; four had concurrent SDH. Ages ranged from 16 to 84 years (median: 53; mean 45); 6 (67%) were men. The majority of cases ( $n=8$ ; 89%) involved trauma. Causes of death included gunshot wound(s) of the head ( $n=5$ ; 56%), multiple blunt force injuries ( $n=3$ ; 33%), and ruptured cerebral aneurysm ( $n=1$ ; 11%). Most traumatic cases had skull fractures ( $n=7$ ; 78%); of those, 5 (71%) involved the orbit. Of the nine cases, only two demonstrated SAH in both the IC and the IO compartments: one trauma case with orbital fractures, and the ruptured cerebral aneurysm. No correlation between IC and IO SDH was seen.

Extension of SAH from the IC to IO compartments under non-traumatic circumstances is likely due to the high volume and arterial pressure, such as in the case of aneurysm rupture. Extension of SAH from the IC to IO compartments under traumatic circumstances is rare; primary optic nerve injury, including from abusive head trauma, is a more likely mechanism of IO ONH. These findings will be expanded upon as the study continues and incorporates a greater number of infant and pediatric cases.

### H119 The Correlation of Pediatric Cervical Nerve Root and Dorsal Root Ganglia Hemorrhage With Hemorrhage at Other Spinal Cord Levels

Marianne E. Beynon, MD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Jo Elle G. Peterson, Oklahoma City, OK 73104; Si Gao, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054; Jennifer C. Love, PhD, Office of the Chief Medical Examiner, Washington, DC 20024; Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Glenn D. Sandberg, MD, Harris County Institute of Forensic Sciences, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will be: (1) familiar with a standardized, concise methodology for evaluating and reporting Nerve Root and Dorsal Root Ganglia (NR/DRG) hemorrhage in the pediatric autopsy, and (2) knowledgeable regarding the correlation between pediatric cervical NR/DRG hemorrhage and NR/DRG hemorrhage at other spinal cord levels.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information regarding the correlation between pediatric cervical NR/DRG hemorrhage and NR/DRG hemorrhage at other spinal cord levels, thereby assisting forensic pathologists and neuropathologists in performing and interpreting the pediatric autopsy.

Evaluation of cervical NR/DRG hemorrhage has become increasingly recognized as a crucial component of the pediatric autopsy by the forensic pathology community since an association between this hemorrhage and pediatric Traumatic Head Injury (THI) was first described in 2005.<sup>1</sup> Matshes et al. postulates that these hemorrhages occur secondary to forces transferred to the NR/DRG during hyperflexion-extension of the infant neck.<sup>2</sup> They further suggest that involvement of C3–C5 nerve roots would lead to diaphragmatic paralysis with subsequent anoxic brain injury.<sup>2</sup> Additional research has supported the association between cervical NR/DRG hemorrhage and pediatric THI, including studies at the Harris County Institute of Forensic Sciences (HCIFS).<sup>3–7</sup> As part of the comprehensive investigation of NR/DRG hemorrhage performed by the HCIFS, a comparison between cervical NR/DRG hemorrhage and NR/DRG hemorrhage at other spinal cord levels was performed.

A nine-month prospective study was conducted, as previously described.<sup>7</sup> All infants, 0–12 months old at time of death, autopsied by the HCIFS were included, excepting individuals with survival time greater than one week after terminal hospital admission. The spinal cord with NR/DRG at all levels was removed via modified posterior approach.<sup>6</sup> The tissue was fixed for two weeks in 20% formalin, then sectioned and Hematoxylin-Eosin (H&E) stained following standard methods. Each section was examined by two persons who were blinded to cause and manner of death. Hemorrhage in each NR/DRG was scored on a scale (0=no hemorrhage, 1=scant, 2=prominent).<sup>7</sup> The scores were standardized to facilitate direct comparison between spinal cord levels.

Over the study period, 62 cases were collected. Sixty infants from birth to 11 months (median age 3.5 months) were included in the study. One case was excluded from the study because the cause of retinal and NR/DRG hemorrhage could not be definitively attributed to (or excluded from) trauma, and one due to administrative error. Forty-nine infants died from natural, non-traumatic causes (non-trauma group) and 11 from traumatic injury (THI; undetermined or homicidal manner; trauma group). The number of NR/DRG recovered from each case varied. Cervical and thoracic sections were present in all 60 cases, lumbar in 57 cases, sacral in 55 cases, and cauda equina in 53 cases. Overall, recovery of thoracic through lumbar NR/DRG (94% and 84%, respectively) was similar to the cervical region. On average, 6 cervical, 4 thoracic, and 1 each of lumbar, sacral, and cauda equina spinal cord levels were examined in each case.

Overall, NR/DRG hemorrhage at the other four spinal cord levels showed good correlation with that of the cervical region. In the non-trauma group, 85.7% of both cervical and non-cervical NR were without hemorrhage, and hemorrhage was absent in 95.9% of cervical DRG and 91.8% of non-cervical DRG. In the trauma group, 90% of cases with cervical NR hemorrhage and 100% of cases with cervical DRG hemorrhage showed hemorrhage at the other levels. All discrepancies between cervical and non-cervical hemorrhage involved rare scores of 1 (sparse hemorrhage), with poor agreement between the two observers, consistent with previously reported data.<sup>7</sup> In addition, a statistically significant difference in NR/DRG hemorrhage severity between the trauma and non-trauma groups was seen at each spinal cord level ( $p < 0.01$ ), as well as the spinal cord in its entirety ( $p < 0.001$ ).

To conclude, these data suggest that forces imparted during trauma are not limited to the cervical spine but may cause significant damage to all levels of the pediatric spinal cord. If Matshes' theory linking cervical trauma and diaphragmatic paralysis is extrapolated to the non-cervical cord, many different body processes may suffer detrimental effects, including intercostal muscle dysfunction, which would further compound respiratory compromise.<sup>2</sup> In addition, non-cervical NR/DRG hemorrhage shows similar promise to its cervical counterpart in distinguishing traumatic and non-traumatic deaths in the pediatric population.

### H120 Ventriculoperitoneal Shunt Occlusion Resulting in Acute Hydrocephalus and Death in Developmentally Delayed Patients: Two Case Reports

Joshua White, BS\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be familiar with the indications for and complications of Ventriculoperitoneal (VP) shunts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting two cases of death related to acute hydrocephalus related to VP shunt occlusion occurring in chronically disabled patients with hydrocephalus.

The standard clinical strategy for managing conditions with chronic hydrocephalus involves the placement of a VP shunt. Although the successful function of VP shunts has improved since their initial implementation, VP shunt failure remains a persistent issue of concern, with approximately half of all VP shunt patients requiring replacement or revision of their shunt.<sup>1,2</sup> One common cause of shunt failure involves the physical obstruction of the device, either by biological tissue or organic material.<sup>1</sup> Although death related to obstruction of VP shunts is a recognized complication, the mortality rate related to VP shunt obstruction is poorly defined. This study describes two cases of death related to acute hydrocephalus resulting from obstruction of VP shunts.

**Case 1:** A 23-year-old female cerebral palsy patient, with additional history of congenital hydrocephalus, mental handicap, a VP shunt, and seizures, was admitted to a hospital for complaints of abdominal pain, nausea, and vomiting of three days duration. She received supportive care for a diagnosis of “gastroenteritis” and was discharged to home in a markedly improved condition. During hospitalization, she had no known neurologic complaints; however, three days after discharge, she was found unresponsive and apneic at her group home. Despite initial successful resuscitation, she was pronounced braindead shortly after admission. A limited, head-only, hospital autopsy was performed at the request of the legal next-of-kin.

Autopsy disclosed diffuse cerebral edema with associated cerebellar tonsillar and cerebral uncal herniation. Evaluation of the VP shunt revealed proximal occlusion by a soft, red-tan substance, which, on microscopic exam, was composed of fibrovascular tissue with chronic inflammatory cells. The cause of death was ruled as complications of hydrocephalus/cerebral palsy, with proximal occlusion of VP shunt.

**Case 2:** A 15-year-old cerebral palsy patient, with additional history of meningomyelocele, seizures, and hydrocephalus with VP shunt, presented to an Emergency Department (ED) with complaints of progressively worsening headache and neck pain. Upon arrival at the ED, he experienced a seizure and became unresponsive. He was resuscitated, and an emergent computerized tomography scan of the head showed increased size of the 3<sup>rd</sup> and lateral ventricles, compared to previous studies. Despite emergent decompression, he died the next day. An autopsy was performed at the request of the legal next-of-kin.

Autopsy revealed marked cerebral edema with associated cerebellar tonsillar herniation and hemorrhage, adjacent medullary hemorrhage, and dilated ventricles. The VP shunt had numerous areas of intraluminal precipitate and dilations along its course but was patent except for a complete obstruction just inferior to the valve and reservoir device, behind the patient’s ear. The cause of death was ruled as acute obstructive hydrocephalus due to VP shunt obstruction related to underlying meningomyelocele and cerebral palsy.

Although VP shunt failure is relatively common, death related to such failure is relatively rare, or at least not well-described in the literature. A 2004 study of pediatric patients in five regional hospitals over a ten-year period reported only eight deaths related to shunt failure.<sup>3</sup> A search for similar studies in older patients could not be found. The presented cases serve to highlight the importance of shunt evaluation at autopsy in cases of sudden, unexpected death in this vulnerable patient population.

#### Ventriculoperitoneal Shunt, Hydrocephalus, Death

### H121 Biochemical and Histopathological Findings in Sudden Unexpected Death in Epilepsy

*Shyam Kishore, MD, Forensic Medicine, All India Institute of Medical Science, New Delhi 110029, INDIA; Chittaranjan Behera, MD\*, Forensic Medicine, All India Institute of Medical Science, New Delhi 110029, INDIA; Sudhir K. Gupta, MD, All India Institute of Medical Science, New Delhi 110029, INDIA; Sudheer Arava, MD, Pathology, All India Institute of Medical Science, New Delhi 110029, INDIA; Asit Ranjan Mridha, MD, All India Institute of Medical Science, New Delhi 11029, INDIA; Ashok K. Jaiswal, PhD, Forensic Medicine, All India Institute of Medical Science, New Delhi 110029, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand the biochemical and histopathological changes in the body of the deceased in cases of sudden and unwitnessed death in epilepsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing various biochemical and histopathological changes occurring in various organs in cases of epileptic death and deciding the cause of death when the epilepsy seizure at the time of death is not witnessed.

One of the causes of death in epilepsy is the Sudden Unexpected Death in Epilepsy (SUDEP). It can occur without being in a status epilepticus or even without a typical seizure. It is estimated to cause nearly 2,000 deaths per year in the United States alone and accounts for as many as 15% of all epilepsy-related deaths. The most consistent risk factor across multiple studies is an increased frequency of Generalized Tonic-Clonic Seizures (GTCS). In a developing country like India, with a huge burden of epileptic patients, sudden unwitnessed deaths are on the rise. These deaths are deemed to become a medicolegal case and autopsy are warranted to establish the cause of death.

Based on these facts, this study was undertaken to have a comprehensive examination of each case of sudden death in epilepsy, including gross findings, histopathology, toxicological, and biochemical analysis. Toxicological screening for alcohol and common antiepileptic drugs was conducted on the femoral blood sample. Biochemical analyses for electrolytes, viz, sodium, potassium, calcium, glucose, and cardiac biomarkers (CPK-MB, CPK-NAC) was done on femoral blood, vitreous, Cerebrospinal Fluid (CSF), and pericardial fluid. The findings were compared with those of non-epileptic cases. Sections for histopathology were obtained from different areas of the brain (cerebral cortex, cerebellum, hippocampus, and any grossly visible pathological lesions), lung (hilar and peripheral region, and any grossly visible pathological lesions), and heart (coronary artery, myocardium any grossly visible pathological lesions) in epileptic and non-epileptic deaths.

Most of the cases of epilepsy were of the generalized tonic-clonic variety and some cases were of partial seizure. Duration of disease was between 1 to 12 years. A history of regular medication use was seen in only a few cases; most were either taking the medicine irregularly or not at all. Seizure attack at the time of death was seen in only some cases and most of the deaths were unwitnessed. No history of epilepsy was found in non-epileptic deaths.

On external examination of epilepsy cases, tongue bite, gingival hyperplasia, and features of aspiration were seen. Internally, non-specific congestion of the internal organs was present. Pulmonary edema was found in all cases of either mild/moderate/marked and coronary artery atherosclerosis. Among the non-epileptic cases, external examination show ligature marks, diffuse burn injury, and electrocution marks. Internally, pulmonary consolidation, subarachnoid hemorrhages, and non-specific organ congestion was seen, which were the cause of death in respective cases.

This study has found a lower potassium level, higher sodium level, and higher CK-NAC and CK-MB levels among epileptic deaths in comparison to non-epileptic deaths. There was no significant difference in the level of calcium and glucose between the two groups. On histopathology of various organs in epileptic deaths, the cerebral cortex shows ischemic changes in five cases, meningeal inflammation in one case, inflammation in the cerebellum in one case, and ischemia and calcification of the hippocampus in one case. The findings in the sections of the lung were pulmonary edema of various grades, pulmonary congestion in 12 cases, bacterial colonization in two cases vegetative matter in two cases and autolysis in one case. Sections of coronary showed fibro-atheromatous plaque in four cases and ischemic changes and replacement fibrosis in five cases. Histopathological examination in non-epileptic cases show no significant findings in the cerebral cortex, cerebellum, hippocampus, the sections of lung, coronary artery, and the myocardium in most of the cases, except fibro-atheromatous plaque in four cases, and pulmonary consolidation in one case.

This study concludes that biochemical and histopathology of the organs contain some specific changes in epileptic deaths, such as lower potassium levels, higher sodium, CPK-MB and CPK-NAC levels, ischemic changes of the cerebral cortex, inflammation of the meninges and the cerebellum, calcification of hippocampus, and focal replacement fibrosis of the myocardium.

#### Sudden Death in Epilepsy, Cause of Death, Biochemical Marker

### H122 Evaluation of the Role of Polymerase Chain Reaction (PCR) -Based Postmortem Respiratory Infectious Disease Panels in Infant Death Investigations

Abigail Jacqueline Grande, MPH\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Joyce L. deJong, DO, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Amanda O. Fisher-Hubbard, MD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will better understand the difficulties in identifying the role of infectious diseases in apparent Sudden Unexplained Infant Deaths (SUIDs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining the contribution from microbiological testing to the investigation of infant deaths.

In 2016, there were 23,161 infant deaths (under one year of age) in the United States, of which most were attributed to congenital malformations, low birth weight, and SUIDs.<sup>1</sup> Although the utility of postmortem microbiology in infant deaths is frequently debated, it is essential in understanding the factors that may have contributed to the death of an infant.<sup>2</sup> Many respiratory pathogens are potentially fatal, including Respiratory Syncytial Virus (RSV), which is the most common cause of bronchiolitis and pneumonia in children under one year in the United States.<sup>3,4</sup> Previous studies examining the role of respiratory infections in infant deaths have found that rhinovirus/enterovirus and RSV were the most commonly detected pathogens, with 60% of cases testing positive for RSV actually contributing to the cause of death.<sup>3</sup> No single respiratory infection has been causally linked to SUIDs, but many studies have demonstrated higher rates of respiratory pathogens isolated from SUID cases in comparison to controls.<sup>5</sup>

For this study, respiratory infectious disease panel results were reviewed. This testing uses a multiplexed nucleic acid test using a FilmArray instrument for the simultaneous qualitative detection and identification of multiple respiratory viral and bacterial nucleic acids in nasopharyngeal swabs. This testing includes the detection of: adenovirus, coronavirus 229E, coronavirus HKU1, coronavirus NL63, human metapneumovirus, human rhinovirus (1, 2, 3, and 4), enterovirus, influenza A (H1-2009, H1 and H3), influenza B, parainfluenza (1, 2, 3, and 4), respiratory syncytial virus (RSV), *Bordetella pertussis*, *Chlamydia pneumoniae*, and *Mycoplasma pneumoniae*. *Bordetella parapertussis* was added to the respiratory infectious disease panel in late 2017. Of note, rhinovirus and enterovirus are of the same genetic family and cannot be definitively distinguished using molecular testing.

This study reviewed 100 infant deaths investigated by medical examiners and/or coroners from multiple counties in Michigan and Indiana from 2014 to 2018. This study was restricted to infants, defined as age zero to one year for a more specific analysis. Of these 100 infant deaths, a respiratory infectious disease panel was performed on a nasopharyngeal swab in 70 cases. Of these 70 cases, 39 infants (56%) tested positive for one or more respiratory pathogens. A total of 53 respiratory pathogens were detected among these 39 infants; nine infants tested positive for more than one respiratory pathogen. Of the 39 infants testing positive for a respiratory pathogen, 24 infants (61%) tested positive only for rhinovirus/enterovirus, with another 9 infants testing positive for one or more of pathogens that included rhinovirus/enterovirus, for a combined total of 33 infants (85%) testing positive for rhinovirus/enterovirus. Adenovirus was positive in 5 cases; coronavirus OC43 and parainfluenza 3 were positive in 3 cases each; influenza B and RSV were positive in 2 cases each; and coronavirus HKU1, metapneumovirus, influenza A, parainfluenza 1, and *Mycoplasma pneumoniae* were positive in 1 case each.

Of the 39 cases with positive respiratory infectious disease panels, the forensic pathologist reported a respiratory infection as a contributing factor to the death in only 16 (41%) of the deaths. Even with a contributing respiratory infection, 13 (81%) of these deaths were still certified as indeterminate due to other possible contributing factors, such as unsafe sleeping conditions.

### H123 Severe Pulmonary Artery Hypertension Persisting After a Late Atrial Septal Defect (ASD) Closure: Presentation of a Case

*Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

**Learning Overview:** After attending this presentation, attendees will understand the pathophysiology and the autopsy findings of pulmonary artery hypertension after a late ASD closure.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that pulmonary hypertension can persist after a late surgical repair of ASD.

ASD is the most prevalent congenital cardiac anomaly in adults, representing ~35% of all congenital heart defects. It consists of a heart defect in which blood flows between the atria of the heart: oxygen-rich blood can flow directly from the left side of the heart to mix with the oxygen-poor blood in the right side of the heart, or vice versa. This can lead to lower-than-normal oxygen levels in the arterial blood that supplies organs and tissues. Due to the high blood flow from left to right, an ASD can also cause right ventricular remodeling and failure, with enlargement of right cardiac chambers, severe arrhythmias, and pulmonary artery hypertension. The left ventricle can be smaller than the right one and a reduced coronary perfusion can occur.

Most adults with ASD are safely treated using available techniques of surgical or percutaneous repair and become free of complications over the long term. However, there is a small fraction of patients who are at risk for post-operative complications, particularly the persistence of elevated pulmonary vascular resistance and pulmonary artery hypertension.

This presentation describes the case of a 47-year-old Asian female (height: 152cm; weight: 36kg) who was found unresponsive by her husband in the bathroom of their house. The husband promptly called the emergency medical services. A cardiopulmonary resuscitation was performed with negative results and the woman was pronounced dead.

According to the medical records, the woman underwent a surgical repair of an atrial septal defect at the age of 37 and suffered from severe pulmonary hypertension, high blood pressure, paroxysmal atrial fibrillation, and multivalvular insufficiency. A few months prior to death, she had an episode of acute heart failure and underwent a chest-abdomen Computed Tomography (CT) and an echocardiogram that showed: persistence of a left superior vena cava probably draining in the coronary sinus, enlargement of the right heart with massive tricuspid regurgitation, enlargement of the pulmonary arteries with severe pulmonary regurgitation, bilateral pleural effusion, atelectasis of the left lung, chronic passive congestion of the liver, and ascites.

At the autopsy, the heart weighed 650 grams and showed: an enlargement of the coronary sinus, a correctly positioned interatrial patch, a notable right ventricular hypertrophy with a small left ventricle, enlarged pulmonary arteries with fatty streaks, and pulmonary and tricuspid valve insufficiency. It was not possible to identify the left superior vena cava detected during the imaging studies; this could be due to the relatively small size of the vessel or to the presence of massive adhesions from prior surgery.

At the microscopic examination, the heart showed multiple myocardiocytes with enlarged nuclei and multiple areas of fibrosis. The lung showed hypertrophy of the media of the arterioles and plexiform lesions, findings consistent with a severe pulmonary artery hypertension.

In this case, since the woman did not have the defect closed until such an advanced age (37 years old), probably all the autopsic findings could be attributed to the ASD. The left superior vena cava persistence may have contributed. A prolonged flow from the left atrium across the ASD to the right atrium caused the right ventricular hypertrophy and pulmonary hypertension. Moreover, the left ventricle was reduced in size and a myocardial fibrosis (presumably due to low coronary perfusion) was observed. It was not possible to understand if, in this case, the delay in surgical treatment was due to a late presentation of the defect or due to different reasons. In any case, the late surgical treatment allowed the subject to become free from the interatrial communication, but not from the advanced right ventricular remodeling and pulmonary vasculopathy, which caused death.

#### Atrial Septal Defect, Pulmonary Hypertension, Heart Remodeling

### H124 Chronic Traumatic Encephalopathy Pathology Following Shotgun Injury to the Brain

Rudy J. Castellani, MD\*, Center for Neuropathology, Kalamazoo, MI 49008; Taylor Tribett, BS, Western Michigan University School of Medicine, Kalamazoo, MI 49007; Theodore T. Brown, MD, Kalamazoo, MI 49008

**Learning Overview:** After attending this presentation, attendees will: (1) assess significance of tau pathology after traumatic brain injury, (2) correlate tau pathology with clinical signs, (3) interpret consensus guidelines for Chronic Traumatic Encephalopathy (CTE) interpretation, and (4) assess appropriateness of the CTE diagnosis for death certification

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying broad misunderstanding regarding brain interpretation for CTE pathology, its significance in terms of clinical problems during life, and the lack of appropriateness of the CTE diagnosis for death certification

CTE was suggested initially in boxers (i.e., dementia pugilistica) who developed neurological abnormalities after long boxing careers. Autopsy studies in the mid-20<sup>th</sup> century variably highlighted Neurofibrillary Tangles (NFT) among the features of dementia pugilistica, prompting the hypothesis that dementia pugilistica shares pathogenic similarities with Alzheimer's Disease (AD). In the past decade, the CTE concept has extended to other athletes, although with limited clinical correlations and more subtle neuropathology. A consensus group has recently set provisional criteria for CTE pathology and highlighted a pattern of phosphorylated tau (p-tau) neuropathology considered "pathognomonic" for CTE. The consensus group did not adopt a staging scheme for CTE and did not address the question of whether CTE pathology represents the substrate for a progressive neurodegenerative disease.

Reported here is the case of a 63-year-old man who suffered a shotgun injury to the brain in his early twenties. He remained neurologically compromised for 42 years after the injury but showed no evidence of neurological disease progression after the initial injury. He had no other Traumatic Brain Injury (TBI) exposure and did not play football or other high-energy collision sports. Neuropathological examination confirmed tissue damage from the shotgun injury, with multiple foci of encephalomalacia. Also present were mammillary body atrophy, atrophy of the fornices, and an atrophic and convex thalamus, gross features occasionally described in historical cases of dementia pugilistica. Mammillary body atrophy and evidence of previous TBI are listed as supportive neuropathological features of CTE. Also present were localized deposits of p-tau within neurons and astrocytes around small blood vessels at the depths of cortical sulci, meeting neuropathological criteria for CTE. P-tau and TDP-43 deposits within marginal brain tissue damaged by penetrating shotgun injury were also present focally, indicating focal proteinopathy as a direct consequence of neurotrauma. No amyloid- $\beta$  (A $\beta$ ) deposits were present.

These findings indicate that CTE pathology may occur in the aftermath of single, severe TBI. The fact that it remained stationary for decades with no evidence of clinical or pathological progression, and no evidence of AD pathology, raises questions about the TBI-progressive proteinopathy paradigm, and the theory that CTE pathology is a hallmark for neurodegenerative disease. The absence of correlation between p-tau pathology in this case and in the CTE literature in general, along with the lack of disease progression in a manner of canonical neurodegenerative disease, suggests that CTE is a descriptive neuropathological, and at times a purely immunohistochemical entity, that lacks clinical meaning. Moreover, an abundance of literature calls into question a cause-effect relationship between TBI and progressive neurodegenerative proteinopathy. The many uncertainties surrounding the CTE concept suggests that CTE is inappropriate for death certification and may lead to unnecessary confusion. More research is needed before concluding that CTE is a cohesive clinicopathological entity responsible for neurological or psychiatric problems during life.

### **H125 Massive Intracranial Bleeding Due to the Rupture of a Rare Spontaneous Pseudoaneurysm of the Middle Cerebral Artery in a Pediatric Patient: A Case Report With Clinical, Radiological, Gross, and Microscopic Findings**

*Lorenzo Gitto, MD\*, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; Serenella Serinelli, MD\*, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210*

**Learning Overview:** After attending this presentation, attendees will understand the features and appearance of a rare intracranial idiopathic pseudoaneurysm.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the features of a rare cause of intracranial bleeding in a pediatric patient.

Pediatric pseudoaneurysms are a rare and underdiagnosed cause of intracranial hemorrhage. Regarding the head and neck districts, approximately 80% of the pseudoaneurysms affect extracranial vessels (mostly carotid and vertebral arteries), while only 20% are intracranial. The most common etiologies of pseudoaneurysm are trauma, infection, drugs, or neoplasm. Spontaneous/idiopathic pseudoaneurysms are rarely observed in the clinical and forensic practice.

A 14-year-old White female was brought to the hospital after she lost her consciousness while attending her morning school session. She had no pertinent familial history or history of traumas. According to her recent medical history, she had a heavy menstrual bleeding, with a three-week-long recurrent mild headache, and a lack of appetite started the night before. On arrival at the emergency department, the neurological examination showed a drowsy but easily arousable girl, with a Glasgow Coma Scale (GCS) score of 13 (E3V4M6). Physical and neurological examinations were unremarkable. A pregnancy test was negative. An Electrocardiogram (EKG) showed no cardiac rhythm alterations. Plain computed tomography of the brain without contrast showed an intra-axial hemorrhage in the right temporal lobe, 6cm in diameter, without evidence of skull fractures; it produced a mass effect, without deviation of the median line structures. Cerebral edema and subarachnoid hemorrhage were also noted. After the neuroradiological study, the GCS score decreased to 10 (E2V3M5).

The patient was referred to the Neurosurgery Department of a primary health care provider. Upon arrival, the patient underwent a plain computed tomography of the brain with contrast that showed an increase of the intraparenchymal hematoma in the right cerebral hemisphere with a 10-centimeter dislocation of the median line structures. The patient immediately underwent a decompressive craniotomy, and an external ventricular drainage was placed. A cerebral angiography was performed, showing an active bleeding from a right middle cerebral artery pseudoaneurysm, and an endovascular aneurysm repair was performed.

Despite the multiple neurosurgical operations, the patient died after three days of coma due to the massive intracranial bleeding.

At the postmortem examination, the young girl was an organ donor, but the whole brain was saved in formalin for a neuropathology consultation. At the examination of the fixed brain, a massive subarachnoid hemorrhage was observed on the right cerebral hemisphere, together with an extensive right temporal lobectomy as a result of the neurosurgical intervention. Following the right branches of the circle of Willis, the right middle cerebral artery was found: it showed the presence of a fusiform vessel dilatation, 2.5x1 centimeters in size, filled by surgical glue.

The microscopic examination of the vessel dilatation confirmed a pseudoaneurysm of the right middle cerebral artery, showing the loss of normal arterial architecture with intermittent disruption of the internal elastic lamina and vacuolar degeneration of the tunica media.

Unlike true aneurysms, pseudoaneurysms are typically found along a vessel wall, distal from a branch point. They differ pathologically from true or dissecting aneurysms. In pseudoaneurysms, there is a disruption of all three layers of the vessel wall with a contained hematoma. They have a specific wall formed by hematoma organization and fibrosis with the surrounding and connective tissue indicating vessel wall injury. Pseudoaneurysms must be distinguished from true saccular aneurysms because of their friable nature, the tendency of rupture, and different pathologic findings.

At the postmortem examination, a massive intracranial hemorrhage or a previous surgical manipulation of the brain may hide the existence of a vessel malformation. Therefore, in the case of pediatric intracranial bleeding, a multidisciplinary approach (clinicians, radiologists, neurosurgeon, pathologists, and neuropathologists) is required, and a careful inspection of the central nervous system structures is mandatory.

---

### H126 Dorsal Root Ganglia and Nerve Root Hemorrhage in Resuscitated Respiratory Syncytial Virus (RSV) Bronchiolitis

Nathan S. Shaller, MD\*, Wake Forest Baptist Medical Center, Winston Salem, NC 27157; Anna G. McDonald, MD, Wake Forest Baptist Medical Center, Winston Salem, NC 27157

**Learning Overview:** The goal of this presentation is to show the ischemia-reperfusion injuries of the central nervous system in resuscitated RSV bronchiolitis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by furthering the understanding of ischemia-reperfusion injury once thought to be specific for trauma.

Autopsy findings in pediatric deaths can be challenging due to the complex, evolving, and occasionally conflicting body of literature that obfuscates the distinction between pathologic findings and artifacts of resuscitation. This presentation reports two autopsy cases of RSV in children with secondary bronchopneumonia and cardiopulmonary arrest that highlight the importance of autopsy, including fundal, brain, spinal cord, spinal nerve root, and dorsal root ganglia examination.

**Case 1:** A 5-month-old girl without significant past medical history was brought by her mother to the Emergency Department (ED) with a one-day history of fever (measured at home at 101°F), cough, and congestion. She was diagnosed with a viral upper respiratory illness, advised to take acetaminophen, and sent home. The girl was brought to the ED later the same evening with decreased intake and multiple episodes of emesis with continued fever (recorded in ED at 103.2°F). She was given ondansetron and discharged home. Two days later, at approximately 4:30 a.m., the father found the infant unresponsive and facedown on the couch. She was brought to the ED pulseless and apneic. Despite maximal cardiopulmonary resuscitative efforts, there was no return of spontaneous circulation.

**Case 2:** A 9-month-old girl with a history of sickle cell trait was brought to the ED for congestion, cough, and fever. A RSV rapid antigen test was negative. A chest radiograph showed clear lung fields throughout. She was diagnosed with an upper respiratory tract infection and discharged home with prednisolone and amoxicillin. The following day, the infant was being transported to the ED by her father when she suffered cardiopulmonary arrest in the father's vehicle. Emergency services were contacted and transported the infant to the ED. She arrived apneic and without palpable pulses. She eventually had return of circulation after approximately 30 to 40 minutes of downtime. A chest X-ray showed a suspicion for multi lobe airspace disease. She was subsequently transferred to Wake Forest Baptist Medical Center Emergency Department where her pupils were noted to be fixed and dilated on arrival. That evening, the decision was made to transfer her care to comfort measures. Late that evening, she had loss of pulses for approximately two minutes with return of circulation. Ophthalmology noted bilateral retinal hemorrhages at this time. Her clinical status deteriorated, and she was pronounced approximately 12 hours after admission.

Autopsy findings for both cases identified RSV genetic material on postmortem nasopharyngeal swab, as well as lungs with bronchiolitis and necrosis of respiratory epithelium. Secondary bacterial bronchopneumonia was also present on microscopic sections in both cases with *Lactococcus lactis* isolates recovered from lung and blood cultures in Case 1. Postmortem indirect ophthalmologic examination confirmed bilateral retinal hemorrhages in Case 2. Spinal cord and dorsal root ganglia were examined in both cases. Case 1 showed no ischemic neurons in the brain sections examined as well as spinal cord and dorsal root ganglia without significant hemorrhage, necrosis, or inflammation. In contrast, examination of the cord in Case 2 showed diffuse hypoxic-ischemic changes of the neurons within the anterior and posterior horns. Dorsal root ganglia from C6/7 showed hemorrhage along the fascicles of the nerve roots with superficial extension into the dorsal root ganglia. Intradural hemorrhage was prominent around lumbar nerve roots. Additionally, Case 2 showed an enlarged spleen with diffusely enlarged red pulp. Sickled red blood cells were identified throughout microscopically examined tissue. These findings suggest an element of red cell sequestration due to sickling in the setting of hypoxic stress of RSV bronchiolitis and secondary bronchopneumonia.

Diffuse hypoxic-ischemic injury of the brain and spinal cord is a non-specific finding in pediatric deaths. Dorsal root ganglial hemorrhage has previously been reported to be mechanistically associated with hyperextension/hyperflexion neck injury in young children. This study proposes that the dorsal root ganglia and spinal cord hemorrhage may reflect ischemia-reperfusion injury in the setting of prolonged resuscitation with return of circulation. These cases highlight the importance of routine spinal cord examination in the pediatric autopsy to further our understanding of reperfusion injury in the central nervous system previously thought to be specific for trauma.

#### Resuscitation, Ganglia, Hemorrhage

### H127 An Evaluation of Cardiac Implantable Electronic Devices in Forensic Practice: How It Can Improve the Medicolegal Analysis of Cause of Death in Postmortem Analysis and Even Answer Unexpected Questions in the Living

*Justine Canales, MD\*, Institut Medico Legal, Tours 37044, FRANCE; Camille Rerolle, MD, Service de Medecine Legale, Tours 37000, FRANCE; Pauline Saint-Martin, MD, PhD, Service de Medecine Legale, Tours 37000, FRANCE*

**Learning Overview:** After attending this presentation, attendees will better understand various situations for which the analysis of a pacemaker or a defibrillator device were useful in forensic practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting several case reports in which the pacemaker or defibrillator interrogation provided essential information to the forensic pathologist.

**Introduction:** Cardiac Implantable Electronic Devices (CIEDs) are commonly implanted in patients suffering from various heart conditions. They encompass Pacemakers (PM) and Implantable Cardioverter Defibrillators (ICDs). Most of the devices have an automatic cardiac rhythm recording feature, allowing it to be interrogated at any moment to provide important information for the patient's follow-up; but interrogation can also be made in a forensic context. Presented here are three cases in which analysis of CIEDs was useful in a routine manner.

**Case 1:** A 30-year-old male was found dead at home. He had attended a party the day before. The deceased had a history of third-degree atrioventricular block. He had a PM since the age of 20. During the autopsy, the cause of death could not be specified. Toxicology and histology were still pending while this abstract was being written. The PM analysis revealed that at 9:18 a.m. the morning of his death, a ventricular tachycardia followed by several minutes of ventricular fibrillation were recorded that did not allow survival. The estimated time of death given by the physician who delivered the death certificate was around 2:30 p.m. the same day. That was not consistent with the device data analysis.

**Case 2:** An 86-year-old male suffered from terminal heart failure. He had a history of ventricular arrhythmia and carried an ICD. He was brought to the emergency room because he had signs of acute decompensated heart failure. His family, who had recently decided with his physician to limit any invasive medical intervention, was not consulted and the patient was transferred to several departments before he died in the intensive care unit, 48 hours after his admission. During the autopsy, signs of severe cardiac heart failure were present and confirmed by histology. Toxicology showed a lethal concentration of digoxine, which was part of the regular treatment of the deceased. The question of a digoxin poisoning that could be partly due to error in prescription and/or in medication administration was asked by the family. First, the ICD analysis showed that the device ran properly. Second, no arrhythmic episode could be detected during the two days of hospitalization. As a high concentration of digoxin is not interpretable by itself if not correlated to cardiac arrhythmia, it was concluded that the cause of death could not be directly related to a digoxin poisoning but was due to terminal heart failure.

**Case 3:** A 45-year-old male, suffering from a Brugada syndrome with a mixed anxiety-depressive disorder, reported being the victim of verbal and physical assault within a six-month period by two individuals. As the physical violence was particularly severe, investigators wanted to know whether the ICD he was carrying for the cardiac condition had registered any abnormal activity and had delivered any electrical shock during the time of his sequestration. The patient's ICD was analyzed with his consent at the request of the investigators. The analysis showed that no abnormal cardiac activity had been recorded within the past two years prior to the complaint.

**Discussion:** The importance of CIED interrogation in a forensic context has already been described in the literature. This analysis can answer questions regarding the circumstances and the cause and manner of death. The first case was classic and provided an example of determining the last event before death. The second case was more unusual and contributed to the analysis of a medical malpractice case. Finally, the last case showed that CIEDs may also be interesting for a case with a living person. These three cases confirm forensic institutes should proceed with a systematic CIED interrogation for all individuals carrying these devices as they can provide important additional information to the medicolegal investigation.

**Forensic Science, Forensic Pathology, Pacemaker**

### H128 A Comparison of Coronary Artery Stenosis Estimates Made by Forensic Pathologists and Medical Students

*Mitchell Messner, BA\*, University of North Dakota SMHS, Grand Forks, ND 58202; Sarah Meyers, MD, Hennepin County Medical Examiner's Office, Minneapolis, MN 55415; Walter L. Kemp, MD, PhD, University of North Dakota School of Medicine, Grand Forks, ND 58202-9037*

**Learning Overview:** The goal of this presentation is to inform attendees about the lack of increased accuracy in estimating the percentage of stenosis that results from training and experience, in that forensic pathologists are not more accurate in this estimation than medical students.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how the accurate estimation of the percentage of stenosis produced by coronary artery atherosclerosis is an important step during the autopsy when determining the cause of death, with an appreciation that training and experience do not necessarily produce better estimates.

**Introduction:** An important step during the performance of an autopsy is the accurate estimation of coronary artery arteriosclerotic stenosis. Although tools, such as diagrams, exist to aid in improving accuracy, previous studies suggest that more experienced/specialized pathologists (i.e., cardiovascular pathologists) are less accurate than non-cardiovascular specialized pathologists (i.e., residents and clinical pathologists) in estimating the degree of coronary artery stenosis. To further explore these contradictory results, a study was designed to compare the accuracy of coronary artery stenosis estimates made by forensic pathologists versus medical students.

**Materials and Methods:** Six forensic pathologists and 12 medical students each independently examined 24 images of coronary artery cross-sections with variable degrees of stenosis and gave an estimate of the degree of arteriosclerotic stenosis. The medical students received no specific training prior to their review of the images. The images, including 12 gross and 12 microscopic images, were made available to each participant in a PowerPoint® presentation. The actual percentage of stenosis for each image was determined using ImageJ by measuring the area of the residual lumen and the area of the native lumen. To determine the area of the native lumen for calculation of the actual percentage of stenosis for the microscopic sections, both the outer edge of the intima and the outer edge of the media were measured. Given that the outer edge of the media was more apparent grossly, final analysis utilized the calculated value based on the outer edge of the media only. The median difference between the calculated percentage of stenosis using outer intima and outer media was 5.9%. The results were analyzed with R, with the non-parametric Wilcoxon Rank Sum Test used to determine statistical significance.

**Results:** Overall, when comparing all 24 images, the forensic pathologists had a median difference between the estimated and actual percentage of stenosis of -12.380 and the medical students had a median difference of -16.50 ( $p$ -value of 0.08542); however, for only the 12 gross images, the forensic pathologists median difference was -15.90 and the medical students was -20.90 ( $p$ -value of 0.2243), and for only the 12 microscopic images, the forensic pathologists median difference was -6.65 and the medical students was -13.050 ( $p$ -value of 0.08398).

**Conclusion:** In estimating the percentage of coronary artery arteriosclerotic stenosis, specific training in forensic pathology does not guarantee accuracy, with this study showing no statistically significant difference between estimates given by forensic pathologists or medical students and each group underestimating the degree of stenosis.

#### Coronary Artery, Stenosis, Atherosclerosis

### H129 Coronary Calcifications in Sudden Cardiac Death (SCD) Cases in Postmortem Computed Tomography (PMCT)

*Katarzyna Michaud, MD\**, Centre Universitaire Romand de, Lausanne 1000, SWITZERLAND; *Stefano Draisci, MD*, Dipartimento Interaziendale Ad Attività Integrata, Modena, ITALY; *Diego Proccichiani, MD*, Dipartimento di Diagnostica per Immagini, Modena 41100, ITALY; *Silke Grabherr, PhD*, Centre Universitaire Romand de Médecine Légale, Lausanne 25, Vaud 1000, SWITZERLAND; *Fabrice Dedouit, MD, PhD*, Centre Universitaire Romand De Médecine Légale, Lausanne 1000, SWITZERLAND

**Learning Overview:** After attending this presentation, attendees will understand modern postmortem imaging of coronary arteries. Attendees will understand how to evaluate the calcifications of coronary arteries of sudden death victims in PMCT and which cases could be a pitfall.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the advantages and possible pitfalls of modern radiological methods used in the evaluation of sudden death cases.

The Coronary Artery Calcium Score (CACS) is an independent predictor of coronary artery disease events in clinical practice and has been found to be a marker of a vascular injury that correlates closely with the atherosclerotic burden. Traditionally, coronary calcification is quantified radiologically by the Agatston score. The radiological grading of coronary artery disease, based on this score, is classified as no evidence of coronary artery disease (0 calcium score), minimal (1-10), mild (11-100), moderate (101-400), and severe (>400). In a living patient, a zero CACS is considered the most powerful negative risk factor for development of a coronary event and the assessment of CACS appears to be the most predictive in the intermediate-risk group. However, it is known that about 4% of patients present non-calcified plaques with a zero CACS.

In postmortem examination, it is possible to measure the CACS after the PMCT examination and before the opening of the body. However, up to the present, the CACS was not evaluated in postmortem practice. Therefore, the goal of this pilot study was to assess the CACS in PMCT in cases of SCD related to Ischemic Heart Disease (IHD).

Consecutive cases of SCD related to IHD for which the postmortem CT and CACS evaluations were available were retrospectively studied. The autopsies were performed in 2017 according to international guidelines. Violent deaths, such as hanging and gunshots, were included in the control group. The radiological examination was performed on a 64-row CT unit using a specific cardiac CT protocol with a non-enhanced sequential acquisition mode. The CACS was calculated by using the software Smartscore 4.0 from Advantage Windows® using a standard Agatston/Janowitz method. Board-certified radiologists trained in postmortem imaging assessed the CACS. All cases were classified into four groups according to the CACS as zero, 1-100, 101-400, and >400.

Twenty-five cases were selected in the study group; 5 women and 20 men; the mean age was  $63.2 \pm 13.3$  years. The CACS was 1-100 for 3 cases, 101-400 for 12 cases, and >400 for 10 cases. All female cases presented CACS below 400 and there were no cases with zero CACS. An acute coronary thrombosis was found in 14 cases, in 9 cases related to a rupture and in 5 cases to an erosion of a coronary plaque. In the control group, 27 cases were included (9 women and 18 men); the mean age was  $55.9 \pm 6.9$  years. The CACS was zero for 10 cases, 1-100 for 11 cases, 101-400 in 3 cases, and >400 in 3 cases.

This pilot study showed that the postmortem CACS was higher in the group of SCD related to IHD than in the control group. In 81.5% of the control population, the CACS was zero or below 100. The severe CACS (>400) was observed in IHD cases but also in controls. More interesting and representing the potential pitfalls, in 12% of SCD cases the CACS was mild, and in 48% of SCD cases it was between 101 and 400, corresponding to a moderate risk in clinical practice. This indicates that forensic pathologists and radiologists should evaluate very carefully all coronaries of sudden death victims, even if calcifications of coronary arteries are not very extensive in PMCT. The correlations found between postmortem imaging of SCD victims and autopsy could further the understanding of coronary syndromes in clinical practice.

#### Sudden Cardiac Death, Coronary Calcifications, Postmortem Imaging

### H130 Manual Large Volume DNA Extraction and Purification From a Large Substrate

Abigail Chesness\*, Oak Grove, MN 55303; Rachel L. Creager, Defense Forensic Science Center, Forest Park, GA; Thomas A. Meyer, MS, Atlanta, GA 30311

**Learning Overview:** After attending this presentation, attendees will understand a new method to extract and purify DNA from a small number of epithelial cells present on a large substrate.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new method for DNA extraction. Current extraction methods are not able to fully submerge large substrates in a single sample tube, and the use of multiple small sample tubes can result in DNA loss and/or contamination. The method in this study takes these issues into account to improve upon the effectiveness of extracting DNA from large substrates.

A new Manual Large Volume (MLV) DNA extraction method has been developed to efficiently and effectively extract and purify DNA from a large substrate. The standard automated extraction protocol for samples with low-level DNA (referred to as standard extraction protocol) doesn't work for large substrates because of the small sample tube size. Currently, the method used at the Defense Forensic Science Center for large substrates, referred to as the multi-tube method, divides a substrate into smaller pieces and extracts each piece individually using the standard extraction protocol. To compare different methods of DNA extraction and purification in this study, a stock solution of saliva diluted with TE buffer at a fixed ratio was used. By using this solution for each method, a percent recovery can be calculated based on the standard extraction protocol. The multi-tube extraction method results in 60%–70% DNA recovery compared to the standard extraction protocol, which can likely be attributed to increased sample manipulation.

The MLV method allows for the entire substrate to be submerged in lysis buffer in a single sample tube, reducing sample manipulation and dilution/concentration steps. The MLV method was compared to the standard extraction protocol and multi-tube method to determine its effectiveness in extracting DNA from large substrates. All methods utilize a lysis buffer with proteinase K and a binding buffer. The standard extraction protocol and the multi-tube protocol use a bead-based automated extraction, while the MLV protocol uses a silica column to separate and purify DNA.

The MLV extraction method resulted in 80%–90% recovery compared to the standard extraction protocol when a diluted saliva sample was used. The MLV extraction method was also shown to be effective for extracting from a paper substrate and was able to yield pure DNA samples at 80%–100% recovery relative to the standard extraction from paper. To give a better understanding of its overall effectiveness and reproducibility, the MLV extraction method will be tested using other substrates that mimic case work samples.

### H131 Eye Temperature Measured After Death in Human Bodies as an Alternative Method of Time-of-Death Estimation in the Early Postmortem Period

Michał Kalisz, PhD\*, Gdansk 80-204, POLAND; Magdalena Wujtewicz, PhD, Medical University of Gdansk, Gdansk, Pomorskie 80-211, POLAND

**Learning Overview:** After attending this presentation, attendees will better understand the process of postmortem body cooling, particularly in the eyeball, and its application in the estimation of the Time Of Death (TOD), especially in the early, several-hours-long postmortem period.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the method of TOD estimation based on measurement of the postmortem eyeball temperature.

TOD estimation is a key matter for forensic pathologist examining the body at the death scene. In such cases, the body temperature should be measured aiming at TOD estimation. This is of great value when the body temperature is still higher than the environmental temperature and the TOD can be calculated on the basis of the difference between the body and the environmental temperature. However, despite the above and other possibilities of the TOD estimation (i.e., depending on postmortem changes such as lividity, rigor mortis or different supra-vital reactions, or even biochemical methods), they are still of not satisfactorily accurate.

In the current study, single (in 20 patients) or double (within a one-hour interval in 10 patients) eyeball and rectal temperature measurements were taken in patients who died in Medical University of Gdansk Hospital Intensive Care Unit. The actual TOD in each patient was exactly known and the body temperature was recorded shortly later (between 0.5h to 3.5h). The temperature was measured using pin probes connected to a high-precision electronic thermometer. The measured eye temperatures ranged from 29.7°C to 33.6°C. Ambient temperatures in all cases was stable (22°C), corresponding to usual room temperature. TOD was calculated using a formula based on Newton's law of cooling previously successfully applied in comprehensive studies on pigs and recent studies on human bodies:

$$t = - \frac{\ln\left(\frac{T - T_a}{T_0 - T_a}\right)}{k_c}$$

(equation 1)

where  $t$  is the time which passed since death (TOD),  $T$  is the temperature of the body site,  $T_a$  is the ambient temperature (constant: 22°C in the present study),  $T_0$  is the initial human eye temperature (assumed to be 35°C), and  $k_c$  is a first order cooling rate constant. Thanks to stable ambient temperature and knowledge of the exact TOD, the actual study allowed the adjustment of the mean value of  $k_c = -0.2 \text{ h}^{-1}$  in comparison to the recent studies. Thanks to both the significantly faster postmortem decrease of eye temperature and the residual or lack of plateau effect in the eye, and no influence of body mass, TOD in the human death cases using equation 1 could be estimated with quite a good accuracy. The maximum TOD estimation error during the postmortem intervals up to 3.5h was slightly higher than 1h minimum in 4 cases among 30, while for the rest of 26 cases it was less than 1h, while mean error for all 30 cases was  $\pm 24$ min. The results from 30 new cases with exactly known TOD show that the presented method of TOD estimation may be of satisfactory accuracy in the early postmortem period, particularly when applied to bodies found at room temperature and in standard environmental conditions.

#### Eye Temperature, Postmortem, Time-of-Death Estimation

### H132 Cold Case Homicides: DNA Testing of Retained Autopsy Sexual Assault Smears

*Michelle S. Clark, MS\*, Farmington, CT; Angela McGuire, MD, Office of the Chief Medical Examiner, Farmington, CT 06032; Kristin Sasinouski, MSFS, CT Division of Scientific Services, Meriden, CT 06451; James R. Gill, MD, Office of the Chief Medical Examiner, Farmington, CT 06032*

---

**Learning Overview:** The goal of this presentation is to highlight the examination of retained medical examiner specimens for DNA testing and their use in cold case homicides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the usefulness of testing archived autopsy sexual assault smears in identifying suspects in cold case homicides.

In 1994, the DNA Identification Act authorized the Federal Bureau of Investigation (FBI) to create a national DNA database of convicted offenders and databases for forensic samples. Prior to this, there was no consistent method for the collection, analysis, and comparison of biological specimens from suspected sexual assault-related homicides.

In the 1990s, vaginal, oral, and anal swabs and smears were collected on certain homicides at the Office of the Chief Medical Examiner (OCME) in Connecticut. The smear slides were reviewed by the medical examiner for sperm, then archived at the OCME. The swabs were sent to the crime lab for ABO blood type identification and possibly Polymerase Chain Reaction (PCR) testing. The crime lab began performing routine DNA testing on samples around 1993. Recent advances in molecular testing have allowed for the extraction of DNA to generate DNA profiles from cytological smears. Therefore, a search for archived vaginal, oral, and anal smear slides was undertaken at the OCME.

An electronic death certificate search was performed for all female homicides between 1990 and 1999. The OCME histology slide archives were searched for sexual assault smears for all 376 female homicides that occurred between 1990 and 1999. Of the 376 female homicides, the OCME had vaginal, anal, and oral slides on 84. Of these, 12 slides had sperm, 44 had no sperm, and 28 had no mention of the presence or absence of sperm in the report. Detectives from the jurisdictions of death were contacted to see if any of the cases were still unsolved. Of the 12 instances with sperm, there were 7 that were still “unsolved.” In these instances, samples were forwarded to the Connecticut State Division of Scientific Services (DSS) for DNA testing and analysis by extraction of DNA from cells on the previously stained and fixed glass slides.

DNA profiles were obtained on all seven cases. Two profiles entered into the Combined DNA Index System (CODIS) resulted in two matches (“hits”). One profile was consistent with the decedent’s husband (who was the suspect). This information was provided to the investigating police agency. Two profiles were mixtures that were not entered into CODIS (vaginal smear with three male contributors and vaginal and oral smear with mixtures of two individuals (one male)). In one case, vaginal swabs detected three contributors (two were male), and the vaginal smear had two contributors (one male). CODIS entries were made for both without any hits. In one case, the vaginal swabs, which included a swabbing of the vaginal smear, detected three contributors (one male), and a CODIS entry was made without any hits.

This review of archival sexual assault smears resulted in DNA profiles that were able to assist in the investigation of three cold case homicide investigations in Connecticut. Given the current advances in both DNA extraction techniques and molecular analysis, medical examiner offices may wish to search their archival histology slides for sexual assault smears that may yield sufficient sperm for DNA analysis on previously unsolved homicide cases.

### H133 Normalization of Polymerase Chain Reaction (PCR) -Based Quantification Using 9947A Human Standard DNA

Grace S. Woods, BS\*, Pleasant Garden, NC 27313; Rachel L. Creager, Defense Forensic Science Center, Forest Park, GA

**Learning Overview:** After attending this presentation, attendees will better understand the use of 9947A human standard DNA as a normalization control for comparing data from multiple quantitative PCR (qPCR) plates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating a method that increases the ability to compare DNA concentrations collected via qPCR on different days or when standards are used toward the end of the recommended storage life.

This study evaluated the effectiveness of using purchased 9947A human standard DNA as a normalization control for Plexor® HY and Quantifiler® Trio quantification kits. Currently, there is no normalization control included in qPCR kits for plate-to-plate comparisons when data is collected on different days or across multiple plates. Differences in quant values when comparing qPCR data collected in different runs may arise for a range of reasons, including differences in the dilution accuracy of the standards, pipetting accuracy of the amplification mix, or because the standard dilutions are near the protocol-specified storage limit and may be degraded. To assess some of these variations, a comparative analysis of quantification standards over time was performed using purified 9947A human standard DNA as a normalization control.

Quantification standards from Plexor® HY and Quantifiler® Trio kits were made and assessed at time points up to 14 days. Each set of standards was plated with purified DNA samples and 9947A human standard DNA using the QIAgility® automated robot. The observed quant value for 9947A can then be used in relation to its known concentration to normalize the sample concentration and allow for a more accurate comparison of quant values. Preliminary data shows that aged standards artificially increase the DNA concentration of plated samples. However, when using 9947A as a normalization control, data can be corrected to real concentration values. The effect of this normalization strategy will be discussed for samples across a wide range of quant values.

Based on the trends of qPCR standards degrading as they approach the recommended storage life and the inherent variables present in the quantification process, a normalization technique is necessary to compare data across multiple plates or from multiple days. This research has shown that artificially increased or skewed DNA concentrations can be corrected to their true value by using purified human standard DNA with a known concentration as a normalization control. Results from this study show this normalization method is useful for longitudinal research studies looking at the effect of modifications to sampling, storage, or extraction procedures.

### H134 Body Coloration Artifacts in Forensic Autopsy

Asit Kumar Sikary, MD\*, ESIC Medical College & Hospital, Faridabad, Haryana 121001, INDIA; Chittaranjan Behera, MD, Forensic Medicine, All India Institute of Medical Science, New Delhi, Delhi 110029, INDIA

**Learning Overview:** After attending this presentation, attendees will understand the various body color artifacts that are introduced to the body before or after death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enabling attendees to differentiate color artifacts from genuine antemortem or postmortem color changes occurring in the body.

Skin and mucosal discoloration are common in various diseases and poisonings. Jaundice, hemochromatosis, cyanosis, polycythemia, pancreatitis, retroperitoneal hemorrhage, carbon monoxide, and cyanide poisoning, etc. impart characteristic discoloration to the skin and mucosa, directing the autopsy surgeon for particular pathology, injury, or poison. It is thus highly important to be aware of coloration artifacts introduced to the external body surface leading to the wrong interpretation of various antemortem and postmortem findings.

Cases of the past 12 years from South Delhi, India, in which color was applied over the body surface before or after death formed the study group. The data were retrospectively collected from the archive of the center, including postmortem reports, inquest papers, and photographs of the cases.

One of the major scenarios of skin coloration in the present study was Holi, a color festivity of Hindus. These colors, when freshly applied, can be differentiated from skin changes; however, attempts to wash the body leaves a tinge of the color and may cause misinterpretation of deep facial congestion with red colors; of early bodily decomposition with green colors; of postmortem lividity over limbs or trunk with purple colors; and of cyanotic changes with blue colors. However, differences can be made by further fading of the color with washing, unusual appearance, or site of the color, and having no correlation with the bodily appearance, condition, injury, or disease.

Another major source of dead body coloration was the after-death ritual of applying turmeric paste. Its color is faded away when scrubbed thoroughly with hot water, leaving a yellow tinge, and may cause misinterpretation with signs of jaundice but can be distinguished by being unusual in site and distribution, no icterus, and no medical or surgical pathology known to cause jaundice.

Beauty products used by the deceased, such as vermilion and black eyeliner, was another source of discoloration. These beauty products always leave traces when cleaned or washed. Traces of eyeliner around eyes lead to misinterpretation, such as a black eye seen in head injury. However, proper history about the application of the product, regarding head injury and anatomical dissection, rules out the black eye phenomenon. Traces of smudged vermilion over the forehead causes confusion with facial congestion. However, it has an unusual distribution and fades away when washed.

Worn clothing stained the body surface as the clothing color was not fast enough. Likewise, ligature material used for hanging stained the ligature mark. These clothing-related colorations of the body or ligature mark are helpful in determining worn clothes or ligature material in doubtful cases. These colors are usually faded in appearance and distribution of the color is over the body regions covered by the cloth. Their colors are washed away with thorough hot water scrubbing. However, being faded in appearance, no one suspects it as an external coloration and, if not thoroughly washed, leads to various misinterpretations, depending on the color.

Finger and palm printing with blue pad ink was another source of body coloration, which is a standard procedure for identification. The ink leaves traces even after thorough hot water scrubbing. The discoloration of the palm can cause a misinterpretation of cyanosis, more so when fingernails are mistakenly stained during the procedure. However, other sites will not show any cyanotic change.

The medicinal dyes povidone iodine and methylene blue have discolored parts of the limbs. These were used for a wound which stained the skin, reddish-brown and greenish blue, respectively. These stains fade with hot water wash and can be misinterpreted as contusion and gangrenous lesions, but regional dissection at autopsy will clear the picture.

If the autopsy surgeon sees the body before washing of the color or takes the history about external coloration whenever there is unusual body coloration, the misinterpretation can be avoided. Touching these types of external coloration, if the color is not completely dried, with a gloved hand or a cotton swab will automatically stain the glove or swab. Examination of clothing will show the discoloration too.

#### Postmortem Change, Postmortem Artifact, Misinterpretation

### **H135 A Study on Detection of A-Helix Protein in Post-Traumatic Epileptogenic Focus by Fourier Transform Infrared (FTIR) Mapping**

*Bin B. Dai\**, Beijing, AB, CHINA; *Siyang Xiang*, Beijing, ASIA, CHINA; *Xu Wang, MD*, China University of Political Science and Law, Beijing, CHINA; *Tiantong Yang*, Haidian District, Beijing 100192, CHINA

### H136 Trends in Novel Opioid Use in the United States From January 2014 Through April 2018 in Medicolegal Death Investigations (MDIs) and Strategies to Improve Early Identification, Detection, and Interpretation

*Barry K. Logan, PhD\*, NMS Labs/Center for Forensic Science Research and Education, Willow Grove, PA 19090; Sherri L. Kacinko, PhD, Willow Grove, PA 19090; Donna M. Papsun, MS, NMS Labs, Willow Grove, PA 19030; Amanda L.A. Mohr, MSFS, Center for Forensic Science Research and Education, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will be able to describe the trends in novel opioids involved in MDI cases between 2014 and 2018, and the structural modifications made to the fentanyl molecule and its implications for toxicity. Attendees will be able to verify that the testing protocols being used in MDI investigations are appropriate and fit for purpose.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating death investigation professionals, coroners, and medical examiners about how to ensure that appropriate toxicology is being performed on their casework and that current and emergent drugs will be detected to assist with the appropriate certification of death and the collection of accurate death statistics.

The current opioid epidemic had its roots in the overprescribing of prescription semi-synthetic opioids in the 1990s and 2000s. Subsequent reductions in the legal availability of these drugs contributed to a demand for illicit opioids, including more easily imported illicit fentanyl. Once the infrastructure was in place to manufacture illicit fentanyl, it was an easy step for the clandestine manufacturers to make different variants with both greater and lesser potency. The same infrastructure allowed for the manufacture of completely novel opioids from the pharma back catalog also.

The impact of this has created a significant challenge for toxicology laboratories in creating and maintaining a relevant scope of analysis, including challenges of what to test for, the appropriate technology to use, the regulatory/accreditation environment, new drug trend intelligence, and availability of standard reference materials.

The early trends in novel opioids included the appearance of acetylfentanyl in 2014, followed by U47700 and furanylfentanyl in 2015, carfentanil in late 2015 and through 2016, then a plethora of boutique fentanyl analogs in 2016 and 2017, some of which persist at lower frequency today. Laboratory trend analysis indicates that while there is no end in sight for opioid abuse-related deaths, in the first half of 2018, it appears that death rates of cases involving opioid abuse have plateaued.

This presentation will review the relative frequency of novel opioid detection in death investigation casework and the concentrations and estimates of the toxicity of the various analogs detected. This presentation will discuss the meaning of cases with the presence of apparent fentanyl metabolite (4-ANPP) but no fentanyl and the need to perform further testing in these cases. This presentation will review the current trends toward toxicities associated with combinations of drug classes, including opioids and benzodiazepines, opioids and stimulants, and opioids and synthetic cannabinoids.

The application of high-resolution time-of-flight mass spectrometry has enabled toxicology laboratories to look retrospectively at the presence of newly discovered drugs in older casework without having to retest the samples and the use of data archiving as a tool for understanding the pharmacoepidemiology of emerging drug toxicity outbreaks.

This presentation will conclude with the description of a model of integrating data from seized drug investigations, MDI casework, and investigations of drug toxicity outbreaks in emergency room populations to support a system for early identification of new substances, notification of stakeholders in public health and public safety, and an early warning system to alert death investigators and toxicology laboratories to emerging trends.

#### Drug Early-Warning System, Opioids, Drug-Related Death

## H137 Acetaminophen Toxicity Deaths in New Mexico: 1990–2016

Lori A. Proe, DO\*, Office of the Medical Investigator, Albuquerque, NM 87102; Sarah Lathrop, DVM, PhD, Albuquerque, NM 87111

**Learning Overview:** After attending this presentation, attendees will understand the nature and scope of acetaminophen toxicity in the United States, interventions to reduce it, and specifics about trends of acetaminophen toxicity deaths in New Mexico.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) providing information on the significance of acetaminophen overdoses in the United States, (2) explaining efforts to reduce acetaminophen toxicity, and (3) discussing trends in acetaminophen toxicity deaths in one statewide medical examiner's office.

**Background:** Acetaminophen is the most commonly used pain reliever in the United States and is found in more than 600 medications.<sup>1,2</sup> At high doses, acetaminophen is metabolized to N-Acetyl-P-benzoquinoneimine (NAPQI), a hepatotoxin.<sup>1</sup> According to the Acute Liver Failure Study Group, most of the approximately 2,000 yearly cases of acute liver failure are caused by acetaminophen toxicity.<sup>3</sup> At least as early as 1977, the United States Food and Drug Administration (FDA) recognized the potential danger of acetaminophen and recommended that warning labels be added to acetaminophen-containing products.<sup>4</sup> Beginning in 1998 and as recently as 2011, the FDA issued rules and recommendations for labeling and dosing of prescription and over-the-counter drugs with warnings about the dangers of acetaminophen hepatotoxicity.<sup>5-7</sup> However, fatalities involving acetaminophen continue and may have increased between 2000 and 2009.<sup>8</sup>

**Purpose:** The goal of this project is to study deaths occurring as the result of acetaminophen toxicity in New Mexico to look for overall trends and to determine whether warning label interventions from the FDA affected the numbers of people dying from acetaminophen toxicity.

**Methods:** This study queried the New Mexico Office of the Medical Investigator's (NMOMI) electronic database for all deaths having acetaminophen in the Cause of Death section from 1990 through 2016. Cases were reviewed for relevance and cleaned in Excel®. Analysis was performed using Statistical Analysis Software (SAS) version 9.4. Categorical variables were compared using either a chi-square test or a Fisher exact test if an expected cell count was less than 5. Continuous variables were compared using a Wilcoxon rank-sum test, or a Kruskal-Wallis for multiple comparisons. P-values of 0.05 or less were considered statistically significant.

**Results:** Between 1990 and 2016, there were 158 acetaminophen-related NMOMI deaths, with a peak number of cases (18) in 2000. In most cases (98, 62%), acetaminophen was ingested with other substances. Hepatic toxicity was significantly more likely if acetaminophen was ingested alone and if alcohol use contributed to death ( $p < 0.0001$  for both). Declines in acetaminophen toxicity deaths were not observed in the years following labeling changes for acetaminophen-containing products. American Indians died from acetaminophen toxicity at significantly younger ages than those in other racial/ethnic groups ( $p < 0.0001$ ).

**Conclusions:** There appears to be no connection between labeling changes for acetaminophen-containing products and the number of acetaminophen toxicity deaths.

### H138 Comparative and Correlation Studies of Biochemical Substances in Vitreous Humor (VH) and Synovial Fluid (SF)

*Supawon Srettabunjong, MD\**, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok 10700, THAILAND; *Wantawanop Thongphap, BSc\**, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkoknoi 10700, THAILAND; *Anchalee Chittamma\**, Faculty of Medicine Ramathibodi Hospital, Mahidol, Ratchathevi 10400, THAILAND; *Wanna Thongnoppakhum\**, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkoknoi 10700, THAILAND

**Learning Overview:** After attending this presentation, attendees will better understand the comparative study of certain biochemical substance levels between two eyes and two knees of the same subject, and between the two compartments, as well as the correlation study between such biochemical substance concentration in VH and SF of the same person, and the essential basic knowledge for forensic application and research when using biochemical substance level in either fluid as a substitute body fluid for unavailable or inadequate blood to solve any forensic issues in daily practice or further research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting critical information of biochemical substance investigation in VH and SF for forensic purposes as it can augment traditional means of forensic investigation.

In forensics, in the case of a lack of blood, the VH and SF become optional postmortem samples. However, few studies have explored SF as a potential source for postmortem biochemistry investigation, and there is still controversy around whether the biochemical concentrations in the VH in both eye compartments are the same. In this study, the concentrations of certain biochemical substances in both VH and SF were evaluated and determined to compare their concentrations: (1) between the VH and SF from both sides, and (2) between the VH and SF themselves. The concentrations of the biochemical substances in both fluids were also evaluated for their correlation. VH and SF samples were collected from 35 cadavers (28 males and 7 females) with the mean age of  $47.3 \pm 16.5$  years (range 18–88 years); all subjects had died within 8h before their samples were collected. The samples were centrifuged, and the supernatant fluids were used for biochemical analysis.

The results indicated no statistically significant difference in the concentrations of all the biochemical substances studied between the VH and SF from both sides ( $p > 0.05$ ). Sodium, potassium, chloride, and magnesium concentrations were significantly higher in the VH than those in the SF, whereas uric acid and creatinine concentrations were higher in the SF compared with the VH. The concentrations of sodium, potassium, glucose, lactate, urea, uric acid, and creatinine between the VH and SF showed statistically significant correlation ( $p < 0.005$ ), but not chloride and magnesium concentrations. The results showed that VH or SF samples from either side can be used for postmortem biochemistry analysis. In addition, due to the significant relationships of the changing concentrations of all biochemical substances studied (except chloride and magnesium) between the VH and SF, the SF can be used as an optional postmortem sample for certain biochemical measurements in forensic applications and further research.

**Postmortem Biochemistry, Postmortem Chemistry, Thanatochemistry**

### H139 The Outbreak of Fentanyl-Related Deaths in Cook County, Illinois, Between October 2015 and December 2017: A Retrospective Study and a Comparison With Previous Data

Lorenzo Gitto, MD\*, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; Steven M. White, MD, PhD, Cook County Medical Examiner's Office, Chicago, IL 60612; Ponni Arunkumar, MD, Cook County Medical Examiner's Office, Chicago, IL 60612; Serenella Serinelli, MD\*, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

**Learning Overview:** After attending this presentation, attendees will better understand the prevalence of fentanyl-related deaths in Cook County, IL, and what drugs are being used with fentanyl.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the recent increase of fatalities due to fentanyl intoxication compared to previous data obtained in the same area.

Fentanyl is a synthetic  $\mu$ -agonist, a phenylpiperidine derivative with a structure closely related to that of meperidine. It is a potent narcotic used for anesthesia and analgesia. Individuals who are prescribed fentanyl for pain are prone to abuse or become addicted to the drug.

Moreover, fentanyl is made illegally and used as a recreational drug, often mixed with heroin or cocaine, since low production costs encourage suppliers to "cut" recreational drugs with it.

Previous research in Cook County found that a cluster of deaths from fentanyl intoxication appeared in late 2005. The study was conducted by Denton et al. between September 2005 and April 2007 and showed approximately 350 fentanyl-related deaths occurred in Cook County.<sup>1</sup> This epidemic had a peak in the middle of 2006, then drastically terminated in early 2007. In recent years, a new epidemic of fentanyl-related fatalities has been observed in Cook County.

To estimate the number and features of deaths due to fentanyl intoxication during the new epidemic, the electronic database of the Cook County Medical Examiner's Office in Chicago was examined for cases of people dying from fentanyl toxicity or combined drug toxicity, including fentanyl, between October 2015 and December 2017. A research using the keyword "fentanil" was also performed in the same period. The data were reviewed for age, sex, race, and cause and manner of death. The fentanyl-related deaths were then subcategorized as to the presence or absence of other drugs. No limits were imposed.

A total of 27,131 cases were identified in the studied period. Among these, 1,256 cases contained the keyword "fentanyl" and 4 cases contained the keyword "fentanil" as a primary cause of death. This study detected 112 cases of fentanyl deaths without other drugs or substances, 147 cases of fentanyl + heroin, 54 cases of fentanyl + ethanol, and 37 cases of fentanyl + cocaine. The remaining 900 cases included multiple drug intoxications (more than two drugs) with fentanyl synthetic analogues and other less frequent drug combinations. In four cases, the death was due to a combination of drugs including carfentanil but no fentanyl. A thorough discussion of the results, including demographic data and the comparison with the previous epidemic, will be shown to attendees.

After a first epidemic between 2005 and 2007, fentanyl intoxications significantly reduced, then reappeared in the recent years. Knowledge about this new outbreak could be useful for public health in monitoring and quickly diagnosing and treating acute intoxication when fentanyl is involved. Moreover, knowing the extent of the current problem could be useful for public safety purposes, while the analysis of the recreational drugs usually combined with fentanyl can contribute to a better-informed public policy that helps reduce risk for intravenous drug abusers.

#### Fentanyl, Toxicity, Synthetic Opioids

## H140 Loperamide Intoxication: Case Reports and a Review of the Literature

Paul Uribe, MD\*, Martin Army Community Hospital, Fort Benning, GA 31905

**Learning Overview:** After attending this presentation, attendees will (1) better understand the pharmacology and physiology of loperamide toxicity, (2) know the incidence of use and misuse of this drug for managing opiate withdrawal symptoms, and (3) be aware of the implications of the 2016 adverse side effect ruling on loperamide by the Food and Drug Administration (FDA).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the growing problem of toxicity and lethality of this readily available over-the-counter medication.

Loperamide is a readily available and increasingly abused over-the-counter anti-diarrheal medication that is a growing cause of medication-related fatalities in the United States. In higher doses, loperamide can produce side effects of cardiotoxicity, cardiac arrhythmias, euphoria, and central nervous system depression. Loperamide is a  $\mu$ -opioid receptor agonist that is metabolized by the cytochrome P450 system.<sup>1</sup> Loperamide has low bioavailability in appropriate doses, and therefore has limited central nervous system activity due to the limited ability to cross the blood-brain barrier. In higher doses, the drug can penetrate the central nervous system and lead to tolerance and, upon cessation of use, withdrawal symptoms. The arrhythmogenic side effects include syncope, QT-interval prolongation, QRS-interval widening, torsade de pointes, ventricular dysrhythmias, and cardiac arrest.<sup>2</sup> Loperamide is increasingly used, and misused, as an inexpensive, readily available, over-the-counter alternative for self-managing the symptoms of opiate withdrawal, including withdrawal from methadone.<sup>2-4</sup>

From 2010 to 2015, there was a 91% increase in reported loperamide abuse.<sup>5</sup> Between 2002 and 2015, 224 adults were referred to a health care facility for intentional ingestions of loperamide as reported to the poison control system.<sup>6</sup> During this period, there were 15 reported deaths involving loperamide, with over half involving single-agent loperamide abuse. There was a spike in the number of cases between 2014 and 2015, which coincided with plentiful online instructions on how to abuse this drug. The availability and misuse of loperamide has resulted in the FDA issuing a warning about the adverse side effects in June 2016.<sup>7</sup> This warning was based on 48 cases of severe cardiac side-effects associated from loperamide misuse from the approval date of loperamide of December 1976 through December 2015, with more than half of the cases reported after 2010.

Depending on what toxicology screens are available, loperamide may be overlooked as routine drug screen panels may not detect this drug. It may also be clinically overlooked in routine drug testing for drug-treatment program compliance. Thorough scene investigation may overlook this relatively innocuous medication. Clinical awareness of this entity is critical to early recognition and treatment. Two unexpected deaths from acute loperamide intoxication are discussed and followed by a discussion of the pharmacology, side-effects, and abuse trends involving this readily available over-the-counter medication.

### H141 Cocaine as the Sole Intoxicant in an Unusual Suicidal Overdose

*Michael Heninger, MD\*, Fulton County Medical Examiner's Office, Atlanta, GA 30312*

---

**Learning Overview:** After attending this presentation, attendees will understand that cocaine can be the sole intoxicant in a suicidal overdose.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing how cocaine can be the sole intoxicant in a suicidal overdose in the circumstances of an unusual personal belief system.

Drug overdoses have become far more common in the United States in the past few years. Recreational drugs have previously often been used repeatedly in accidental overdoses with the intent of no serious lasting consequences. Drugs selected in suicide are thought to be dangerous by the users who desire the most serious consequence. Although there is considerable overlap between the drugs commonly used in suicidal versus accidental overdoses, the use of perceived less-dangerous stimulants is rare in suicides.

Cocaine is often the only drug detected in an accidental overdose and frequently one of many in either a suicidal or accidental overdose. Cocaine can be inhaled, snorted, injected intravenously, ingested orally, or absorbed vaginally or rectally, all with potentially fatal outcomes. Cocaine as the only potentially lethal substance used to commit suicide is rare. No other cases are known in per this research in a setting with thousands of accidental cocaine deaths over many decades.

Reported is an intentional overdose using cocaine as the only dangerous substance of a 37-year-old Black female, who was otherwise in excellent health. The decedent was found by her mother, expired in her bed in a prone position with her face in a pillow. Paramedics were summoned and noted that she was in rigor and did not attempt to resuscitate her. Pink fluid stains were on the pillow under her face. A container with only a small amount of residual pink fluid made cloudy with a white residue was found. Drug paraphernalia, including a small clear plastic bag with small white rocks and trace amounts of residual white power along with green leafy vegetable material, was noted. Also obtained was a small container of commercially available of 24K edible gold leaves. The decedent had a history of schizophrenia and/or bipolar disorder with previous suicidal ideation.

The lab results showed a cocaine level of 2,500ng/ml, benzoylecgonine level of 4,100ng/ml, and a cannabinol level of 1.5ng/ml.

The intent was well documented with a mysterious handwritten note of several pages entitled "Death Ritual Protocol." Select quotes included: "Invocation of Eji Ogbe accompany me on the road," "Eat drugs save cocaine for last snort as much as possible," and "My father will come to life with me. The ground will open up." Web-based searches of several of the proper names listed in the note indicated they are part of a religion or system of divination called Ifa. It appears to have originated in West Africa among the Niger-Congo ethnic group centuries ago and is practiced there and throughout the Americas. It plays a role in many syncretic religions such as Santeria, Candomble, Palo, Umbanda Vodou, and others. The notes indicated a clear intent to die, but also the intent to not stay dead.

### Suicide, Cocaine, Overdose

### H142 The Utilization of Preliminary Urine Drug Screens in Heroin- and Fentanyl-Related Deaths

*Gerald Feigin, MD\*, Sewell, NJ 08080*

---

**Learning Overview:** The goal of this presentation is to show how to use preliminary urine drug screens in routine drug-related deaths to help rapidly and accurately determine a reasonable initial cause of death.

**Impact on the Forensic Science Community:** Pending every drug-related death causes undue difficulties for families of decedents. This presentation will impact the forensic science community by demonstrating how to use preliminary drug screens to create a cause of death on a death certificate. Follow-up and amendments can be made after final toxicology is received.

Positive urine drug screens rapidly and accurately predict findings in postmortem confirmatory toxicology and avoid pending cases.

An examination of 200 consecutive heroin- and fentanyl-related deaths shows a very strong correlation between preliminary urine screen for heroin (opiates). Fentanyl, because of the very rapid respiratory depression, often may not be present in urine screens. However, using a “cheat” with minimally diluted cardiac blood often shows fentanyl positivity. When drug-related deaths have negative results on preliminary screens, novel fentanyl analogs are often present and frequently require more extensive toxicologic testing. Although a urine drug screen is not a substitute for postmortem blood toxicology, it is a very good tool for rapid guidance in determining cause of death.

Cocaine, methamphetamine, methadone, and benzodiazepines, such as alprazolam, clonazepam, and diazepam, were not considered for this presentation. They clearly contribute to cause of death either directly or indirectly. The screen that was used will detect cocaine metabolite, methamphetamine, opiates, and benzodiazepines. A separate screen is used for fentanyl. Cocaine is often seen in combination with all of the above. A separate presentation will be made in regard to combination drug deaths in the future. It should be noted that there is no therapeutic level of heroin, cocaine, or fentanyl when used in non-medical circumstances.

When death certificates are pending, this causes stress to families who have already lost a loved one. Waiting for final toxicology to be received can take weeks to months depending upon jurisdiction. This prevents families from receiving death benefits, funeral directors from being paid, and children of decedents from receiving needed money. Using preliminary drug screens, when positive, to create an initial cause of death such as “Adverse Effect of Drugs” on a death certificate, followed up by a more precise cause of death by listing all the responsible agents is a reasonable alternative to universally “pending” every and all drug deaths at time of autopsy. This also simplifies amendments by allowing only one line to be changed, the cause line, as opposed to all other items in amendment such as how, where, when did injury occur.

---

### H144 A Modern Application of Forensic Anthropology in Coroner and Medical Examiner Offices: A Preview

*Katharine Chapman Pope, MA\*, Division of Forensic Science, Wilmington, DE 19801; Lindsay H. Trammell, PhD, Saint Louis County Office of the Medical Examiner, St. Louis, MO 63134; Sharon M. Derrick, PhD, Texas A&M University-Corpus Christi, Corpus Christi, TX 78412; Elizabeth A. Miller, PhD, California State University Los Angeles, Los Angeles, CA 90032*

---

**Learning Overview:** The goals of this presentation are to: (1) inform the medicolegal community of the value of forensic anthropology in death investigation, (2) apprise attendees of the details of obtaining valuable assistance in casework from a forensic anthropologist, (3) discuss the certification process within the field, and (4) impart through case examples exactly how forensic anthropologists can assist them in their casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the utility of forensic anthropologists in daily tasks of a medical examiner/coroner office.

Forensic anthropologists are gaining attention in the medicolegal community as an underutilized resource whose multi-layered approach to death investigation can be invaluable. Medicolegal death investigators, law enforcement, medical examiners/coroners, criminalists, attorneys, and judges often rely on discipline-specific experts to enhance their expertise. Forensically trained anthropologists are knowledgeable in all aspects of death investigation and can assist in field recovery of decedents, classification of cause and manner of death, identification of unknown decedents, and prosecution or defense of suspects in court. Although anthropologists began serving as consultants in death investigations much earlier, forensic anthropology as a discipline was recognized by the American Academy of Forensic Sciences (AAFS) in the mid-1970s, and the American Board of Forensic Anthropology (ABFA) came into existence in 1977.

Forensic anthropologists are experts in locating clandestine graves and recovering remains from a variety of contexts, such as fire scenes, graves, surface scatters, collapsed buildings, plane crashes, or any scene in which a body is not recently deceased, fully visible, and/or intact. With their knowledge of osseous/cartilaginous tissue anatomy and archaeological recovery methods, anthropologists can differentiate non-human remains during scene searches, and recover remains and associated evidence under circumstances far removed from the routine death scene. These skills save time and effort for each agency involved.

From the autopsy table to the laboratory, the forensic anthropologist can provide a full spectrum of analyses, from biomechanical evaluation of fractures to timing of injuries and healing, to differential diagnoses of pathological conditions. At the request of the medical examiner/coroner, the anthropologist may retain specimens from a fleshed body and remove soft tissue for analysis of the bone or cartilage. Anthropological assessments may establish patterns of trauma in child or elder abuse cases or differentiate inflicted from accidental injury. In skeletal cases, the anthropologist can sort commingled remains into individuals, estimate the number of individuals represented, construct demographic profiles, and reconstruct what happened to the remains from the time of death to the time of recovery, thereby enhancing the opportunity for personal identification. Following analysis, the anthropologist can properly curate skeletal remains and reinvestigate unidentified cold cases.

### H145 The Histomorphology of Cranial Fracture Healing: Case Examples

*Carolyn V. Isaac, PhD\*, Kalamazoo, MI 49008-8074; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007*

---

**Learning Overview:** After attending this presentation, attendees will understand the types of histologic changes that are manifest within healing cranial fractures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the histologic features of several examples of healing/healed cranial fractures, including samples from differing age groups, different fracture/healing time, and varying types of histology stains used.

This study recently received a National Institute of Justice grant for the investigation of cellular and morphologic characteristics of healing cranial vault fractures, to develop a time-since-fracture database specifically related to cranial fractures. This database is composed of cranial fractures with a known date and time of injury, with samples submitted to the Western Michigan University School of Medicine from numerous partner offices/institutions. The development of specific protocols for radiologic evaluation, as well as sample decalcification and processing are ongoing. A series of several stains, including hematoxylin and eosin, trichrome, and Alcian Blue/Orange G, are prepared for each sample, and a group of blinded forensic pathologist and anatomist reviewers evaluate the histologic sections for the presence or absence of numerous specific features. As the total number of samples submitted increases, the hypothesis is that a reliable, reproducible, histomorphological timeline for cranial fracture healing will be established, with possible notable variations related to fracture location, concomitant morbidities, and age of patient/decendent. This time-since-fracture database will be helpful in evaluating other forensic cases, where the timing of cranial fracture is in question.

As arrangements with partner organizations are ongoing and sample preparation protocols are being refined, the database currently contains approximately two dozen samples, with decedent ages ranging from approximately 2 months to nearly 78 years of age and known injury ages ranging from acute (minutes) to 42 years. In this initial report, this study will present examples of the types of cases currently in the database. These will include cases of acute fractures, where virtually no histologic evidence of healing exists, cases with several hours of healing, cases with days-to-weeks-to-months of healing, and cases which are, for all practical purposes, considered completely healed, with a post-injury healing time of many years. Photomicrographs of histology sections with each stain will be provided, focusing on the important aspects of the healing process that are highlighted by each stain.

Although one aim of this presentation is to provide an illustration of the histologic features of cranial fractures of varying age and in different aged cohorts, an additional goal is to use the presentation as an outreach to the forensic pathology community to recruit more partner offices/institutions for this important project. Only with a sizeable sample will this project attain the numbers necessary for reliable statistical conclusions. Cases of healing cranial fractures of definite known time-of-injury are not very common; however, with more partners involved in the study, the hope is that an adequate sample size will be attained so that this time-since-fracture database will represent a solid and reliable resource for forensic scientists faced with questions regarding cranial vault fracture healing time.

*This research project is supported by funding provided by a National Institute of Justice grant.*

### H146 A Comparison of Three Methods for Assessment of Bone Decalcification Time and Quality of Histological Slides for Cranial Fracture Healing Investigation

Jered B. Cornelison, PhD\*, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Carolyn V. Isaac, PhD, Kalamazoo, MI 49008-8074; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will: (1) learn an easy, accurate, and non-destructive method for determining whether bone samples are decalcified; (2) learn the amount of time required to decalcify cranial vault bone using three different decalcification methods among three different age cohorts; and (3) understand which decalcification methods affect the quality of bone histomorphology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing best practices for human bone decalcification aimed at investigating the microscopy of bone and fracture healing. As such, the results of this study will be used as a standard protocol for decalcification of cranial bone from various aged decedents.

As part of a National Institute of Justice grant investigating cranial fracture healing, several decalcification techniques were explored to determine the amount of time for processing and the resulting quality of the healing bone histomorphology. Forensic histology laboratories often use Hydrochloric acid (HCL) because it provides the most expedient bone decalcification. However, there is evidence, that nitric acid and Ethylenediaminetetraacetic acid (EDTA) decalcification yield better results in non-human bone for the visibility of tissues, cells and molecules active in bone biology.<sup>1</sup> As most studies of cranial bone decalcification and healing use small animal models, this is an important first step to determine the methods best suited for human bone decalcification.

The sample is comprised of 50 samples from 23 individuals, ranging in age from 2 months to 77 years. Samples were fixed in 10% formalin for two to four weeks. Before decalcification, all bone sample dimensions and weights were recorded. Where possible, bone samples were cut into three sections for immersion in 10% EDTA, 5% nitric acid, and 7% HCL, and placed on an orbital shaker. Radiographic techniques were used to determine the degree of decalcification. In the initial radiographic inspection, settings were adjusted until radiopacity was consistent across the bone sample. These same settings were used in subsequent examinations until radiopacity was absent throughout the sample, indicating decalcification was complete. It was found that the radiographic technique varied primarily according to bone thickness and, secondarily to age. Thinner samples, such as infant cranial bone and thin areas of adult bone (e.g., pterion), required a setting of 40KVp to 48KVp and 0.9mAs to 1.8mAs. Older children and diploic bone required a setting of 50KVp and 2.5mAs.

After decalcification was complete, samples were rinsed in water for at least an hour to halt the decalcification process. Each sample was then cut with a scalpel and placed in a cassette for paraffin embedding and slide preparation. Three different histological stains were used, including Hemotoxylin and Eosin, Masson's Trichrome, and Alcian Blue Hematoxylin with an Orange G counterstain, resulting in 150 histological slides. Slides were assessed for the quality of cell, cell nuclei, and tissue visibility.

The results of the decalcification study show that for infants, juveniles, and adults HCL decalcification was the most rapid technique, followed by nitric acid and EDTA. For infants, HCL required 1 to 2 days, Nitric Acid required 2 to 5 days, and EDTA required 5 to 27 days for decalcification. For juveniles, HCL required 4 days, and nitric acid required 7 to 8 days for decalcification. Adult samples were more variable, requiring 2 to 4 days with HCL, 3 to 10 days with nitric acid, and 13 to 60 days with EDTA. EDTA decalcification times tended to increase with age; older aged adults required more decalcification days. A review of slide quality indicates that nitric acid and EDTA yield optimum results, with highly visible nuclei and greater stain color gradient contrast than HCL.

In conclusion, for high-quality slides produced relatively rapidly (1 to 10 days), nitric acid is the best decalcification technique for viewing histological structures related to bone. However, the gentle effects of EDTA chelation allowed samples to be used for immunostains and other special stains useful for investigating cells and tissues involved in bone healing.

*This project was supported by a National Institute of Justice grant.*

### H147 Drugs and Homicide in Memphis and Shelby County: A Continued Epidemic of Violence—2014–2016

David W. Coates, MS\*, West Tennessee Regional Forensic Center, Memphis, TN 38105; Benjamin J. Figura, PhD, West Tennessee Regional Forensic Center, Memphis, TN 38105; Sherri L. Kacinko, PhD, Willow Grove, PA 19090; Kevin Jenkins, MD, West Tennessee Regional Forensic Center, Memphis, TN 38105; Paul V. Benson, MD, University of Tennessee Health Science Center/Shelby County Medical Examiner, Memphis, TN 38105

**Learning Overview:** After attending this presentation, attendees will understand the trends of select drug usage among homicide victims from 2014–2016 in Memphis, TN, and how it has changed since 1984–1986.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reporting on the detection of drugs in homicide victims and discussing statistical points of interest previously reported in the late 1980s.

The West Tennessee Regional Forensic Center performs autopsies on medicolegal, violent, or otherwise unnatural deaths in Memphis and Shelby County. Toxicological data is an important asset for determining the significance that drugs and alcohol have on the manner and cause of death, including homicide-related deaths. Specimens, including blood, urine, vitreous humor, liver, and gastric contents, are collected during autopsies and screened using common analytical toxicology methods, such as immunoassay, full-scan Gas Chromatography/Mass Spectrometry (GC/MS) or Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS). Positive findings are typically confirmed and quantified by GC/MS or Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). From 1980 to 1986, drug-related homicides increased according to a study by Harruff et al.<sup>1</sup> Exhaustive research showed that no current studies on drug-related homicides in Memphis and Shelby County have been published since 1988. This study reviewed toxicology findings from homicide cases examined at the West Tennessee Regional Forensic Center from 2014–2016. The purpose of this research was to determine the presence or absence of drugs in homicide victims and determine if any statistical trends were present.

Toxicology findings for known homicide cases from 2014–2016 were collected to build a data set in which decedent age, race, sex, and cause of death were tabulated. It was decided to focus this study on cases with positive results for THC, opiates, amphetamines, benzodiazepines, and ethanol. Previous research indicated that THC was not previously tested for but was included in this study due to its known widespread usage. Homicide victims were sorted according to their cause of death into the following major categories: gunshot wounds, blunt force trauma, stab wounds, delayed homicide, and other, and the frequency of positive results for each drug was recorded. Age as well as other demographics of homicide victims were categorized similarly to those used during the 1986 study to make comparisons. While previous research revealed that cocaine had risen to the most often-detected drug in homicide victims at the end of 1986, cocaine was found to be the third most-common toxicology result at the end of 2016. THC was found to be the most common positive toxicological result, accounting for 240 of the 460 total positive toxicological screens in the current study. Gunshot wounds remained the most prevalent cause of death associated with homicides in which drugs were detected, accounting for 83.7% of all drug-positive deaths. The most common victims of homicide, regardless of toxicology results, are African American males between the ages of 20 and 24 years. Review of these results indicated that illicit drug usage is widespread among homicide victims in Memphis, TN, and remains a common finding in homicide autopsies.

**THIS ABSTRACT WAS NOT PRESENTED.**

## H149 The Tale of an Operating Room Fire Fatality

Tasha Zemrus Greenberg, MD\*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919

**Learning Overview:** After attending this presentation, attendees will understand the incidence, etiology, features, and consequences of Operating Room (OR) fires.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating medical examiners and forensic investigators about key features of OR fires, guiding the incident investigation and autopsy, and stressing the importance of interagency cooperation in the investigation.

On January 6, 2015, the fire department was contacted about an OR oxygen flash fire. Saline was used to douse the fire with minimal room damage. Fire investigators advised securing the OR until their inspection the next day. Upon arrival, the OR had been cleaned. A bed and pillow present showed burn marks. Items from the trash were retrieved. It was then reported that a patient was involved and had expired. The fire chief, hospital president, and police department were notified, and a detective was assigned.

At that time, the case was reported to the Tarrant County Medical Examiner's Office (TCME). The body was retrieved from a funeral home, and an autopsy was performed on January 8, 2015. On January 12, 2015, materials from the OR were received, including an orogastric tube, corrugated plastic tubing, oxygen face mask, blanket, plastic fragment, black strap, hospital gown, black covered foam, foam head rest, and two pillows with variable thermal damage and soot deposition in the face mask.

The patient's medical history included chronic obstructive pulmonary disease, amiodarone-related lung toxicity, hypertension, hyperlipidemia, diastolic heart failure, abdominal aortic aneurysm, gastroesophageal reflux disease, diverticulosis, and chronic anemia.

She presented to the hospital in December 2014 with abdominal pain due to diverticulitis with a small bowel obstruction and pelvic abscess and underwent small bowel resection with anastomosis on December 16, 2014. She developed respiratory failure requiring intubation, pneumonia with sepsis, acute kidney injury, and atrial fibrillation. She was extubated yet required 100% oxygen on BiPap, necessitating a tracheotomy in the OR.

The patient was wearing a Phillips® Respiration Fitlife full-face mask with a nasogastric tube coming out from under the mask with 100% oxygen flowing when Bovie electrocautery was used for the tracheotomy, causing the oxygen flowing through the mask to catch fire, leading to burns of the head, neck, right shoulder, and airway. It was not specified in the OR note if monopolar or bipolar diathermy was used. An emergent cricothyrotomy was performed; she failed extubation trials and expired later the same day after withdrawal of care.

There are multiple published reports of OR fires, estimating that 600-700 OR fires are reported each year, with many more unreported.<sup>1</sup> The most common situations include use of laser or cautery with an endotracheal tube, but any high oxygen concentration situation is a risk factor.

Recommendations by the American Society of Anesthesiologists Task Force on Operating Room Fires include use of diathermy, reduce build-up of oxygen beneath the surgical drape, and turn off oxygen one minute prior to using laser or cautery, with open communication between surgeon and anesthesiologist.<sup>2</sup> If a fire occurs, disconnect the oxygen supply, use a saline wash, and remove the cautery device. It is recommended to never use electrocautery when FiO<sub>2</sub> levels are greater than 50%.<sup>3</sup> CO<sub>2</sub> flooding of the surgical field can decrease the risk of fire in patients who cannot tolerate ventilation interruption.

The fire triad consists of fuel (tube/mask), oxidizing agent (oxygen), and ignition source (laser or electrocautery). OR fires are seen most commonly in head and neck surgeries and are less common now that less flammable anesthetic agents are used.

Findings at autopsy included thermal injuries of the head, neck and right shoulder, as well as the upper airway, in addition to emphysema, pneumonia, atherosclerotic cardiovascular disease with right ventricular dilatation, nephrosclerosis, diverticulosis, lymphadenopathy and splenomegaly. Toxicology was not contributory. The death was ruled an accident due to acute upper airway thermal injury due to medical equipment fire with chronic obstructive pulmonary disease, pneumonia, and hypertensive atherosclerotic cardiovascular disease with heart failure as contributory conditions.

The family filed a civil lawsuit against the surgeons, anesthesiologist, anesthesiology group, president, and vice president of the hospital as defined in the Texas Civil Practice and Remedies Code Section 74.001. The case was settled out of court for an undisclosed amount of monetary damages.

### H150 The Botanical Survey in the Collection of Scientific Evidence for Reconstructing the Dynamics of Deaths From High Falls: A Case Report and Review of Literature

Isabella Aquila, MD\*, Institute of Legal Medicine, Catanzaro 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Barbagallo, MD, Institute of Legal Medicine, Catanzaro, ITALY; Francesco Sicilia, MD\*, Institute of Legal Medicine, Catanzaro, ITALY; Vincenzo Rania, MD, Institute of Legal Medicine, Catanzaro, ITALY; Santo Gratteri, MD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Pietro Tarzia, MD, Institute of Legal Medicine, Catanzaro, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of forensic botany in crime scene investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of botanical surveys in reconstructing the dynamics of death from high falls.

Scene investigation plays an important role in a crime. Often the crime scene is an open environment consisting of trees, plants, and shrubs. The forensic pathologist must compare the botanical elements with the evidence present on the victim.<sup>1</sup> Although the discovery of botanical elements on the scene is very common, to date forensic botany is a resource still underestimated. Investigators often fail to identify all elements and sometimes this evidence can be degraded or indistinguishable. For this purpose, DNA sequencing and biomolecular investigations become fundamental.<sup>2</sup> In literature, forensic botany was used to determine the path followed by the victim and to exclude other possible routes.<sup>3</sup> Forensic botany was crucial for demonstrating that the primary scene of a crime was falsified.<sup>4</sup> Sometimes, the crime scene and autopsy do not provide sufficient evidence. For example, in deaths from high falls, the forensic pathologist may have difficulty establishing the point of fall, the trajectory, the collision with obstacles, and the point of impact.

Reported here are two cases of death from high falls. The first case concerns a child who fell from the sixth floor of her home. The circumstantial data showed that the victim had fallen from the bathroom's window although there were some doubts about her suicide because of the presence of a gazebo that could be a possible way to escape from her house after a family quarrel. The girl was found on the ground near a gazebo that was completely destroyed. The gazebo was on the ground floor in the apartment of a neighboring family. About 1.5 meters from the gazebo, there was a separating hedge, more than two meters high. During the inspection, some botanical elements corresponding with the separating hedge were found on the victim's clothes and hair. The external examination excluded signs of a scuffle or violence. The botanical elements suggested an impact of the body on the hedge and subsequently a projection toward the gazebo with following breakage. According to the evidence on the scene, investigators established the mode of death due to suicide.

In the second case, an elder male was found on the ground, below a hill. The scene consisted of undergrowth vegetation. The head was resting on a blood-stained stone. Some shredded leaves were found in the victim's left hand, and some thorns were attached to the left sleeve of his sweater. Autopsy showed that the victim had widespread abrasions and bruises. A head injury was found, with petechiae (Wischnewsky Lesions) on the gastric mucosa. The autopsy showed no signs of scuffling and revealed that he died by frostbite because he was restrained due to head injury. There were doubts about the mode of death that were clarified by the botanical analysis of the point of fall and impact, confirming the hypothesis of a fall from height by accident.

Falls may be from a great height (more than ten meters) or from a medium height (less than ten meters). In the first case, there is a disproportion between the external injuries and the severity of organ lesions. In the second case, there are more external injuries.<sup>5</sup> In fatal falls, the evidence on the scene or autopsy findings are often insufficient to establish the dynamics. In the two cases reported, this study shows how the comparison between the data on the scene and the botanical findings on the corpse allow a reconstruction of the dynamics in relation to the external environment. The botanical analysis allowed calculation of the point of fall, the trajectory, and the point of impact precisely. These data were fundamental, together with other evidence collected, to determine the mode of death. For this reason, it is important, especially in cases of fatal falls in open environment, to: (1) evaluate the entry and exit ways of the area, (2) record the position of the corpse, (3) compare the botanical elements on the scene with the evidence on the clothes or victim, and (4) exclude signs of violence and other causes of death at autopsy.

### H151 Deaths Due to Illegal Immigration: Always Drowning?

*Isabella Aquila, MD\**, Institute of Legal Medicine, Catanzaro 88100, ITALY; *Fabrizio Cordasco, MD\**, Università Magna Graecia CZ, Catanzaro, ITALY; *Francesco Sicilia, MD\**, Institute of Legal Medicine, Catanzaro, ITALY; *Santo Gratteri, MD*, Viale Europa, Germaneto, Catanzaro 88100, ITALY; *Matteo A. Sacco, MD*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; *Pietrantonio Ricci, MD, PhD*, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to describe the impact of differential diagnosis in suspected drownings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the role of autopsy and forensic investigations in landings of illegal immigrations.

The phenomenon of illegal immigration causes many victims every year. In most cases, the lack of safety measures on the boats increases the incidence of tragic accidents. Between 2002 and 2017, more than 300,000 immigrants died during illegal disembarkations on the Mediterranean Sea. This phenomenon still occurs on Ionian coasts.<sup>1</sup> In the majority of cases, the cause of death is drowning. Death also occurs due to pre-existing diseases, trauma, hypothermia, dehydration, and postpartum complications. The dangers include shipping incidents or crimes committed by smugglers against migrants who escape when they notice the authorities of the coast guard. The differential diagnosis between drowning and other causes of death is often complicated and requires multiple investigations. This issue is analyzed through a case of suspected drowning that occurred during an illegal landing.

**Case Report:** An unidentified Black youth, 14-16 years old, was found dead on a beach. The cause of death was unknown; the investigators suspected a drowning during an illegal landing. A judicial inspection and a radiological investigation (Computed Tomography/Mass Spectrometry (CT/MS)) were conducted. An autopsy, with histopathological investigation and search for diatoms, was performed. The data were compared and analyzed. Finally, a protocol provided by the International Criminal Police Organization (INTERPOL) for the identification of the corpse was activated.

**Results:** The external examination showed the presence of algae, sand, and piloerection with skin maceration. The autopsy revealed a wide fracture of the left femur. A massive pulmonary thrombus-embolus was found; other clots were found in the heart and were also within the structure of the papillary muscles and tendons, until the superior and inferior vena cava. A histopathological investigation showed the presence of diatoms within the lungs and other organs.

**Discussion:** Drowning is an asphyxia that is caused by the entry of water within the airway. Globally, deaths by drowning are estimated to be 370,000 per year.<sup>2</sup> Drowning may often occur in cases of illegal landings of migrants. In these cases, the forensic pathologist must exclude other causes of death before the diagnosis of drowning. Also, he must investigate signs of trauma, violence, or skin injuries on the body. In the case reported, the external examination didn't show typical signs of asphyxia. The autopsy did not show the presence of water in the stomach or bowel; the radiological investigations supported the autopsy findings. In addition, the histopathological investigation revealed the presence of diatoms within the lungs and other organs. This data could confirm the diagnosis of drowning. However, the autopsy revealed that the real cause of death was a pulmonary thromboembolism due to the femoral fracture. The diagnosis of drowning, therefore, was excluded. Finally, the dynamics were reconstructed: the boy was thrown into the sea and the trauma caused the left femur fracture; later he reached the shore, where he remained for about two days until he died of pulmonary thromboembolism. The case reported shows the importance of a careful interpretation of the data. The finding of diatoms is not always pathognomonic for drowning, and the diagnosis requires the exclusion of other possible causes. Therefore, a comparison of multiple forensic surveys is essential before diagnosis.

**Conclusions:** Illegal immigration is a major public issue. In case of illegal landings, forensic sciences are necessary to investigate cases of violence or deaths linked to the phenomenon. In these cases, the forensic pathologist performs a differential diagnosis with drowning. Many forensic surveys must be carried out before this diagnosis. Autopsy remains the gold standard for excluding other causes of death and to establish time and manner of the event.

### H152 An Unusual Case of Suicide Due to a Gas Mixture Poisoning

Isabella Aquila, MD\*, Institute of Legal Medicine, Catanzaro 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona, ITALY; Santo Gratteri, MD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Luigi De Aloe, MD\*, Institute of Legal Medicine, Catanzaro, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Foggia 71100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of ethanethiol in acute poisoning by suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the chemical characteristics of the substance and its role in the putrefactive process.

The inhalation of volatile substances as a suicide method is rare, while the use of the same as abuse substances is quite common worldwide and is called Volatile Substance Abuse (VSA). In the majority of cases, the use of these substances as a suicide method is practiced by adult prisoners; the use of the same as abuse substances is more common in adolescents representing an important cause of mortality and morbidity in the young population. The most common types of volatile substances are aliphatic (butane, propane), aromatic (glues, lacquers, solvents), and halogenated hydrocarbons (spray paint, propellants). The methods of a substance's intake are: direct inhalation of the substance ("sniffing," inhalation by nose or the mouth), the inhalation through a cloth that is impregnated ("huffing"), and inhalation through a plastic bag. Liquefied Petroleum Gas (LPG) ( $\text{CH}_3 \text{CH}_2 \text{CH}_3 + \text{CH}_3 \text{CH}_2 \text{CH}_3$ ) is an odorless volatile substance and usually it is added with ethanethiol ( $\text{CH}_3 \text{CH}_2 \text{SH}$ ), a harmful gas with a bad odor (garlic). Ethanethiol has caused a neurological action on the central nervous system causing fatal respiratory depression. From the analysis of the literature, the main causes of death by acute poisoning are cardiac arrest (Sudden Sniffing Death Syndrome) and asphyxia, while the main causes of death due to chronic abuse are cardiomyopathy, myocardial infarction, and central nervous system toxicity.<sup>1,2</sup> Postmortem analysis on biological fluids and tissues is performed by the gas chromatography method.

A Belarusian boy (weight 100kg, height 185cm) was found dead in his home (ambient temperature: 26°C). The boy was in the kitchen in a supine position with a black plastic bag wrapped around his head with a hole from which he passed a gas hose connected to a domestic LPG tank. A judicial inspection was conducted to exclude any signs of a scuffle or break-in. At home, antipsychotic drugs were found. The analysis of the witnesses among the family members showed that the boy was suffering from psychosis with hallucinations and a history of drug addiction. The psychological autopsy showed his sister's suicide from height fall. The boy and his sister were both adopted by an Italian family. An autopsy was performed. The corpse appeared in a putrefaction state (12 hours after death). The hypostasis were abundant in red-bluish color at the back, chest, and neck. The lungs showed edema with anthracosis areas. The heart revealed small sub-epicardic petechiae. The buccal cavity showed a mucous hyperemia. A toxicological and histopathological investigation was carried out. The organs' analysis was limited by the presence of putrefaction, in particular on the brain and pancreas. The toxicological analysis showed an increase of blood glucose and the presence of antipsychotic drugs due to pharmacological therapy. Butane and propane concentrations were found in the blood, bile, and adipose tissue. Ethanethium's concentration was detected in peripheral blood and urine.

The analysis of this case shows that the gas mixtures used as suicide methods can be lethal even at low concentrations. In the case of LPG, the chemical analysis shows that the most lethal or responsible gas in the genesis of death is ethanethiol. The lethal effect of ethanethiol can be due to the -SH chemical group, which has a high biological toxicity with potential affinity for hemoglobin. The lethal effect is also due to the mixture of gas with the known toxicity of butane and propane.<sup>3</sup> From the forensic point of view, in the analysis of the postmortem interval, it is crucial to underline that, in cases of gas mixture poisoning, the presence of ethanethiol speeds up the putrefaction due to the -SH chemical group for the composition of sulfuric methemoglobin responsible for the putrefactive process.

### H154 Spleen Attenuation and Routine Measurements With Regard to Cause of Death and Estimation of Spleen Weight: A Study on Postmortem Computed Tomography (PMCT)

Vasiliki Chatzaraki, MD\*, Institute of Forensic Medicine Zurich, Zurich, Europe CH-8057, SWITZERLAND; Wolf Schweitzer\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Michael Thali, MD, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Garyfalia Ampanozi, MD, Institute of Forensic Medicine, Zurich 8057, SWITZERLAND

**Learning Overview:** The goal of this presentation is to show how spleen characteristics as interpreted by imaging tools like PMCT can contribute in the determination of a cause of death and predict accurately the actual spleen weight before an autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stating that various peri-mortem conditions, such as hospitalization, long or short agonal interval, and cause of death may influence organ findings on imaging. Additionally, by the increasing usage of postmortem imaging as a supplemental tool to autopsy worldwide, organ measurements and weight estimation must be validated.

**Objectives:** The spleen is the largest lymphatic organ of the human body. Its size, weight, and macroscopic features are of great forensic importance as acute organ responses or chronic diseases can be reflected in the spleen's appearance during an autopsy and may contribute to the determination of a cause of death.<sup>1</sup> PMCT is an invaluable supplement to traditional forensic autopsy.<sup>2,3</sup> The first goal of the current study was to investigate spleen attenuation on PMCT with respect to different causes of death, macroscopic spleen findings during autopsy, the presence of Contrast Agent (CA) rests, and hospitalization prior to death. The second goal was to evaluate the utility of PMCT to perform routine measurements for estimating the actual spleen weight measured during autopsy.

**Materials and Methods:** The autopsy protocols and PMCT data of all cases with PMCT and full forensic autopsy from 2015 to 2017 were reviewed retrospectively. Spleen attenuation in Hounsfield Units (HU), Width (W), Thickness (T) in cm and axial maximal Surface (S) in cm<sup>2</sup> were measured on PMCT. The cause of death, macroscopic spleen findings (paleness, contraction, congestion), and Spleen Weight (SW) during autopsy, whether death occurred in hospital or not, and the usage of CA prior to death were listed retrospectively for each case. Cases <18 years old, postmortem interval >4 days, asplenia, organ explantation, severe spleen injuries, and cases with artifacts or gas within the spleen on PMCT were excluded. Statistical analysis was performed to investigate first the spleen attenuation values among different causes of death, macroscopic findings, hospital and non-hospital deaths, and CA usage, and second, to assess the utility of PMCT for estimation of the actual spleen weight.

**Results:** One thousand thirty-five cases were included in this study, 972 of them for exploring spleen attenuation and 1,026 for evaluating spleen measurements for the prediction of spleen weight. Spleen attenuation average was 49.51HU ±6.54HU. Spleen attenuation was significantly higher for cases with CA rests on PMCT (52.05HU±9.22HU), contrary to cases without CA (49.3HU±6.24HU) and significantly lower for hospital-deaths (48.44HU±8.82HU) compared to non-hospital deaths (49.77HU±5.79HU). Spleen attenuation did not differ significantly among the different macroscopic spleen findings. Sixteen different cause-of-death groups were identified, and spleen attenuation was significantly lower for multiple organ failure (43.71HU±11.2HU) compared to fatal hemorrhage (50.01HU±6.42HU), intoxication (50.05HU±5.40HU), strangulation-asphyxia (50.83HU±5.41HU), hypothermia (52.44HU±4.31HU), and metabolic disorders (52.57HU±7.39HU). Spleen W was 8.60cm±1.78cm, T: 4.10cm±1.08cm and S: 26.63 cm<sup>2</sup>±10.72cm<sup>2</sup>. The average SW was 188.69g±108g. There were strong positive correlations among W-T-S and SW, and the correlations were expressed as linear regressions with equations for predicting SW based on W, T, and S on PMCT. There were no statistical differences between calculated SW and actual SW. The regression equations overestimate smaller SW and underestimate larger SW.

**Conclusion:** Spleen attenuation on PMCT differs significantly among several causes of death. CA usage and prior hospitalization must always be taken in account during spleen radiological findings' interpretation as CA increases the organ attenuation and intravenous fluid therapy during hospitalization decreases attenuation causing hemodilution. PMCT can accurately estimate SW based on spleen measurements on axial PMCT slices.

### H155 “Enlightened”: The Effect of Training Forensic Pathology Residents With LED-Enhanced Point-and-Shoot Cameras for Forensic Macro Photography

Valeria Hofer\*, University of Zurich, Zuerich CH-8057, SWITZERLAND; Michael Thali, MD\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Rosa M. Martinez, MD\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND; Wolf Schweitzer\*, Universitat Zurich, Zurich CH-8057, SWITZERLAND

**Learning Overview:** After attending this presentation, attendees will better understand that training forensic pathology residents in the use of properly set up point-and-shoot cameras can yield satisfying results in forensic macro photography.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a very low-cost modification of a point-and-shoot camera with an added camera-mounted Light-Emitting Diode (LED) lamp and by demonstrating how training amateurs with respect to forensic macro photography can generate satisfying results.

**Introduction:** With increasing exposure of our forensic pathology residents to event scene and death scene photography as well as for clinical forensic medicine deployments, where forensic scientists lack capacity for photography support, the need to burden them with technical extra training becomes more acute. With a team of Forensic Pathology Residents (FPR) of 10–15 people, operative advantages arise from buying affordable point-and-shoot rather than Digital Single Lens Reflex (DSLR) cameras. While the hard restrictions for macro photography (aperture, exposure time, ISO number) create an actual operation space without added light, adding light by mounting a simple LED torchlight using a 3D-printed lamp Mount (LEDMNT) seemed to massively increase image quality. This is an intervention study comparing the image quality before and after training a number of FPR without other formal photography training.

**Methods and Materials:** This study used four test objects and compared the image quality achieved by six FPR before and after specific individual training in which they were instructed in optimal settings for ISO number, aperture, exposure time for 10-15 minutes each, and after additionally adding the added LEDMNT. For each image, a score S was awarded based on image characteristics read out from the Exchangeable Image Format (EXIF) meta-data contained in the digital files and based on subjective impression of image focus (1 rater), that would result in any S theoretically ranging from 0 to 40.

**Results:** For each step along the training, scores increased: (1)  $S=14\pm4$ ; (2)  $S=21\pm2$ ; and (3)  $S=30\pm4$ , with statistically significant differences comparing (2) to (1), (3) to (2), and (3) to (1). The images also showed subjective aspects of improvement; most notably, they were more focused and appeared to contain less noise.

**Discussion:** While training FPR alone (without adding LEDMNT) already increased the image quality both objectively and subjectively, adding extra light (LEDMNT) added another significant quality improvement. Bringing very affordable camera-mounted extra light in macro photography therefore must be regarded as a significant step beyond knowledge, insight, and training.

#### Virtopsy, Forensic Macro-Photography, In-House Training

### **H156 Multiplanar Reconstruction (MPR) of Antemortem Computed Tomography (CT) Images to Visualize Sphenoidal Sinus and Cranial Base Morphology for Identification Purposes**

*Carlos J. Zambrano, PhD\**, Office of the Chief Medical Examiner, Oklahoma City, OK 73105; *Angela Berg, RN*, Office of the Chief Medical Examiner, Tulsa, OK 74107; *Marc Allen Harrison, MD*, Office of the Chief Medical Examiner, Oklahoma City, OK 73105; *Eric Duval, DO*, Office of the Chief Medical Examiner, Oklahoma City, OK 73117; *Inas Z. Yacoub, MD*, Office of the Chief Medical Examiner, Oklahoma City, OK 73105

---

**Learning Overview:** After attending this presentation, attendees will understand how to process an antemortem CT image series into a 2D projected image using Multiplanar Reconstruction (MPR) that can be used, in conjunction with or in lieu of conventional antemortem radiographs, to establish positive identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a simple methodology to project an antemortem CT series that can be easily compared to a postmortem radiograph or postmortem CT. Additionally, this methodology can be used to provide an antemortem radiograph of a missing person that could be used to compare to unidentified skeletal remains.

Establishing positive identification via scientific means is a primary objective of the medicolegal death investigation. Identity can be determined quickly via fingerprint comparison if the decedent has prints on record. In cases in which there are no prints on file or the decedent is in advanced stages of decomposition or completely skeletonized, the use of other methods such as DNA or radiographic comparisons is necessary. Radiographic comparisons are a likely means for positive identification because they obviate the practical and logistic limitations of other methods and are often readily available in many instances.

Clinical medicine has steadily increased the use of CT imaging since their introduction resulting in the possibility of using antemortem CT data for identification purposes. Although CT scout films may be taken during a clinical exam, the image quality and/or view may not provide sufficient points of concordance to conclude a positive identification when comparing them to postmortem radiographs. A solution to this is to utilize software that allows MPR of the CT data to create a projected image to facilitate comparison to postmortem radiographs or CT. This methodology is particularly useful when dealing with skeletal remains and could provide an additional approach for identification via radiological comparisons from antemortem CT images of missing persons to unidentified skeletal remains within the National Missing and Unidentified Persons database (NamUs).

Obtaining antemortem CT scans during a death investigation is a common occurrence; however, technical knowledge on how best to utilize this data varies greatly between personnel and agencies conducting a death investigation. This presentation will: (1) present free and cost-effective software options to create an MPR of antemortem CT data, (2) provide a basic review and steps on how to create a 2D projection from the MPR, (3) present three examples of 2D projections that achieve positive identification by using sphenoidal sinus and cranial base morphology, (4) discuss future research utilizing MPR of antemortem CT data, and (5) the utility of creating projections of missing persons in NamUs to possibly aid in the identification of unidentified individuals. The implementation MPR-projected images from an antemortem CT series will provide forensic anthropologists, radiologists, odontologists, and pathologists another avenue for the positive identification of remains.

---

### H157 3D Anatomical Model Acquisition and Reproduction of Human Organs: Which Perspectives for Forensic Pathology?

Antonio Guajana, Palermo 90149, ITALY; Francesco Di Paola, University of Palermo, Palermo, ITALY; Marco Arrigo, Palermo 90145, ITALY; Stefania Zerbo, MD, Via Del Vespro, 127, Palermo 90100, ITALY; Elvira Ventura Spagnolo, MD\*, University of Palermo, Palermo 90127, ITALY; Gennaro Baldino, Patti, ITALY; Daniele Daricello, MD, University of Palermo, Palermo 90127, ITALY; Dario Saguto, MD, Palermo, ITALY; Mariella Farella, MD, Palermo, ITALY; Giosue' Lo Bosco, PhD, Università degli studi di Palermo, Palermo 90123, ITALY; Fabio Bucchieri, MD, Palermo, ITALY; Francesco Cappello, Palermo, ITALY; Antonina Argo, Palermo 90100, ITALY

**Learning Overview:** The goal of this presentation is to draw attention to obtaining virtual 3D models of human organs, which can help to visualize gross and micro-anatomical features from a 360° perspective that could be used as strong evidence during cross examination in trial.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to obtaining virtual 3D models of human organs.

This technology was initiated to support university medical students in their learning activities during a human anatomy laboratory. In literature, there are several examples of virtual reality models and systems developed to teach about human anatomy and some of them are an excellent reproduction of the reality. However, these supports do not address one very important aspect: touch and handle the reality.<sup>1,2</sup>

The use of such technology has turned out to be an excellent innovative instrument for the scientific community, not only for learning purposes, but making it possible to visualize gross and micro-anatomical features from a 360° perspective that could be used as strong evidence during cross-examination in trial.

This system has a built-in database of 3D human organ models. This database was used to map the models for augmented reality recognition steps to anchor the educational tags and to reproduce real human organs with a 3D printer. Furthermore, to achieve proper virtual representation of the models, this study has conducted an accurate digital acquisition with latest generation instruments and, consequently, the data processing. The process begun on the physical model is defined as reverse engineering, and digital resolution up to 0.1mm was realized using a 3D portable scanning system with a structured light flash bulb, permitting a highly detailed digital model to be produced. Non-invasive technology has proved particularly suitable in relation to the physical characteristics of the real organs, including the dimensions, the complexity of the external surfaces, and the constraints on manipulation.

The application to a real case of the hanging of a young female victim allowed the guarantee of an augmented reality and 3D reconstruction of the anatomical structures of the neck for permanent visualization and peer-review evaluation in court, worthy of mention as tools for cross examination.

### H158 The Value of Postmortem Computed Tomography (PMCT) in the Examination of Advanced Decomposed Bodies

Alessandro Santurro, MD\*, Sapienza, University of Rome, Rome 00161, ITALY; Gaia Cartocci, Rome, ITALY; Matteo Scopetti, MD, Sapienza University of Rome, Rome, ITALY; Vittorio Gatto, MD, Sapienza University of Rome, Rome 00185, ITALY; Mariantonia Di Sanzo, MD, Rome, ITALY; Raffaele La Russa, MD, Rome, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the importance of PMCT in the examination of advanced decomposed bodies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of PMCT as a useful tool in detecting postmortem gas, even in very small amounts, and by allowing better discrimination of natural biological changes from pathologic processes in advanced decomposed bodies.

Decomposed bodies represent a real challenge for forensic pathologists because putrefaction processes can impressively alter the appearance of the bodies. In this context, PMCT represents an accurate procedure, allowing one to distinguish between normal postmortem changes and pathologic findings (i.e., between putrefactive gas present in normal decompositional processes and pathologic gas collections contributing to death, such as air embolism, pneumothorax, or pneumoperitoneum).

Between May 2013 and November 2016, ten forensic cases (8 males, 2 females) were selected from those admitted to this study's Forensic Unit by the local inquiring authorities to ascertain the cause of death. The Postmortem Interval (PMI) ranged from 7 to 887 days. All the bodies were PMCT-scanned prior to autopsy according to a standardized scanning protocol. PMCT data were transferred to a workstation for post-processing image reconstruction and were finally analyzed using a viewing software.

The internal putrefactive state was determined using the Radiological Alteration Index (RAI), determined by PMCT in seven selected sites, including the major vessels (left innominate vena and abdominal aorta), selected bones (vertebra L3), selected organs (heart cavities, liver parenchyma and vessels, and kidney parenchyma), and subcutaneous tissues and muscles (subcutaneous pectoral tissues), according to a standardized protocol (grade of gas present: 0, I, II, or III).<sup>1</sup> After PMCT scans, a complete conventional autopsy of each body was performed. The Grade of External Putrefaction (GEP) was assigned by the forensic pathologist during the external examination of the bodies, according to a standardized classification (beginning, moderate, advanced, major, mummified).<sup>2</sup> Causes of death were further investigated by histological, immunohistochemical, and toxicological examinations.

As expected, the PMCT image evaluation and the internal state analysis of putrefaction revealed that, in the selected seven sites, the RAI was >70 in all bodies, meaning advanced decomposed status. The gas grade was higher in correspondence of the major vessels, heart cavities, vertebra L3, heart cavities, and subcutaneous pectoral tissues. Coherently, the GEP assessment at the cadaveric external examination revealed the presence of transformative phenomena from "major" to "mummified" in all the examined bodies.

This study offers an overview of the common findings in advanced decomposition that may dramatically alter a body's appearance and consequently add more difficulty in determining the cause of death, significantly increasing the risk of bias and leading to misinterpretation of the autopsy findings. Radiological imaging by PMCT as an adjunct to conventional autopsy in advanced decomposed bodies has been proven to be a useful tool in detecting postmortem gas, even in very small amounts. Putrefaction can be described in postmortem imaging as gas accumulation within vascular system, body cavities, parenchyma, and soft tissues.

Conclusively, the radiological investigation offers an indisputable support to conventional autopsy in cases of decomposed bodies, increasing its performance and allowing the study of findings that would otherwise be difficult to identify. For these reasons, the correct interpretation of PMCT data is fundamental to avoid the misunderstanding of instrumental evidence and to facilitate the differential diagnosis between natural decomposition and pathological processes.

### **H159 An Interesting and Timely Dental Identification in a Uniquely Posed Decomposed Female Using Premortem Computed Tomography (CT) Images and Postmortem Radiographs**

*Tasha Zemrus Greenberg, MD\*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919; Roger D. Metcalf, DDS, JD, Tarrant County, Fort Worth, TX 76179*

**Learning Overview:** After attending this presentation, attendees will appreciate an interesting case of dental identification performed at the Tarrant County Medical Examiner's Office (TCME).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating medical examiners and forensic odontologists about the utility of postmortem dental radiograph comparison with premortem CT scan images and the importance of having a qualified forensic odontologist as part of an identification team to aid in the process of identification in difficult cases in which fingerprints cannot be obtained.

The Tarrant County Medical Examiner's Office in Fort Worth, TX, possesses a state-of-the-art Human Identification Laboratory whose director is a board-certified forensic odontologist who holds a diploma in Forensic Human Identification from the Faculty of Forensic and Legal Medicine of the Royal College of Physicians in London. The Human Identification team also consists of a board-certified forensic anthropologist and two fingerprint examiners. In 2016, the office identified approximately 89% of 751 unidentified decedents within 24 hours of arrival by fingerprint analysis. Approximately 2% of cases at TCME require dental analysis for identification.

On July 18, 2018, a decomposed female was found in an apartment residence. She had last been known to be alive in June 2018 by her mother who requested a welfare check when she was unable to contact her. The decedent was found standing at the kitchen sink with her upper body slumped into the sink. The interior of the apartment was extremely hot (104.9°F), though there was an air conditioner present. There were no illegal drugs, prescription medications, alcohol, or paraphernalia found in the apartment.

The decedent was known to be a 55-year-old White female with a history of schizophrenia, hypertension, mental retardation, and gastroesophageal reflux. She was non-compliant with her medications and had multiple psychiatric hospital admissions.

At the time of the postmortem examination, the body was cold following refrigeration. Rigor mortis was absent, having passed in the small and large muscles. Livor mortis was not readily discernible. The body was malodorous with near complete mummification and moist decomposition of the left upper extremity, sloughing of hair and scalp with exposure of portions of the skull, degloving of the left hand, exposure of the bones of the left third through fifth fingers, absence of the left ear, dessication of the eyes, and purge fluid present in the external nares, oral cavity, and anus. Maggots were present up to one-quarter inch in length as well as fly eggs and small millipede-like insects.

Record searches were conducted based on the tentative identity. Database searches included Tarrant County Sheriff's Office (TCSO) database and the Texas Crime Information Center/National Crime Information Center (TCIC/NCIC). Possible records were located with TCSO, the Texas Department of Public Safety (TXDPS), and the Federal Bureau of Information (FBI). However, postmortem fingerprints were unable to be obtained due to the state of decomposition.

Antemortem radiographs were requested from the treating hospital and a Compact Disc (CD) of images of her head was received on July 19, 2018. Comparisons were made using a transverse (axial) plane postmortem X-ray image of the skull and appropriate "slices" from the antemortem CT scan, and a definitive identification based on dental features was made the same day.

This case of dental identification illustrates the utility of comparing postmortem radiographs with premortem CT scans for identification purposes, as well as the importance of having a qualified forensic odontologist available for these unique cases in which fingerprints are unable to be used.

### H161 Fatal Nitrous Oxide Intoxication—Suicide or Accident?

Serge Schneider, PhD, Laboratoire National de Santé, Dudelange 3555, LUXEMBOURG; Martine Schaul, MD, Laboratoire National de Santé, Dudelange 3555, LUXEMBOURG; Thorsten Schwark, MD\*, Laboratoire National de Santé, Dudelange 3555, LUXEMBOURG

**Learning Overview:** After attending this presentation, attendees will: (1) have been provided with an overview of Nitrous Oxide (N<sub>2</sub>O) abuse and its—potentially fatal—risks, and (2) be acquainted with the toxicological analysis of N<sub>2</sub>O.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sensitizing crime scene investigators, forensic pathologists, and forensic toxicologists to the dangers of N<sub>2</sub>O abuse, thus improving crime scene work, autopsy procedures, and subsequent toxicological analysis.

N<sub>2</sub>O (“laughing gas”) is an odorless gas that is used as a (weak) anesthetic in clinical settings. Due to its dissociative and euphoric effects, and its easy availability, it is also widely abused in a recreational context. The gas is usually inhaled (e. g., out of filled balloons) and due to the short half-life of the substance, the effects wear off quickly. The toxicity of N<sub>2</sub>O is low; however, if inhalation occurs in a limited space, displacement of oxygen may lead to hypoxia and, ultimately, death. In chronic users, N<sub>2</sub>O is known to interact with vitamin B12 containing enzyme systems, and N<sub>2</sub>O abuse may lead to hematological, immunological, and neurological symptoms. Even though some abuse-related fatalities have been reported, deaths caused by N<sub>2</sub>O inhalation are rare events.

Here, the unexpected death of an 18-year-old boy is described. The deceased was found by his mother fully dressed in a prone position in his parents’ house. A 25L plastic bag, connected to a whipped cream steel siphon using a plastic tube, was pulled over his head and fixed around his neck. The police secured five used cream charger capsules originally containing 7.5g of N<sub>2</sub>O each on a table close to the deceased; one additional empty capsule was found in the capsule holder applied to the empty siphon.

According to his parents, the boy had been in a depressed mood in the days prior to his death since his girlfriend had left him but had not expressed any suicidal thoughts. A school friend reported that the deceased had told him he had previously inhaled “laughing gas.”

Autopsy and histology results were unremarkable except for scattered conjunctival petechiae, congestion of the inner organs, and brain and lung edema. Toxicological analysis using static headspace Gas Chromatography/Mass Spectrometry (GC/MS) analysis proved the presence of N<sub>2</sub>O in lung tissue and blood; a screening for alcohol and licit and illicit drugs was negative. Considering autopsy and toxicological findings, asphyxiation caused by oxygen depletion and N<sub>2</sub>O inhalation was ascertained as the cause of death.

As previously described by Bäckström et al., N<sub>2</sub>O concentrations in the inspired air of 25 % suffice to depress the sensation of dyspnea in the person inhaling the gas, thus leading to sudden unconsciousness due to hypoxia.<sup>1</sup> It is assumed that the administered N<sub>2</sub>O volume in this case was at least 3.8L (7.5g N<sub>2</sub>O equal 3.8L at 0°C); considering the five additional capsules found at the scene, it may even have been significantly more (up to 45g N<sub>2</sub>O, equaling approx. 23L at 0°C). By introducing the gas into the reduced remaining space of the plastic bag, N<sub>2</sub>O levels that are sufficient to explain a sudden unconsciousness and subsequent incapacity to act can easily be provoked. Further investigations in the peer group of the deceased confirmed that he had abusively used N<sub>2</sub>O before so that the manner of death in this case was ruled an accident rather than a suicide.

The presented report illustrates a rare case of fatal N<sub>2</sub>O inhalation, and clearly emphasizes the hazards accompanying “laughing gas” abuse.

### H162 Accidental Corrosive Acid Poisoning in an Infant: A Case Report

*Manoj Bhusaheb Parchake, MD\*, Seth GS Medical College & KEM Hospital, Mumbai, Maharashtra 400012, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand the pattern of corrosive injuries on the mucous surface of the mouth and skin of an infant and its interpretation. Attendees will also learn the causes behind accidental corrosive acid poisoning.

**Impact on the Forensic Science Community:** This presentation will impact the forensics science community by serving in the diagnosis and treatment of corrosive poisoning in an infant. This presentation will help the forensic expert rule out child abuse cases and implement preventive measures.

Corrosive substances may cause severe to serious injuries of the upper gastrointestinal tract, and the poisoning can even result in death. Accidental ingestion of caustic agents continues to be a major concern for pediatric emergency department clinicians. Corrosive agent ingestions are seen most frequently in young children between one and three years of age, is very rare in infants, and can cause severe acute injury and long-term complications. A 3-month-old male infant was brought to the hospital with a history of blackening of the tongue, injuries over his body, and difficulty breathing after taking some medicine. The pediatrician suspected child abuse and hence sent a call to forensic medicine. After evaluating the infant and detailed history from the relative, it was confirmed that the blackish color was a corrosive injury on the mucosal surface of the mouth, lip, and chest and a reddish color on neck folds and the back. After an ultrasonography, severe epiglottis edema was noticed, and no esophageal or upper digestive tract perforation. On blood investigation, severe acidosis was observed, and the infant was immediately put on a ventilator and treatment began. Aspirated fluid was sent for chemical analysis.

The blackish color of the corrosion and normal urine, favored sulfuric acid poisoning. Phenol corrosive injury is brownish in color with greenish or even black color urine on exposure to air, while nitric acid has is a yellowish color corrosion. On treatment, gastric lavage and emetics were contraindicated and nothing was given orally for two to three days. Broad spectrum antibiotics and IV fluids were given to the infant. On further history it was found that concentrated sulfuric acid was kept in medicine bottle and given by mistake by the infant's aunt. The pattern of corrosive acid injury was blackish in color and the injuries over the chest and neck folds were due to the dribbling of the acidulated fluid from the angle of the mouth. It was confirmed by the forensic science laboratory that sulfuric acid was present in the medicine bottle. Regarding the manner of injuries, it was likely to be accidental as it is common practiced in the slums of Mumbai to keep cheap locally available sulfuric acid in a soda bottle or cold drink bottle or any bottle that is available, such as a medicine bottle.

#### Accidental, Corrosive, Poisoning

## H163 Homicide by Intramuscular Cyanide Injection: Investigation and Adjudication

Megan R. Hall, BA\*, Eastern Virginia Medical School, Norfolk, VA 23507; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will: (1) be familiar with the presentation of cyanide poisoning, (2) be aware of historical examples of cyanide poisoning, and (3) have learned about the adjudication of a case of homicide by intramuscular cyanide poisoning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through increased competence in recognizing the signs and symptoms of cyanide poisoning and understanding the adjudication of a case of a homicide by cyanide injection.

Fatalities from cyanide are relatively rare. Most cyanide fatalities involve ingestion by mouth or inhalation of cyanide gas.<sup>1</sup> Ingestion of cyanide has been used in homicides, such as the unsolved case of the “Tylenol® murders” in Chicago, in which several people died from unknowingly ingesting acetaminophen laced with cyanide. Its gaseous form has been used in genocide, as was seen with the use of Zyklon B in Nazi Germany. Suicide by cyanide gas or ingestion is more common than homicide; both are infrequent in the United States, as cyanide is difficult to obtain.<sup>2</sup> Historical records show that cyanide was ingested in pill form by Nazi officers to commit suicide; it was mixed with Kool-Aid® in the Jonestown mass suicide; and the computer scientist Alan Turing laced an apple with cyanide when persecuted for his sexual orientation. Fatalities by cyanide injection, particularly homicidal, are rarely reported.<sup>2,3</sup> This report presents the investigation, autopsy, and adjudication of a case of homicide by cyanide injection.

A young woman returning from work, on exiting her car, was attacked by a man who had been hiding in her bushes. He stabbed her in the left buttock with a needle, injecting something, and ran away. The victim cried out to her mother in agony and collapsed. Emergency medical services were activated and noted that the victim was unresponsive, with decorticate posturing, and with a gaze that was fixed to the left. Communication with her mother was hindered by a language barrier; seizure was initially suspected.

On emergent transport to the local hospital, she was in distress; hypotensive, with progressively falling blood pressure; in acute respiratory failure; and in metabolic acidosis, with a profound anion gap. Global hypoxic-ischemic encephalopathy on Computed Tomography (CT) scan developed within hours; death ensued 20 hours after the assault. Hospital toxicology on plasma drawn about four hours after the assault identified cyanide at a level of 4.053mg/L (reported normal range, non-smoker, less than 0.025mg/L; smoker, average 0.41mg/L; death, associated with values greater than 3mg/L).

Forensic autopsy identified a dermal puncture on the left buttock, found no competing cause of death, and no pregnancy. The postmortem toxicology report confirmed the presence of cyanide.

In the meantime, police developed information implicating the decedent’s ex-boyfriend, who was also the father of the decedent’s 2-year-old child; they were in the middle of a custody battle. He was also a suspect in an assault on the same victim two and one-half months earlier, during which the assailant, who attacked her when she exited her vehicle, tossed a cupful of chemical liquid into her face.

Approximately 15 months after her death, trial began. Evidence submitted by prosecution included security footage from outside the decedent’s home that captured the attack, a description of the assailant by the victim’s mother, forensic evidence from the defendant’s computer, including multiple web searches such as “what if cyanide gets injected?” and “how many mg of cyanide will kill you?,” and documentation that he purchased a hypodermic needle from an internet seller. The hypodermic needle was delivered to a pizza parlor he frequented, with testimony from the employees that he witnessed retrieving it. Prosecution was unable to document how or where the defendant might have purchased cyanide.

Defense focused on a claim that the defendant could not have attacked the decedent because he was 2.5 hours away, in a different city, as illustrated by phone records. However, the defendant’s phone, although remaining in that city, was not used for outgoing phone calls or texts for a period of 22 hours (from 3 hours prior to the attack until 19 hours afterward).

The defendant was found guilty of first degree murder; sentencing is pending.

### H164 Validation of a Urine Drug Screen Assay in the Postmortem Setting

Emily Wolak, DO\*, Albuquerque, NM 87111; Sarah Lathrop, DVM, PhD, Albuquerque, NM 87111; Monique Dodd, PharmD, Albuquerque, NM 87112; Hannah A. Kastenbaum, MD, University of New Mexico, Albuquerque, NM 87131

**Learning Overview:** This goal of this presentation is to review the utility of a Urine Drug Screen (UDS) for the purposes of triaging autopsies, discussing if this method is a valid substitution for blood testing, and if it has potential to maximize operational efficiency. As advised by National Association of Medical Examiners (NAME) guidelines, individuals should undergo a complete autopsy when “death is by apparent intoxication.” Consequently, the high number of drug-related deaths across the country adds financial burden to many offices. There may be a place for point-of-care UDS assays in the postmortem setting where they can serve as a source of preliminary information regarding the presence of potentially fatal substances. In this way, the assay can guide further testing and management of the case. If a urine assay is found to be a valid and inexpensive substitute for blood testing in the postmortem setting, the operational efficiency implications are significant.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework for the use of a UDS assay as a potential substitute for blood testing in certain cases.

**Methods:** This study tested the performance of a UDS assay compared with toxicological analysis of postmortem blood as the gold standard for 87 cases requiring full autopsy at the New Mexico Office of the Medical Investigator. Ten common drug classes of abuse were analyzed: methamphetamine, amphetamine, cocaine, opioids, barbiturates, Tricyclic Antidepressants (TCAs), methadone, Tetrahydrocannabinol (THC), benzodiazepines, and Phencyclidine (PCP). Blood toxicology was tested through National Medical Services (NMS). The case pathologist interpreted the results of the UDS, and these interpretations and photographs of the card were documented. Once the toxicology reports from NMS were complete, the final interpretation of the urine screen by the case pathologist was compared to the NMS blood toxicology results. For each of the ten classes of drugs tested for by the UDS, the numbers of concordant and discordant pairs were calculated. McNemar’s test for correlated proportions was used, with a *p*-value of 0.05 or less considered statistically significant. Sensitivity and specificity were also calculated.

**Results:** For the 87 cases tested, the postmortem blood was analyzed with either the NMS basic toxicology panel (68 cases) or an expanded panel (19 cases). Discrepancies between the UDS and blood Gas Chromatography/Mass Spectrometry (GC/MS) were classified as either “triage-relevant” or “triage-irrelevant” for purposes of cause and manner of death investigation. For example, false negative cocaine on the UDS was considered triage-relevant, whereas false negative THC was considered triage-irrelevant. All false positives were considered to be triage-irrelevant. Three decedents had partial results due to assay error (failure of urine to move up the well), and so data was only included for those drug classes with results present. By McNemar’s test, only the opioid drug category had a statistically significant difference in results discordance between the UDS and NMS blood toxicology results. The remaining nine classes of drugs showed no statistically significant difference between NMS and UDS results. Forty-six of 87 cases (53%) had a discordance of some type between the UDS and NMS results; however, 16 of those (35%) were “excused” due to testing differences, or if the drug was present in the urine only (and not in the blood). Nineteen of the 87 cases (22%) had a triage-relevant discordance, such as a false negative detection of a potentially fatal drug.

**Conclusion:** Of the ten classes of drugs analyzed, only opioids showed a statistically significant discordance. For this study’s purposes, this is a triage-relevant discrepancy as opioid false negatives can inaccurately alter the course of the death investigation. However, it should be noted that this discrepancy was not due to assay error, because the majority of false negative opioids on the urine screen were due to fentanyl, which is not detected by this assay. Most importantly, a lack of statistical significance does not necessarily imply clinical irrelevance, if even a small number of false negative results could adversely impact downstream clinical decision making. It was concluded that while the UDS screen is consistent with blood GC/MS findings for most classes of drugs, it is at the discretion of the forensic pathologist to incorporate all investigative information when utilizing the UDS as a potential triage tool.

*This study was funded by the Forensic Sciences Foundation Acorn grant.*

#### Assay, Drug Screen, Autopsy

### H165 An Immunohistochemical Study of Central Nervous System (CNS) Damage in Two Drug Abusers (Synthetic Cannabinoids, Synthetic Cathinones, and Phenethylamine Derivatives)

Mio Takayama, PhD\*, Fukuoka University, Fukuoka 814-0180, JAPAN; Masayuki Kashiwagi, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Aya Matsusue, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Brian Joseph Waters, MS, Fukuoka University, Department of Forensic Medicine, Fukuoka 814-0180, JAPAN; Kenji Hara, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Natsuki Ikematsu, BPharm, Fukuoka University, Fukuoka 814-0180, JAPAN; Shin-ich Kubo, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the immunohistochemical changes that occur in the brains of abusers of novel psychoactive substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the abuse of novel psychoactive substances, such as synthetic cannabinoids, synthetic cathinones, and phenethyl amine derivatives, and how they affect the brains of users.

**Introduction:** Drug abuse remains a major social problem in society today. In forensic autopsy cases, drugs such as methamphetamine, amphetamine, and illegal herbal products are occasionally detected. This study examines CNS damage immunohistochemically in drug abusers.

**Materials and Methods:** Two cases were selected from cases autopsied at Fukuoka University within 48 hours of the postmortem interval, where synthetic cannabinoids, synthetic cathinones, or phenethylamine derivatives were detected. Case 1 involved a man in his early 30s. Toxicological analysis revealed the presence of 6-APB, 6-MAPB, DL-466,  $\alpha$ -PHP, and mepirapim in the blood and urine. His cause of death was acute drug intoxication. Case 2 also involved a man in his early 30s. Toxicological analysis revealed methamphetamine, amphetamine, DL-466,  $\alpha$ -PHP, N-fluoropentyl-AB-PINACA, and 5-Fluoro-AMB in the blood or urine. His cause of death was asphyxia by choking on regurgitated stomach contents. The hippocampus and cerebellum were collected from formalin-fixed forensic autopsy brains from each case. Histochemical stainings were observed with Hematoxylineosin (HE) and Luxol Fast Blue (LFB). Immunohistochemical stainings were performed using antibodies against MAP2 (1: 200, Abcam plc, UK), Glucose Transporter 5 (GLUT5) (1: 200, Abcam plc, UK), GFAP (1: 1000, Abcam plc, UK), and Iba-1 (1: 350, Abcam plc, UK) with the EnVision™ Detection System/HRP according to the manufacturer's instructions. MAP2 and GLUT5 were for neurons, GFAP was for astrocytes, and Iba-1 was for microglia.

**Results:** The histochemical stainings from Case 1 showed morphological changes in the neurons from Dentate Gyrus (DG) to CA3 in the hippocampus. Fewer granule cells in the granular layer of the cerebellar cortex were observed. Immunohistochemically, the immunoreactivity of the pyramidal cells lessened from CA2 to CA1 with MAP2, and in DG with GLUT5. An increase of GFAP-positive astrocytes in DG and Iba-1-positive microglia overall in the hippocampus were observed. In the cerebellar cortex, the immunoreactivity of granule cells in the granular layer lessened with MAP2. GFAP-positive astrocytes increased in the granular layer, and the fibers of the astrocytes were rosary-shaped in the cerebellum. In Case 2, histochemical stainings showed no significant findings in the hippocampus and cerebellum. Immunohistochemically, the MAP2-positive pyramidal cells from CA3 to Subiculum (SUB), and GLUT5-positive pyramidal cells in SUB and from DG to CA3 were observed. GFAP-positive astrocytes increased in the pyramidal cell layer. Immunoreactivity of MAP2-positive and GLUT5-positive were shown in Purkinje cells and molecular cells.

**Conclusion:** The hippocampus and cerebellum in the brains of two drug users who abused synthetic cannabinoids, synthetic cathinones, or phenethylamine derivatives were examined immunohistochemically. Some morphological and immunoreactive changes were observed in the neurons, astrocytes, and microglia. To understand more clearly about the pathological findings of the relationship between drug abuse and damage to the brain, more cases and other immunohistochemical stainings need to be examined.

### H166 Filicide-Feticide-Suicide: An Unusual Variant of Triadic Death

*Nilesh K. Tumram, MD\*, Department of Forensic Medicine and Toxicology, Nagpur, Maharashtra 440013, INDIA*

---

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the triadic death, which may be a distinct type of homicide-suicide-feticide of the killing of children by a parent (filicide-suicide) and the killing of the fetus inside womb of mother (feticide). The terms “maternal filicide” or “paternal filicide” are used respectively when the perpetrator is the mother or the father of the victim. A rare case of maternal filicide-feticide is reported, in which the mother poisoned her son and then herself consumed the same poison, causing the live fetus to die because of the poisoning of the mother.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating awareness of another rare form of filicide-feticide-suicide, presenting a case highlighting the fact that such a manner is rarely been seen.

Murder-suicide, homicide-suicide, and dyadic death all refer to an incident in which a homicide is committed, followed by the perpetrator’s suicide almost immediately or soon after the homicide. Homicide of a child by its parents is called filicide. Homicide-suicides are relatively uncommon and vary from region to region. However, on review of literature, there is no mention of a case in which there is a killing of a child by the mother by giving poisonous material in milk and similarly consuming the same poison for self-killing.

In the present case, there was stress caused by repeated domestic quarrels to the pregnant mother having one child. In a fit of rage, the mother mixed insecticide granules in the milk of her son and made him drink it. Then the mother drank the remaining portion of the milk. The son became ill in a few minutes and laid unconscious with his mother, who also fell unconscious after some time. The mother knew that consuming the poison herself could harm her fetus too, but still committed the act, leading to the death of the fetus inside her womb. Thus, there was an unusual variant of filicide- feticide-suicide that caused a triad of death that can aptly be termed as triadic death.

This study presents a case of triadic death in which the method of killing and suicide was poisoning, and the unborn fetus died due to the consequences of self-poisoning by the young woman. This presentation will also discuss the importance of having knowledge of such a manner of death while dealing with medicolegal cases.

---

#### **Filicide-Feticide, Suicide, Triadic Death**

### H167 The Evolution of the Opioid Crisis in Cuyahoga County, Ohio, From 2012 to 2016

Vaishali S. Deo, MD\*, Case Western Reserve University School of Medicine, Cleveland, OH 44106; Thomas P. Gilson, MD, Cuyahoga County Medical Examiner's Office, Cleveland, OH 44106

**Learning Overview:** The goal of this presentation is to characterize fentanyl overdose victims of 2016 and compare them with heroin-associated fatalities of 2012.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the role of the medical examiner in addressing multiple aspects of the opioid crisis by serving as a public health data source and a bridge between different stakeholders (law enforcement, public health officials, medical community, etc.) to combat the opioid epidemic.

Fentanyl and its analogs have emerged since 2014 as the leading driver of opioid mortality in the United States. This is in contrast to the scenario that was seen immediately prior when heroin came to prominence after the initial wave of overdose deaths associated with prescription Opioid Pain Relievers (OPR). It has been assumed that the drug abuse population has remained the same throughout, but there is little evidence characterizing the fentanyl overdose victims. The objective of this study is to look at the deaths associated with fentanyl in 2016 and compare the characteristics of 2016 fentanyl (with or without heroin) overdose deaths with heroin-associated fatalities in 2012 in Cuyahoga County, OH. This study also looks at the three-year prescription data of cases of 2016 fentanyl overdose deaths in Cuyahoga County for prescription of OPR and evidence of "doctor shopping" and compares it with the prescription data of 2013 heroin-associated fatalities. The retrospective prescription data of 2013 was more complete than that of 2012 as full medical examiner access to the prescription drug monitoring program was initially delayed until then.

Socio-demographic characteristics of cases of fentanyl overdose deaths in 2016 were compared with those of heroin fatalities in 2012. Data were abstracted from Cuyahoga County Medical Examiner case files. The prescription data of 2016 fentanyl mortalities were retrieved from the records of the Ohio Automated Rx Reporting System (OARRS), the prescription drug monitoring program for the state of Ohio. Doctor shopping was defined as five or more prescribers of a controlled substance (e.g., OPR) in a 12-month period.

The number of fatalities in Cuyahoga County increased from 160 heroin-related deaths in 2012 to 417 fentanyl-related deaths in 2016. However, no significant differences in socio-demographic characteristics were seen among cases of 2016 fentanyl and 2012 heroin overdose deaths. In both the cohorts, the overdose victims were predominantly 35 to 64 years of age (60%–64%), White (84%) males living in an urban setting (44%–45%). Analysis of OARRS data of 2016 fentanyl overdose deaths showed 70% of the cases having records on file in OARRS, which was similar to the 2013 OARRS records of heroin fatalities. However, doctor shopping showed a decline from 36% in 2013 to approximately 22% in 2016.

This study reports a substantial increase in fentanyl-related deaths in 2016 compared to heroin deaths in 2012. Baseline demographics between both cohorts are similar. OPR drugs remain a current factor in the drug crisis. This study emphasizes the role of the medical examiner in providing data for opioid-associated mortality, support, and collaboration with public health partners.

### H169 Aqueous Fluid as a Viable Substitute for Vitreous Fluid in Postmortem Chemistry Analysis

*Daniel C. Butler, MD\**, Medical University of South Carolina, Charleston, SC 29403; *Cynthia A. Schandl, MD, PhD*, Medical University of South Carolina, Charleston, SC 29425; *S. Erin Presnell, MD*, Medical University of South Carolina, Department of Pathology, Charleston, SC 29425

**Learning Overview:** The goal of this presentation is to describe the correlation between vitreous and aqueous analytes and the use of aqueous fluid in the pediatric autopsy setting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that in certain circumstances, particularly pediatric autopsies, vitreous fluid is not sampled due to the risk of introducing hemorrhagic artifact to the globe of the eye. In the current study, aqueous fluid is shown to significantly correlate with vitreous fluid. If predictable differences are considered, aqueous fluid may be sampled in place of vitreous fluid without the risk of introducing artifact.

**Background:** Vitreous fluid analytes can be a valuable investigative tool in postmortem forensic examinations. While clinical practice relies on blood for analyte analysis, postmortem chemistry is complicated by factors such as continued cell metabolism and autolysis with cell membrane degeneration, making it unsuitable in the forensic setting. As a preserved site with low cell counts, vitreous fluid is somewhat isolated from these changes, allowing for an evaluation of antemortem chemistry. However, in pediatric forensic autopsies where head trauma is present, vitreous fluid sampling is discouraged if eye removal is warranted to evaluate for retinal hemorrhages so as not to introduce hemorrhagic artifact. Whereas vitreous humor is the predominant fluid of the eye, filling the space between the lens and retina, the anterior chamber between the iris and cornea contains a smaller volume of aqueous fluid, which, when sampled, does not introduce hemorrhagic artifact to the posterior chamber as it is physically separated from the retina. Procurement and analysis of aqueous fluid was proposed as a substitute for vitreous fluid.

**Methods:** Vitreous and aqueous fluid were sampled concordantly from 22 pediatric decedents (median age=0.67 years) and 42 adult decedents (median age=45 years) at the Medical and Forensic Autopsy Division of the Department of Pathology and Laboratory Medicine at the Medical University of South Carolina between 2011 and 2018. Aqueous fluid was sampled with a 25-gauge needle and vitreous fluid was sampled with an 18-gauge needle at the time of autopsy. Sodium (Na), potassium (K), chloride (Cl), urea nitrogen (UN), creatinine (Cr), and glucose (Glc) aqueous and vitreous concentrations were compared to determine correlation and reliable difference. Samples above or below the detectible limit were excluded from the study.

**Results:** Spearman's rank-order analysis detected significant correlations between pediatric, adult, and combined pediatric/adult samples, respectively:  $\rho=0.89$ ,  $\rho=0.93$ , and  $\rho=0.84$  between vitreous Na and aqueous Na;  $\rho=0.96$ ,  $\rho=0.93$ , and  $\rho=0.93$  between vitreous K and aqueous K;  $\rho=0.53$ ,  $\rho=0.81$ , and  $\rho=0.79$  between vitreous Cl and aqueous Cl;  $\rho=0.91$ ,  $\rho=0.93$ , and  $\rho=0.95$  between vitreous UN and aqueous UN;  $\rho=0.79$ ,  $\rho=0.85$ , and  $\rho=0.86$  between vitreous Cr and aqueous C; and  $\rho=0.81$ ,  $\rho=0.77$ , and  $\rho=0.77$  between vitreous Glc and aqueous Glc.

Simple linear regression was utilized to assess associations in aqueous analytes based on corresponding vitreous analyte values in pediatric, adult, and combined pediatric/adult samples, respectively. For Na, aqueous values were 23%, 8%, and 12% higher than vitreous Na on average; aqueous K was 6%, 8%, and 5% higher than vitreous K on average; aqueous Cl was 34%, 15%, and 18% lower than vitreous Cl on average; aqueous UN was 3%, 2%, and 2% lower than vitreous UN on average; aqueous Cr was 31%, 13%, and 11% lower than vitreous Cr on average; and aqueous Glc was 11%, 29%, and 16% lower than vitreous Glc on average.

**Conclusion:** Significant correlation exists between vitreous and aqueous analytes with predictable differences.

Taking into account these differences, aqueous fluid analysis of Na, K, Cl, Cr, UN, and Glc concentrations would be a viable substitute for vitreous in the postmortem setting; however, a more robust study population with further consideration of postmortem interval, age, gender, race, and cause of death is required to determine the difference between aqueous and vitreous analyte values with a higher degree of specificity.

### H170 The Frequency of Cannabinoids in a Medical Examiner Population

*Caitlin N. Markey, Lansing Catholic High School, Lansing, MI 48912; Michael A. Markey, MD\*, Sparrow Forensic Pathology, Lansing, MI 48912; Patrick A. Hansma, DO, Sparrow Forensic Pathology, Lansing, MI 48912; Luke R. Vogelsberg, Sparrow Forensic Pathology, Lansing, MI 48912*

---

**Learning Overview:** After attending the presentation, attendees will: (1) have a better understanding of how often cannabinoids are detected in various types of death that fall within the jurisdiction of the medical examiner's office, (2) be able to compare this frequency with the reported frequency of cannabis (marijuana) use, and (3) be able to compare the frequency in which cannabinoids are detected with the frequency in which ethanol is detected in these cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic community by documenting the current use of cannabis in the medical examiner population and suggesting trends that the forensic community may expect to see with increasing legalization of cannabis use in the United States.

Within the past several years, many states have legalized the use of cannabis for medicinal use. There has been an ever-increasing push to expand the legalization of cannabis for recreational use. Eight states and the District of Columbia have current laws legalizing cannabis for recreational use. Proponents of marijuana legalization profess its safety, but with the expected trend of legalizing marijuana use, the question of its potential impact on mortality must be considered.

Recently published data from The Substance Abuse and Mental Health Services Administration indicates that self-reported current use of marijuana (cannabis), defined as use within the past month, in the United States for the year 2016 was 8.9% of the population (those 12 years of age or older). The same agency reported that for the state of Michigan, the estimated current use of marijuana by the same population was 10.45% (averaged for the years 2014 to 2016). For comparison, the self-reported current use of ethanol in the United States for the year 2016 was 50.7%.

The electronic database of a forensic pathology practice that provides medical examiner services to several counties in mid-Michigan was queried for death investigations that included a postmortem examination and toxicology testing for the period of January 1, 2017, to May 31, 2018. During this time, 929 death investigations included a postmortem examination, and, of these, 884 had toxicology testing also performed. The cases evaluated included 193 natural deaths, 424 accidental deaths, 168 suicides, and 40 homicides.

In all cases reviewed, 21.7% had a postmortem toxicology screen (blood, urine, or other) that was positive for cannabinoids (THC and/or THC-COOH), significantly higher than the reported frequency of "current use" in the United States and Michigan. By type of case, the breakdown of a positive toxicology screen for cannabinoids was as follows: 45% of homicides, 25.7% of accident drug intoxications, 25% of suicides, 21.9% of drivers in motor vehicle accidents, 21.5% of drownings, 16.6% of natural deaths, and 15.4% of passengers in motor vehicle fatalities.

By comparison, in all cases reviewed, 23.5% had a postmortem toxicology screen positive for ethanol, significantly lower than the reported "current use" in the United States.

The results of this study indicate that cannabinoids are present at a higher-than-expected frequencies in the studied medical examiner population when compared to baseline reported marijuana use (using current data based on self-reported).

### H171 Generalized Organomegaly and the Use of Performance-Enhancing Substances Identified Following Sudden Death

Stephanie Diu, BA\*, Rutgers Robert Wood Johnson Medical School, Piscataway Township, NJ 08854; Jennifer L. Hammers, DO, Pittsburgh, PA 15219

**Learning Overview:** The goal of this presentation is to highlight the death of a 43-year-old Caucasian male due to hypertensive and atherosclerotic cardiovascular disease, in which the use of body-building enhancers was a significant contributing factor.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the potential effect of anabolic steroids on organ structure and how these changes can lead to organomegaly and cardiovascular damage.

**Introduction:** Performance-enhancing drugs are pharmacologic agents that professional and recreational athletes use to improve competitive performance or physical appearance. These drugs include anabolic-androgenic steroids, human growth hormone, and blood boosters such as erythropoietin.<sup>1</sup> There are significant gaps in scientific knowledge regarding the adverse health effects of performance-enhancing drugs. Anabolic-androgenic steroids have been associated with increased systolic and diastolic blood pressure, left ventricular hypertrophy, cardiomegaly, and acute myocardial infarction.<sup>2,3</sup> There is evidence that mortality is significantly increased in steroid abusers over non-abusing athletes.<sup>2</sup> Case reports typically feature a male poly-drug user with drug toxicity being the most common cause of death and extensive cardiovascular disease being a notable feature.<sup>4</sup> Per this study's research, this is the first case report linking generalized organomegaly with use of performance-enhancing drugs.

**Materials and Methods:** This case involved a well-developed (6 feet 4 inches, 252 pounds), trim, muscular 43-year-old Caucasian male who collapsed suddenly while exercising on a treadmill. He had been complaining of headaches with facial reddening over the weeks before death. He was known to use body-enhancing substances.

**Results:** Postmortem examination revealed generalized organomegaly and extensive cardiovascular disease. The pancreas was uniformly markedly enlarged and weighed 450 grams. The kidneys weighed more than 300 grams each, the liver weighed 3,350 grams, and the spleen weighed 450 grams. The decedent was found to have cardiac hypertrophy (630 grams), concentric left ventricular hypertrophy (2.1cm), and right ventricular hypertrophy (0.6cm). There was atherosclerosis with slight (50%) multifocal luminal impingement in the basilar artery and Circle of Willis arteries, as well as marked three-vessel coronary artery atherosclerotic stenosis (75%–95%). Further examination revealed a remote myocardial infarct in the left lateral ventricular wall (3cm x 3cm x 2.1cm), and an adjacent recent myocardial infarct in the posterior lateral left ventricular wall (5cm x 3cm x 2.1 cm).

**Discussion:** Generalized organomegaly could be an adverse effect caused by body-enhancing substances and warrants further investigation in future studies. The potential dangers of performance-enhancing drugs are likely underreported because anabolic-androgenic steroids are not routinely screened during autopsy, as testing for performance-enhancing substances can be difficult and expensive.<sup>1</sup> In addition, it is often difficult to obtain a complete and accurate history regarding the use of these substances. This case emphasizes the need for further investigation regarding the prevalence of performance-enhancing drug use and the mechanisms by which these drugs cause adverse effects.

### H172 Three Deaths in Tarrant County, Texas, Related to the Use of 25H-NBOMe, 25B-NBOMe, or 25I-NBOMe

Tasha Zemrus Greenberg, MD\*, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919; Robert D. Johnson, PhD, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104; Richard C. Fries, DO, Fort Worth, TX 76104; Susan J. Roe, MD, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104

**Learning Overview:** After attending this presentation, attendees will understand the clinical presentations of NBOMe intoxication after review of three cases from the Tarrant County Medical Examiner's Office (TCME).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating medical examiners and toxicologists about behaviors associated with NBOMe drugs and by helping identify cases in which these drugs should be considered.

The recent increase in the use of NBOMe compounds, variants of the 2C-X series of psychoactive phenethylamines with significantly greater potency, have resulted in numerous deaths around the world as well as Emergency Department (ED) admissions by individuals suffering from erratic and dangerous behavior.<sup>1</sup> The NBOMe compounds act via the 5-HT<sub>2A</sub> receptors, leading to intense hallucinations with actions that can be self-directed or focused on other individuals. The effects last between four and ten hours, and users report euphoria, mental/physical stimulation, feelings of empathy, alterations in consciousness, and hallucinations. ED staff may be faced with individuals who are very difficult to control. Medical examiners may receive a decedent with a history of bizarre behavior prior to death.

Case 1 involved a 20-year-old male who became unresponsive after taking a capsule. Emergency Medical Services (EMS) found him in convulsions. Two other young men at the scene also became unresponsive. All were transported to the hospital for suspected overdoses. The first man expired. The friends recovered and told a detective that they had ingested gel caps filled with a white powder called NBOMe. Postmortem toxicology testing was positive for 25B-NBOMe at 47.9ng/mL and 25H-NBOMe at 0.030ng/mL in hospital blood, as well as THC, oxycodone, hydrocodone, and hydromorphone in hospital urine. The death was attributed to NBOMe toxicity.

Case 2 involved a 22-year-old male found lying supine on the living room floor of a home that was in extensive disarray. There was copious blood throughout the residence and surrounding the decedent. A window in the dining room was broken from the inside with blood and hair on it. The decedent's girlfriend revealed that four days prior, they had taken "hits of acid" with two male acquaintances; the decedent took four doses. After several hours, he became aggressive and demanded the males leave. They returned hours later and found him lying "bloody" and unresponsive on the floor, although they did not report it. The girlfriend was not at the residence; however, she presented to an ED with an orbital fracture and concussion, sustained in an altercation with the decedent.

At autopsy, he had multiple injuries, including sharp force injury of the right ear with a portion of the pinna absent, as well as reduced livor mortis and organ pallor consistent with acute blood loss. Initial toxicological examination on biological specimens was negative. Case circumstances directed subsequent testing for novel psychoactive drugs. 25H-NBOMe [2-(2,5-dimethoxyphenyl)-N-(2-methoxybenzyl) ethanamine, monohydrochloride] and 25B-NBOMe [4-bromo-2,5-dimethoxy-N-[(2-methoxyphenyl)methyl]-benzeneethanamine] were identified. The death was attributed to exsanguination due to sharp force injury of the ear, with drugs considered a contributory factor to his behavior.

Case 3 involved a 20-year-old male seen on surveillance video at a car dealership jumping on and smashing a windshield, then driving his vehicle through a glass window. When confronted by police, he behaved erratically and ignored commands. One officer discharged his Taser<sup>®</sup>, and another discharged his firearm, both striking the decedent. He died due to gunshot wounds to the neck, chest, and abdomen. Toxicology testing was positive for 25I-NBOMe [2-(4-iodo-2,5-dimethoxyphenyl)-N-[(2-methoxyphenyl)methyl]ethanamine] at 0.76ng/mL and THC at 3.1ng/mL in femoral blood, and 25H-NBOMe in urine. The drugs were considered a contributory factor to his behavior.

The extreme behavior demonstrated in two of these cases is not unusual, as agitation and aggression are often reported in cases involving the NBOMe compounds. Extreme behaviors may be dose dependent. Some individuals may not measure the drugs correctly and/or may not know what they are ingesting.

Due to the lack of literature available for these specific NBOMe compounds, it is difficult to interpret the concentrations seen in these cases. As the prevalence of these drugs continues to rise, it is important to publicize the dangerous and often lethal side effects of these compounds.

### H173 Accidental Overdose Deaths Involving Fentanyl and the Growing Trend of Counterfeit Prescription Pills in New Mexico

Jolee T. Suddock, DO\*, Department of Pathology, University of New Mexico, Albuquerque, NM 87131; Sarah Lathrop, DVM, PhD, Albuquerque, NM 87111; Garon Bodor, MS, University of New Mexico, Office of the Medical Investigator, Sandia Park, NM 87047; Matthew D. Cain, MD, Office of the Medical Investigator, Albuquerque, NM 87102

**Learning Overview:** After attending this presentation, attendees will understand trends in fentanyl-related overdose deaths in New Mexico (NM) and describe the prevalence of counterfeit prescription pills in relation to demographics and region.

**Impact on the Forensic Science Community:** This study will impact the forensic science community by providing a better understanding of at-risk populations in relation to fentanyl overdose death and by providing analysis that will aid in the construction and implementation of targeted prevention strategies.

**Background:** Fentanyl is a potent synthetic opioid known to be illegally manufactured and used recreationally. It has become increasingly prevalent in the United States and has significantly contributed to the opioid epidemic. Various news sources have cited overdoses in which individuals are unaware of fentanyl contamination. Although counterfeit prescription pills mixed with fentanyl have been reported in other states, there has only recently been a spike in these cases in NM. NM has encountered several cases in which apparent prescription pills were found at the scene, yet toxicology reports have detected only a high concentration of fentanyl. To combat the evolving fentanyl epidemic, it is vital to characterize these cases to develop targeted interventions.

**Purpose:** The purpose of this study is to evaluate which counterfeit prescription pills are most commonly encountered, determine whether differences exist in concentrations of fentanyl in pill versus intravenous death, and determine if regional clusters exist.

**Methods:** Data for drug-related deaths, confirmed by epidemiology and forensic pathologists, were retrieved from the NM Office of the Medical Investigator database from 2014 to July 2018. All accidental deaths involving fentanyl were evaluated for the presence of pills found at the scene and a history of prescription abuse. Deaths involving probable injection of an illicit drug, such as heroin and/or methamphetamine, were used as a comparison for the concentrations against individuals taking counterfeit pills but were not the focus of this study. Cases in which fentanyl patches were observed, or the decedent was legitimately prescribed fentanyl, were excluded. In addition to statistical analysis, these cases were geocoded using Google® Fusion Tables.

Analysis was performed using Statistical Analysis Software (SAS). Categorical variables were compared using either a chi-square test or a Fisher exact test if an expected cell count was less than five. Continuous variables were compared using a Wilcoxon rank-sum test or a Kruskal-Wallis for multiple comparisons. P values of 0.05 or less were considered statistically significant.

**Results:** There were 158 cases of accidental overdoses involving fentanyl in NM. Of those cases, 55 involved prescription fentanyl patches (27 prescribed, 23 non-prescribed, and 5 had an unknown prescription status) and 29 involved suspected counterfeit pills. Decedents were primarily White non-Hispanic and Hispanic males ( $p < 0.02$ , mean ages 38.1 and 38.4, respectively).

The cases involving suspected counterfeit pills were chosen based on the presence of pills at the scene or in which a substantiated history of illicit prescription pill purchase was available. Oxycodone was the most commonly encountered (14 cases), followed by alprazolam (10 cases), morphine (3 cases), and oxycontin (1 case). One case involved an unidentified pill. Fentanyl concentrations for cases of suspected pill overdose were not significantly different than those of intravenous drug use. The earliest case appeared in late 2014 and involved an oxycodone addict who died of a remarkably high fentanyl concentration. Afterward, the majority of cases appeared in 2016 and onward, with a spike in 2018 ( $p < 0.0001$ ). While this data is preliminary, there have been at least three cases in which the individual thought they were consuming oxycodone, but the pills actually contained fentanyl.

These cases were plotted by year and by drug using Google® Fusion Tables. A majority occurred near Albuquerque, NM, likely with population concentration a significant contributing factor. However, alprazolam and oxycodone mimics were noted to appear in southern NM in 2017 and are clustered near interstates. These data are being shared with the Drug Enforcement Agency and discussions are ongoing.

#### Fentanyl, Overdose, Counterfeit Pills

## H174 A Five-Year Retrospective Study of Drug Abuse Deaths in Maryland (2013–2017)

Ayomide Oludoyi, BSc\*, University of Maryland, Baltimore, Baltimore, MD 21201; Sarah J. Sides, BS\*, University of Maryland, Baltimore, Baltimore, MD 21201; Alyssa Dean, MS\*, University of Maryland, Baltimore, Baltimore, MD 21230; Allison C. Klein, BA, University of Maryland Baltimore, Graduate School, Baltimore, MD 21201; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Mary G. Ripple, MD, Baltimore, MD 21223; Ling Li, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** After attending this presentation, attendees will better understand the epidemiological characteristics and current trend of drug abuse deaths in America.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the urgent need for more aggressive regulatory, educational, and treatment measures to address the tremendous increase in fatal drug abuse deaths, especially fentanyl-related deaths.

Deaths involving drug use have been rapidly rising over the years, especially with the introduction of fentanyl into the drug community. In 1992, drug deaths accounted for 249 cases in the State of Maryland, while 25 years later, drug-related deaths were 2,333 in total, approximately a ten-fold increase in 2017.<sup>1</sup> This accounts for nearly 50% of deaths investigated by the Office of the Chief Medical Examiner (OCME) in Maryland.

Using OCME death records for the State of Maryland, a retrospective study was performed to examine drug-related deaths over a five-year period from 2013 to 2017. The OCME is a statewide medical examiner's system, and therefore has jurisdiction over the entire state with a total population of 6,052,177.<sup>2</sup> This study showed that there were 7,869 drug-related deaths from 2013 to 2017, which was a 60.2% increase from 928 in 2013 to 2,333 in 2017. Death rates were analyzed as fatalities per 100,000 population. There was a consistent rise in death rate across the state of Maryland; however, Baltimore showed the most significant rise, from 43.8/100,000 in 2013 to 127.2/100,000 in 2017.

Total drug deaths steadily increased from 2013 to 2015 (31.2%), with a sharp rise between the years 2015 to 2017 (approximately 73%). The White and African American ratio was 2.4:1. The male and female ratio was 2.3:1.

The deaths were arranged by age into ten-year intervals. Data showed that the age of the decedents increased, with the highest percentage (76.7%) in the age group 61–70 years old. This may indicate a new trend in drug abuse deaths for the elderly. The age group of 31–40 years old also increased significantly by 65%.

Fig. 1 shows the trend of all the drug abuse deaths in the past five years. The data revealed that the sharp rise in drug abuse deaths was caused by fentanyl/fentanyl analogue intoxication. In 2013, there were only 60 deaths due to fentanyl intoxication, while in 2017, there were 1,610 fentanyl-related deaths, nearly a 27-times increase. Of the 1,610 fentanyl-related deaths, 820 (50.1%) were caused by mixed fentanyl with cocaine and/or heroin/methadone. The OCME also witnessed a significant increase in deaths due to multiple fentanyl analogues, including acetylfentanyl, butyrylfentanyl, despropionyl fentanyl, furanyl fentanyl, 4-fluoroisobutyryl fentanyl, arylfentanyl, tetrahydrofuran fentanyl, methoxyacetyl fentanyl, and cyclopropyl fentanyl, as well as carfentanil.

Fentanyl/fentanyl analogues and fentanyl mixed with heroin and/or cocaine abuse has become an epidemic in Maryland. This study recommends that more aggressive regulatory, educational, and treatment measures are necessary to address the tremendous increase in fatal drug abuse deaths, especially fentanyl-related deaths.

### H175 Fatal Rodenticide Poisoning in Association With Synthetic Cannabinoid Use—Is It Industrial Contamination?

Rochelle A. Simon, MD\*, Baltimore, MD; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; John Stash, DO, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to illustrate the clinicopathologic features of vitamin K-dependent antagonist coagulopathy associated with the use of tainted synthetic cannabinoids and explore a hypothesis of how the cannabinoids came to be contaminated with rodenticide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by alerting investigators and pathologists to the potentially fatal coagulopathy that may occur with the use of synthetic cannabinoids tainted with brodifacoum, exploring a hypothesis of contamination, and discussing prospective testing to evaluate this hypothesis.

Synthetic cannabinoids have been used recreationally to mimic the psychotropic effects of marijuana, and there has been a relatively recent increase in the number of associated fatalities. These compounds are reportedly consumed as an alternative to cannabis because of accessibility, enhanced effects, and relative undetectability, among other reasons. Synthetic cannabinoids are more variable in content, potency, and function when compared to naturally occurring cannabis. Recent outbreaks of life-threatening vitamin K-dependent antagonist coagulopathy in association with synthetic cannabinoid use have been reported, affecting the states of Illinois, Maryland, Indiana, Missouri, and Wisconsin.<sup>1</sup>

This case involves a 33-year-old male synthetic cannabinoid user who presented to emergency medical services with complaints of hematuria and penile bleeding. The patient went into cardiac arrest before reaching a hospital and resuscitative efforts were ultimately unsuccessful. Postmortem examination identified numerous contusions on the extremities and torso, while analysis of hospital blood showed low hemoglobin (4.0g/dL) and hematocrit (13.1%) with elevated Prothrombin Time (PT of 316.3secs) and International Normalized Ratio (INR of 26.6). Internal examination revealed soft tissue hemorrhage around multiple organs, generalized organ pallor, and gastrointestinal hemorrhage. Toxicologic analysis performed on hospital blood revealed the presence of brodifacoum, a second-generation anticoagulant rodenticide. These clinicopathologic findings are similar to those recently reported in fatal and non-fatal incidents occurring across regions of the United States.

Investigations to determine how rodenticide may have been introduced into synthetic cannabinoids in these life-threatening cases are ongoing. Speculative reports of possible intentional lacing exist in the literature; it has been hypothesized that since both rodenticides and synthetic cannabinoids are metabolized in the liver, saturation of liver enzymes with rodenticide may potentiate and prolong the desired psychotropic effects of the drug.<sup>2</sup> A more worrisome concern is that synthetic cannabinoids are being contaminated intentionally with brodifacoum to cause death. However, a more likely hypothesis is that synthetic cannabinoids may be contaminated at the manufacturing level, during production or storage.

Due to its long half-life and consequent ability to kill after a single exposure, brodifacoum has been banned as a readily accessible, small-quantity, consumer product in the United States.<sup>3</sup> Brodifacoum, and others in this class (such as bromadiolone), are only available for commercial use. In contrast, in China, where most synthetic cannabinoids are manufactured, these rodenticides are widely available. In fact, reports have implicated brodifacoum second only to bromadiolone in the incidence of rodenticide poisoning in this region.<sup>4</sup>

The relative prevalence of accidental brodifacoum poisoning and accessibility of brodifacoum in China raise the possibility of industrial contamination of synthetic cannabinoids outside of the United States, which may produce a fatal coagulopathy. Toxicologic evaluation for brodifacoum in all cases of synthetic cannabinoid use may help to determine the extent of contamination, as low levels may be present in non-fatal or non-life-threatening cases, in addition to fatal cases of acute synthetic cannabinoid intoxication. It is recommended that all autopsy cases which test positive for synthetic cannabinoids also be screened for brodifacoum and other second-generation vitamin K-dependent anticoagulants to evaluate the extent of contamination.

### H176 An Excipient-Induced Oxycodone Fatality

*Deanna A. Oleske, MD, District 23 Medical Examiner's Office, St. Augustine, FL 32095; Drake Ryan Thrasher, BS\*, Birmingham, AL 35205; Jeff Walterscheid, PhD, Quality Forensic Toxicology, San Antonio, TX*

**Learning Overview:** After attending this presentation, attendees will be able to differentiate death due to injecting extended-release tablet formulations instead of relying specifically on low concentrations of oxycodone in postmortem blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of oxycodone in fatal toxicity and challenging assumptions of lethal ranges when considering the adverse vascular effects of parenteral administration of an extended-release tablet.

Opiates such as oxycodone are among a class of semi-synthetic analgesic narcotics indicated for relief of postsurgical pain. Opiate toxicity manifests through its sympatholytic properties of decreased cardiac output and respiratory depression, along with observable side effects such as urinary retention and miosis. Extended-release preparations of oxycodone are often formulated with polyethylene oxide to reduce dosing frequency and curb abuse by preventing rapid absorption. When used outside the parameters of intended delivery, such as intravenous injection, the user is abusing the drug to achieve a larger dose in a shorter time.

However, intravenous delivery creates a condition in which the extended-release excipients can cause fatality without the accompanying signs of opiate intoxication and result in relatively low postmortem concentrations of oxycodone. Patients reporting to emergency care will paradoxically suffer from shortness of breath, fever, and diarrhea. In these cases, Thrombotic Thrombocytopenic Purpura (TTP) -like illnesses later determined to be thrombotic microangiopathy have been diagnosed in patients who crush and inject tamper-resistant opiates (e.g., oxycodone and tapentadol). This is likely due to vascular inflammatory reactions and hemolysis from particulates in the suspension. Although thrombotic microangiopathy and TTP-like illnesses have been reported in the literature from intravenous injection of tamper-resistant opiates, none to date have been described in the forensic literature with appropriate quantitative toxicologic analysis.

Presented here is a case in which the decedent created and injected a formulation consisting of crushed oxycodone and tapentadol tablets mixed into a solution containing promethazine and meperidine. The decedent was found approximately eight hours after sending a voice-to-text message, with slurred slow speech, stating his last wishes. A tourniquet was in place around the upper arm with two injection marks in the antecubital fossa. The decedent was clutching a 50-milliliter syringe with a large bored needle that contained a clear, brown-tinged, viscous fluid. Autopsy findings were consistent with a typical opiate-associated fatality (pulmonary edema, urinary retention). Review of the prescription drug database showed the decedent had chronic opiate dependence, currently taking oxycodone, with a remote prescription for tapentadol. No prescription bottles were found on scene.

The toxicology showed a number of substances, including ethanol, diazepam, oxycodone, meperidine, methocarbamol, tapentadol, and promethazine. However, all were within moderate concentrations and inconsistent with fatal toxicity. Microscopic examination showed endothelial swelling of the arteries in the kidney and fragmented red blood cells (schistocytes) consistent with thrombotic microangiopathy.

This presentation shows how, under these circumstances, the mechanism of death should be carefully elucidated in deaths resulting from intravenous drug abuse of tamper-resistant substances with less reliance and emphasis on reference ranges of the measured drug concentrations. In conclusion, this study describes a death resulting from injecting crushed tamper-resistant, extended-release oxycodone and tapentadol tablets.

#### Oxycodone, Extended-Release, Intravenous

### H177 A Medical Examiner's Office Review of Mechanisms of Injury in Crush-Related Deaths

Catherine Rood, BS\*, Syracuse University, Syracuse, NY 13244; Robert J. Bready, MS, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601; Dennis J. Chute, MD\*, Dutchess County Medical Examiner's Office, Poughkeepsie, NY 12601

**Learning Overview:** The goal of this presentation is to show attendees how rare traumatic asphyxia is reported and what other mechanisms of injury are named in crush-related deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by indicating what mechanisms of injury pertain to crush-related deaths.

Entrapment from cars, trees, and other work-related machinery producing crushing injuries and traumatic asphyxiation are rare.<sup>1,2</sup> Traumatic asphyxia, also known as crush or compression asphyxia, is caused by external pressure on one's body that compresses the chest and abdomen, preventing respiration, the uptake of oxygen, and removal of carbon dioxide.<sup>3</sup>

Typical pathological findings in such asphyxia deaths include petechiae of the face, neck, and upper chest, congestion, cyanosis, subconjunctival hemorrhaging, edema, and abrasions. In the blunt force trauma deaths, rib, sternum, and spine fractures, lung contusions, transection of the aorta, and lacerations to organs may be found. At autopsy, the pathologist may find evidence of asphyxia and blunt force trauma. This may cause discrepancies as to how the cause is to be certified. In a retrospective study of cases brought into the Dutchess County Medical Examiner's Office over a 14-year period, 17 out of 11,260 (0.15%) cases were identified in which an individual was crushed by a heavy object. This study was specifically interested in what were the mechanisms of death. In this review, this study found five cases (29%) were certified as due solely to crush/compressional asphyxia, nine cases (53%) to blunt force trauma, and three deaths (18%) attributed to a combination of the traumatic asphyxia and blunt trauma. Three examples are presented below.

**Case 1:** A 19-year-old male was found pinned under a vehicle after a scissor jack collapsed. The deceased was last seen alive by his grandmother 25 minutes prior to finding him. Autopsy findings noted abrasions of the upper abdomen, petechiae on the face, neck, and upper chest, and mild brain edema. The medical examiner ruled his death an accident by compressional asphyxia.

**Case 2:** A 57-year-old male was crushed by a cinder block-making machine on the job. The deceased was working on the machine when it trapped him between a metal brace and a metal plate holder. A coworker witnessed the event and immediately hit the emergency break to reverse the machine. Autopsy findings noted patterned abraded contusions of the chest and back, fractures of the sternum and multiple ribs, bilateral hemothoraces, bilateral lung contusions, and transection of the aorta with hemorrhaging. The medical examiner ruled his death an accident by crushing injury to the chest with thoracic fractures and injuries to the lungs and aorta.

**Case 3:** A 58-year-old male was pinned by a steel beam at a construction site. The deceased was operating an excavator while demolishing a building when a roof beam fell from the collapsing building and entered the cab of the excavator. A coworker filmed the event as it proceeded. Autopsy findings noted petechiae of the eyelids, conjunctivae, face, neck, and upper torso, and depressed right chest wall associated with right rib cage fractures. The medical examiner ruled his death an accident due to a combination of blunt impact injuries of the chest and compressional asphyxia.

**Conclusion:** Traumatic asphyxia can occur under varied circumstances. In these cases, scene investigation may help the forensic pathologist reconstruct the sequences of events, provide insights as to why the decedent was unable to escape, and how quickly the circumstances transpired. An estimate of the period of survival may be assessed by witness accounts and the injuries discovered at autopsy. In addition to hallmark features that help medical examiners determine mechanism of death, one should consider whether a reflex closure of the glottis occurred, as has been speculated by Byard et al. (i.e., when there is torso compression, the glottis closes from reflex deep inspiration).<sup>4</sup> This reflex produces an increase in central venous pressure, which results in suffusion of the head.<sup>5</sup> Such reconstructions and examinations into mechanisms of death have practical applications toward preventing work-related accidents as well as for future legal proceedings. For example, forensic pathologists may be called to opine in civil litigations as to whether there was conscious pain and suffering at the time of the event. In review of the cases, this study found a significant number of these deaths involved blunt force trauma and the minority purely traumatic asphyxiation.

#### Traumatic Asphyxia, Blunt Force Trauma, Crushing Deaths

## H178 Blunt Force Decapitation in West Tennessee: A Ten-Year Review (2008–2018)

William Sago, MD\*, Memphis, TN 38105; Paul V. Benson, MD, University of Tennessee Health Science Center/Shelby County Medical Examiner, Memphis, TN 38105

**Learning Overview:** After attending this presentation, attendees will understand the accidental and suicidal blunt force decapitation injury case characteristics, postmortem findings, and reports of circumstances commonly associated with these cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a rare type of death by reviewing literature and multiple cases from West Tennessee.

Decapitation due to blunt force injuries is a rarely seen cause of death in most death investigation jurisdictions. Although decapitation due to blunt force injuries is a rare cause of death in civilian populations, it is reported to have occurred in the United States and various other countries.<sup>1-4</sup> Accident and suicide accounted for all the manners of death in the cases reviewed. Blunt force decapitation suicides due to train-induced trauma are reported.<sup>2</sup> Rare and unusual cases have been reported of suicides with self-decapitation by hanging and as motor vehicle-assisted decapitations.<sup>3</sup> Accidental decapitations due to traffic accidents and failure to use seat belts have also been reported.<sup>4</sup>

This study provides a ten-year review of decapitation due to blunt force injuries in cases referred to the West Tennessee Regional Forensic Center in Memphis, TN, including cases from 3 of the 13 counties served by the West Tennessee Regional Forensic Center including Shelby County, Fayette County, and Obion County. Methods included searching the West Tennessee Regional Forensic Center database to extract data based on coding of the cause of death. Results showed seven deaths resulting from blunt force decapitation between 2008 and 2018 in West Tennessee with the most recent case occurring in 2015. The yearly distribution of these seven cases within the past ten years ranged from one death in 2008, one death in 2009, one death in 2010, no deaths in 2011, no deaths in 2012, two deaths in 2013, one death in 2014, one death in 2015, no deaths in 2016, no deaths in 2017, and no deaths in 2018.

All the decapitation deaths due to blunt force trauma studied were White males. The ages of the victims ranged from 14 to 69 years old. Three of the deaths were reported as suicidal manner of death. One suicidal death involved blunt force injuries due to a train. The remaining two suicidal deaths involved motor vehicle-assisted decapitation with a ligature tied to a stationary object. Of these two motor vehicle-assisted decapitation suicidal deaths, one decedent was restrained by a seat belt and the other was not. One suicidal decapitation by train and one motor vehicle assisted decapitation case included a suicide note. One motor vehicle-assisted decapitation suicide did not have a suicide note. The remaining four deaths were reported as accidental manner of Death. Two of the accidental cases involved a motor vehicle crash, one accidental case involved a pedestrian hit by motor vehicle, and one accidental case was due to an aircraft crash. Review of autopsy reports, autopsy photos, and scene photos showed one case coded as decapitation was a partial decapitation and two cases coded as decapitation were decapitation from the mandible superiorly. The aircraft crash case involved fragmentation of the decedent with decapitation.

This retrospective study provides a review of blunt force decapitations reported to the West Tennessee Regional Forensic Center from 2008 to 2018. Although death due to blunt force decapitation is rare, the seven cases reported at the West Tennessee Regional Forensic Center show some similarities to other cases reported throughout the world.

### Decapitation, Blunt Force, Suicide

## H179 Accidental Residential Fire-Related Fatalities: A Seven-Year Study in a Forensic Autopsy Population (2010–2017)

Allison C. Klein, BA\*, University of Maryland Baltimore, Graduate School, Baltimore, MD 21201; Kelsey Mason, BS\*, University of Maryland Baltimore, Baltimore, MD 21201; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Mary G. Ripple, MD, Baltimore, MD 21223; Ling Li, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** After attending this presentation, attendees will learn the groups of people at risk for accidental fire-related fatalities, the conditions which predispose residences to fire, and the epidemiological implications for studying fire deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing its understanding of the risk factors and potential fire prevention measurements in fire-related deaths. It is also important for forensic investigators to document whether a fire or smoke detector was present or functional in any fire-related death investigation.

The majority of deaths from fire are accidental residential events, caused by smoking, electrical malfunctions, improper usage of faulty heating, and clothing igniting on fire from cooking accidents.<sup>1</sup>

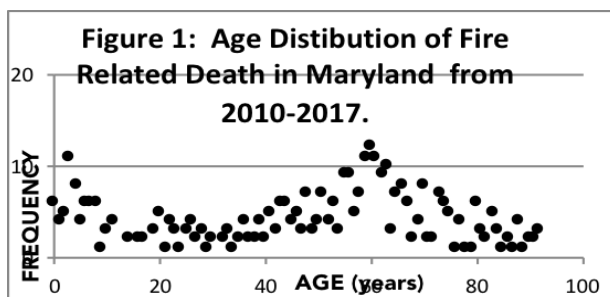

Using death records obtained from the Office of the Chief Medical Examiner (OCME) for the state of Maryland, a retrospective study was conducted on fire fatalities over a seven-year period (2017–2010). The OCME is responsible for conducting death investigations and certifying the cause and manner of unnatural and unexplained deaths, including homicide, suicide, unintentional injuries, deaths that are unattended, or sudden unexpected deaths in the State of Maryland. The data collected at OCME provides an invaluable source of data for identifying statewide epidemiological trends, which affect public health and, therefore, aid in the identification of at-risk groups.

This study revealed that OCME investigated 378 cases of fire fatalities over the ten-year period. Of those, 309 (81%) deaths were due to accidental fire, 19 (5%) deaths were homicides, and 18 (4.7%) cases were suicides. There were 32 (8.5%) deaths with manner of death undetermined. The male-to-female ratio was 2:1.4. The ages of the victims range from 9 months to 92 years, with an average age of 46.95 years. The age groups with the highest frequency of deaths were the elderly (>60 years old) and juveniles (<18 years old) (Fig 1). Many elderly individuals live alone and may not maintain electrical appliances as they should.<sup>2</sup> The isolation of elderly victims and the potential inability to ambulate quickly, or at all, constitutes two main reasons this population is at risk of fire death. Infants and juveniles must rely on assistance from others to escape fires unharmed. A lack of sufficient escape route planning may also contribute to the increased number of juvenile victims.

Of the 309 accidental residential fire deaths, 56 (18%) were caused by smoking. Six victims were smoking cigarettes while receiving oxygen therapy for cardiovascular and/or respiratory diseases. In approximately 8% of cases, the source of fire was attributed to electrical malfunction or heating sources. In addition, cooking implements left unattended were the source of 3% of deaths in the home.

One of the objectives of this study was to identify the presence and function of fire or smoke detectors. However, the data concerning fire alarm systems was often not recorded or unknown in the death investigation reports. It is important to document whether a fire or smoke detector was present or functional in any fire-related death investigation. Smoke alarms provide an early warning of a fire, giving people additional time to escape, and working smoke alarms reduce the risk of fire-related deaths.

Residential fire prevention efforts should target home safety education focused on the elderly and children to maximize survival for these at-risk groups. Education regarding the combustibility of smoking materials and the hazards of smoking on oxygen therapy must also be directed at those at risk and their caretakers. The development of easily maintained and technologically advanced fire and smoke monitoring systems could also aid in the prevention of fire death and aid in future epidemiological research.

### H180 Trousseau's Syndrome in Forensic Medicine

Henry J. Carson, MD\*, Cedar Rapids, IA 52411

**Learning Overview:** After attending this presentation, attendees will be able to: (1) recognize migratory thrombophlebitis associated with malignancy in forensic cases, (2) apply principles of thromboembolic processes to cause and manner of death, and (3) provide usable information to survivors about unexpected medical conditions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping improve competence to correlate thromboembolic phenomena with carcinoma and improve patient outcomes by providing detailed information for reports that answers more questions and provides a valuable mechanism of death.

In 1865, Armand Trousseau described a syndrome of migratory thrombophlebitis as a complication of carcinoma. Understanding this syndrome may provide insight to the underlying mechanism of death in certain cases. Two patients were encountered who died from cardiovascular disease that was proximally related to complications of occult gallbladder carcinoma and the thromboembolic complications of Trousseau's syndrome.

The first subject was an 83-year-old White woman who was admitted to the hospital for congestive heart failure. She died shortly after admission. Autopsy demonstrated evidence of heart failure with thrombosis of the left anterior descending coronary artery, but also an adenocarcinoma of the gallbladder. It was concluded that the patient died from complications of an acute thrombosis of the left anterior coronary artery that could be related to the thromboembolic phenomenon of Trousseau's syndrome.

The second subject was a 76-year-old man who had undergone cardiac bypass surgery one-week antemortem. He had returned home and died after a short walk. At autopsy, numerous formed thromboemboli were recovered from the pulmonary arteries. Incidentally, the gallbladder had a well-differentiated adenocarcinoma. It was concluded that the patient died from pulmonary thromboembolism, which could have been related to thromboembolic phenomena of Trousseau's syndrome.

In the United States, gallbladder carcinoma has an incidence of 1.13 cases per 100,000 population. Women are three times more likely to develop gallbladder carcinoma than men. The most consistent anatomical correlation with gallbladder carcinoma is cholelithiasis. The development of Trousseau's syndrome, which can lead to thromboembolism, can occur in 1%–11 % of cancer patients. Pancreatic cancer is most highly correlated with Trousseau's syndrome and Pulmonary Embolism (PE), but other malignancies are associated with this syndrome. Trousseau's syndrome can be seen as a chronic form of disseminated intravascular coagulation or a prothrombotic state, in which cancer leads to hypercoagulability by various mechanisms. The role of thromboembolism in these patients establishes a mechanism of death by forming blood clots that obstructed critical blood vessels.

While medical data sufficient to affirm a cause of death based on clinical circumstances were available in the present cases, autopsies provided more information about the mechanism of death in these patients, and provided comfort to the survivors in both families that the outcomes were more bearable, especially in light of the autopsy findings, in which an elusive, serious cancer was found, which would have caused considerable morbidity and likely eventual fatality if the family member had not died beforehand from competing causes.

**Forensic Science, Thromboembolism, Gallbladder Neoplasms**

## H181 Exercise-Associated Hyponatremia: An Update

Paul Uribe, MD\*, Martin Army Community Hospital, Fort Benning, GA 31905

**Learning Overview:** After attending this presentation, attendees will better understand the critical nature of recognizing Exercise-Associated Hyponatremia (EAH) as a potentially fatal complication of overhydration and extreme exertional exercise that requires rapid diagnosis and treatment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) introducing attendees to this subset of acute hyponatremia that occurs exclusively in elite athletic populations; and (2) explaining the underlying physiology, the importance of rapid diagnosis and treatment, and the far-reaching implications of this condition for diagnostic and treatment algorithms developed for military training exercises.

EAH is a preventable condition associated with overconsumption of hypotonic fluids in a setting of extreme physical exertion that exceeds the renal capability to diurese.<sup>1</sup> EAH is seen in elite athletic populations, such as marathon runners, triathletes, and military training populations.<sup>2</sup> Long-held misconceptions regarding how much fluid intake is required during exercise exacerbates the problem of EAH.<sup>3</sup> The treatment of severe hyponatremia has traditionally focused on correcting the sodium deficit slowly to prevent the potentially lethal complication of central pontine myelinolysis. This traditional approach for the treatment of chronic hyponatremia does not apply to the current model of EAH in this population of elite athletes. The drop of serum sodium is due to water overconsumption during extreme exercise, can occur rapidly, and must also be corrected rapidly to avoid the fatal complication of irreversible cerebral edema, also termed Exercise-Associated Hyponatremic Encephalopathy (EAHE). Once recognized, the sodium deficiency must be corrected with 3% hypertonic saline as soon as possible. Rapid correction of the sodium deficits in acute exertional hyponatremia does not result in the classic complication of central pontine myelinolysis and avoids the complication of EAHE.<sup>4</sup> If treated per the traditional model in which the sodium deficit is corrected gradually, the use of 0.9% saline or other isotonic solutions in these patients can worsen volume overload, This leads to potentially fatal complications, such as pulmonary edema and EAHE.

The underlying physiology of EAH is hallmarked by the sodium-conserving actions of anti-diuretic hormone. These patients develop Syndrome Of Inappropriate Antidiuretic Hormone (SIADH) in which vasopressin is paradoxically released, likely as a sodium conservation measure.<sup>5</sup> This increase in vasopressin allows the renal tubules to conserve salt and also retain water, which prevents the usual diuresis from fluid resuscitation or continued overhydration. This inability to off-load excess fluid greatly predisposes these patients to pulmonary edema and ultimately irreversible cerebral edema.

This presentation reviews three fatal cases of EAH, examines the underlying physiology behind EAH, and reviews the diagnosis and treatment algorithms currently in development by the United States Army.<sup>6</sup>

### Hyponatremia, Exercise, Electrolytes

### H182 Sudden Unexpected Death in Pemphigus Vulgaris: An Autopsy Report

Asit Kumar Sikary, MD\*, ESIC Medical College & Hospital, Faridabad, Haryana 121001, INDIA

**Learning Overview:** The goal of this presentation is to discuss sudden death in a case of pemphigus vulgaris. The fatal event was precipitated by the steroid used for the treatment of a skin disease.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting that the forensic pathologist should be aware of the medication history of the deceased and any complications of the medications, even when the dose is well regulated.

Sudden deaths form a significant proportion of autopsies globally. The incidence of sudden deaths varies globally owing to the variations in the prevalence of various diseases in different countries and environmental and genetic factors. The incidence of sudden death has been reported to vary from 1.8% to 31% in various studies worldwide. While most of the sudden deaths are attributed to cardiac and respiratory causes, dermatological conditions are rarely implicated in sudden deaths.

As per the World Health Organization (WHO), the death rate due to skin diseases in India is about 1.63 per lac population. Most common fatal skin diseases include Harlequin ichthyosis, epidermolysis bullosa, Ehlers-Danlos Syndrome, methicillin-resistant *Staphylococcus aureus*, toxic epidermal necrolysis, basal cell carcinoma, squamous cell carcinoma, scleroderma, leishmaniasis, and pemphigus, among others. The literature on complications of steroid therapy in pemphigus patients is limited.

A 57-year-old non-alcoholic, non-hypertensive, and non-diabetic man was diagnosed with severe pemphigus vulgaris 14 weeks prior to his death and was under systemic steroid therapy (oral prednisone 80mg/day) since then. His skin lesions were improving; however, his blood pressure recorded during the last follow up, one week before death, was 150/100mm Hg and pulse was 100/min. During the 14 weeks of treatment, the patient had gained 10kg weight. On the fateful day, the deceased collapsed while taking a bath in the morning and was brought to the emergency department of a hospital where he was declared dead on arrival.

At postmortem examination, pemphigus lesions were present over the trunk and thighs evenly in the form of collapsed blisters, erosions, and crusting. Inflammatory and healing changes were seen in some of the lesions over the thighs. Histopathological examination of skin lesions confirmed pemphigus vulgaris with intraepidermal separation of keratinocytes and “rounding off” at the suprabasal layer. The lungs weighed 580gm each, and on histopathology, showed severe interstitial lung disease with capillary congestion, and hemosiderin laden heart failure cells with old hemorrhages. The liver weighed 2,017gm and showed micro vesicular steatosis with focal vascular dilatation and congestion on microscopy. The spleen showed congestion of red pulp with depletion of white pulp and medial hypertrophy of blood vessels on microscopic examination. The heart was enlarged and weighed 518gm without any valvular or aortic outflow obstruction. Hypertrophy of cardiac myocytes was observed on histopathology. Renal vasculatures showed medial hypertrophy with intimal thickening and mild peritubular capillary congestion on histopathology. The vitreous glucose level was 105gm/dl.

These findings suggest that the deceased was suffering from chronic systemic hypertension and chronic cardiac failure, which was potentially aggravated by the steroid treatment, causing sudden collapse.

#### Autoimmune Disease, Hypertensive Changes, Steroid Therapy

### H183 Sudden Death Caused by Bilateral Diaphragmatic Eventration in Myotonic Dystrophy Type 1

Sulin Wu, PhD\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will understand the pathophysiology and genetic basis of myotonic dystrophy, a multisystem inherited disorder that represents the most common muscular dystrophy observed in adults.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a case of sudden death related to respiratory compromise caused by bilateral diaphragmatic eventration and associated restrictive lung disease in a woman with a known clinical diagnosis of Myotonic Dystrophy Type 1 (MD1).

A 48-year-old woman with a known clinical diagnosis of MD1 was found unresponsive in her home. She was pronounced dead at the scene. A clinical diagnosis of MD1 had been rendered at the age of 13 years, although no genetic/molecular testing had ever been performed. At 39 years of age, she was diagnosed with chronic obstructive pulmonary disease and restrictive lung disease.

A medicolegal autopsy was performed, which disclosed a mildly obese (BMI=29.4) adult female. On internal examination, the lungs appeared somewhat hypoplastic, with a combined weight of 470 grams. The diaphragm was intact, but was markedly elevated bilaterally, with associated decrease in pleural cavity volume. Much of the diaphragm was parchment-thin and nearly translucent. Additional gross findings at autopsy included changes consistent with hypertensive and atherosclerotic cardiovascular disease. Microscopic examination of the diaphragm showed deformation and degeneration of skeletal muscle, with fat and fibrous tissue replacement and residual muscle fibers containing numerous central nuclei and rare cytoplasmic vacuolization. The cause of death was ruled respiratory compromise due to restrictive lung disease due to bilateral diaphragmatic eventration due to MD1, with underlying hypertensive and atherosclerotic cardiovascular disease. The manner of death was natural.

Myotonic dystrophy is the most common muscular dystrophy observed in adults.<sup>1,2</sup> The condition is a multisystem disorder, characterized by muscle weakness, myotonia, cardiac conduction abnormalities, and various other manifestations, with cardiac and respiratory issues being responsible for most deaths.<sup>3-5</sup> MD1 is the most common form of the disorder, resulting from an autosomal dominant inheritance of a triplet-repeat disorder.<sup>3,4</sup> The presented case is a bit unusual in that she was diagnosed with the juvenile form of MD1 but experienced only limited clinical manifestations for most of her adult life. Respiratory involvement in the disorder is a complex phenomenon, related to variable involvement of chest wall muscles and the diaphragm, with associated apnea and chronic hypoxemia; restrictive lung disease in MD1 patients is a recognized indicator of cardiac events and risk of death.<sup>6,7</sup> A recently published case of MD1-related death emphasizes the fact that fat-replacement of muscle can contribute to death.<sup>8</sup> In the present case, the marked diaphragmatic eventration, with associated pulmonary compromise, represents another unusual manifestation of MD1. Clinicians and pathologists should remain aware of this rare presentation of MD1.

### H184 Mutations of Plakophilin-2 (PKP2) in Sudden Unexplained Death (SUD)

*Junyi Lin, Shanghai, CHINA; Bi Xiao, Shanghai, CHINA; Ziqin Zhao, MS, Shanghai, CHINA; Sisi Cheng, Shanghai, CHINA; Yiwen Shen, Shanghai, CHINA; Mingchang Zhang\*, Department of Forensic Medicine Fudan University, Shanghai 200032, CHINA*

**Learning Overview:** After attending this presentation, attendees will know PKP2 mutations may occur in cases of SUD, specifically in patients without evidence of fibrofatty change, and that PKP2 protein defect in itself is arrhythmogenic.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing attendees to the results of DNA sequencing of PKP2 extracted from postmortem heart tissues of 25 Western patients dying from SUD and 25 Chinese Han patients dying from SUD.

SUD remains a puzzle in forensic medicine. PKP2 has been linked to Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC), which may cause life-threatening ventricular arrhythmias and sudden death. Fatal arrhythmias resulting in sudden death also occur in the absence of morphologic cardiac abnormalities at autopsy and have been linked to ion channel mutations in a subset of cases, but so far not to PKP2. This study sequenced all 14 exons of PKP2 in DNA extracted from the postmortem heart tissues of 25 Western patients and 25 Chinese Han patients dying from SUD. The primers were designed using the Primer Express 3.0 software. Direct sequencing for both sense and antisense strands was performed with a BigDye Terminator DNA sequencing kit on a 3130 xl Genetic Analyzer. Mutation damage prediction was made using Mutation Taster and Polyphen. In 6 of the 25 cases of Western SUD samples, 6 PKP2 mutations (p.F339S, P665S, p.P665S, p.Y217TfsX45, p.E540, and p.S615T) were identified, 3 of which were probably pathogenic according to Mutation Taster and Polyphen. In 2 of 25 cases of Chinese Han SUD samples, 2 PKP2 mutations (p.R691Q, p.L366P) were identified, 1 of which was probably pathogenic according to Mutation Taster and Polyphen. The present study also confirms that the PKP2 mutation (p.Y217TfsX45) which was found in a patient dying of SUD could reduce the expression of PKP2 and could also promote the autophagy to decrease the expression of Cx43.

Data collected in this study suggest a link between the PKP2 mutations and SUD cases in both Western and Chinese Han population. However, PKP2 mutations are more frequent in Western SUD cases than in Chinese Han population cases and have complications in that medical examiners who perform molecular genetic screening in cases of SUD need to be aware that PKP2 mutations may also be able to cause fatal arrhythmias even in patients with a morphological normal heart.

### H185 The Use of High-Mobility Group Protein (HMGB1) to Determine Time Since Death: An Autopsy-Based Study

Puneet Setia, MD\*, All India Institute of Medical Science, Jodhpur, Rajasthan, INDIA; Rutwik D. Shedge, MSc, All India Institute of Medical Sciences, Jodhpur 342005, INDIA; Anupama Modi, MSc, All India Institute of Medical Sciences, Jodhpur 342005, INDIA; Purvi Purohit, PhD, All India Institute of Medical Sciences, Jodhpur 342005, INDIA; Praveen Sharma, All India Institute of Medical Sciences, Jodhpur 342005, INDIA

**Learning Overview:** After attending this presentation, attendees will be informed regarding the importance of Enzyme Linked Immune-Sorbent Assay (ELISA) utility in the evaluation of time since death. The goal of this presentation is to update attendees regarding the use of HMGB1 as an easy, cheap, and reliable marker to determine time since death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new method to determine time since death, which can be utilized even at the grass root level.

Determining time since death is one of the most important aspects of forensic work. Since time immemorial, time since death has been estimated using various techniques. The earlier standards included checking livor mortis, hypostasis, rigor mortis, signs of decomposition, forensic entomology, etc.<sup>1</sup> These standards are of a subjective nature and depend upon non-scientific aids such as gross observation for their recording. Since these were never accurate, the quest for better methods led to the development of postmortem biochemistry, especially in the vitreous humor.<sup>2,3</sup> The major shortcoming of this method was that the results were applicable only for a short postmortem interval, merely a few hours.<sup>4,5</sup>

A group of non-histone nuclear proteins with high electrophoretic mobility were discovered in 1973 and were termed High Mobility Group (HMG) proteins. These include three superfamilies, HMGB, HMGN, and HMGA. Out of these, HMGB1 is the most abundant as well as the most well-studied protein. HMGB1 is an important protein that plays a critical role as a DNA chaperone, chromosome guardian, autophagy sustainer, and protector from apoptotic cell death. HMGB1 is released by eukaryotic cells upon necrosis. This property has been made use of in estimating Postmortem Interval (PMI) in animal models using Wistar rats.<sup>6,7</sup>

This presentation is part of an ongoing study on the determination of time since death using serial estimation of HMGB1 in blood, liver, spleen, and brain tissues harvested during routine medicolegal autopsy. The selection criteria for the cadavers is in-hospital death undergoing medicolegal autopsies, and those who do not have any condition that increases tissue necrosis/cell death. The blood and tissue samples are removed at the time of the autopsy and further subjected to extraction of serum and tissue supernatant (in phosphate-buffered saline) at regular time intervals of zero, three, six, and nine hours. The levels of HMGB1 in serum and tissue supernatant are being assessed using a commercially available ELISA kit. The initial results have shown positive correlation between the HMGB1 levels and time since death. The results of various tissues, such as liver, brain, spleen, and blood, and their correlation will be presented. The use of ELISA as the method for analysis makes it a cheap, rapid, and easily available procedure that can be utilized even in the busy mortuaries of developing countries as well as in the peripheral centers where facilities for advanced research and analysis are not available.

#### High-Mobility Group Protein (HMGB1), Time Since Death, Enzyme-Linked Immuno-Sorbent Assay

### H186 Fatal Angioedema Due to a Delayed Hypersensitivity Reaction Associated With Hair Dye and a Temporary Tattoo

Ami L. Jackson, DO\*, Winston-Salem, NC 27104; Jerri McLemore, MD, Wake Forest School of Medicine, Winston-Salem, NC 27157

**Learning Overview:** The goal of this presentation is to increase awareness of a possible hypersensitivity reaction at autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enforcing the need for thorough investigation of the circumstances surrounding death, including friend and family interviews.

A young woman was found dead on her bedroom floor after complaining of a sore throat the previous evening. Two days prior, the decedent sat through a five-hour hair salon appointment to dye her hair a darker color. The decedent had dyed/bleached her hair a lighter color in the past, but this most recent hair treatment consisted of a dark color that she had not used before. She had complained of the fumes being too strong while her hair was being treated. Discussion with family members revealed no other changes in her daily routine, no history of recent exposures to new foods or chemicals, and no history of recent insect or other animal bites or exposures. She had no known history of allergies or predisposition to allergic reactions. Further investigation revealed the decedent had purchased a temporary tattoo from a European website approximately ten months prior to death.

At autopsy, the decedent had swollen lips and marked edema of the soft tissues of the larynx, the epiglottis, and vocal folds, along with periorbital and conjunctival petechiae. Microscopic analysis of the edematous tissue revealed an exuberant band of lymphoplasmacytic inflammatory cells in the submucosa with less intense mononuclear inflammation within the deeper tissue. A stain for mast cell tryptase was positive for numerous mast cells throughout the tissue. No other anatomic cause of death was found.

Hypersensitivity reactions, mainly in the form of allergic contact dermatitis or erythema, have been linked to a number of cosmetic products, including hair dyes. A common ingredient of darker tints of hair dyes is Paraphenylenediamine (PPD), an ingredient that imparts a dark color and is present in dark dyes used for fabrics; hair coloring products; paints and lacquers; cosmetics, particularly eye shadow; and shoe polish to name only a few items. PPD is also commonly used as the dark pigment in temporary tattoos, especially henna tattoos, sold outside of the United States. PPD derivatives have been implicated in the development of cross reactions and the development of angioedema in susceptible persons.<sup>1</sup> Fatalities associated with PPD usually involve intentional ingestion of this product as a means of suicide, predominantly in India.<sup>2</sup> Review of the medical literature uncovered one case report similar to this case of a delayed hypersensitivity reaction with angioedema connected to the use of a temporary tattoo followed by use of hair dye containing PPD a year later; however, no death was associated with this prior reported case.<sup>3</sup>

This case demonstrates the need for recognition of a possible hypersensitivity reaction at autopsy and thorough investigation, including extensive interviews with friends and family by medical examiners/coroners and death investigators, to pinpoint possible immunologic triggers. Outside of the fields of dermatology and cosmetology, the potential for this type of hypersensitivity reaction is not well known.

### H187 Fatal Clostridial Necrotizing Fasciitis Resulting From Skin Popping in Heroin Abusers

Hannah Elysse Bielamowicz, MD\*, Travis County Medical Examiner's Office, Austin, TX 78724; Kendall V. Crowns, MD, Travis County Medical Examiner's Office, Austin, TX 78724; Keith Pinckard, MD, PhD, Travis County Medical Examiner, Austin, TX 78701; Michelle S. Montonera, MS, Travis County Medical Examiner's Office, Austin, TX 78724

**Learning Overview:** After attending this presentation, attendees will gain a basic understanding of the production techniques of Black Tar Heroin (BTH) and its potential for bacterial contamination, examine the clinical presentation and autopsy findings of three cases of clostridial necrotizing fasciitis, and evaluate the pathophysiology of and risk factors associated with Necrotizing Soft Tissue Infections (NSTIs) in Injecting Drug Users (IDU) of heroin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the relative predominance of clostridial species in necrotizing fasciitis associated with subcutaneous or intramuscular injection of BTH. The relative prevalence of spore-forming bacteria in IDU-related NSTIs has been reported, but accounts of postmortem examination and pathologic findings in the forensic literature are sparse.

BTH has been the predominant form of heroin in the United States west of the Mississippi River since the 1980s. The initial production of BTH from opium requires boiling at temperatures of 150°C in acidic conditions, likely destroying any clostridial spores that may be present. Given this fact, contamination with bacterial species or spores most likely occurs via the addition of adulterants or during transport. Of note, during preparation for injection by the user, dissolution of heroin in an acidic solvent and heating to near-boiling temperatures effectively kills most bacteria, but these methods are ineffective at neutralizing clostridial spores.

Three adult individuals with histories of Intravenous Drug Abuse (IVDA) each presented to the hospital with severe soft tissue infections of their extremities secondary to skin popping of BTH. The nidus of infection in two cases was the shoulder, while that of the third case was the right thigh. Each individual was given intravenous antibiotic therapy and underwent surgical debridement of their wounds. One individual arrested mid-procedure and expired; the other two individuals succumbed to hypotensive shock less than 24 hours after surgery. Antemortem blood and tissue cultures of two cases grew *Clostridium sordellii*; the third case grew two species of *Clostridium*, not *C. perfringens*, which were unable to be further classified. Autopsy findings of all cases included at least one abscess of the extremity with surrounding erythema. Histologically, the lesions exhibited edema, acute inflammation, and necrosis of the skin, soft tissue, and muscle. Death in each case was attributed to *Clostridium sordellii* sepsis or necrotizing fasciitis and sepsis.

The major risk factor associated with the development of soft tissue infections caused by anaerobic spore-forming bacteria is skin popping. This leads to inflammation and devitalization of tissue, while also circumventing the bloodborne immune system that may otherwise thwart infection. Simultaneous injection of heroin with a vasoconstrictor such as cocaine generates tissue ischemia. All these factors promote anaerobic conditions for spore germination and toxin production.

Necrotizing fasciitis due to BTH injection appears to be primarily a clostridial disease, whereas the more typical pathogens are *Staphylococcus aureus* and *Streptococcus pyogenes*. *Clostridium sordellii* is among the most commonly isolated, in addition to *C. perfringens* and *C. novyi*. *C. sordellii* produces two cytotoxins that cause severe soft tissue edema, often without gas or purulence, marked leukocytosis, and rapidly fatal hypotensive shock. Interestingly, it has been isolated from BTH samples in prior studies.

Clostridial infection should be considered in an individual with a history of chronic narcotism and evidence of intramuscular or subcutaneous injection of heroin, the main risk factor associated with this disease. It should be noted that the region of inflammation may be subtle yet still cause death by a toxin-mediated illness. Care must be taken not to misdiagnose such a case as acute overdose if elevated drug concentrations are present. Postmortem cultures may not yield results due to the fastidious nature of certain anaerobic organisms, or they may be non-contributory due to prior antibiotic therapy during hospitalization. Therefore, correlation with antemortem blood or tissue cultures is imperative.

While there are many articles in the clinical literature on the subject of IDU-related clostridial soft tissue infections, a review of the forensic literature showed only one study which discussed necrotizing fasciitis due to spore-forming clostridial agents in connection with BTH. This presents three further cases of a rare but significant association between clostridium species and soft tissue infections in injecting heroin abusers.

#### Heroin, Clostridium, Necrotizing Fasciitis

### H188 Cable-Tie Neck Ligatures: A Series of Five Cases

Nicole B. Ahmed, BA\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; Laura Bauler, PhD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Joyce L. deJong, DO, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Jacqueline J. Pender, MD, Miami-Dade Medical Examiner Office, Miami Beach, FL 33139; Theodore T. Brown, MD, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will understand about occasional deaths that occur in association with cable-tie neck ligatures. Five cases will be highlighted, including a double-homicide, a suicide, and a combined homicide-suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to the use of cable ties as ligatures for potential strangulation.

Asphyxial deaths occur due to decreased oxygenation of tissues related to depleted environmental oxygen, chemical interference with oxygen utilization, external or internal airway obstruction, trauma or compression resulting in the inability to breathe, or external neck compression, which may involve airway and blood vessel compromise. Most deaths related to external neck compression involve a neck ligature. Such ligature-related cases are typically categorized into two subtypes: hanging, in which the victim's body weight contributes to the compressive force of the ligature, and strangulation, in which the victim's body weight does not contribute to the compressive force of the ligature. While asphyxiation is not an uncommon suicide mechanism, suicide via ligature strangulation is rare because the patient is often unable to maintain tension in the ligature after losing consciousness. Ligature strangulation is much more common in homicides. The use of cable ties as ligatures for strangulation has been reported in the scientific literature and news media, but its occurrence is rare. This study presents a series of five forensic cases in which cable-tie ligatures were discovered about the necks of the decedents.

The first two cases were related to a combined double-homicide/suicide in which two brothers, aged 11 and 15 years, were strangled with industrial cable ties by a family friend with a history of paranoid schizophrenia, who then hanged himself. One of these cases involved a unique mechanism in which the cable tie was not around the anterior neck, but instead was around the anterior chin with marked posterior compression of the mandible and pharynx. In case three, a middle-aged man with a history of alcoholism and depression had an argument with his mother shortly prior to securing two cable ties tightly around his neck. Cases four and five represent a homicide-suicide scenario in which cable ties were found loosely fastened around the decedents' necks. A father and his 6-year-old son were found dead and decomposing in the enclosed compartment of a motor vehicle, the interior of which had been soaked with gasoline and other volatile hydrocarbons. Both succumbed to asphyxia via inhalation of volatile hydrocarbons, with the cable-tie ligatures presumably in place as a back-up mechanism to ensure their deaths.

Intentional self-harm accounts for most asphyxial deaths reported nationally.<sup>1</sup> Although suicide by ligature strangulation is rare, it has been reported in the medical literature.<sup>2</sup> Suicide via strangulation using cable ties has also been reported.<sup>3-5</sup> Despite the presence of several media reports of cable ties used in homicidal strangulations, reporting of such cases in the scientific literature is rare.<sup>6</sup> Suicides employing multiple methods are referred to as "complex suicides."<sup>7</sup> Cases four and five are a situation where the neck cable-tie ligatures represent a presumed planned secondary method for ensuring both deaths.

### H190 It's Not Just Assault Rifles: A Case Study of a Mass Shooting Involving a Shotgun

Brooke H. Blake, MD\*, University of Texas Medical Branch Galveston, Galveston, TX 77555; Erin A. Barnhart, MD, Galveston County Medical Examiner's Office, Texas City, TX 77591

**Learning Overview:** After attending this presentation, attendees will better understand the most common shotgun and its prior use in mass shootings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the less common use of shotguns in mass shootings and providing a review of shotgun ballistics for forensic pathologists. While shotgun injuries are common, death tolls from single events do not generally reach the double digits.

There is no consensus definition of mass shooting; however, the Congressional Research Service defined it as “incidents occurring in relatively public places, involving four or more deaths—not including the shooter(s)—and gunmen who select victims somewhat indiscriminately.”<sup>1</sup>

Since its introduction in 1951, the Remington® Model 870 has become the best-selling shotgun of all time—more than 12 million have been made, and it is used in several different countries by law enforcement, the military, and civilians.<sup>2</sup> With multiple different variants and modifications and cheaper cost, the Model 870 is used in a myriad of different situations: self-defense, clay and field shooting, hunting (deer and fowl), and tactical. These guns normally hold five or seven shells that are easily fed into a bottom-loading chamber to allow for reloading without pausing.

Ten people were killed and 13 injured in a mass shooting incident at a large local high school. The victims were confined to one room and two small closets. The suspect was arrested approximately 29 minutes after the first shot was fired. Police discovered a .38 caliber Rossi® revolver on scene and a Remington® 870 12-gauge short-barreled shotgun that the suspect relinquished on scene. Both were legally owned by a relative. The suspect discarded the Rossi® revolver early in the attack after emptying the chamber and fired all remaining shots from the Remington® 870. The barrel had been sawed off even with the magazine tube, and double aught buckshot (each pellet is a .30 caliber size) was recovered at the scene. The shooter wore a bandolier with the ammunition and reloaded by hand. Police first engaged the suspect within four minutes of the first shot; however, he was able to hold off police with the shotgun only and continue his spree until surrendering to the police without sustaining injury.

At autopsy, shotgun pellets were recovered from each decedent, each within the double aught buckshot caliber. The ammunition used had approximately eight pellets per shot; multiple decedents had more than eight, indicating they had been hit by multiple shots and often in fairly tight configurations.

Out of 143 weapons used in mass shootings (lone shooter in a public place with 3+ deceased) in America from 1982–2012, one public database notes that 71 were semiautomatic handguns (50%), while 21 shotguns were used (15%).<sup>3</sup> This case shows that while semiautomatics are the most commonly used, shotguns can be just as deadly and may be more readily accessible.

## H191 Elevator-Related Deaths

Joseph A. Prahlow, MD\*, Western Michigan University School of Medicine, Kalamazoo, MI 49007; Zuhha Ashraf, MD, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033; Natalie Plaza, MD, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033; Christopher B. Rogers, MD, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033; Pamela A. Ferreira, MD, Columbia, MD 21044; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Melissa M. Blessing, DO, Harris County Institute of Forensic Sciences, Houston, TX 77054; Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Science, Houston, TX 77054; Michael A. Graham, MD, Saint Louis University School of Medicine, St. Louis, MO 63104; Kelly L. Sandberg, MS, Franklin County Coroner's Office, Columbus, OH 43201; Krista L. Timm, MD, Denver, CO 80204; Theodore T. Brown, MD, Kalamazoo, MI 49008; Patrick E. Lantz, MD, Wake Forest School of Medicine, Winston-Salem, NC 27157-1072

**Learning Overview:** After attending the presentation, attendees will be aware of risk factors associated with elevator-related injury and death, including factors related to the decedent and those associated with the elevator and surrounding environment, as well as factors connected to other persons' actions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reviewing multiple deaths associated with elevators, with varying causes and mechanisms of death, occurring in multiple jurisdictions over the past several decades.

Injuries and deaths related to elevators are relatively rare but have been reported in both the medical/scientific literature, as well as the popular press.<sup>1-4</sup> Mechanisms of injury/death include asphyxia-related injuries, Blunt Force Injuries (BFI), such as those resulting from crushing trauma and falls from heights, avulsion types of injuries, and environmental injuries. Decedents include elevator maintenance personnel, construction workers, elevator users, and those involved in risk-taking behavior. Occasional natural deaths and non-elevator-associated traumatic deaths also occur on elevators.

This study reports on 57 elevator-related deaths, occurring in 8 different jurisdictions, and encompassing cases occurring over the past 40 years. The series of cases does not include every elevator-related case occurring in each of the jurisdictions during the listed time-frame. Therefore, frequency data cannot be calculated based on this study. Rather, the collection of cases represents an attempt to gather a wide variety of case types, to gain an understanding of how such deaths occur, and how elevator-related injuries and deaths may be avoided. In addition to an overall review of the cases, select cases will be highlighted to emphasize important forensic considerations as well as preventive strategies.

Of the 57 cases included in this review, 20 had causes of death which could be categorized as BFI related to falls, 14 could be categorized as traumatic asphyxia, 10 involved crushing types of BFI, 5 involved other blunt force trauma, 1 involved complications of spine trauma, 1 case involved decapitation, 2 involved drowning, and 3 were electrocutions. In one case, a cause of death could not be determined secondary to decomposition. The manner of death in all but two cases was certified as accidental. There was one suicide and one undetermined.

Several important potential preventive strategies are highlighted by the series of cases. For maintenance and construction workers, as well as the general population, elevators, elevator shafts, and all the mechanical and electrical aspects related to them, must always be recognized as potentially dangerous, especially when they are under construction, under repair, or when they are not functioning normally. Constant vigilance and awareness around elevators is necessary to avoid potentially life-threatening accidents. For the general population, suggested strategies to avoid injury and death include the following: do not use improperly functioning elevators; report malfunctioning elevators immediately; do not attempt to forcibly enter or exit an elevator; do not enter or exit a "stuck" elevator; do not attempt to repair a malfunctioning elevator; do not enter an elevator shaft; do not "play" on elevators or in elevator shafts. For construction and maintenance workers, the recognition that elevators are potentially dangerous is even more important, as the nature of work in and around elevators places such persons at greater risk of injury and death. Employing appropriate safety devices, precautions, and protocols can help to avoid accidental injury and death. Examples include wearing safety harnesses; shutting down elevator function while working above, below, or near elevators; and following all industry safety regulations.

## H193 Tractor-Related Fatalities

Tracy C. Johnson, BS, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; Abigail Jacqueline Grande, MPH, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Amanda O. Fisher-Hubbard, MD\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be more familiar with the variety of environmental and occupational settings in which tractor-related fatalities can occur, as well as trends in certification of these deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by quantifying the frequency of physical injuries associated with tractor-related fatalities and examining the relationship of these traumatic injuries to underlying medical conditions, which can aid forensic pathologists in elucidating the medically relevant contributions to a given fatality.

Tractor-related fatalities remain a significant cause of preventable deaths, despite governmental attempts to reduce their prevalence. Approximately half of all agricultural fatalities are associated with farm tractor accidents.<sup>1</sup> The rural setting of many of these accidents also results in delayed transportation and treatment; the majority of deaths occur at the site of the accident.<sup>2</sup> These fatalities can vary widely by mechanism of death, contributions from underlying natural disease, environmental settings, and affected population. The majority of tractor-related fatalities involve overturned tractors, also known as tractor “rollovers.” The most common injury pattern leading to death in these fatalities is crushing of the chest from the weight of the overturned tractor. While tractor-related fatalities most commonly affect farmers, a significant portion of these deaths affect other occupations, including construction and manufacturing workers, military personnel, students, and others.<sup>3</sup>

This study hypothesizes that most tractor-related fatalities are accidental deaths and that most of these accidents include a component of asphyxia.

For the purposes of this study, a “tractor” is considered a four-wheeled or tracklaying automotive vehicle used especially for drawing heavy equipment; this also includes riding lawn mowers. This study examined a series of cases in which death occurred in the setting of tractor operation. To capture all tractor-related deaths, a search was conducted using multiple methods, including searching for the term “tractor” in the investigator narrative of the investigative report, in the *Vehicle Type* of the investigative report, and in the *Injury Description* of the death certificate. A search was also conducted for the term “lawn” in the *Injury Description* of the death certificate. This study includes cases investigated by medical examiners across multiple counties in Michigan from 2008 to 2018.

A total of 126 potential tractor-related cases were identified using the above search techniques. Of these 126 cases, 35 met the criteria for the purpose of this analysis. These decedents ranged in age from 1 to 90 years, with mean and median ages of 61 and 63 years, respectively. Only four (11%) of the 35 decedents were female. The majority of these deaths (77%) were certified as accidental; this study also located two (6%) suicides and six (17%) natural deaths related to tractor operation. Four of the deaths occurred at work, while 26 were not at work, and the remaining five deaths were unknown. Only two of the decedents were not the operator of the tractors at the time of the incidents; this included a 2-year-old passenger and a 1-year-old pedestrian. Of the 29 non-natural deaths, eight involved an overturned tractor causing blunt force injury and/or asphyxiation of the operator. Six of these 29 deaths involved a tractor versus a moving vehicle, including a snowmobile versus tractor, a moped versus tractor, and four lawn tractors versus cars. The remaining non-natural deaths included three fallen tree branches, three falls from the tractor, three carbon monoxide poisonings, two drownings, two pedestrians run over by the tractor, an entanglement in the tractor machinery, and a farm animal attack.

As hypothesized, the majority of tractor-related fatalities examined were accidental deaths. Notably, a minority of these accidental deaths involved asphyxia due to an overturned tractor. To conclude, tractor-related fatalities include a wide variety of causes of death, often occur outside of an occupational setting, and involve a wide age-range of decedents.

### Tractor, Lawn Mower, Traumatic Asphyxia

### H194 Postmortem Computed Tomography (PMCT) in Shooting Fatalities

*Marloes E.M. Vester, MD\**, Netherlands Forensic Institute, The Hague, ZH 2497GB, NETHERLANDS; *Rick R. Van Rijn, PhD*, Amsterdam University Medical Centers, Amsterdam 3544MT, NETHERLANDS; *Chandra Y. Gerrard, BS*, University of New Mexico, Department of Radiology, Albuquerque, NM 87106; *Kurt B. Nolte, MD*, Office of Medical Investigator, Albuquerque, NM 87131-0001; *Reinoud D. Stoel, PhD*, Laan van Ypenburg 6, Den Haag, NETHERLANDS; *Gary M. Hatch, MD*, University of New Mexico, Department of Radiology, Albuquerque, NM 87106

**Learning Overview:** After attending this presentation, attendees will understand the accuracy of PMCT compared with autopsy and PMCT in fatal cases of firearm injuries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing guidance concerning the use of PMCT in fatal cases of firearm injury.

PMCT has become integrated into the evaluation of decedents in some United States medical examiner offices and in medicolegal offices in several other countries. This study investigated the value of a total-body PMCT scans in firearm injury-related deaths.

This retrospective medicolegal autopsy case series was performed using data from a statewide, centralized, academically based, United States medical examiner's office. Firearm injury deaths that occurred between January 1, 2016, and December 31, 2016, were reviewed. Only cases with a total-body PMCT and a total-body autopsy were included.

Autopsies were performed and documented by unblinded board-certified forensic pathologists acquainted with the PMCT results. PMCT results were reevaluated by a forensic radiologist, blinded for autopsy results, and scored by body region (head-neck, thoracoabdominal, and extremities). Injuries for these body regions were scored as absent, minor, or major. The PMCT injury scores per body region were compared to autopsy results with McNemar's test. An exemplary Bayesian network was built with HUGIN® to help visualize the determinative value of these results.

Out of the annual 7,000 cases investigated at the Office of the Medical Investigator (OMI), 376 had firearm injuries. From these identified cases, 247 cases were excluded due to a lack of a total-body PMCT and/or a total-body autopsy, or the presence of disruptive surgery, an old firearm injury, or a long postmortem interval with the resulting decomposition.

Based on the final autopsy reports, a total of 129 cases with firearm injuries remained, of which 47 were suicides, 80 homicides, 1 case was undetermined, and 1 case was determined as accidental. The decedents consisted of 104 males and 25 females, aged 3-83 years old (median age 35 years). Based on PMCT results, 102 (79.1%) cases had injuries relevant to the cause of death in a single body region, with 51 cases having injuries in the head-neck region, 50 cases in the thoracoabdominal region, and 1 case having a single injury of the leg. The remaining 27 cases had injuries in more than one region. Additionally, in 96 of the cases, the bullet or fragments of the bullet were retained.

When comparing the total-body autopsy results with the total-body PMCT results, for those 102 cases with single body-region injuries relevant to the cause of death (thus based on PMCT), 12 potentially relevant injuries (cardiac and major vessel diseases and arm injuries) outside the particular body region, were additionally identified by autopsy. These 12 injuries were in 12 different cases, of which 5 were in the head-neck region group and 7 in the thoracoabdominal group. Yet, in all 12 of these cases with missed injuries, there was evident firearm injury to the body, also noted by PMCT. It is believed that it is unlikely these additionally identified abnormalities by autopsy contributed to the death. In cases where more than one region were injured, autopsy performed better in identifying injuries. Per this study, it is believed that PMCT can accurately identify the key injuries in fresh decedents with firearm injuries, but without surgery, for nearly all cases in which a single body region was injured.

#### Autopsy, Computed Tomography, Gunshot Wound

## H195 Jay Dix Day Lecture Series 2019

*Michael A. Graham, MD\**, Saint Louis University School of Medicine, St. Louis, MO 63104; *Joseph A. Prahlow, MD\**, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; *James R. Gill, MD\**, Office of the Chief Medical Examiner, Farmington, CT 06032; *Jonathan Hayes, MD\**, Office of the Chief Medical Examiner, New York, NY 10001; *Andrew M. Baker, MD\**, Hennepin County Medical Examiner, Minneapolis, MN 55415; *Joyce L. deJong, DO\**, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; *Tracey S. Corey, MD\**, Louisville, KY 40207

**Learning Overview:** A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual series of lectures is intended to provide the non-forensic pathologist forensic scientist a comprehensive basic review of selected topics in forensic pathology to increase familiarity and understanding and enhance inter-discipline communication.

This year's lecturers will discuss the medicolegal investigation of deaths related to environmental conditions; deaths due to asphyxia; the investigation of suicide; deaths due to firearm injuries; and deaths related to sports. After attending this presentation, attendees will understand how and why deaths related to the previously specified topics occur and will learn a systematic approach to the evaluation of such deaths that can easily be implemented in their daily practices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a comprehensive review of what causes and contributes to deaths related to the previously specified topics. Attendees will be able to systematically evaluate deaths that they encounter in their daily practices in which the previously specified topics may have played a role.

There are multiple factors that can play a role in deaths that are related to the environment. This lecture will review human and environmental factors that potentially affect a person's ability to survive under a variety of environmental conditions. What constitutes "hostile" environmental conditions, how humans attempt to adapt to changes in the environment, and what prevents successful adaptation to changing environmental conditions will be discussed. There will be discussion on how humans get into hostile environments, how they attempt to adapt to these conditions, and what factors prevent adaptation and/or escape from inhospitable environments. Deaths caused or contributed to by cold, heat, altitude, drowning, animals, and lightning will be among the topics discussed.

Human life requires the uptake and utilization of oxygen along with the release of metabolic waste. Failure of these processes leads to asphyxia. Proper evaluation of asphyxial deaths requires knowledge of the entities that cause asphyxia, pathophysiologic mechanisms, asphyxia death scenarios, and factors that contribute to death. This lecture provides comprehensive discussion of the investigation of deaths that may involve asphyxia.

Suicide can be accomplished in many ways, some overt and others covert. The accurate recognition of suicide has important implications for the decedent's survivors, estate, and others. Unlike most other manners of death determinations, an assertive determination of the decedent's intent is fundamental in certifying a death as suicide. The proper investigation of a suicidal death may offer insight into the motivation for the death and provide information in the development and implementation of preventive strategies. This lecture will comprehensively discuss the investigation and interpretation of findings in suicidal deaths.

Firearm fatalities are a major cause of non-accidental morbidity and mortality in the United States. Multiple factors and mechanisms are involved in producing firearm injuries. Understanding and evaluating firearm injuries requires a basic understanding of how these injuries are produced and how to distinguish them from other types of trauma. This lecture will provide a comprehensive review of these issues.

There are multiple factors that can play a role in deaths that are temporally related to participating in and, occasionally, being a spectator at sporting or other recreational activities. This lecture will review several issues that arise in the context of investigating deaths that occur in relation to sports/recreational events. Understanding factors that are involved in these deaths also helps in instituting safety measures to protect participants and spectators.

The death of an apparently healthy infant is a devastating event for the infant's survivors and is accorded significant attention by society. Infant death may be caused by a wide variety of diseases and injuries. Accurate recognition of the cause, mechanism, and manner of death has important implications for the survivors, other interested investigative and health agencies, and society in general. Recognition of factors involved in sudden unexpected infant deaths can help in enhancing the safety of other family members and serve as a basis for formulating death-prevention strategies. This lecture will discuss the investigation and interpretation of findings in sudden unexpected deaths involving infants.

### Medicolegal, Death Investigation, Forensic Pathology

### II Closing Judicial Psychiatric Hospitals: Not Guilty by Reason of Insanity Offenders' Socially Dangerous Treatment Inside the Psychiatric Community Network—An Italian Perspective

Felice F. Carabellese, MD\*, University of Bari, Bari 70124, ITALY; Luca Castelletti, MD, USL, Toscana, ITALY; Franco Scarpa, MD, USL, Toscana, ITALY; Donatella La Tegola, PhD, University of Bari, Bari 70124, ITALY; Roberto Catanesi, MD, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the treatment practices of socially dangerous offenders inside the psychiatric community network called REMS (Residence for the implementation of Security Measures).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the security measures that the new national residential network is developing to share common good practices of care.

Two years after the introduction of Italian forensic psychiatric reform, the new national residential network for subjects in security measures is now trying to develop and share common good practices of care, according to the contents of the new legislation. In this work, progressive steps of assessment and care of those admitted to the REMS will be illustrated, as well as the way new scenarios may impact the role of expert judgement in the courts and their effects on forensic subjects' referrals. Some critical points fostered by the new system, including criteria for admissions and clinical rationale for releases to lower levels of security, are discussed further in this work.

Regarding risk issues, the forensic and general psychiatric network may benefit from an integration with recovery-oriented models, looking at the risk-taking paradigm and strength model.<sup>1</sup> Concept of risk, in this manner, is viewed as life challenges in prosocial goals, real social integration, autonomy, advocacy, and the protection of rights.<sup>2</sup> The combination and integration of both concepts of risk, according to a patient's features, his environment, service provision, and quality of networks may better suit the specific institutional and cultural Italian ground for security measures.

Inclusion of different ways of conceiving risk may foster a patient's active involvement into pathways of care and a more active participation of staff members to care programs as they better identify themselves as mental health staff members, despite also being custodial agents. The closing of Judicial Psychiatric Hospitals (OPGs) has put the duty of adopting evidence-based strategies of violence risk assessment functionally at the development of risk management and caring strategies.<sup>3,4</sup>

It is a priority to introduce the daily practice of using reliable instruments of violence risk assessment, bearing in mind that they have statistical limits and their use may present side effects in terms of prolonged hospitalizations.<sup>5,6</sup>

In many regions, and at the national level, an agreement is requested to promote quality networking of the main actors and the interested stakeholders. The juridical system (i.e., courts and surveillance judges), community psychiatric services, lawyers, forensic experts, and social services work together with the goal of developing shared practices to provide effective assessments and regulations.

The closure of forensic hospitals represents a valid opportunity for Italian psychiatry to plan and allocate proper resources to sustain this reform, including training and education for all professionals involved in the processes of care.

## Psychiatry & Behavioral Science – 2019

### I2 The Hearsay Rule: An Adversary to the Mental Health Field—Which Field Is Next?

Amber N. Bridges, MD\*, LAC+USC Institute of Psychiatry and Law, Los Angeles, CA 90033

**Learning Overview:** After attending this presentation, attendees will understand: (1) how a recent California case impacts the admissibility of hearsay material relied on by expert witnesses, (2) how the case is restricting an expert's ability to use collateral material informing their opinion when testifying in involuntary civil commitment cases, and (3) how such restrictions may hinder mental health treatment and, ultimately, the patient.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of how an expert's use of collateral sources has been generalized and applied beyond that of the original landmark case.

In the 2016 case, *People v. Sanchez*, the defendant was convicted of multiple criminal felonies with gang enhancements after a gang expert witness opined that the defendant was likely a member of the Delhi gang.<sup>1</sup> The expert did not interview the defendant and based his opinions on collateral information. The defendant contended the expert's testimony on grounds of hearsay, which inspired the California Supreme Court to revisit the proper use of the hearsay rule. The Court ruled that "when any expert relates to the jury case-specific out-of-court statements and treats the contents of those statements as true and accurate to support the expert's opinion, the statements are hearsay." Consequently, the Court reversed the defendant's gang enhancement charges.

According to California Evidence Code § 1200, (The Hearsay Rule), "hearsay evidence is evidence of a statement that was made other than by a witness while testifying at the hearing and that is offered to prove the truth of the matter stated. Except as provided by law, hearsay evidence is inadmissible." Prior to the *Sanchez* ruling, California courts generally allowed experts to testify using hearsay statements on the basis that they were used to assist the expert in forming an opinion and not to be used as true facts by the trier-of-fact. Post-*Sanchez*, many courts are no longer permitting testifying experts to use hearsay information. This includes mental health experts, who because of this ruling, are prohibited from using data obtained from a patient's treatment team or family members when testifying at civil commitment writ or conservatorship hearings.

Mental health providers have the unique challenge of treating patients who are frequently unable or unwilling to provide necessary information due to symptoms of their mental illness. It is common practice for mental health experts to rely on statements from a patient's family members regarding the patient's medical history, observed symptoms, and changes in functional status. Collateral information from family members is often a crucial aspect of clarifying a patient's diagnosis, as well as vital to constructing an appropriate disposition plan for the patient; particularly when the patient has been reliant on family members for housing and financial support. The absence of such vital information could be markedly detrimental to the mental health expert's testimony and risks depriving the trier-of-fact from gaining a thorough understanding of the issue being addressed.

Frequently, mental health experts rely on relevant third-party information, in addition to direct patient assessment, as a basis for forming clinical opinions. Barring such information during expert testimony may limit the expert's ability to sufficiently prove the need for continued involuntary hospitalization or conservatorship.

Other challenges include the feasibility of requiring multiple witnesses to testify in court rather than allowing the expert witness to present statements on their behalf. The financial consequences of having each witness with relevant information (including, but not limited to, multiple health care providers, law enforcement officers, and patients' family members) taking time away from their duties to testify in court may not be reasonable. There is also the risk of potential witnesses, such as family members and treatment providers, damaging their relationship with a patient when testifying about them in court. A case example that illustrates some of the repercussions of the *Sanchez* ruling's application to the mental health field will be presented. A discussion regarding how this ruling could eventually impact other fields of expertise will also be addressed.

### I3 The Art of Manliness: Law, Gender, and Sexuality in a 19th-Century Case Study

*Annarita Franza, PhD\**, Department of Experimental & Clinical Biomedical Sciences, University of Florence, Florence, ITALY; *Vincenzo Lusa, JD\**, Rome 00151, ITALY

---

**Learning Overview:** After attending this presentation, attendees will understand the role of jurisprudence in the investigation of sex and gender issues in individuals with Disorders of Sex Development (DSD) (i.e., congenital conditions in which development of chromosomal, gonadal, or anatomical sex is atypical).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a multidisciplinary framework based on the analysis of a 19<sup>th</sup>-century case study that will demonstrate the impact of jurisprudence in identifying the biological sex, gender identity, and social-sex role in a person with sex or gender non-conformity.

Carmela C. was born in 1880 in Castelvetro, an Italian medieval village near Trapani. When she was in her 20s, her parents, Caterina and Antonio, took her to the Civil Hospital in Palermo because she had not yet had her period. Here, Carmela was examined by the physician Saverio Tomasini who diagnosed multiple genital anomalies. Moreover, Tomasini conducted a lengthy interview with Carmela at which she confessed to having sex with female partners and feeling her gender was masculine. Apart from her physical aspect, Carmela was a charming girl with long black hair. Carmela did not recognize herself as a woman; attending to any female activities or getting married to a man disgusted her. She desired to be a coachman and meet the girl of her dreams. So, Carmela was more than glad when Tomasini told her she was not a girl. She had genital reconstructive surgery and masculinized her name in Carmelo. The physician Giuseppe Castellana, who wrote a scientific paper on this case, operated. In the years that followed, Carmelo became a coachman and a husband.

This unique case was the occasion for Tomasini to rethink the role of legal medicine and jurisprudence in the assignment of sex in newborns with DSD. He confronted the Italian Civil Code in a transnational perspective with the French and German Codes and intensely discussed Art. 374. Tomasini analyzed the Prussian Criminal Code in which sex reassignment is highly recommended in infants with ambiguous external genitalia after 18 years of age in the presence of a medicolegal expert who would certify the conformity of the patient's anatomical and psychological sex in keeping with his/her status and gender role (Art. 19-23). Tomasini thus proposed a review of Art. 374, including a medical certification of "uncertain sex" for newborns with DSD. He then analyzed Art. 105, 106, 107, and 112 of Italian Civil Code studying the relationship between DSD, marriage, and divorce. Tomasini's analysis underlined the issue of legally recognizing a "third gender," a process started in 2013 when Germany allowed an "indeterminate" gender option on birth certificates. In 2014, both Australia and India permitted the registration of a person's sex as "non-specific." Even as Lesbian, Gay, Bisexual, Transgender (LGBT) rights in Italy have evolved significantly over the course of the past years, DSD persons may still face some legal challenges because of incomplete legislation.

In conclusion, DSD presents a unique challenge regarding medicolegal management; increasing the focus on forensic sciences will help to protect a person's sexual identity beyond stereotypes and prejudices.

---

#### Disorders of Sex Development, Case Report, Intersex

### I4 Use of the Minnesota Multiphasic Personality Inventory®-2 (MMPI®-2) and Rorschach Test in Forensic Psychological and Psychiatric Evaluations Regarding Parenting in the Context of Marital Conflicts

*Ignazio Grattagliano, PsyD\*, University of Bari, Bari 70124, ITALY; Romy Greco, PsyD, University of Bari, Bari 70124, ITALY; Anna Convertini, University of Bari Italy, Department of Psychology, Bari 70124, ITALY; Giancarlo Di Vella, MD, PhD, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY; Valeria Affatati, PhD, University of Bari Italy, Bari 70124, ITALY; Lucrezia Cavallo, PhD, University of Bari Italy, Bari 70124, ITALY; Filippo Campobasso, PhD, Bari 70124, ITALY; Luciana Lo Bianco, PhD, University of Bari, Department of Psychiatry, Bari, ITALY; Ylenia Massaro, PhD, Bari 70124, ITALY; Valentina Stallone, PhD, Bari 70100, ITALY; Roberto Catanesi, MD, Bari 70124, ITALY*

**Learning Overview:** The goal of this presentation is to reinforce the importance of correctly using reliable tests to make accurate assessments for couples in conflict who undergo evaluations in the forensic field by the courts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of correctly using reliable tests to make accurate assessments of couples in conflict who undergo evaluations in the forensic field by the courts.

Evaluation of parenting skills and competencies is an interdisciplinary activity. It involves various subjects, including adults, minors, and families, in addition to the contexts to which they belong. These assessments appear to be even more decisive and important when unresolved conflicts and tensions occur between couples who have children. Such situations require the intervention of judicial authorities, keeping in mind the best interests of the children involved. Given the sensitivity and importance of these assessments, which also assume a prospective profile for the decisions that judges make, it is essential that psychologists and psychiatrists, appointed by magistrates and lawyers, carry out such evaluations by applying scientific protocols recognized by the scientific communities at national and international levels.

The MMPI®-2 and Rorschach tests are the most widely used psychodiagnostic tools in the world as personality assessment instruments and guarantee great scientific reliability; they are instruments that are widely used in many studies all over the world.

The hypothesis of this study is that couples in highly turbulent relationships who involve their children in their conflicts create many psychological problems for them. The higher the level of conflict, the higher the scores on psychodiagnostic indices of the two tests should be.

**Methods:** Fifty-nine couples who had come to the attention of ordinary courts and tribunals for minors were evaluated in Italy: 118 people in total. All Rorschach and MMPI®-2 tests that were administered to both members of these couples were examined. During the appraisals, two different tests were used—the MMPI®-2 and the Rorschach—to better guarantee higher scientific objectivity measurements by crossing the psychodiagnostic data of two different instruments, which are equally valid in personality assessment.

**Results:** Parental suitability: (1) in 8% of cases, parental suitability was evaluated as fully present both in the father and the mother; (2) in 11% of cases, parental suitability was considered fully present in the mother, and deficient but recoverable in the father; (3) in 5% of cases, parental suitability was fully present in the father, and deficient but recoverable in the mother; (4) in 2% of cases, parental suitability was a recoverable deficit in the mother, but in contrast, not recoverable in the father; (5) in 7% of cases of parental suitability, there was a recoverable deficit in the father, but not recoverable in the mother; (6) in 50% of cases, parental fitness was assessed as deficient but recoverable for both the mother and father; (7) in 3% of the sample, mothers were assessed as deficient but recoverable, but not evaluative in the father (i.e., the inability to evaluate derives from the subject being removed from the administration of psychodiagnostic tests, which were experienced as persecutory); and (8) in 14% of cases, at the outcome of the appraisals, the judges evaluated the situation of conflict and violence in the family, in which the children were also involved, to be so serious as to suspend parental authority of both parents and to award custody of the children to other people or to place them in communities for minors.

The initial hypothesis of this study was confirmed. Most conflicted couples had high scores on the MMPI®-2 test relative to the clinical scales of social/relational isolation, of suspiciousness, the scales that signal manipulative behavior. Regarding the Rorschach test, on the other hand, the psychodiagnostic indices most often represented in the most highly conflicted couples concerned the area of psychosocial adaptation, those of relational problems, and those of difficulties in controlling emotions and impulses.

**Conclusion:** If correctly used, the MMPI®-2 and Rorschach tests are confirmed as excellent tools for conducting measurements and evaluations in relation to expert activities concerning the evaluation of competence and parenting skills.

#### Marital Conflicts, Tests, Courts

## I5 Aging and Prison: A Study of a Large Number of Italian Penitentiaries

*Ignazio Grattagliano, PsyD\*, University of Bari, , Bari 70124, ITALY; Carlo A. Romano, University of Brescia, Department of Jurisprudence, Brescia 25122, ITALY; Luisa Ravagnani, PhD, University of Brescia, Department of Jurisprudence, Brescia 25122, ITALY; Silvio Tafuri, Department of Biomedical Sciences and Human Oncology, Bari 70100, ITALY; Francesco Paolo Bianchi, PhD, Department of Biomedical Sciences, Bari 70100, ITALY; Carlo P. Campobasso, MD, PhD, University of Campania, Napoli 80138, ITALY; Graziamaria Corbi, PhD, Campobasso 86100, ITALY; Patrizia Gasparo, University of Bari, Department of Psychology, Bari 70100, ITALY; Roberto Catanesi, MD, Bari 70124, ITALY*

**Learning Overview:** The goal of this presentation is to increase awareness of the condition of elderly prisoners in prison. With careful consideration of the complexities and difficulties that exist within the Italian prison system, and in full compliance with national and supranational frameworks, this study was conducted with the goal of surveying the conditions of elderly prisoners.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of the awareness of the condition of elderly prisoners in prison.

It is well known that elderly people are more vulnerable when compared to younger adults within the same community because of their advanced age. A precise age limit is not implied here, although 65 years is considered the starting point of old age. Therefore, vulnerability is one of the characteristics of the elderly. Such individuals may need health care services, social assistance, and/or protection by the community due to any number of problematic situations and limitations, including illness. Such people may be unable to take care of themselves and are unable to protect themselves from significant harm, exploitation, abuse, violence, and other risks.

Vulnerability and fragility are distinct concepts. Fragility is an accumulation of deficits in the physical, social, and psychological spheres and manifests itself throughout the full continuum of life, regardless of age. Vulnerability is an accumulation of deficits in terms of relative risk and scarce resources. Individual, situational, health, behavioral, resource, biological, and environmental factors can influence fragility. Fragility domains form a triad: (1) physical, (2) psychological, and (3) social. The presence of all three renders a person fragile and puts them at risk for adverse events. Without a doubt, physical frailty can be influenced by psychological and social fragility. For these reasons, this research's hypothesis is that prisoners over 65 years of age manifest difficulties and hardships in adapting to the detention regime, which are, in many ways, both different and more numerous when compared to other adult prison inmates. Interventions aimed at relieving such problems must keep in mind both the obligation of the prisoners' incarceration and atoning for their crimes, while at the same time protecting the rights of these individuals, especially because they are older and therefore generally more vulnerable. One possible alternative could be granting probation and employing alternative measures of detention.

**Methods:** This study distributed a detailed questionnaire to over 100 prisoners who are currently serving prison sentences in both Northern and Southern Italy (the regions of Lombardy and Apulia). The questionnaire concerned personal data, characteristics of the crime committed, imprisonment, pre-existing psychophysical health conditions and subsequent incarceration, family news, and other information related to the execution of the sentence.

**Results:** As far as the crimes committed are concerned, the most frequent are offenses related to the participation in mafia-style organizations, white-collar crime, particularly heinous crimes, long criminal careers, financial and administrative offenses, and related offenses, as well as the trafficking and marketing of narcotic substances. Psychophysical health conditions and the adaptation to prison often turn out to be precarious.

**Conclusions:** The increased percentage of the elderly prison population is a worldwide phenomenon and is certainly linked to a complex causality. The main reasons for this phenomenon are: demographics, legal issues, state of health, inappropriate response to social changes, reduction of psychiatric and geriatric care, and lower capacity for reintegration of the senior prisoner

The basic question appears to be: Are Italy's prison facilities, which were originally designed to host and contain young, healthy prisoners who do not suffer from chronic diseases, suitable for receiving elderly prisoners who suffer from disabilities and chronic diseases? The extreme passivity of life during detention most likely has a negative effect on the psychic and cognitive state of the elderly prisoners. Furthermore, many of these inmates suffer from psychiatric pathologies and need treatment, re-education, and social/healthcare assistance, which are different from the needs of the rest of the adult prison population.

---

### Elderly, Prison, Illnesses

### I6 Assessing the Risk of Violence for Psychopaths: What Is the Right Method?

*Sebastien S. Prat, MD\*, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3K7, CANADA; Gary A. Chaimowitz, MD, Saint Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand the relationship between psychopathy and violence and assessing the level of risk within this population.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping identify the issues when assessing psychopathy.

Psychopathy is a common diagnosis made when assessing violent offenders. The Psychopathy Checklist-Revised (PCL-R) is the gold standard tool to assess the presence of this diagnosis. Newer tools have been developed, such as Psychopathy Personality Inventory, but this is not commonly applied to the forensic context at this time. However, assessing psychopathy does not equal assessing risk, and psychopathy needs to be assessed by trained clinicians. The development of the assessment tools has evolved to identify the criteria that accurately define this pathological construct.

Why is psychopathy so often associated with the risk of inappropriate behavior? Most of the research has been conducted in forensic settings. Moreover, some studies focused on the criminal behavior rather than the personality disorder. According to some research, the antisocial item of the PCL-R, which is associated with violent behavior, misidentifies the antisocial behavior of some individuals with psychopathy. Some suggest that we should differentiate between psychopathy and PCL-R-diagnosed psychopathy, although at this time, PCL-R is considered the only reliable tool. The other issues that are identified when assessing the risk of violence is related to the fact that high scores on the PCL-R are not associated with high risk. Therefore, using other risk assessment tools is necessary to accurately identify the risks; some of them have an item directly related to the PCL-R, but include many more aspects that allow a broader assessment.

Some clinicians continue to use psychopathy as the sole method to identify risk without appreciating the difference between diagnosis and behavior. Besides identifying the key aspects of psychopathy and risk of violence, this presentation will be an opportunity to present the legislation of the Dangerous Offenders in Canada. Under some specific circumstances, an individual may be qualified a Dangerous Offender and be sentenced to jail time for life. An alternative may be to be qualified as a Long-term Offender which will impose 10 years of probation after being released from custody.

#### **Psychopathy, Violence, Assessment**

## I7 A Psychopathologic and Etiologic Analysis of Psychopathic Traits in Klinefelter Syndrome

Raphaëlle Jouin\*, Rennes, Bretagne 35000, FRANCE

**Learning Overview:** The goal of this presentation is to provide an understanding of psychopathic traits in Klinefelter syndrome and to analyze their etiologic and psychopathologic components.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the general comprehension of genetic and epigenetic mechanisms in psychopathy.

Klinefelter Syndrome (KS) (also known as 47, XXY) is the most common aneuploidy (1/650) of sexual chromosome abnormalities among males (0.1% to 0.2% of the male population). This syndrome is largely underdiagnosed because of a large phenotypic variability. Physical (tall, sparse hairiness, gynecomastia), hormonal (hypogonadism with low testosterone levels), and psychological symptoms (normal to low average total Intelligence Quotient (IQ), low verbal IQ, various cognitive symptoms) are commonly described, as are high levels of psychiatric comorbidities, including aggressiveness. Higher risks of committing sexual crimes and arson (compared to criminal controls) was recently depicted.<sup>1</sup> However, because of the small prevalence of persons involved, only a few studies provide quantitative or qualitative robust results on forensic populations.

A small sample of KS, including three male adult inpatients presenting aggressive or violent symptoms or criminal history, were recruited in Belgium and France to assess their psychopathic traits using the Psychopathy Checklist-Revised (PCL-R) of Hare.<sup>2</sup> First, results showed weak scores on facet 1 (interpersonal). However, scores assessing affective traits (facet 2), lifestyle, especially impulsivity (facet 3), and antisocial traits (facet 4), as well as item 11 (promiscuous sexual behavior) seemed higher.

Results could be related to characteristic genetic features with consequences on neural development (limbic system and temporal lobe abnormal cortical volume, hemispheric specialization shortcoming). These involve alterations of both complex cerebral (attention, empathy), and behavioral regulation functions (inhibition, mental flexibility, emotional response modulation, control of own actions).<sup>3,4</sup>

Interestingly, some similar findings also underlie current etiologic and psychopathologic hypotheses of psychopathy.<sup>5,6</sup> Nevertheless, double diagnosis is scarce among KS. In addition, some KS features are antagonistic with those hypotheses (e.g., testosterone levels) without prohibiting clinical psychopathic traits among KS.<sup>7,8</sup>

Given these discrepancies, the well-documented syndrome of KS, which allows reasoning on both genetic and epigenetic mechanisms, also introduces the concepts of adaptability and neuronal ecology, which may clarify murky interactions of biological, psychological, and social factors entangled in the development of psychopathy.

### **I8 Aggression Is Inversely Related to Serum Cholesterol**

*John L. Young, MD\*, Yale University, New Haven, CT 06511-4048*

---

**Learning Overview:** After attending this presentation, attendees will understand the correlation between lower cholesterol and more aggressive behavior, which will be helpful in situations in which this correlation may be important.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by focusing on the knowledge and understanding of the subject of cholesterol levels and rates of violence. Attendees will broaden and deepen their knowledge of an important arm of the physiological chemistry that underlies human aggressive behavior, whether it is “accidental” or against self or others. This will make attendees better ethics consultants and expert witnesses. This presentation will advance the field of forensic behavioral science as well by further extending and strengthening the scope of potential new treatments for aggression as well as enhanced preventive measures.

Most clinicians across all fields of practice today would consider it a mark of thoroughness and even of excellence in their performance as practitioners when they do not omit checking their patients’ serum cholesterol, no matter what the purpose of the office visit may have been. Clinicians base this practice on the clinically demonstrated connection between control of cholesterol levels and good cardiovascular health. It is a clinical impression that enjoys a strong base in established theory.

At the same time, it is becoming gradually clear that another clinical correlation of well-controlled serum cholesterol concentration is likely to be in play. A growing number of observers are reporting associations between lowered cholesterol levels and increased serious violent behavior. This unexpected result naturally raises questions well worth answering through appropriate queries. Some would suggest that the finding is pure coincidence. Others consider the relationship likely to be merely an indirect one, that the actual operating factor happens to be linked to either the lowered cholesterol or to the increased aggression. Examples include an endocrine phenomenon or epiphenomenon, chemical or structural resemblances suggesting as they can significant functional relationships. This may come about through shared metabolic pathways that have varied status among different groups of investigators.

Unlike the connection of lower serum cholesterol with better cardiovascular health, the phenomenon of its correlation with more violent behavior currently lacks a widely accepted theoretical explanation. Such an absence is a matter of serious concern since the safety of innocent persons is at stake. Ethics expertise is of unusually serious importance since several of the competing values in this case are of such heavy weight. Also, they could turn out to be considerable in number, depending on the details of the investigation that might be proposed or on the clinical or legal decision to be made. In no particular order, the concerns or values may, among others, include beneficence, non-maleficence, autonomy, privacy, safety, and justice

#### **Cholesterol, Violence, Accidents**

## I9 Serotonin and Aggression in Children and Adolescents: A Systematic Review

R. Ryan Leahy, MD\*, Charleston, SC

**Learning Overview:** After attending this presentation, attendees will gain knowledge concerning the relationship between low serotonin (5H-T) and aggression in children and adolescents. Attendees will understand that the burden of predicting violence and homicide risk assessment increasingly falls on the clinical psychiatrist.<sup>1</sup> This presentation will also discuss the potential of using serotonergic genetic markers to aid in the possible identification of aggression.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the genetic and biological relationship between low 5H-T and aggression in children and adolescents. Aggression is one of the most frequent concerns that trigger a child and adolescent psychiatric referral.<sup>2</sup> Youth homicides and assault-related injuries result in an estimated \$18.2 billion in combined medical and work-loss costs.<sup>3</sup> Studies have shown that low 5H-T has been associated with aggression in animal and adult studies. However, there has been a paucity of studies in relation to children and adolescents and the results have been inconsistent.

Aggressive behavior is complex and associated with multiple biological, psychological, and environmental factors. Aggression is often divided into two types: impulsive and premeditated. Neuromodulators associated with aggression include dopamine, norepinephrine, MAOA, and nitrous oxide synthetase. Serotonin remains one of the better-understood neuromodulators involved in impulsive aggression. A systematic literature search was conducted of the following databases: Embase®, PubMed®, PsycINFO®, and Google® Scholar. Studies published through January 25, 2018, were considered. The key words aggression, violence, adolescent, adolescents, juveniles, serotonin, 5-HT, 5-HIAA, 5-hydroxyindoleacetic acid, tryptophan, serotonin transporter gene polymorphism, 5-HTTLPR, and serotonin plasma membrane transport proteins were used, which included a PubMed® “Mesh” search. Inclusion criteria for the review included children and adolescents <18 years old, English language peer reviewed journals, physical aggression as the dependent variable, and serotonin as the independent variable. Exclusion criteria were the following: case reports, review articles, posters, abstracts, published in languages other than English, studies that defined aggression solely as suicide, greater than >18 years old, animals studies, and participants with co-morbid substance use disorders. One hundred fourteen studies were initially identified, and 12 studies were included for the review. The 12 studies can be grouped by how serotonin is measured into the following categories: cerebrospinal fluid (3), acute tryptophan depletion (1), prolactin response to fenfluramine (1) and genetic studies (7). The genetics articles reviewed included studies of the 5HT1B receptor polymorphism and the serotonin transporter gene (5-HTT or SLC6A4). Two common serotonin transporter gene polymorphisms include the 5-HTTLPR (promoter polymorphism), and the 5-HTT Variable Number Tandem Repeat (VNTR). Both are believed to regulate the transcription of the serotonin transporter gene.

The review found that the adolescent CSF studies had strong correlation with aggression. Studies of the 5-HTT (VNTR) and the 5HT1B polymorphism found no association with aggression. The rs16859448 TT Single Nucleotide Polymorphism (SNP) of the serotonergic FEV transcription factor had strong association with aggression. The studies looking at the 5-HTTLPR (promoter polymorphism), had mixed results but the strongest correlation in two gene X environmental studies that included other neuromodulators and environmental risk factors. Low childhood 5-HT function appears important but not sufficient for childhood aggression in the prolactin response to fenfluramine. Finally, in a study of Acute Tryptophan Depletion (ATD), the overall sample indicated increased aggression under the ATD. This presentation will also discuss behavioral and pharmacological treatments for youth aggression.

Limitations of the studies included relatively small sample sizes, adult controls in some studies, and primarily male and Caucasian samples. The use of broadband rating scales was often used rather than the more narrowband youth aggression rating scales. In conclusion, there appears to be a relationship to low 5-HT and aggression in children and adolescents. Further research is needed, particularly in the study of genetics and identifying potential future markers for identifying youth aggression.

## I10 An Update on Female Arsonists: A Systematic Review

*Alick Wang, BSc\*, McMaster University, Hamilton, ON L8S4L8, CANADA; Yedishtra Naidoo, MD, McMaster University, Hamilton, ON, CANADA; Sebastien S. Prat, MD, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand the recent developments in the understanding of the key psychopathologies and characteristics of female arsonists during this decade and explore the differences between previous research and more recent studies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting key aspects of the latest research in female arsonists and emphasizing the unique nature of female arsonists and the challenging aspects of understanding and treating them.

**Background:** The psychiatric literature regarding arson, fire setting, and pyromania is quite rich. However, despite key differences between male and female arsonists, there are relatively few studies directly investigating female arsonists or gender-related differences among fire setters. At present, there is only one review article on this topic, published in 2010. This study sought to perform a systematic review of the literature and determine whether there has been any evolution in the understanding of this topic since 2010.

**Methods:** Two independent reviewers conducted the literature search using the electronic databases MEDLINE®, Web of Science®, and PsycINFO®. The search was limited from January 1, 2010, to January 1, 2018. Study selection, data analysis, and reporting were conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Extracted data included the authors, year of publication, country of study population, study type, sample size, sample characteristics, gender, fire-setter status of the study population, age, definition of fire-setting behavior, and characteristics of female fire setters identified.

**Results:** A total of 270 articles were identified and seven were selected for review. Despite a large variation in methodology, including national surveys, case-control, and retrospective studies, most of the studies demonstrated consistent findings. Female arsonists are often victims of abuse, family disorganization, and low socioeconomic status. Studies published prior to 2010 describe depression and psychosis as key psychopathologies. More recent studies demonstrate a high proportion of substance abuse and personality disorders among female arsonists compared to male arsonists. There is also a higher prevalence of psychotic disorders when compared to non-fire setters.

**Conclusions:** Female arsonists are a unique patient population, distinct from both male arsonists and non-arsonist female offenders. This study reviews the existing literature and reveals that there has been some evolution in the understanding of female arsonists, although studies published before and after 2010 are mostly consistent. Hopefully, this knowledge will improve the understanding of female arsonists and help guide further research. Using the data collected from this systematic review, more detailed analyses could be performed in the future for a more detailed characterization of the literature.

---

**Female, Arson, Systematic**

### I11 Spousal Homicide: What Do We Know and How Do We Prevent It From Happening?

Alexia Delbreil\*, *Chu La Milétrie Département De Médecine Légale, Poitiers, Nouvelle-Aquitaine 868021, FRANCE*; Jean-louis Senon, *University of Poitiers, Poitiers, FL, FRANCE*

---

**Learning Overview:** After attending the presentation, attendees will: (1) understand the psychopathological basis of spousal homicide, (2) be able to identify the risk factors associated with this crime, and (3) understand how France and, more broadly, Europe, have developed prevention measures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing practical data of a crime that remains under-studied and by showing how to implement measures that are crucial for the safety of these victims.

Spousal homicide is a term used when the victim is killed by her/his partner or ex-partner. This type of murder is the most frequent one when looking at murders happening within the family circle. It also constitutes 16% to 20% of murders. Prevention measures regarding spousal homicide are under-developed because of being perceived as an exceptional situation. However, research has shown that the offenders committing spousal homicide have a well-defined profile, along with their *modus operandi*, compared to the other types of homicide.

The circumstances leading to such a tragic event are related to several factors, including the personality of each individual of the couple, situational crisis, and the quality of their relationship. This crime is often portrayed by the media as a horrific one, scaring the community, notably because it occurs in a close relationship, which is supposed to be where anyone could feel safe. This crime is primarily committed by males, aged 30 to 60 years old, when the couple is in the process of breaking up or when there is persistent conflict in their relationship. The home is where this crime commonly occurs. Alcohol is frequently found as a contributing factor at the time of the offense. Prior violent behavior of the offender toward the victim is also often a characteristic. Contrary to other types of homicide, no current or past psychiatric history is found. From a pathopsychological perspective, jealousy and willingness to control the victim are often seen as precipitating factors. Other psychological elements of the offender can explain why he decides to act out, such as anger, fear of abandonment, and the need to make these feeling stop. At this point, research regarding female offenders in the context of spousal homicide remains limited. So far, the data suggests that their motivation is different from male offenders. This speaks to the necessity of continuing studying this area to understand the origin of this behavior.

National and European measures were recently developed to help improve the support of women victims of violence from their partner and to find the most appropriate means to prevent any escalation toward lethal actions. These measures may not help resolve every situation because there remain cases in which no prior violence existed before the impulsive and lethal act of their partner. It is necessary to know the common risk factors that are associated with the spousal homicide situation in order to prevent it from happening. Informing professionals who may be in the best position to detect these situations, but also the public, is necessary to help these potential victims.

---

#### Homicide, Domestic Violence, Acting Out

## I12 Linguistic Indicators for Psychological Violence Detection in the Language of Domestic Abusers

Victoria Guillén, PhD\*, University of Alicante, San Vicente del Raspeig, Alicante 03690, SPAIN

**Learning Overview:** After attending this presentation, attendees will understand language indicators for psychological violence detection in the family unit, as well as linguistic techniques and methods for that purpose.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how to detect psychological violence in cases involving domestic violence and how to gather the necessary evidence in language to demonstrate its presence.

Forensic linguistics-analyzed evidence is examined in this presentation for psychological violence detection in the language of domestic abusers. According to the Istanbul Convention (*The Council of Europe Convention on Preventing and Combating Violence against Women and Domestic Violence*) of May 11, 2011, domestic violence is: "... acts of physical, sexual, psychological, or economic violence that occur within the family or domestic unit or between former or current spouses or partners, whether or not the perpetrator shares or has shared the same residence with the victim." (Chapter I, Art. 3.b) Domestic violence is a surface manifestation of the power and dominance that some men exert over women in the family unit. It is often the case that when the victim tries to empower herself or break up with the offender, he will then try to regain power and control over her by using different strategies, ranging from psychological violence to force, whose purpose is to influence her decision and resume the relationship. Although in theory, the law protects women and children from the different forms of violence related to the social phenomenon of domestic violence, in practice, it is very difficult to prove psychological violence in court, for the very simple reason that, unlike physical and sexual violence, psychological violence leaves no ostensive trace in the target victim. However, its effects and consequences, as psychologists claim, can be even more devastating and destroying for the victim. The personalities of both the aggressor and the victim, as well as the effects of psychological violence on the psyche of the victim, have been studied extensively in the field of psychology. However, to the best of our knowledge, psychological violence has not yet received specifically dedicated scientific study in the field of forensic linguistics.

The goal of this presentation is twofold. On one hand, this presentation analyzes linguistic indicators that can be useful for psychological violence detection in cases involving domestic violence. On the other hand, this work presents the linguistic technique and methods that proved to be fruitful for the detection of psychological violence in such cases. These include semantics, speech act theory, discourse analysis, genre theory, and quantitative analysis. It is hypothesized that the language of the domestic abuser provides the linguist with direct access to different manifestations of psychological violence, (e.g., harassment, stalking, and emotional manipulation.)<sup>1,3</sup>

This presentation raises two research questions: Can linguistics help us detect indicators of psychological violence? If so, what type of evidence can the linguist collect in the language of the offender to show that there are indicators of psychological violence? The investigation is grounded in the empirical work conducted in a court case. The corpus of questioned documents consists of six letters and the abundant Whatsapp messages the offender sent to the target victim over 270 days.

Findings from this piece of empirical research show that psychological violence is inflicted by the domestic abuser over the target victim through malicious language use. Consequently, language is employed as a weapon against the target victim and "... acts as a precursor to and instigator of forms of conflict, and typically accompanies acts of violence in all its forms" (e.g., obsessional harassment, stalking, emotional manipulation).<sup>4</sup> Moreover, the offender typically resorts to strategic language use since it is designed to achieve a long-term or overall goal.

### Forensic Linguistics, Psychological Violence, Emotional Manipulation

### I13 Bullying and Sexting on Social Networks

*Cinzia Gimelli, PsyD, PhD\*, Science & Method, Reggio Emilia 42124, ITALY; Luciano Garofano, PhD\*, Accademia Italiana di Scienze Forensi, Parma 43100, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will have an integrative viewpoint about this complex field of cyber crime from a psychological and design perspective.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing how availability and the use of social networking sites creates both opportunities and risks for young users.

This presentation evaluates the applicability of the current legal framework to cyberbullying and sexting, two types of (potentially harmful) behavior that are increasingly occurring between peers in the social networking environment. This analysis includes a mapping of applicable legislative provisions at the European and Italian level, an analysis of the Terms of Service of the largest social networking provider, Facebook®, as well as an overview and assessment of self-regulatory initiatives that have been taken by the industry in this area in Italy. The goal is to identify several solutions for a comprehensive strategy to ensure that risks of cyberbullying and sexting are dealt with in a manner that empowers young users.

**Introduction:** At young ages, there is an increase in reports of intimidation, harassment, intrusion, fear, and violence experienced through Information Technologies (IT). Hacking, spamming, identity theft, child pornography, cyberbullying, and cyber stalking are just a few examples of cyber crimes. In this study, the most common types of cyber crimes, epidemiological data, and the profiles of cyber victims and aggressors are approached. The studies that identify the factors contributing to IT misuse and to growing online vulnerability, principally in adolescents, are also discussed. Likewise, the central explanatory theories for the online victimization and the risk factors for victimization and perpetration online are addressed. Some cyber crime prevention strategies are anticipated, particularly among young people, seeking to provide clues to the consolidation of recent policies, namely at the digital design level.

The new age of mobile communication brought on by the internet has meant that people now have mobile access to a wealth of information and services. Although the benefits of mobile information access are acknowledged through the empowering influence over its audience, a concern is noted with reference to largely uncensored forums offering mobile communication exchange to young generations. The proliferation of mobile technologies available, in conjunction with applications facilitating social networking, has steadily increased the attack surface minors are exposed to in an online environment. Most minors engaging in online activities do so through mobile technologies such as cell phones. This device, because of its mobility, offers access to the internet that circumvents controls of supervision.

**Results:** This multidisciplinary study presents an approach that offers an alternative to existing solutions, available to the commercial market, that are driven by static configurations. This newer form of communication has many benefits to adolescents and plays an important role in their social lives. Despite the numerous benefits of these technologies, there are also several potential risks that can be detrimental to the mental health and well-being of adolescents.

**Conclusion:** This study proposes the necessity of performing revisions in clinical psychological practices and assessments, such as in forensic and legal policies regarding bullying and cyberbullying. In addition to improving legal success, this will reduce bullying prevalence rates, psychological distress, and psychopathology that can be comorbid or emerge because of this behavior.

This proposal will benefit young generations engaging in online interactions through the implementation of proactive strategies and it is critical that child psychologists, mental health providers, and forensic experts be informed of these potential risks so that effective forms of prevention can be found to educate adolescents and their families.

---

**Public Health, Cyberbullying, Social Networks**

### I14 The Rorschach Test and Perpetrators of Homicide

*Ignazio Grattagliano, PsyD\*, University of Bari, Bari 70124, ITALY; Salvatore Zizolfi, MD, SSPsa Swiss Society of Psychoanalysis, SRR Roman S, Como 22100, ITALY; Antonella Valerio, Section of Criminology and Forensic Psychiatry, Bari 70110, ITALY; Daniele Zizolfi, MD, School of Specialization in Psychiatry, Faculty, Como 22100, ITALY; Stefania Zecca, PhD, Rorschach Psychotherapeutic Expert, Bari 70100, ITALY; Alessio Ostuni, MD, Sections of Legal Medicine and Criminology, Bari 70124, ITALY; Roberto Catanesi, MD, Bari 70124, ITALY*

**Learning Overview:** The goal of this presentation is to show that criminal activity—just as in any other human behavior—is a reflection of one’s personal history and level of psychic functioning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that criminal activity, as with any other human behavior, is a reflection of one’s personal history and level of psychic functioning (i.e., organization of personality).

**Objective:** The hypothesis of this study is that it is possible to identify correlations between certain aspects of mental functioning in addition to criminological and forensic variables that are closely related to a crime. Moreover, this study hypothesized that a trace of this correlation exists in the Rorschach test.

The existence of a correlation between aspects of personality and crime has been theorized and that criminal activity reflects the personality traits of the perpetrator, his life, and the way he interacts with the world around him. Investigative psychology was born and developed on the assumption that behaviors expressed during an act of aggression, the choice of the victim, and the mode of action is, in some way, connected to the personal history of the aggressor and to his mental and behavioral functioning, in addition to the quality of his relationships.

**Methods:** This study examined the Rorschach protocols administered to a sample of homicide perpetrators who underwent psychiatric examination as ordered by Judicial Authorities to ascertain the ability of the subjects to understand their intent and will at the time the crime was committed. These data were taken from the database of the Section of Criminology and Forensic Psychiatry of the University of Bari, Italy, from 1998 to 2014. The goal of this study was to identify psychometric and psychodiagnostic variables associated with characteristics of the crime committed and correlate them to the crime scene, describing them as either “organized” or “disorganized.” The sample consisted of 49 subjects—43 males (87.7%), and 6 females (12.2%), 24 unmarried (48.9%), 21 married (42.9%), and 4 separated (8.2%). Education levels ranged from 0 years (5 subjects, 10.2%) to 13 years (9 subjects, 18.4%), while the majority had an education level of five years (15 cases, 30.6%), and eight years (20 cases, 40.8%). Twenty-four subjects were between 25 and 44 years old (48.9%), and 11 subjects were between 45 and 54 years old (22.4%). Eleven subjects were between 55 and 64 years old (22.4%); two of the subjects were minors, and one was older than 65 years of age. Eight of the subjects had no previous psychiatric diagnoses (16.3%). The following psychiatric diagnoses were formulated for the remaining 41 subjects (83.7%): 13 schizophrenia, 1 delusional disorder, 1 bipolar disorder, 5 depression, 4 psychoorganic syndrome, 13 personality disorder, and 4 limited intellectual functioning.

The results of this psychiatric report indicated that 23 (46.9%) subjects were recognized as fully chargeable, 10 subjects (20.4%) were shown to have a partial defect of mind, and 16 subjects (32.6%) were shown to have a total defect of mind. The means used to carry out the offenses are as follows: 15 (30.6%) used a sharp object or cutting weapon, 12 (24.5%) used a firearm, 8 (16.3%) resorted to physical assault, 6 (12.2%) used asphyxiation, and 8 (16.3%) through other various means (3 stoning, 3 precipitation, 2 by means of an automobile).

In 14 cases (28.6%), the murder was considered “premeditated.” In the remaining 35 (71.4%), the homicides were found to be “impromptu and not premeditated.” In 31 cases (63.3%), the crime scene was described as “organized.” In 16 cases (32.6%), the crime scene was described as “disorganized.”

**Results:** The Rorschach test has been confirmed as a particularly effective and sensitive tool in the study of normal and pathological personalities, including within the field of forensic psychiatry, when it is rigorously applied to standardized, reliable, and validated methods of administration, labeling, and evaluation, in addition to the use of representative samples of normal subjects. It is particularly evident that some of the Rorschach indices may be significantly correlated with the crime scenes that are described as “organized” and “disorganized.”

**Conclusion:** This study has confirmed how the Rorschach test, which is certainly useful in the clinical study of thought functioning, the examination of reality, affectivity, and of the ability to correctly represent oneself and others in relationships, can offer one psychic split that may also play another important role in the field of forensics.

#### Homicide, Perpetrators, Rorschach Test

### I15 Firearm-Bearing Rates During Neuropsychiatry Hospital Admission

*Oktay Cavus, MSc\**, Üsküdar University, Istiklal Cad No 108 Aznavur Pasaji Kat 5 Beyoglu, Istanbul 34430, TURKEY; *Gokben Sayar, PhD*, Uskudar University, Altunizade Mah Haluk Turksoy Sk No 14, Uskudar, Istanbul 34662, TURKEY; *Sevil Atasoy, PhD*, Uskudar Universitesi Adli Bilimler Enstitüsü, Altunizade Kampusu, Uskudar, Istanbul, TURKEY; *Kadri Dalgic, MAFS\**, Krav Magen Academy, Istiklal Cad No 108 Aznavur Pasaji Kat 5 Beyoglu, Istanbul 34330, TURKEY

**Learning Overview:** The goal of this presentation is to assess the demographic characteristics and psychiatric diagnostic profiles of subjects admitting to a psychiatric hospital while bearing a firearm.

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community by drawing attention to the importance of securing a hospital environment and reducing the potential risks for violence and/or suicide.

Most completed suicides and homicides are reported to be committed with firearms. Although psychiatrists are in a strategic place to reduce firearm morbidity and mortality, the number of studies investigating the practices of firearm risk management is limited.

Data was pooled from the hospital databases to evaluate the admissions to a neuropsychiatry hospital with a firearm between January 2011 and December 2016. The medical files of the subjects who were reported to have a gun with them were evaluated.

Data revealed that 384 (0.0074%) of 51,666 subjects admitted to the hospital had a firearm. Forty-four individuals who were admitted to the hospital with a firearm were excluded due to readmissions, so 340 subjects were included in the study. A clear majority of the subjects who were admitted to the hospital with a firearm were males (96.7%,  $n=329$ ). The diagnosis of the subjects with a firearm were as follows: anxiety disorders 18.2% ( $n=62$ ), major depressive disorder 13.8% ( $n=47$ ), alcohol- and substance-related disorder 22.9% ( $n=78$ ), schizophrenia 7.6% ( $n=26$ ), bipolar disorder 8.5% ( $n=29$ ), and other disorders 3.5% ( $n=12$ ). Additionally, 25.2% ( $n=86$ ) of the subjects who were admitted with a firearm were recorded as being a visitor of an inpatient. Although 340 subjects were admitted to the hospital with a firearm, 254 of them were patients and only 157 (61.8%) of the patients were registered as a “gun owner” on the medical files. In the cases of the other 32.2%, the gun ownership status of the patient was not detected by the psychiatrist or psychologist.

It is concluded that during admission to the hospital, a careful security search for the presence of weapons is necessary. Electronic equipment such as metal detectors can assist in detecting firearms and securing the hospital environment. Considering the multitude of psychiatric patients carrying weapons, a more detailed psychiatric evaluation must be considered in gun license applications. Strategies must be developed for effective gun owning prevention without exacerbating stigma or discouraging psychiatric patients from seeking treatment.

#### Mental Illness, Firearm, Admission

### I16 I Am Not Pregnant: A Multidisciplinary Approach in a Case of Feticide Due to Denial of Pregnancy

*Ilaria Santoiemma\**, Bari 70124, ITALY; *Alessio Ostuni, MD*, Sections of Legal Medicine and Criminology, Bari 70124, ITALY; *Matteo Favia*, Bari, ITALY; *Sara Sablone, MD*, Institute of Legal Medicine, Bari 70124, ITALY; *Francesco Introna, MD*, Dim Sezione Di Medicina Legale, Bari 70124, ITALY; *Felice F. Carabellese, MD*, University of Bari, Bari 70124, ITALY; *Roberto Catanesi, MD*, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the complexity of a case of feticide, due to the particular prior relationship between the murderer and the victim.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of using a multidisciplinary approach, including psychiatric-criminological investigation, forensic-pathologist analyses, radiological imaging, and genetic testing, to provide the judge with a key to interpretation of the crime.

Feticide is a rare crime, with a percentage in Europe that ranges from 0.07% in Finland to 8.5% in Austria, per 100 births. It consists of the homicide of a newborn by its mother during delivery or afterward.

The presented case regards the death of an infant found on the seashore. After investigations were conducted by the police, a 22-year-old woman was charged with the murder of her own child.

Two inspections of the seashore were made. In the first, the baby was found supine, almost completely buried by the shore and the waves. The body was not rigid, hypostasis was not present, and the temperature of the corpse was uniform with the water's temperature. The umbilical cord was fragmented; no blood or sign of mummification were present. Reddish areas with an irregular distribution were present on the anterior part of the body. All the postmortem parameters used to estimate the time since death suggested four to five days. The second inspection was made a few days later because of the discovery of a dark stain on the seashore that turned out to be blood.

A DNA test was performed and showed a match between the baby and the 22-year-old woman and also confirmed the blood found on the stain belonged to both the baby and the mother. An X-ray, a Computed Tomography (CT), and a sonogram were performed and revealed a bi-parietal transverse fracture and regular pulmonary ventilation. The autopsy confirmed the cranial fracture and that no malformations were observed. All analyses concluded that the baby's death occurred a short period after delivery, and the cause of death was a hemorrhagic shock secondary to the non-completion of the umbilical cord.

Due to its complexity, the case required a multidisciplinary approach to establish the reasons behind the mother's unusual behavior. After a psychiatric evaluation, it was determined that the mother was affected by a borderline and narcissistic personality disorder, a low IQ with high level of egocentricity, and affective and cognitive immaturity. Nevertheless, this diagnosis was not enough to explain the crime committed. It was decided that the unusual defensive mechanism of the mother toward the gestation was denial of the pregnancy. From the psychiatric investigation, it also emerged that this was her second pregnancy and the first one also was characterized by denial behavior.

Denial of pregnancy is a rare condition and remains a phenomenon little known to health care professionals. It is characterized by a woman's lack of awareness of being pregnant; this is a dysfunctional defensive mechanism that does not allow the physical and emotional development in which women adapt to their future maternal role.

From a psychiatric point of view, denial of pregnancy can be divided into two groups: psychotic and non-psychotic. After the psychiatric investigation, it emerged that the denial of the pregnancy was a non-psychotic type and was based on a prolonged affective disorder, which means that the woman was not psychologically prepared to give birth. Based on the denial of pregnancy, feticide can be considered an impulsive, not predetermined, behavior fueled by a sense of anguish due to the sudden and unexpected confrontation of the denied reality—the birth. The mother's solution was the most primitive but functional—throw out the baby.

The described case poses challenging legal and psychiatric issues that require careful consideration. In the first place, the diagnosis of this type of disorder is important in Italian law because it can change the imputation, with a significant reduction in the number of years of sentencing in prison and, secondly, because it is important for the judge to have an explanation for such a dramatic behavior that is in contrast with social expectations before issuing a sentence.

#### **Feticide, Denial of Pregnancy, Personality Disorder**

### I17 Overkill by Proxy

*Alessio Ostuni, MD, Sections of Legal Medicine and Criminology, Bari 70124, ITALY; Giuliana D'anna, University of Bari-Section of Legal Medicine, Bari 70124, ITALY; Federica Mele, MD\*, Institute of Legal Medicine, Bari, ITALY; Davide Ferorelli, Bari, ITALY; Biagio Solarino, PhD, Università degli Studi di Bari, Bari 70125, ITALY; Roberto Catanesi, MD, Bari 70124, ITALY; Francesco Introna, MD, Dim Sezione Di Medicina Legale, Bari 70124, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will better understand an uncommon case of overkill by proxy and its significance from a forensic psychiatric standpoint rather than a forensic pathology standpoint.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the need for a universal definition of overkill and the importance of its possible variant from a criminalistic and juridical point of view.

Murder by proxy is a type of murder in which the murderer commits the act under the orders of another, acting as his or her proxy. There are two common scenarios for proxy murders: (1) a person takes a contract out on another person, and (2) a person manipulates a lover into murdering someone for him or her.

A 27-year-old man was found and extracted from a well. At first glance, a nautical rope tightened around the victim's neck and multiple traumatic injuries were observed. Autopsy findings and histopathological exams allowed the chronological reconstruction of events: a quarrel occurred inside an indoor sports complex causing contusions and defensive lesions. Subsequently, a nautical rope was tightened around the victim's neck. He was then dragged on the street and violently hit on the frontal region with a metal bar, causing skull fractures and brain hemorrhage. Last, a violent contusion with a large stone caused instant death because of a hinge fracture type 1 and the brainstem lesion. The murderer then tried to burn the victim's body, without results, then threw him into a well full of water, where the body was found.

The coexistence of multiple wounds and different modes of action led the forensic pathologist to classify this murder as overkill. A few hours later, the offender was arrested and the victim's partner (ex-wife of the killer) was also investigated. The man perpetrated the crime, but both people organized it, so a forensic psychiatric consultation was conducted on each of them.

The murderer admitted having killed his rival in love, incited by his ex-wife (who had shouted him, "If you want me, kill him."). The murderer's psychiatric evaluation documented an intellectual disability (IQ 41), a personality disorder, and a history of alcohol abuse. The ex-wife witnessed all the stages of the murder, without feeling any remorse toward her new partner. The psychiatric evaluation of the ex-wife documented a severe personality disorder (cluster B, with prevalence of narcissistic and borderline traits).

The crime story originates from a complicated relational linking, a "romantic" love triangle that involved the husband, the ex-wife, and the victim. The woman had a dominant personality, and easily manipulated her ex-husband; the man was a weak person, willing to do whatever to recover his marriage. She wanted to continue the romance with her lover, but when the victim wanted to stop the relationship, she decided to punish him ("If you are not mine, you will not be any other's."), planning the homicide using her ex-husband as a killer without getting her hands dirty.

The case presented is not a crime of impulse but a premeditated murder, fueled by revenge, committed in a rough and superficial manner.

Overkilling is considered a sex-motivated murder, with hatred and a destructive will toward the partner. However, what makes this case interesting is that the victim's partner was not the material author of the murder. So, it can be considered this is a real murder by proxy, but with typical methods of overkilling.

The collaboration between the forensic pathologist and forensic psychiatrist was very useful. The medicolegal analysis helped to direct the investigations toward a passionate crime; the psychiatric-forensic investigations allowed clarification of the dynamics of the murder and provided an explanation to such a cruel crime. The integrated work between forensic pathologist and forensic psychiatrist was fundamental to understand the meaning of such a brutal murder.

## I19 The Psychopathologic Profile of Cannibals: A Review of Five Cases

Sophie Raymond, MD\*, Umd Henri Colin, Hôpital Paul Guiraud, Villejuif Cedex, Val De Marne 94806, FRANCE

**Learning Overview:** The goal of this presentation is to highlight the importance for forensic and health care practitioners to analyze the patterns of a crime scene, as well as the characteristics of both the offender and the victim.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of anthropophagy, by means of analyzing the cannibal's psychopathologic profile.

**Background:** In modern societies, human cannibalism (or anthropophagy) is rare and remains to most an unthinkable act of violence—a sensational crime that attracts the attention of the media. Classifications of cannibalism have varied over time. However, most authors agree on the existence of three categories, based on underlying motivations for this type of act: survival, ritual, and pathological. International psychiatric literature on the topic is sparse due to significant methodological problems, such as collecting enough data and generating unbiased analysis from adequately sized samples. The present work seeks to explore human cannibalism by presenting and comparing data concerning offenders, victims, and crime scene behaviors.

**Method:** This retrospective and descriptive study includes all five of the cannibal patients admitted to the Henri Colin High Secure Unit in France between 2000 and 2018. Information concerning sociodemographic, clinical, and forensic features was gathered from a variety of sources—medical records, police reports, written expert opinions, court transcripts, and autopsy reports.

**Results:** Most offenders were found to be men with a mean age of 26 years, who were mostly single, unemployed, living with the victim prior to the assault, and with a history of psychiatric disorder. The population of offenders falls into two psychopathologic profiles. First, three of them had a diagnosis of schizophrenia, with delusional themes of persecution and possession. The assault was characterized by brutality, lack of premeditation, precipitating factors (substance abuse and cessation of psychotropic medication). The act was part of a parricidal acting out, the ingested parts exclusively coming from relational zones (face, eye, phalanges). In the second group, the remaining two patients had a personality disorder with psychopathic and pervert tendencies. The act was part of a lethal acting out against a known victim and was characterized by the satisfaction derived from destruction, a desire for control, obsessions of omnipotence, and pre-existent cannibalism fantasies (paraphilia).

**Conclusion:** The results from the present study on five cannibal patients are consistent with case reports in the literature.<sup>1,2</sup> Offenders fall into two psychopathologic profiles: suffering from either a severe mental illness, such as schizophrenia; or a significant personality disorder comorbid with paraphilia. Several forensic features associated to each profile are detailed. Biases in this study do not allow for the generalization of these findings, and further studies are needed to better characterize this type of act.

### I20 The Vicarious and Literal Consumption of Identity: Interpreting Psychological Cannibalism

*Julian C.W. Boon, PhD\*, University of Leicester, Leicester, Leicestershire LE1 7RH, UNITED KINGDOM; Lynsey F. Gozna, PhD, University of Leicester, Leicester LE1 7RH, UNITED KINGDOM*

---

**Learning Overview:** After attending this presentation, attendees will better understand psychological cannibalism and its putative etiology. Attendees will have also been advised on the ramifications for forensic intervention and law enforcement's effective case management stratagem.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) enhancing competence in identifying signs of psychological cannibalism, particularly in the context of stalking and threat cases; and (2) increasing the understanding and consideration of appropriately tailored assessment tools for utilization in investigative domains and in the context of therapeutic (forensic mental health) and correctional settings.

This presentation articulates the nature of a little-understood and previously unidentified form of cannibalism that is principally psychosexual in nature. This presentation states how psychological cannibalism represents an extreme form of stalking that could result in a heightened risk of reputational, familial, or physical harm.

Moving away from the physical act of cannibalism, it is argued that a certain psychological disposition can result in the quest for the identity of another, that is, someone for whom the perpetrator wishes to become. The underlying etiology of this psychological and corresponding behavioral presentation will be discussed in its various forms and include illustrations of cases. These briefly include some of the legion impersonators of the late celebrity Elvis Presley, the murderer of the Beatle John Lennon, and other non-celebrity examples.

The psychological challenges occur, it is argued, during the process and realization of the perceived transition from the rejection of "own self," followed by the search, identification, and fixation processes in the acquisition/development of the "new self." Cases have incorporated a focus on achieving a pseudo-celebrity, pseudo-intellect, and/or pseudo gender and sexual identity change. It will be argued that this can be an extremely tortuous and dangerous condition from a victim/investigative/treatment perspective. The pattern is not uncommonly that of adulation of an obsessional nature, which in time subsumes the victim's identity, lifestyle, and personal life. The consequences of this insidious process are not only painful for the primary victim, but also for their loved ones.

The cases range from the seemingly benign Elvis Presley pretenders to the lethal consummation of another's identity by causing their death. It will be discussed, physically consuming victims by psychological cannibalists is not a necessity, though they may wish to retain their body as reifying, comforting evidence of their having taken over the victim's identity. However, it is a possibility that when the fixated cannibal wants complete consumption/annihilation of another's fixated identity, only physical consumption would serve as being sufficient. This will be discussed in the context of a typology of cannibalistic need to set the scene for broader considerations of the challenges in risk and the prediction of future harm. Ultimately, the difficulties facing practitioners in understanding the presentation of psychological cannibalism are varied in regard to the complexities of harm.

### I22 Child Pornography and Child Sex Dolls: An Expanding Virtual Phenomenon

Dean Michael De Crisce, MD\*, *Special Treatment Unit, Avenel, NJ 07001*; Sebastien S. Prat, MD\*, *St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3K7, CANADA*; Eleanor B. Vo, MD\*, *OmaDesala Psychiatric Services, Ewing, NJ 08618-2111*; Jessica Morel, DO\*, *Fayetteville, NC 28306*; Renee Sorrentino, MD\*, *Institute for Sexual Wellness, Weymouth, MA 02188*; Matthew E. Hirschtritt, MD, *University of California, San Francisco, CA 94122*

**Learning Overview:** After attending this presentation, attendees will understand the global expansion of child pornography and other simulated and digital materials geared toward individuals with pedophilic arousal. Issues to be reviewed include: (1) international prevalence, (2) ease of access, (3) general internet phenomenon regarding child pornography, (4) simulated child pornography, (5) child sexual dolls, (6) characteristics of users, and (7) challenges in risk considerations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by elucidating the scope and expansion of materials geared to pedophilic arousal in order to assist forensic mental health experts in evaluating these behaviors.

Global expansion of online access has led to increased production, distribution, and use of digital child pornography. Where these materials were once difficult to obtain and store in print, they are now readily, and covertly, accessible in digital format through anonymous file sharing, on the deep web, and even on regular internet sites. Evidence gathered from identified child pornography users likely represents only a small fraction of the total number of individuals who access digital child pornography, as apprehension is limited. Further, little is known about users of simulated child pornography, child anime, and other such materials. Creators of these materials have attempted to avoid prosecution and appeal to users by using offshore servers, creating “simulated” child pornography, and even by manufacturing anatomical child “dolls” for sexual use. The scope of distribution and use of these items is staggering, and associated websites are estimated to have millions of viewers.

Evidence from forensic populations suggests that individuals who engage in digital child pornography, in contrast to those who commit hands-on child molestation, are more likely to be younger, to have completed college, to be employed, to be of higher socio-economic class, and less likely to have an active or history of a substance use disorder, serious mental illness, or significant antisocial traits. In addition, they are less likely than hands-on offenders to have a criminal history (e.g., incarceration or court appearance). However, like hands-on offenders, they are almost exclusively male. Though there is considerable debate in the field, there is mounting evidence that degree of engagement in digital child pornography (e.g., sorting and organizing image files, editing images, renaming files) is a stronger indicator of subsequent child pornography engagement, in part because of the ease with which large databases of pornography (that may unexpectedly include images of children) can be downloaded from the internet. Even less is known about child anatomical doll users, given the covert nature of their use. However, self-report data among adult anatomical doll users suggests that the clear majority are male, middle-aged (mid-30s to mid-50s), White, not partnered, well educated, heterosexual, and use their dolls for sexual stimulation and gratification.<sup>1</sup> Most anatomical doll users report revealing their use in online forums.

As the result of rapidly and continually expanding literature on sexual deviancy, the field has incorporated factors that have been empirically demonstrated to either contribute to, or protect from, sexual offense risk. Risk assessment methods have typically focused on hands-on offenders and utilize actuarial risk instruments that operationalize historical and dynamic risk factors to provide the most accurate risk prediction that has been available thus far. The field is moving toward greater standardization and heightened responsiveness to emerging literature, thereby enhancing the aims and integrity of forensic science. However, few instruments have been devised to assist in the assessment of solely child pornography users and none for digital or simulated child pornography users. As the phenomenon expands, this is an area of increasing concern and needed research.

This panel presentation will explore the online phenomenon of materials geared to pedophilic arousal, discuss known characteristics of users, and consider risk approaches to assessment when comparing hands-on offenders with non-hands-on offenders. Time for discussion will be available, including the ethics and legality of the availability of these materials.

#### Child Pornography, Pedophilic Disorder, Forensic Psychiatry

### I23 A Psycho-Criminological Profile of Child Sex Offenders

*Mathieu Lacambre, MD\*, French Forensic Psychiatry Society, 505 Rue De La Mogère, Montpellier, Languedoc-Roussillon 34000, FRANCE; Cindy Prudhomme, CHU, Avenue Doyen Gaston Giraud, Montpellier, FRANCE; Helena Berthet, CHU, Avenue Doyen Gaston Giraud, Montpellier, FRANCE; Philippe Courtet, MD, CHU, 371 Venue Doyen Gaston Giraud, Hôpital Lapeyronie, Montpellier, FRANCE*

**Learning Overview:** The goal of this presentation is to specify the psycho-criminological profile of perpetrators of sexual violence against minors and their respective dangers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving understanding of child sexual assault and prevention of sexual abuse.

Based on a cross-sectional, observational case-control pilot study of the neuropsychological and criminological characteristics of convicted child sex offenders, this study explored and compared several variables to specify neuropsychological alterations and their relationship to the aggression. The results of the evaluations of 64 men convicted of child sexual assault were compared to the results of 64 males (control) matched by sex, age, and level of education. The usual psychiatric criteria were reported (antecedents, current diagnosis and lifetime, treatment), and the following parameters were assessed: level of depression via the Montgomery–Åsberg Depression Rating Scale (MADRS), decision-making strategies via the Iowa Gambling Task (IGT), impulsivity via the Barratt Impulsiveness Scale (BIS 11), inhibition (the Stroop test), working memory (N-back), cognitive distortions (the Bumby scale), social desirability (the Marlow Crowne scale), and level of insight via the Beck Cognitive Insight Scale (BCIS).

Criminologically, according to data, homosexual acts are more often conducted outside the family circle; whereas, when they occur within the family, they will be repeated more often.

The main statistical analyses highlighted five distinct profiles: (1) Impulsive deficiency—low IQ, poor inhibition, high level of impulsivity in all three dimensions (cognitive, motor, and planning), history of depressive disorders and violent suicidal behavior, prepubertal victim(s); (2) Incestuous stepfather—rather old, high social desirability, alcohol-smoking with intoxication at times of aggression, insight based on certainties with low introspection, low impulsivity scores, pubescent victim(s); (3) Pedophile—elderly, without a psychiatric history, without taking drugs during the aggressions, low impulsivity, capacity of introspection, extrafamilial victims, homosexual; (4) Opportunistic—rather young, married, without children, without addiction, negator, already convicted for sexual offending, smoker, assault with violence of pubescent victim(s); and (5) Predator—left-handed, low level of insight, assault with violence, lack of denial, prepubertal and heterosexual victim.

These results clearly show a polarization between perpetrators of sexual violence suffering from current or past psychiatric disorders, several times assaulting a prepubescent victim without violence in the family, versus violent sexual aggressors assaulting pubescent victims with violence outside the family.

In addition, these data account for the particular neuropsychological alterations of the perpetrators of pedosexual aggression, but especially of the heterogeneity of the profiles. The precise evaluation of these dimensions should allow the evolution of specific interventions by prioritizing specific objectives (depression, addiction, insight, cognitive distortions, impulsivity) for targeted treatment (anti-impulse treatment, libido control, cognitive remediation) in an integrative (psychological, educational, psychiatric) manner.

According to the observed deficits, the coordination of targeted interventions would increase the effectiveness of the treatment of the patient on the one hand, and also actively work toward the prevention of the recidivism of the perpetrators of sexual violence, on the other hand, according to the profile met.

### Sex Offenders, Pedophilia, Risk Assessment

### I24 A Sample of Men Convicted of or Charged With a Sex Offense: Penile Plethysmography (PPG) Results

Emily D. Gottfried, PhD\*, Medical University of South Carolina, Charleston, SC 29407; R. Gregg Dwyer, MD, EdD, Medical University of South Carolina, Community & Public Safety Psychiatry Division, Charleston, SC 29407

**Learning Overview:** The objective of this presentation includes informing those involved in the assessment of persons who have sexually offended of considerations of the use of PPG as it relates to diagnosis and, in turn, risk of reoffending

**Impact on the Forensic Science Community:** The goal of this presentation is to discuss the data of a sample of men who underwent PPG testing to help standardize the assessment and add to the literature base of the use of PPG in this population.

The use of physiological measures in evaluations of sexual offenders has mixed reviews.<sup>1,3</sup> PPG has been called the gold standard of physiologically assessing male sexual arousal. It can be used to aid in the diagnosis of paraphilic disorders by identifying paraphilic sexual arousal. Although it has been shown to be valid and reliable in some studies, the use of the PPG in evaluations of sexual offenders has also been the subject of criticism<sup>1-4</sup> There has been a call for more research on the use of PPG in assessing men convicted or charged with a sex offense.

This presentation will focus on results from PPGs administered to a sample of approximately 80 men undergoing sexual behavior evaluations. The sample included men referred for a pretrial evaluation, assessment of sexual violence risk under a state's Sexually Violent Predator (SVP) Act, and professional sexual boundary violations. Many of the evaluations were assessing dangerousness for civil commitment under the SVP Act, which requires a prior arrest for a sexually violent offense and the presence of a mental abnormality or personality disorder that makes the examinee likely to engage in acts of future sexual violence if not civilly committed in a secure setting for long-term care and treatment. These evaluations took place in the Sexual Behavior Clinic and Lab of a large academic medical center in the southeastern United States from 2011 to 2018. Data will be presented on the number of PPG tests that did not meet minimum requirements for interpretation and the likely reasons as to why these tests were invalid, including rates of suspected dissimulation. Additionally, this presentation will describe the PPG scenarios that generated the highest level of sexual arousal for the whole sample and in men who only offended against children. Differences in level of responding between men with only child victims and those with pubescent/adult victims will also be discussed.

## I25 Understanding Sexual Offenders: The Importance of Personality Dimensions

Ingrid Bertsch, MA\*, University Hospital Center of Tours, Tours 37044 Cedex 9, FRANCE; Christian Réveillère, Université De Tours, Tours, FRANCE; Thierry H. Pham, Mons, BELGIUM; Robert Courtois, PhD, Tours, FRANCE

**Learning Overview:** The goals of this presentation are: (1) to provide attendees with an understanding of how sexual offenders behave, (2) to learn how to describe the personality traits of sexual offenders, and (3) to be better prepared to apprehend sexual offenders through a global approach.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing further knowledge about: (1) violence and sexual violence, (2) understanding and evaluating a sexual offender's personality, and (3) the therapeutic approaches for sexual offenders.

The interest in sexual violence, and especially in the perpetrators, has intensified in recent years. The psychological heterogeneity of sexual offenders remains a major difficulty for therapists and researchers involved in understanding these patients.<sup>2</sup>

Among the factors of sexual offenders described in the literature, personality has been put forward as a factor of vulnerability or protection because it offers a holistic approach (impact on emotional feeling, behavior, and social relationships) while addressing the specific needs of everyone.

This population can be portrayed by studying the personality of sexual offenders from a clinical angle (using standardized clinical scales) and in relationship to normal functioning using the Big Five Inventory (BFI) model or bio-psycho-social models such as Temperament and Character Inventory (TCI).<sup>5-7,10,13</sup>

Compared to non-sexually violent patients, the personality of sexual offenders is marked by: (1) a negative emotional experience—they show a lack of self-confidence, loss of self-esteem and less narcissism, more intense feelings of negative emotions, an increase in the neurotic dimension, and will be more prone to develop mood disorders, rapid mood swings, and depression; (2) strong impact on social skills—they show signs of social stress, a decrease in extraversion and openness, difficulty maintaining appropriate social distance, more avoidant, dependent, passive-aggressive personalities, insensitivity to social cues, lack of cooperation, lack of self-direction, quirks, and the presence of schizoid or paranoid behavior; (3) impact on behavior—unlike non-sexually violent men, sexual offenders show better self-control, low impulsivity, drug addiction, presence of obsessive traits, less use of excess violence during assaults, and less sadism or anti-sociality.<sup>1-4,8-10,12,14,15</sup> They exhibit novelty-seeking that can lead to substance abuse.<sup>15</sup>

This study will be presented in two forms: a literature review dealing with the personality of sexual offenders and a presentation of the results of a preliminary study conducted with 30 French sexual offenders and 30 non-sexually violent offenders, assessed with the BFI.<sup>11</sup> The goal is to provide a global picture of the personality dimensions of sexual offenders, specific profiles of subgroups of sexual offenders (extra- or intra-familial, abusers of adults or children, hands-on or hands-off offenders), explanatory perspectives, and implications for therapy.

### I26 Sex Offender Reading Levels: Recidivism, Referral, and Age of First Offense

Taylor J. Willis\*, Claflin University, Orangeburg, SC 29115; Emily D. Gottfried, PhD, Medical University of South Carolina, Charleston, SC 29407; R. Gregg Dwyer, MD, EdD, Medical University of South Carolina, Charleston, SC 29407

**Learning Overview:** The goals of this presentation are: (1) to inform those involved in the assessment of sexual offenders of the considerations of reading levels as they relate to etiology and, in turn, the risk of reoffending, and (2) to provide treatment providers with data on the potential impact of reading ability for treatment planning use.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the ability of evaluators of sexual offending behavior to determine etiology and risk and by helping treatment providers develop treatment plans with a likelihood of successful outcomes.

This presentation focuses on the reading levels of 1,135 adults who committed sex offenses and were being reviewed for potential civil commitment under the South Carolina Sexually Violent Predator (SVP) Act. Previous studies suggest that the majority of inmates in America are functionally illiterate and that the improvement of basic skills would help decrease the rate of recidivism.<sup>1</sup> Other qualitative studies have reported a correlation between recidivism of juvenile delinquents and low academic achievement. These studies also reported a trend of below grade-level reading scores among incarcerated youth.<sup>2,3</sup> It was hypothesized that juvenile offenders who had been arrested and remanded to juvenile justice facilities would have lower reading levels than juvenile offenders who were not remanded to a juvenile justice facility. This study hypothesized that the reading level would increase as the age of the offender's first sex offense increased (i.e., individuals who had their first sex offense arrest at an older age would have higher reading scores than individuals who were of younger age at first sex offense arrest). It was predicted that the reading levels of offenders would decrease as the number of prior sexual offenses increased. It was also hypothesized that sex offenders who were referred to the next step in the process for civil commitment under the SVP Act would have lower reading scores.

Preliminary data indicated that reading levels ranged from 0 to 15.0 (15<sup>th</sup> grade) with an average level of 8<sup>th</sup> grade. Approximately 46% ( $n=520$ ) of the overall sample had a history of juvenile arrests for any offense, with 27.5% (129) of those inmates having been detained in a youth detention facility. In this sample, 31.9% of offenders had been convicted of a previous sex offense. Also, 42.2% ( $n=1,047$ ) of the offenders were referred to move on to the next step of being considered for civil commitment.

## I27 Characteristics of a Forensic Inpatient Sample in a Strict Security Facility: An Update

Natalie Armstrong Hoskowitz, PhD\*, Bridgewater, MA; Lauren Miller, PhD\*, Bridgewater State Hospital, Bridgewater, MA 02325; Joseph Toomey, PhD\*, William James College, Newton, MA 02459

**Learning Overview:** The goals of this presentation are: (1) to update attendees and add to the literature regarding descriptive characteristics of this understudied subpopulation, (2) to identify the frequency and type of referrals for forensic services and the appropriateness of these referrals, and (3) to make suggestions on how to address inappropriate referrals at the corrections and community levels.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by expanding the knowledge of forensic inpatient characteristics and inappropriate referral questions and applying this information to their own community, correctional, or inpatient settings for comparison.

Available research cataloging characteristics of individuals receiving inpatient psychiatric services have attended to systemic factors affecting their rate of admission for civil commitment (e.g., access to mental health care, socioeconomic status), as well as clinical and demographic characteristics of the patients within the hospitals that treat them (e.g., most frequent psychiatric diagnoses, length of admission, etc.).<sup>1,2</sup> However, less is known about the characteristics of individuals admitted for forensic inpatient services (e.g., treatment for competency restoration, criminal responsibility, etc.). Regarding these characteristics, much of the extant literature focuses on inpatient samples outside of the United States.<sup>2-5</sup> Currently, studies from the United States suggest individuals receiving forensic inpatient services may differ both within this group (e.g., cognitive impairment impacting competency restoration) and also from other inpatients (i.e., those involuntarily civilly committed) with regard to demographic and clinical characteristics (e.g., intellectual disability diagnosis).<sup>6-8</sup> Finally, the reasons that individuals are referred for forensic psychiatric services within the United States vary not only by reason (e.g., acute psychosis, behavior management, etc.), but also by location (e.g., referrals from the community, correctional settings, etc.). As a result, it is currently unknown how many of these individuals referred for services are appropriate for treatment in a strict security inpatient environment. Recently, there has been a call for a census of individuals populating forensic mental health inpatient facilities, and there is recognition in the psychiatric community that the future of mental health law will be at least partially predicated on understanding the characteristics of the population served.<sup>9,10</sup> This study aims to add to the literature by enumerating on the demographic and clinical characteristics of an updated sample of United States forensic inpatients in a strict security facility, as well as by identifying common referral reasons and the appropriateness of these referrals.

Data were obtained from an archival review of records of male inpatients from a strict security New England state hospital. Data will be obtained from July 2018 through January 2019. Demographic and clinical characteristics for inclusion are derived from studies cited in footnotes. Reasons for referrals (e.g., competency restoration, self-injurious behavior) will be also culled from the archival records. Referral appropriateness will be operationalized by comparing initial referral questions to the opinions in reports completed by forensic evaluators following the inpatient evaluation period. Specifically, the “goodness of fit” between evaluator opinions and the initial referral question will be coded qualitatively by forensic evaluators who did not author reports in archival records. Data will be analyzed using non-parametric and descriptive analyses in SPSS software. Results will be discussed in the context of practical applications for attendees, including suggestions on how to address inappropriate forensic referrals to inpatient facilities. Limitations and future directions will be presented.

### I28 Implementing Cognitive Behavioral Therapy for Psychosis (CBTp) With Forensic Patients: The Identification of Barriers to Positive Treatment Outcomes

*Kyrsten M. Grimes, MA\*, University of Toronto Scarborough, 1265 Military Trail, Scarborough, ON M1C1A4, CANADA; Konstantine K. Zakzanis, PhD, University of Toronto Scarborough, 1265 Military Trail, Scarborough, ON M1C1A4, CANADA*

---

**Learning Overview:** The goals of this presentation are: (1) to review the literature on the effectiveness of CBTp in forensic populations relative to non-forensic populations; and (2) to review the ways in which forensic patients with schizophrenia differ from their non-forensic counterparts, particularly with respect to factors that may act as barriers to positive treatment outcomes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating clinicians on factors that are likely to impact treatment outcomes when implementing CBTp. It will also serve to advance research on utilizing CBTp with forensic patients by qualitatively synthesizing the literature.

It is generally established that patients with schizophrenia have impairments in both neurocognition and metacognition. It is posited that deficits in neurocognition may place an individual at greater risk of developing deficits in metacognition. According to cognitive theories of psychosis, hallucinations and delusions develop, in part, because of metacognitive deficits. Recent research has begun to target these deficits in psychosocial treatments, such as CBTp. CBTp attempts to reduce positive symptoms by targeting the underlying cognitive biases thought to underlie them. Research generally indicates that CBTp is effective in reducing positive symptomatology, with medium- to large-effect sizes. However, very little research has investigated the efficacy of CBTp in forensic samples. Research in forensic populations is often undertaken with the purpose of identifying risk factors for violence. Research examining in what ways forensic and non-forensic patients with schizophrenia differ in any other regard, particularly with respect to neurocognition and metacognition, is lacking. The efficacy of psychosocial interventions for psychosis in forensic samples should be examined independently of non-forensic samples, as forensic patients often have numerous comorbidities, which may influence the severity of metacognitive and neurocognitive deficits and therefore impact treatment effectiveness.

Of the research that has been conducted, the findings generally indicate that CBTp is less effective for this group than non-forensic patients with schizophrenia with little overall change. The implication of the following factors on metacognition will be reviewed as it pertains to forensic populations: comorbid personality disorders, history of violence, and substance use. Taken together, each of these factors independently are associated with deficits in metacognition, either directly or indirectly through associated deficits in neurocognition, though greater research is needed in these areas. As such, it is hypothesized that forensic patients with schizophrenia may represent a subgroup of patients that are more resistant to CBTp due to greater impairment in metacognition.

---

#### CBTp, Schizophrenia, Treatment Outcomes

## I29 The Relationship Between Mental Illness, Criminal Offenses, and Discharge

Simmi Patel, BS\*, Voorhees, NJ 08043; Serge Sevy, MD, Manhattan Psychiatric Center, New York City, NY

**Learning Overview:** After attending this presentation, attendees will understand the difficulty in discharging patients who have a history of incarceration and psychiatric illness. During this presentation, the relationship between mental illness, criminal offenses, and discharge will be discussed as well as the issues related to the legal and mental illness system of discharging patients with criminal offenses who suffer from psychiatric disorders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating attendees on the complex issues of discharging a stable psychiatric patient with a criminal history.

Due to the stigma and potential consequences of discharging a psychiatrically stable forensic patient, Loch argues that discharging a patient back to the community is a daunting and complex task that can be unfavorable to many patients.<sup>1</sup> Fazel et al conducted a study that involved 12,056 patients of which 53% were violent offenders.<sup>2</sup> That study concluded that there is evidence from psychiatric services that forensic patients have a lower offending rate than other groups being discharged. The study argues there is reluctance by hospital teams to discharge patients due to the “problematic transition” from the hospital to the community. The stigma and lack of assistance for forensic patients impedes their discharge into the community.<sup>2</sup> For many forensic patients, after prolonged hospitalization, there is a need of assistance and close supervision. The goal of the discharge objectives is to assist the patient as well as protect the public. Due to the potential concern of forensic patients committing a crime in the community due to psychiatric illnesses, the issue that arises is: the boundary between the right of the patient to be discharged versus the right of the public to be protected.<sup>3,4</sup> Violent behavior, social maladjustment, and stigma are negative setbacks that play an important role in discharge for forensic patients. This case report will illustrate the challenges of discharging a stable psychiatric patient who committed a serious crime due to a psychiatric illness.

The discussion will present the case of a 54-year-old African American female with a complex history of criminal offenses and a diagnosis of schizophrenia. The patient has multiple incidents of self-injuries secondary to auditory hallucinations. She was incarcerated from June 1982 to June 1987 and given a three-year probation sentence for armed robbery. She was later charged with murder and served 22/25 years for first-degree manslaughter. However, at the time of her release, she was transferred to a state psychiatric facility due to non-compliance and similar delusions to her instant offenses. Due to her poor response to anti-psychotics, she was treated with clozapine, which was titrated to reach therapeutic level. The patient improved significantly; however, she continued to suffer from paranoid, grandiose, and religious delusions. The patient has failed three Human Forensic Committee (HFC) interviews, which has brought her discharge into a rather complex situation. At her first hearing in September 2017, she was not approved for discharge because of her persisting delusions and intent to purchase a gun after discharge. Consequently, she failed another HFC interview in October 2017 because she believed that her crime was staged and that the man she killed was brought back to life. She believed that she was acting in good faith. Subsequently, through several interviews from November 2017 to June 2018, the patient has denied her intent to buy a gun. She believes that a gun is “inappropriate and improper.” Currently, the patient feels comfortable and confident enough to call the police if she ever feels threatened in the community. Due to the therapeutic effect of clozapine, she is more rational and logical, despite some persistent delusions. She is pleasant on the wards and participates in group activities and discussions. Her team feels ready to discharge her and the patient is awaiting another HFC interview.

This presentation will discuss the question: how is discharge affected by persisting psychiatric symptoms for patients who have a criminal history? This presentation will provide information from psychiatric evaluations, psychological evaluations, human forensic committee results, past medical history, criminal history, and previous psychiatric hospitalization.

### Forensic Patient, Incarceration, Discharge

### I30 A Poorly Thought-Out Method to Reduce Homelessness: Proposed California Assembly Bill 1971

Aadhar R. Dhamecha, MD\*, Redondo Beach, CA 90277

**Learning Overview:** The goals of this presentation are: (1) to summarize California Assembly Bill (AB) 1971 that expands the definition of grave disability for involuntary civil commitment, (2) to review the primary purposes of this legislation with regard to decreasing homelessness in California, (3) to review the evidence and opinions for and against AB 1971, and (4) to discuss the proposed bill's potential legal and societal ramifications on the community and forensic psychiatry as well as on persons who are homeless and mentally ill.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a thorough analysis of AB 1971. The bill's medical, psychiatric, legal, and public ramifications will be illustrated through a case example.

According to existing California civil commitment laws under the Lanterman-Petris-Short (LPS) Act, if a person, as a result of a mental illness, is a danger to others, a danger to self, or gravely disabled, he or she may be taken into custody and placed involuntarily in a facility for 72-hour treatment and evaluation.<sup>1</sup> Currently, "grave disability" means a condition in which a person, as a result of a mental illness or chronic alcoholism, is unable to provide for his or her basic personal needs for food, clothing, or shelter.<sup>1</sup>

AB 1971 expands the definition of "grave disability" to include a condition in which a person, as a result of a mental illness, is unable to provide for his or her basic personal needs for medical treatment, if the failure to receive medical treatment results in a deteriorating physical condition that will more likely than not lead to death within six months.<sup>1</sup>

Proponents of the bill cite that more than 800 individuals who were homeless died on the streets of Los Angeles County in 2017.<sup>2</sup> They suggest that the bill would prevent such unnecessary deaths in those who are both homeless and unable to tend to their medical needs because of their mental illness. Consequently, the bill would allow such individuals to be civilly committed and be given an LPS conservator who would act as a surrogate medical decision-maker in order for the conservatees to obtain necessary treatment for their medical conditions.<sup>2</sup>

Opponents of the bill argue that there are no data that demonstrate how many of those who were homeless and died suffered from mental illness that impaired their willingness to seek medical care.<sup>2</sup> Opponents also cite a lack of current or planned infrastructure to treat and house the population this bill is meant to help, further questioning the effectiveness of the bill in its stated purpose.<sup>2</sup>

Legal issues include whether this bill infringes upon the civil rights of those who are homeless and mentally ill. Opponents argue it is dangerously expansive at the expense of individual liberties.<sup>2</sup> Additionally, the passage of this bill would require multiple physicians, rather than one, to address the specific criteria of "grave disability." That is, psychiatrists would need to assess symptoms of mental illness and whether they impact the patient's capacity to refuse medical care, and other medical specialists would need to assess the diagnosis, treatment, and prognosis of the patient's medical condition. Moreover, the fiscal impact is expected to be significantly large with increased medical, legal, and housing costs that, according to analysts, are unpredictable and non-reimbursable, a gloomy outlook for a state that already has a high cost-burden in public services.<sup>2</sup>

Scrutinized in its entirety, AB 1971 brings more problems than solutions in its attempt to combat the homelessness crisis in California.

#### Civil Commitment, Homelessness, Refusal of Medical Care

### I31 **Assessing the Propensity for the Future Risk of Revenge in Secure Forensic Settings and in the Community: An Evidence-Based Approach**

*Lynsey F. Gozna, PhD\*, University of Leicester, School of Psychology, George Davies Centre, Leicester LE1 7RH, UNITED KINGDOM*

---

**Learning Overview:** The goal of this presentation is to develop awareness of an approach to the holistic assessment of the risk of harm regarding revenge-oriented thoughts, fantasies, and acts. This will be particularly relevant for forensic practitioners from criminal investigation to prosecutors and broader forensic mental health and correctional settings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by heightening understanding of the complexities and inter-relationships between revenge-oriented personalities, underlying mental health conditions, cognitive processes, and, ultimately, behaviors intended to cause harm. This approach seeks to assist the consideration of how to best tailor the choice/administration of psychometric assessments while increasing confidence in the creation of revenge-based formulation from the most recent evidence-based review.

It is proposed that there is a critical need for forensic practitioners to develop a consideration of revenge when working with clients in applied settings, not only in regard of recent offenses, but in a holistic manner to ensure that risk is fully conceptualized. Although revenge is considered routinely as one of the more prevalent motives in the context of criminal justice and clinical forensic practice, its conceptualization requires more in-depth interpretation to truly formulate risk of future harm and the propensity for revenge-oriented acts. The definitional challenges further require revenge to be assessed more fully than at a surface-level (proximate) understanding of the original transgression and the response, resulting in the potential for limited psychological insights. Ultimately, the act of revenge is the outcome of several complex processes requiring consideration of any underlying predisposition and the baseline propensity for revenge (trait and state), the relevance of any prior traumatic events experienced, cognitive processes such as fantasy and violent ideation, grievance thinking and rumination, and the resources and opportunities available to act.

Currently, the possibilities for the assessment of revenge are challenging in that any approach is heavily focused on the emotion of anger with limited consideration of broader elements that can stimulate such behavior and impede the capacity to develop a holistic interpretation and risk formulation. This is critical when attempting to identify the roots and routes of revenge and how this can be fueled in complex, dynamic environments, whether already brewing or through the exploitation of vulnerable individuals for whom revenge can become a new narrative and focus. This presentation will outline challenges in comprehensively assessing propensity for revenge to ensure a psychologically meaningful outcome.

A psychometric critique of measures comprising anger and aggression, personality (normative and disordered), post-traumatic stress and embitterment, empathy, rumination, violent ideation, forgiveness, and vengeance/revenge will be presented. This has been based on a consideration of revenge across offenses and contexts and further draws on findings from a recent scoping review on human-induced trauma in addition to discussions with subject matter experts in the fields of forensic mental health and trauma. Hence, it has been possible to develop a process model for considering the critical elements of revenge when conducting tailored formulations of risk.

---

#### **Revenge, Risk, Assessment**

### I32 Ethical Challenges in Forensic Psychiatric Practice

*Joseph Ferencz, MD\*, St. Joseph's Healthcare, Hamilton, ON L8P 3K7, CANADA*

---

**Learning Overview:** The goal of this presentation is to provide an overview of the challenges associated with the practice of psychiatry in a forensic context with specific attention given to the conflicts associated with multiple simultaneous roles and their potential resolution.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying and clarifying potential ethically challenging situations in the practice of forensic psychiatry, and by posing alternative potential solutions to be considered.

The discipline of psychiatry poses ethical issues that are unique in medical practice. The authority to detain, the reliance on subjective assessment, poorly defined boundaries as related to roles, diagnoses, and treatments all contribute to frequent ethical conflicts, morally distressing decisions, and the potential for abuses. Furthermore, the nature of the relationship between psychiatrists and their patients may be intensely personal and patients may be particularly vulnerable. For reasons such as these, it has been suggested that psychiatry requires its own unique approach to ethical problem solving. Forensic psychiatry, as a subspecialty, brings with it a variety of additional challenges that have been explored by a number of commentators. The ethical risks associated with issues of dual agency, confidentiality, bias, and expert competency are ever present. Consequently, forensic psychiatric practitioners must be particularly vigilant and familiar with their professional codes of conduct. The practice of recovery-oriented care with individuals who have been found unfit to stand trial or not criminally responsible, and who are subject to dispositions of the courts or review boards, presents an additional array of ethical tensions. The assessment and management of risk in a rehabilitative context raises many issues related to autonomy, confidentiality, and conflicting roles.

This presentation will focus on several of the complex ethical scenarios that arise in the treatment and rehabilitation of forensic psychiatric patients and will discuss several current approaches to their analysis. The issues associated with the provision of clinical services, such diagnosis, acute treatment and rehabilitative care, and risk-related activities such as dangerousness assessment and risk management, will be explored. A number of proposed solutions to these dilemmas will be reviewed with regard to their strengths and weaknesses. A specific integrative model for the management of these conflicts will be presented.

---

**Forensic, Psychiatry, Ethics**

### I33 Mistaken Identity: Cultural, Religious, and Ideological Beliefs in Forensic Evaluation

Sheresa Christopher, PhD\*, Medical University of South Carolina, Charleston, SC 29407; Emily K. Shier, LPC, NCC, Medical University of South Carolina, Charleston, SC 20407

**Learning Overview:** The goal of this presentation is to educate attendees about various religious, cultural, and ideological beliefs that have the potential to be misidentified by forensic evaluators as being psychological in nature. This presentation also seeks to help evaluators recognize these beliefs in their practice and discuss implications for forensic examinees and the legal system.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving understanding of the ideas or concepts held by subgroups of the population that may be mistaken for psychosis in forensic evaluations. Appropriate identification of these beliefs will in turn increase the accuracy of diagnosis in a forensic context and thus provide more accurate and valid information for the referring court system.

This presentation will focus on cultural and religious considerations in forensic evaluation. Further, this presentation will discuss ideas or concepts held by sub-groups of the population that may be mistaken for psychosis.<sup>1,2</sup> Although it is clear that culture, religion, and ideology must be considered in clinical and forensic evaluation, several cultural, religious, and ideological beliefs may be mistaken for symptoms of mental illness (e.g., delusional beliefs or perceptual disturbances).<sup>3</sup>

For instance, individuals who identify as sovereign citizens believe the United States government does not have authority over them.<sup>4</sup> They express beliefs in a Uniform Commercial Code, Admiralty Court, note copyrights are placed on names, and discuss having beliefs related to individuals who identify as a corporation. Further, they derive meaning from the use of capital letters when writing names, cite the importance of the Fourteenth Amendment, and speak of Redemption. Similarly, individuals who identify as Christian may describe experiences in which God is communicating with them and speaking audibly at times.<sup>1</sup> They may assert that God is responsible for providing them with direction, consolation, and empowerment, and/or reference the existence of prophecy. While the above-described beliefs may be accurately identified as delusional at times, they are not innately pathological in and of themselves and require a knowledgeable and skilled evaluator with understanding of cultural and religious considerations in the context of forensic assessment.

Mistaken identification of these beliefs as psychotic in nature may have a significant negative impact on individuals who hold these beliefs as well as on the legal system. This presentation will briefly outline several different cultural and religious beliefs and discuss the ways in which they may be falsely identified as psychotic in nature. Specifically, beliefs held by those who identify, practice, or believe in ideology who identify as Christian, Muslim, Sovereign Citizens, Moorish-Americans, Voodoo, Freemasons, those who believe in reptilians, or those who hold culturally based attitudes regarding trust. Additionally, the implications of misidentifying symptoms of mental illness for legally involved individuals and the legal system as a whole will be discussed.

### I34 The Phenomenon of Suicide-Pesticide: Case Reports and a Review of the Literature

Federica Fersini\*, Viale Felsina 16/2, Bologna, ITALY; Chiara Palazzo, MD, Via Imerio 49, Bologna, ITALY; Paolo Fais, PhD, Department of Medical and Surgical Sciences, Unit, via Imerio 49, Bologna, ITALY; Susi Pelotti, MD, University of Bologna, Paolo Fabbri 88, Bologna 40100, ITALY

---

**Learning Overview:** After attending this presentation, attendees will consider the phenomenon of suicide-pesticide and the importance of a comprehensive forensic investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by confirming that companion animals had significantly greater odds of being a medicolegal case in all categories.<sup>1</sup>

The combined event of a suicide and the killing of a pet is an event relatively unexplored in forensic literature. Frequently, the killing method is the same for human and pet, but, according to Oxley, little is known about how the bond between humans and pets may infer suicidal and/or homicidal ideation.<sup>2,3</sup> Forensic psychiatrists have tried to study this phenomenon considering the significance of the killing of a pet, as the animal is part of the family. In some individuals, the bond with pets prevents them from committing suicide.

In fact, concerns about who would care for their pets after they commit suicide could potentially influence the ideation of killing the pet before or together with suicide. Certainly, postmortem examination and forensic analysis could reveal key elements to better characterize similar events.

Recently, the phenomenon in the United States and the United Kingdom was investigated through media reports showing the variety of circumstances related to extended suicide. A number of similar cases have been experienced in Italy, but not all cases come to the attention of the forensic pathologist, so the phenomenon is underestimated.

Here is reported two case studies: one is a planned complex suicide-“pesticide” of a woman and her dog perpetrated by the ingestion of psychoactive drugs in combination with self-strangulation of the woman and intentional drug fatal intoxication in the dog; the second is a “pesticide”-homicide-suicide casework.

Data obtained from the death scene investigation, autopsy, and toxicological analyses will be reported.

### I35 A Fatal Pulmonary Embolism in a Hospitalized Psychiatric Patient: A Medicolegal Analysis

Biagio Solarino, PhD, Università degli Studi di Bari, Sezione di Medicina Legale, P.zza Giulio Cesare, 11, Bari 70125, ITALY; Alessio Ostuni, MD\*, Sections of Legal Medicine and Criminology, Policlinico of Bari Italy, Piazza Giulio Cesare 11, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Policlinico Teaching Hospital of Bari, P.zza Giulio Cesare, 11, Bari 70124, ITALY; Salvatore Moliterno, MD, Section of Legal Medicine University of Bari, P.zza Giulio Cesare 11, Bari 70124, ITALY; Roberto Catanesi, MD, P.zza Giulio Cesare, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand that venous thrombosis among patients with severe mental disorders can result from various mechanisms that cause blood vessel injury or venous stasis, potentially determining fatal consequences due to the occurrence of a Pulmonary Embolism (PE).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by deepening awareness about specific psychiatric disorders and how guidelines must be incorporated in order to prevent fatal thromboembolic complications and to, ultimately, avoid the risk of a lawsuit for alleged negligent medical care.

Psychiatric patient mortality is three-fold higher than the rate in the general population and nearly 60% is due to cardiovascular disorders. Specific risk factors included lifestyle issues and adverse effects of long-term medication, as well as an increased occurrence of obesity, diabetes, and hypertension.

Venous Thromboembolism (VTE) is the combination of PE and Deep Venous Thrombosis (DVT) and is known as a risk factor for sudden death in patients hospitalized in mental health units.

PE accounted for nearly 4% of unexpected sudden deaths in psychiatric patients; nevertheless, risk factors of VTE have not systematically been investigated in psychiatric inpatients.<sup>1</sup>

The main causative factor in these cases is immobility associated with venous stasis. Injuries to the extremities during physical restraint or compression and a reduction in blood flow of the extremity veins may also have prothrombotic effects enhancing tissue factor expression in endothelial cells, resulting in thrombosis formation.

Treatment with antipsychotics, especially phenothiazines, results in an increased platelet aggregation. Metabolic symptoms caused by antipsychotics, such as body weight increase, hyperleptinemia, hyperglycemia, and dyslipidemia, are known to be risk factors for VTE and to interfere with the coagulation and fibrinolysis processes.

**Case:** The case of a 45-year-old man with bipolar affective disorder and metabolic syndrome was reported. He went to the Psychiatric Emergency Department for management of a psychotic mood disorder associated with violence and property damage. During hospitalization, he was difficult to manage and aggressive toward the medical staff. Hence, he was given clonidine and lorazepam, then treated with aripiprazole and valproic acid. Four-point and two-point physical restraints were intermittently applied for five days. The vital parameters were normal, apart from occasional tachycardia. After removal of the physical restraints three days later, he collapsed and all efforts to resuscitate him failed. The patient's family filed a wrongful death lawsuit against the hospital, alleging that negligent medical care at the psychiatric ward led to his death. A medicolegal examination was requested.

An external examination of the body revealed obesity (1.85 m; 120 kg) in the absence of traumatic injuries. At autopsy, a saddle embolus completely occluding the right and left pulmonary arteries and extending throughout the peripheral branches of the pulmonary arterial circulation was observed. Dissection of the deep veins showed patchy occlusive thrombosis of the left popliteal vein, extending the ipsilateral saphenous vein. Morphological and histological heart and kidney examinations were in accordance with hypertrophic cardiomyopathy and renal chronic disease. PE was identified as the cause of death.

**Discussion:** A comprehensive analysis of the patient's medical records was performed. During hospitalization, the patient had never experienced cardiovascular or pulmonary symptoms. The patient's obesity, age, and immobility assessed low or intermediate clinical probabilities for pulmonary thromboembolism. Hence, the possible medical liability for not having administered heparin prophylaxis was herein discussed.

**Conclusion:** The goal of this case is to underline the importance of making a correct analysis of VTE risk factors in hospitalized psychiatric patients. This case further suggests the need to incorporate the presence of psychiatric disorders and exposure to antidepressants and/or antipsychotics in scoring systems for pulmonary thromboembolism.

### I36 Awareness and Attitudes of Health Care Professionals in Unperceived Pregnancies

*Oktaý Cavus, MSc, Üsküdar University, İstanbul 34430, TURKEY; İnci Y. Tezbasan, BSc\*, Uskudar University, İstanbul 34662, TURKEY; Gokben Sayar, PhD, Uskudar University, İstanbul 34662, TURKEY; Sevil Atasoy, PhD, Uskudar Üniversitesi Adli Bilimler Enstitüsü, İstanbul, TURKEY*

**Learning Overview:** The goal of this presentation is to determine the level of awareness and attitudes of health care workers regarding unperceived pregnancies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the importance of better training regarding pregnancy for first responders, health care professionals, and teenagers.

Unperceived pregnancy is a phenomenon in which the expectant mother is unaware of her pregnancy despite its advanced stage. The expectant mother becomes aware of her pregnancy either at 20-weeks gestation or later. While the identification of the pregnancy at 20-weeks gestation is defined as “partially unperceived pregnancy,” the identification of the pregnancy just before the birth or during labor is defined as “total unperceived pregnancy.”

This study sought to determine the level of awareness and attitudes of health care workers regarding unperceived pregnancies. A sociodemographic form and awareness and attitude questionnaire were used as data collection tools in the research. In this questionnaire prepared by the researchers, two clinical vignettes were given and the participants’ views about the table were asked after each clinical vignette. The study group consisted of 240 people with a mean age of 31.3 years and a standard deviation of 8.3. When the participants were examined according to their occupation, it was observed that 71.2% were psychologists, 16.2% were psychiatrists, and 12.5% belonged to other health services. The results of this study suggest that the psychologists, psychiatrists, and other health workers who participated in the research were indecisive to the vignettes that define unperceived pregnancies and that they had difficulty in recognizing and interpreting the clinical situation.

Thinking that the clinical situation may be associated with concealed pregnancy, psychosis, or mental retardation due to a clinical mental disorder, not knowing pregnancy signs and that the situation may be explained by inexperience, that it may be due to negligence and irresponsibility, that it may be the unconscious denial of an unwanted pregnancy, or that the woman was not aware of her reproductive capacity were all considered in close proximity. The fact that one-fourth to one-third of the participants were indecisive for each question shows the confusion the table created. The most important step to take for the early detection of unperceived pregnancies, in order for the mother candidate to have appropriate pregnancy follow-up and psychological support, for the birth and growth of the newborn to be physically and psychological healthy, and in order to prevent the forensic problems and familial crises that unperceived pregnancies would create, is to raise awareness about the unperceived pregnancies for, first, the health care personnel and then for society.

#### Unperceived Pregnancy, Health Care Professionals, Awareness

### I37 Sudden Death Caused by Hyponatremia Related to Psychogenic Polydipsia

Rohan P. Kedar, MD\*, Department of Psychiatry, Livonia, MI; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will understand that sudden death may occur as a result of Psychogenic Polydipsia (PPD), a condition associated with various psychiatric conditions, especially schizophrenia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting two cases of sudden death occurring in schizophrenic patients, wherein autopsy findings disclosed abnormal vitreous electrolyte values consistent with low-salt/hyponatremia produced by PPD.

Sudden, unexpected death in the context of psychiatric illness is not rare. Common scenarios include suicides and accidental deaths related to substance abuse. Other scenarios include deaths related to concurrent medical conditions, such as heart disease, deaths from trauma, and deaths related to complications of therapy.

PPD represents a disorder characterized by the compulsive consumption of large amounts of water as a secondary effect of an underlying psychiatric illness. Importantly, there is no intent of self-harm, and there is no identifiable underlying organic explanation for the behavior, such as a hormonal imbalance. Patients with schizophrenia are at most risk for PPD. In severe cases, dilutional hyponatremia can occur, with subsequent brain edema, seizures, coma, and death. This report presents two cases of sudden unexpected death occurring in schizophrenic patients in which autopsy findings determined that the cause of death was related to PPD.

Case 1 involved a 48-year-old, mentally handicapped, schizophrenic man who was noted to be in distress while at his group home. Emergency Medical Services (EMS) personnel were summoned and found the man in asystole. All resuscitative efforts were to no avail. In addition to schizophrenia, the man suffered from grand mal epilepsy, renal insufficiency due to lithium damage, with a known medical history of PPD, for which he had been placed on fluid restriction. A medicolegal autopsy was performed, which disclosed a slightly enlarged and dilated heart, mild coronary artery atherosclerosis, but no other gross abnormalities. Microscopic examination and toxicology testing were non-contributory. Vitreous electrolyte measurement revealed a sodium of 78mEq/L (normal: 135mEq/L–155mEq/L) and a chloride of 58mEq/L (normal: 105mEq/L–135mEq/L). The cause of death was ruled as: part I–seizure disorder; part II–PPD due to schizophrenia. The manner of death was considered natural.

Case 2 was that of a 47-year-old man who was found dead in his bed. He had a known past medical history of schizophrenia and obesity. A medicolegal autopsy was performed, at which he was noted to have marked cardiomegaly (heart weight of 640 grams; normal <400 grams), as well as mild coronary artery atherosclerosis. Microscopic examination confirmed the myocardial hypertrophy but disclosed no other significant findings. Urine and drug screens were negative for drugs of abuse. Vitreous electrolyte testing revealed a sodium level of 85mEq/L and a chloride level of 110mEq/L. The cause of death was ruled as: part I–hyponatremia due to PPD related to schizophrenia; part II–cardiomegaly and atherosclerotic cardiovascular disease. The manner of death was natural.

Although PPD is most common in schizophrenic patients, it may also affect patients with other psychiatric disorders, including mood disorders and substance use disorder.<sup>1</sup> The exact mechanisms underlying the development of PPD are not known. However, psychiatric medications are not generally considered to contribute significantly, as there are known cases of PPD occurring prior to the use of currently prescribed psychotropic medications.<sup>2</sup> Patients with PPD are at increased risk of morbidity and mortality. The cases presented serve to remind the medical and psychiatric communities that PPD is a potentially lethal manifestation of psychiatric illness.

#### Psychogenic Polydipsia, Hyponatremia, Sudden Death

### I38 The Brains of Suicides by Violent Methods Reveal a Distinct Biology

*Giovanna Punzi\**, Baltimore, MD 21231; *Gianluca Ursini, MD, PhD*, Baltimore, MD 21205; *Leonardo Collado Torres, PhD*, Lieber Institute for Brain Development, Baltimore, MD 21205; *Joo Heon Shin, PhD*, Baltimore, MD 21205; *Roberto Catanese, MD*, P.za Giulio Cesare, Bari 70124, ITALY; *Andrew E. Jaffe, PhD*, Baltimore, MD 21205; *Thomas M. Hyde, MD, PhD*, Baltimore, MD 21205; *Joel E. Kleinman, MD, PhD*, Baltimore, MD 21205; *Daniel R. Weinberger, MD*, Baltimore, MD 21205

**Learning Overview:** After attending this presentation, attendees will understand how the distinct state of mind associated with suicide by violent means may relate to a more salient biology that can be observed postmortem in brain tissue.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a novel key to suicide biology derived by behavior analysis.

Suicide is the tenth leading cause of death for all age groups combined and is on the rise across the United States, according to recent reports by the Centers for Disease Control and Prevention (CDC). As suicidal ideation is a limited predictor of outcome, recent research has turned to the detection of “more objective” biological markers (i.e., genetic marks) for the development of prevention approaches. This may be especially relevant for suicides by violent means, since features of impulsive aggression represent a better predictor of self-destructive acting out, a strong behavioral endophenotype, as well as a valuable research target, being associated with higher prevalence and lethality. In this regard, in completed suicides, the biology underlying the choice of a violent method should represent a more precise feature to target to detect genetic signatures for the behavior at large. Of note, in searching for suicide biomarkers, most studies do not address the relevance of the means adopted, hence they do not consider the possibility of a method-specific frame of mind that ultimately generates the behavior.

Previous discovery findings and further replication suggest that differences in Dorso-Later Prefrontal Cortex (DLPFC) expression of a human-specific non-coding RNA (lincRNA) may influence emotional regulation, aggressive behavior, and suicide by violent means. In the present study, RNA-sequencing (RNA-seq) data from postmortem human brain (228 Caucasian patients; adults) were examined to validate, at a genome-wide level of significance, association of the lincRNA specifically with suicide by violent means and to detect further candidates potentially related to the same signal.

Attribution of suicidal method was determined blind to the postmortem RNA-seq data. Cause and manner of death and contributory causes or medical conditions related to death were obtained from medical examiner documents. The choice of a specific method likely reflects the interplay of multiple determinants, including the availability of a particular suicidal means. However, at the individual level, preferences toward one or the other group appear to influence the ultimate pattern of choices. Cases in which manner of death was pending or not determined at the time of the curation and suicidal samples with ambiguous, or indefinable means of suicide, regarding the level of violence employed, were excluded. Among the remaining suicides, most deaths distinctly fell within the violent or non-violent category. When this was not obvious, an in-depth behavioral assessment was obtained using detailed narrative summaries based on all available sources of historical information, including interviews with next of kin. The differential expression analysis was conducted on all features, including genes, exons, junctions, and expressed regions data, correcting for diagnosis, sex, age, and qSVs, a measure of RNA integrity. A gene-set enrichment analysis was also performed on the top-list differentially expressed features. At  $P_{FDR-corr.} \leq 0.05$ , minimal signal (i.e., ~10 expressed regions) arose when comparing non-suicide with suicide (all types of method); differentially expressed features further decreased when looking only at suicide by non-violent means. However, comparison between non-suicides and suicides specifically by violent means produced a remarkably greater list of features (i.e., over 1,400 expressed regions). These results validate, at a genome-wide level of significance, previous findings and suggest the engagement of specific signaling and cellular type. These results confirm that classifying suicide by method is key in revealing the underlying different biology.

### 139 The Contribution of Suicide Notes in the Resolution of Doubtful Cases of Suicide: From the Psychological Autopsy to the Forensic Evidence—A Case Report and Review of the Literature

Isabella Aquila, MD\*, Institute of Legal Medicine, University Magna Graecia of Catanzaro, S Venuta-Medicina Legale, viale Europa, Catanzaro 88100, ITALY; Ada Maida, MD, Institute of Legal Medicine, Viale Europa, 88100, Catanzaro, ITALY; Santo Gratteri, MD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Viale Europa, 88100, Catanzaro, ITALY; Luigi De Aloe, MD\*, Institute of Legal Medicine, Viale Europa, 88100, Catanzaro, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Via Thailandia N 1, Crotona, ITALY; Valerio Riccardo Aquila\*, Via Dante Alighieri, Crotona, ITALY; Pietrantonio Ricci, MD, PhD, Department of Clinical and Experimental Medicine, Section of Legal Medicine, University of Foggia, Foggia 71100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the contribution of the suicide note in the resolution of doubtful cases of suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the role of the psychological autopsy in suicide cases.

Suicide is a public health issue. Among young people, it represents the second cause of mortality. Approximately 10,000,000 people die every year from suicide and this number will rise to 15,000,000 by 2020.<sup>1</sup>

Italian epidemiological studies report that hanging (52.1%) is prevalent among men; falling (35.1%) and hanging (33.4%) is prevalent for women. A major propensity for suicide is found among older people.<sup>2</sup> Suicide is related to psychiatric disorders, previous attempts of suicide, alcohol or other substance abuse, a history of mistreatment, divorces, and unemployment.

Often, a suicide note is present, which is a letter left by the victim to explain the reasons for the suicide. From these notes, we can analyze the cause, the contest, and the choice of suicidal method. It is crucial proof in the investigation because it helps us understand, in doubtful cases, if it is an actual suicide. However, a suicide note can be also falsified.<sup>3</sup>

There are cases in which the suicide note is not present. In these cases, it is possible to perform a so-called psychological autopsy, a retrospective investigation into the victim's life and the potential causes that led to the suicide. The method consists of thorough structured interviews of relatives, friends, or doctors, collecting all available information about the victim to obtain a valuation of his/her life, personality, mental health, and relationships.<sup>4</sup>

There are different types of suicide notes (i.e., farewell, instructions, accusations of others, requests for forgiveness, and justifications), and they are often handwritten on paper. This facilitates, through a calligraphic comparison, the demonstration that the victim, and no other, wrote the note, rejecting the hypothesis of murder.<sup>3</sup> There are some cases in which the victim writes the note on clothes or on his/her skin, while with the advent of new technologies, young people also use email, social networks, and telephone messages. In these cases, the so-called social-mobile autopsy is conducted.<sup>5</sup>

Reported here is the case of a middle-aged woman found dead at home. The interview of relatives by the police highlighted that the woman's son found her body hanging from a rope knotted to an internal railing of the dwelling. However, during the scene inspection, the forensic pathologist and the investigators found the woman's body lying on a bed, with the rope cut at the node. The external examination of the woman presented a double-cutaneous furrow with characteristics of vitality and bruising. The morphology of the furrow insinuated doubts about the mode of death considering the contrasting witnesses of family members and the movement of the body, which did not allow understanding of exactly how it was suspended. During the investigation of her house, investigators found, in the bedroom, a handkerchief with the following suicide note: *Prayer before falling asleep to Mary. O Virgo, it's late. Everything falls asleep on the earth, it's time for rest, do not move away from me. Put your hand on my eyes like a good mother, close them to the things below. My soul is full of troubles and sadness the fatigue that awaits me is here near me. Put your hand on my forehead and stop my thought, sweet will be my rest if blessed by you because tomorrow the poor son wakes up stronger and happily resumes the weight of the new day. Put your hand on my heart and give back to God an eternal love. Amen*

The site inspection is very important in discriminating the circumstances in doubtful cases, in finding incongruities, background, and motivation that allows an explanation of the facts. The forensic investigation does not end with the detection of signs and analysis of the suicide location, but there is a clear necessity of coordination between the various sources of information: relatives, friends, and acquaintances, as well as diaries, notebooks, notes, computers, and more. The psychological autopsy is a new method to better understand the circumstantial data of the crime scene investigation, postmortem examination, and autopsy.

## I40 When Freedom of Speech Harms: 13 Reasons Why and Its Influence on Suicide in Youths

Sharon L. Guo, MD\*, USC Institute of Psychiatry and Law, Los Angeles, CA 90033

**Learning Overview:** After attending this presentation, attendees will: (1) know the difference between protected and prohibited speech as guaranteed by the First Amendment, (2) become familiar with the landmark cases relating to the First Amendment and the media, and (3) have a better awareness of how past legal decisions may change because of technological advances in media.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising their understanding of the phenomenon of suicide contagion; in particular, how media can influence vulnerable youth to model self-injurious behavior. In addition, there will be a discussion of landmark cases in which the media's freedom of speech was challenged based on its negative impact on society, namely, inciting violence.

Evidence of the effect of the media on suicide has been supported by the literature. The "Werther effect" was coined in 1974 by sociologist, David Phillips, after a rise in suicides committed by young men after reading Goethe's 1774 novel, *The Sorrows of Young Werther*, in which the tragic protagonist ends his life. Phillips substantiated the phenomena of copycat suicides, which has been supported by many ensuing studies. Another important consideration is age-specific effects because youth tend to imitate behavior, such as that shown in suicide clusters. Therefore, when the media focuses on suicide, youth may be highly susceptible to engaging in suicidal behavior.<sup>1-5</sup>

In 2017, Netflix®, a media service self-described as "the world's leading internet television network with 130 million subscribers in over 190 countries," released the show, *13 Reasons Why*.<sup>6</sup> In the season finale, the 16-year-old protagonist is shown cutting her wrists with a razor and then bleeds out and dies in a bathtub.<sup>7</sup> In the weeks and months following the program's debut, at least one Los Angeles County psychiatric emergency department noticed a surge of young patients who were admitted involuntarily. For example, a mother brought her adolescent daughter to the emergency room after the daughter sent her a suicidal text message with a knife emoji the morning after viewing *13 Reasons Why*.

Considering the content in *13 Reasons Why*, which depicts suicide and targets a teenage audience, the constitutional protection of freedom of speech under the First Amendment may be challenged. The United States Supreme Court case in *Brandenburg v. Ohio* held that freedom of speech is not protected when it is "directed to inciting or producing imminent lawless action and is likely to incite or produce such action."<sup>8</sup> The use of this reasoning in subsequent legal cases whereby the media's right to freedom of speech was upheld, as well as cases in which the media were censored and found liable, will be presented.

This presentation will not only discuss the impact of *13 Reasons Why* on the viewing public but will also highlight whether there may be a need to rethink the First Amendment guidelines in the 21<sup>st</sup> century. In addition, how the right of the media's freedom of speech can be balanced with that of society's right to be protected from harm, via its application in blogging, internet privacy, and other social media, will be addressed.

### Freedom of Speech, Suicide, Media

### I41 Parental Alienation: Misinformation and Fake News

William Bernet, MD\*, Brentwood, TN 37027

**Learning Overview:** After attending this session, attendees will understand that widely distributed misinformation presents a threat to the integrity of forensic sciences. Parental Alienation (PA) will be used as an example, to show that misinformation regarding that topic has appeared in the popular press, presentations at conferences, journal articles, and books published by professional organizations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the evaluation of forensic clients (e.g., child custody evaluations) and improve the training of forensic psychiatrists (regarding PA).

Misinformation sometimes arises in the context of forensic psychology and psychiatry. In recent years, misinformation regarding the topic of PA has been expressed in peer-reviewed journal articles, presentations at scientific meetings, and books intended for mental health and legal professionals. PA is a mental condition in which a child—usually one whose parents are engaged in a high-conflict separation or divorce—allies himself strongly with one parent (the preferred parent or alienating parent) and rejects a relationship with the other parent (the target parent) without legitimate justification. The child's rejection of the target parent must be without justification for the child to be considered alienated; if a parent has been abusive or severely neglectful, the child's rejection of that parent is understandable and does not constitute PA. This presentation addresses and refutes three false statements that have been stated repeatedly.

The meme that "PAS is junk science" has taken on a life of its own. An influential psychiatrist, Paul J. Fink, stated in 2003 that Parental Alienation Syndrome (PAS) constitutes "junk science," and he repeated that opinion many times. In 2010, he reiterated—in his column in *Clinical Psychiatry News*—that PAS was "junk science invented by a psychiatrist."<sup>1</sup> After receiving letters objecting to Fink's statements, the management of *Clinical Psychiatry News* arranged for him to issue an apology and a clarification. Fink then said, "I do not deny that parental alienation occurs and that a lot of people are hurt when there is an alienator."

A common false allegation is that "Parental alienation has not been recognized by professional associations." In fact, mainline professional organizations have acknowledged the reality of PA through their publications, national and international meetings, and educational programs for their members. For example, the American Academy of Child and Adolescent Psychiatry (AACAP), the Association of Family and Conciliation Courts (AFCC), the American Psychological Association (APA), the American Academy of Pediatrics, and the American Professional Society on the Abuse of Children (APSAC) have published documents that explicitly recognize the reality and importance of PA.

Many critics of PA have alleged, "Parental alienation is not admissible in court under *Daubert* and *Frye* standards." Is PA admissible under *Frye v. United States*?<sup>2</sup> This rule merely requires that admissible expert opinion must be based on a scientific technique that is generally accepted as reliable in the relevant scientific community. Based on the information in this presentation, it can easily be shown that the concept of PA has been endorsed or accepted by numerous professional organizations. Is PA admissible under *Daubert v. Merrell Dow Pharmaceuticals*?<sup>3</sup> The factors to consider include: whether the theory or technique employed by the expert is generally accepted in the scientific community (explained previously in this presentation); whether the theory or technique has been subjected to peer review and publication (bibliographies and data bases include hundreds of articles from peer-reviewed journals); and whether the theory or technique can be and has been tested (has been accomplished in quantitative research).

While the clear majority of mental health and legal professionals who work with divorced families agree with the reality of PA, a small number of detractors of PA have generated a great deal of misinformation and fake news. Fake news appears to be endemic in Western and democratic societies, where a free press and online media encourage the transmission of both truth and falsehood.

### I42 Repressed Memory Syndrome Goes to Court: The Lopez Hearing

Vivian Shnaidman, MD\*, Skillman, NJ 08558

---

**Learning Overview:** After attending this presentation, attendees will be familiar with: (1) repressed memory syndrome, (2) its legal implications, (3) how it might come up in a civil setting, and (4) the concept of the *Lopez* rule (referring to a hearing to determine whether or not the statute of limitations can be extended to a time when a victim actually learns about damages).<sup>1</sup> The interplay between repressed memory and damages has been a legal minefield in many landmark cases and now this study introduces the concept of a statute of limitations to further complicate the scenario and explore and understand how these factors all interact, utilizing a recent New Jersey case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing previously unconsidered issues: (1) repressed memory, (2) damages to the victim, (3) the statute of limitations, and (4) understanding how appropriate forensic psychiatric evaluation and testimony can assist the legal system in making judicially appropriate decisions.

Repressed Memory Syndrome is defined as a situation in which an individual suddenly remembers an event, typically traumatic, that occurred years earlier. The literature has been divided on repressed memory, although conventional wisdom tells us that everyone has had memories that have been forgotten and then remembered. It is only when these memories arise and then become used in a legal arena that they become contentious.

A Statute of Limitations is a legal time limit beyond which legal action can no longer be taken in a court of law. For example, there is no Statute of Limitations on murder in the United States. Different crimes and different torts (civil wrongs) have different time limits. In New Jersey, child sexual abuse has a Statute of Limitations until age 23, two years after turning 21, the full age of majority, to file criminal charges.

In addition to criminal charges, individuals also have the right to file civil charges for damages, at least in the United States. In the case explored in this presentation, a 46-year-old man, JP, saw a photo on Facebook® on Thanksgiving Day 2014 of his cousin with “Uncle Jimmy” and after a moment of confusion, suddenly recalled, in vivid detail, two occasions on which his biological father sexually assaulted him.

This presentation will investigate the history of this case, the evidence JP presented to the civil court, his own psychiatric and personal history, and the testimony of the two opposing experts (with no identifying details). This author was brought in by the court as a tiebreaker, not to decide whether JP was actually molested, but on a matter of law: Was there sufficient evidence provided that the court should permit a *Lopez* hearing to extend the statute of limitations by an additional 21 years?

This presentation will review similar case law throughout the country and the world in case attendees find themselves in a similar situation one day and will refresh our repressed memories as to how to request and review a psychiatric-legal question from the attorney who hires you!

The story of this case is fascinating for many reasons and brings up the not trivial matter of how two extremely experienced and well-regarded experts could obfuscate to the point that the court needed to bring in an additional expert to explain all the jargon and help the court understand whether the Statute of Limitations should be extended.

To decide whether this case merited a *Lopez* hearing, the entire case was reviewed, and JP was evaluated. This method and the outcome will make an interesting group discussion for the attendees.

The surprise ending will be revealed to anyone who stays until the end!

### J1 A Pre-Osborn Timeline of Events and References Concerning Handwriting Examination and Forgery

*Judith A. Gustafson, BS\*, Internal Revenue Service, Chicago, IL 60607*

---

**Learning Overview:** After attending this presentation, attendees will be aware of pre-20<sup>th</sup> century events and references to handwriting identification, document examination, and forgery law.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of significant events concerning handwriting examination that occurred before the modern era of document examination.

In most standard document examination reference books, the history of document examination generally begins with Albert Osborn in the early 20<sup>th</sup> century. Osborn is widely considered to be the founder of modern document examination. Information prior to 1900 is treated briefly and spread among several sources.

This presentation will expand upon material presented in previous publications, providing a summary of these events and references in a brief, chronological format. This information may be of value in court testimony where document examiners may be asked about the history of their field.

The earliest mention of a law dealing with forgery may have occurred as early as 80 BC in ancient Rome with a law concerning the falsification of documents. In the 1500s and 1600s, the English Parliament created laws concerning forgery, with a “comparison of hands” said to be good evidence in such criminal cases.

Early courts sometimes relied on the use of “recognition witnesses”—people who were familiar with a given writer’s handwriting and would testify to it in court. The late 1700s saw the first specially qualified witness in an English-speaking court testify on a handwriting identification based on a direct comparison rather than on the use of a recognition witness.

While there is little written history of document examination in America until the late 19<sup>th</sup> century, there are references to an 1808 Louisiana law code that allows for an examination by “two persons having skill to judge of handwriting” and a recorded handwriting testimony in the early 1800s. In mid-century, a notable debate concerning handwriting examination occurred over the authorship of controversial Revolutionary War-era writings known as the Junius Letters. In Europe, handwriting examination also played a part in the “Dreyfus Affair,” a late 19<sup>th</sup>-century French political scandal.

Legal decisions of the 1880s and 1890s affirmed the importance of handwriting evidence and the use of experts and saw the first testimony on typewriter identification. Several early texts on handwriting examination were published in the decade of the 1890s by authors Daniel Ames, William Hagan, and Persifor Frazer, setting the stage for Osborn and the modern era of Document Examination.

### J2 Education and Training in Forensic Document Examination: A Discussion of Issues and Ideas

Mara L. Merlino, PhD\*, Kentucky State University, Frankfort, KY 40601; Veronica B. Dahir, PhD\*, University of Nevada, Reno, Reno, NV 89557; Mauricio Alvarez, PhD, University of Nevada, Reno, Reno, NV 89557; Chris Sanchez, MA, University of Nevada, Reno, Reno, NV 89557; J. Guillermo Villalobos, MA, University of Nevada, Reno, Reno, NV 89557; Chris Swinger, MA, University of Nevada, Reno, Reno, NV 89557; Denise Schaar Buis, MA, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will understand how members of the field of forensic document examination view training and education practices. Current discussions of the advantages and challenges of changing training and education paradigms will be highlighted in the context of examiner opinions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community by presenting conversations about the importance of creating systematic and standardized training programs with empirical and measurable benchmarks to demonstrate mastery and competence of trainees.

The National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) has been engaged in efforts to improve the reliability and validity of the methods, procedures, and conclusions in all areas of forensic practice. OSAC discussions have included topics such as the cross-disciplinary standardization of reporting language; creation of clear, concise, and empirical standards for demonstrating expertise in the field; and meaningful, recognized certification or licensure. Among these discussions is the specification of programs of study that will qualify trainees to gain employment as experts in the field. Conversations around forensic document examination have included debates about the merits of modular training compartmented to a 24-month program of study; identifying a single recognized certifying organization; requiring certification for trainers/mentors; requiring private laboratories to adhere to the standards set for government labs; and standardization of document examiner education and training.

Previous research addressing the training and education of Forensic Document Examiners (FDEs) revealed that the most common factor that FDEs cited as a positive contributor to their training was access to high-quality materials ( $n=34$ ). For instance, the availability of textbooks, publications, and actual cases allowed FDEs to build upon the knowledge and experience of experts. Hands-on experience with trainers ( $n=22$ ) as well as working with highly skilled trainers ( $n=30$ ) were also among the most common things listed contributing to high-quality FDE training. Finally, FDEs reported that the repetition inherent in working through many cases gave FDEs experience that directly applied to work that they would be conducting in the field ( $n=18$ ). A few participants ( $n=4$ ) indicated that being taught to take a conservative approach to document examination ensured that their opinions and conclusions were defensible and supported by evidence.<sup>1</sup>

This presentation will compare the results of a recent survey of the education and training background of professional document examiners (National Institute of Justice Award # 2015-DN-BX-K069) with results from the 2014 survey, highlighting similarities and differences in their views on current training and suggestions for improvement. The current movement toward an educational model of training standards and practices will be discussed.

Further discussion will center around the ongoing discussions in the field about creating standardized training programs that incorporate the identification of relevant knowledge, skills, and abilities; creating measurable and objective course goals; specifying learning objectives that incorporate introductory-, intermediate-, and mastery-level goals; creating valid and reliable measures of learning; and creating objective and measurable benchmarks for determining training effectiveness. This discussion will include information about identifying constructs to be measured, how to measure the reliability and validity of assessment techniques, and constructing standardized tests and measures.

### J3 Evaluation of Gray Value Measurements of Visual Spectral Data to the Characterization of Alcohol-Based Inks From Colored Felt-Tipped Blending Markers

*Clarra G. Moore, BS\*, Sam Houston State University, Huntsville, TX 77340; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX 77340*

---

**Learning Overview:** After attending this presentation, attendees will understand the use of gray value measurements to objectively detect and compare the most discriminating optical properties of colored felt-tipped blending markers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a simple method for analyzing a previously unstudied type of ink, expanding upon the limited knowledge of felt-tipped pens. The proposed protocols in this research can be used by questioned documents examiners to characterize these types of samples.

Ink analysis began in the early 1900s with fountain pen ink comparisons and has since expanded into one of the most researched areas in the questioned document field. Pen ink analysis includes determining the origin and components of the ink, comparing known and unknown samples, and dating ink samples. Ink analysis typically serves to authenticate documents and/or analyze any alterations. Most pen ink research concentrates on ballpoint pens and, more recently, gel pens, both of which are the most common types of pens encountered in questioned document examinations. Fiber- and felt-tipped pens first appeared in the mid-1900s and now are commonly used in artistic fields, such as drawing, graphic design, crafting, and calligraphy.

The felt-tipped markers used in this study were Copic® Sketch markers from the Japanese company Too Corporation. Initially, Copic® created markers for the manga industry. However, they are now being used in a wide variety of applications. Copic® markers are valued for their long shelf life, replaceable felt-tipped nibs, and refillable ink cartridges. The color name system has three main parts. The first part of the name is a letter or letters denoting color family, the second part is a numeric value of saturation, and the third part is a numeric value of brightness. Copic® Sketch markers are one of four types of markers sold by Copic®. The Copic® Sketch markers come in 358 different colors, as well as three types of nibs. They are also marketed to have the blending characteristics of watercolor paint. The applications of these markers vary from manga and comics to fashion and interior design.

Samples were prepared by marking one ink stroke on regular white office paper. Forty-two alcohol-based inks from colored felt-tipped blending markers were analyzed based on visual spectral data obtained from a Visual Spectral Comparator (VSC), and gray value measurements were recorded for purposes of differentiation. The types of markers studied have never been comprehensively researched, and no published research was found in the literature on the possibility of using the gray values gathered from images to analyze inks. It is hypothesized that the combination of illumination types and recorded gray values can be used to objectively distinguish between different inks in the context of comparative examinations. The present portion of this study deals with the implementation of the method of objectively comparing gray value data from alcohol-based blending marker inks.

The 42 ink samples were analyzed using various illumination types (i.e., Infrared (IR) reflectance, IR luminescence, and Ultraviolet (UV) fluorescence) and filters ranging from the visible to the near-IR range (up to 850nm) to detect the optical properties of the samples. The optical properties of the ink samples were observed. Standardized color checkers and images of samples collected in IR absorbance and/or luminescence modes were then analyzed using ImageJ to extract ten replicate gray values of the samples. The images of the ink samples could be separated into four main groups, depending on the samples' optical characteristics. Within these four groups, most comparisons of ink stroke pairs could be visually distinguished from each other based on their optical properties. Thirteen inks showed completely distinctive optical characteristics. Based on the standardized color checkers, gray values ranged from about 24 to 235. Many ink pair comparisons were discernible based on the gray values of at least one illumination source and filter. A few ink samples had overlapping ranges of gray values, which led to difficulty distinguishing between samples. The method of using the VSC6000 combined with ImageJ gray value analysis shows potential in distinguishing between ink samples from colored felt-tipped blending markers.

---

#### Questioned Documents, Ink Analysis, Blending Markers

### J4 Laser Printer Identification: A Real Case Study

*Jasna Galekovic\**, Forensic Science Centre Ivan Vucetic, Moi, Zagreb 10000, CROATIA

---

**Learning Overview:** The goal of this presentation is to inform attendees of the possibilities of identification of a laser printer used for producing counterfeit banknotes, based on specific printer defects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that individual defects of laser printers can be used as tools for the identification of specific laser printers used to create counterfeit banknotes or documents.

Due to their widespread use and availability, laser printers are often used as tools to produce counterfeit documents and banknotes. Forensic document examiners are often faced with requests to determine if seized counterfeit documents or banknotes were produced with a seized laser printer. Identifying the possible source of printed documents or banknotes can be quite a difficult and demanding task for forensic examiners.

An actual case study is presented in which police investigators found a counterfeit banknote and, during the investigation, a laser printer was seized as the possible instrument for producing the counterfeit banknote. The objective of this examination was to determine if the counterfeit banknote was produced by the seized laser printer.

The examination was performed using non-destructive methods—video-spectral and stereomicroscopic analysis. After detailed examination of the counterfeit banknote, it was concluded that the counterfeit banknote was produced by a device (laser printer or photocopier) using Cyan, Magenta, Yellow, and Black (CMYK) colored dry toner. On the front side of the counterfeit banknote, in the lower left corner of the paper, the specific traces of CMYK toner particles were found. Those toner particles were in the form of several parallel lines and looked like the traces of a specific printer or photocopier defect marks.

The next step of the examination process was to take test samples from the seized laser printer. After detailed examination of those samples, identical marks were found, repeated in the same position and with the same distance on all samples. The fact that the distance between those marks was constant on all samples led to the presumption that they were the result of photosensitive drum defects. The photosensitive drum was taken out of the printer and, after detailed microscopic examination, the specific scratches on the drum surface were found. The defects on the drum surface were compared with the specific clusters of toner particles that were present on the counterfeit banknote, and their shape was identical. Based on those findings, it was possible to determine that the seized laser printer was used for producing the counterfeit banknote.

---

#### Laser Printer Identification, Drum Defects, Counterfeits

### J5 Measuring the Frequency Occurrence of Handwritten Numerals: An Expanded Database

Thomas W. Vastrick, BS\*, Apopka, FL 32703; Ellen M. Schuetzner, BA, Chicago, IL 60646-3728; Kelsey Osborn, Forensic Science Institute, Edmond, OK 73034

---

**Learning Overview:** After attending this presentation, attendees will be informed of the most recent frequency occurrence measurements for the features added to the overall handwriting database. Attendees will know about the expanded database and understand the quality control processes that are the bases for the integrity of these studies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing expanded foundational and statistical bases for associations of known handwriting specimens to writings in question.

Beginning in 2009, members of the forensic document examination community began making a concerted effort to design and implement a course of study to develop statistically based frequency of occurrence proportions of handwriting, hand printing, and numerals for use in handwriting comparison analyses. The group formed after noting several court rulings in which judges admitted handwriting comparison in court but noted concern over the limited foundational bases for the axioms of the science. In 2010, two document examiners and two statisticians received a grant from the National Institute of Justice to undertake the first of the frequency occurrence studies. This study was formally presented at the 2015 American Academy of Forensic Sciences (AAFS) Annual Scientific Meeting in Orlando, FL, and published in 2017.<sup>1</sup>

There had been several studies in the past, most of which were of limited scope. It was also noted that there was little in the way of population sampling design built into the previous studies. The statisticians worked diligently to design an appropriate protocol for population sampling based on published material concerning intrinsic and extrinsic factors in handwriting and how those factors could, and should, be addressed in the collection process. A protocol was developed and overseen by the team during the first study.

In addition, the statisticians developed a protocol for quality assurance by utilizing attribute agreement analyses into the study protocols. These analyses studied the potential of variance by multiple forensic document examiners, or by one forensic document examiner, over time. It was decided that any feature used in the database must pass the protocol with a 100% score; in other words, no deviation of results scored by the assessors/forensic document examiners.

To date, the results have been approximately 1,000 features having been studied for frequency occurrence proportions within the United States. Several past studies have concluded that the pattern recognition areas of the forensic sciences should report conclusions based more on a statistical foundation than on experience alone. The development of a frequency occurrence proportion database is designed to directly address that recommendation. The results of the first two studies have been reported in court with resounding success. Additional studies have been mapped out for the purposes of expansion of the database. This expansion includes additional features and a larger population sampling.

This study is the third frequency occurrence study. Both the first and second studies have been published in the *Journal of Forensic Sciences*, the second being published in 2018. It is the purpose of this study to begin to expand the existing handwriting database to provide a larger foundation of statistical study into the heterogeneity of handwriting features.

### J6 Cognitive Human Factors and Forensic Document Examiner Methods and Procedures: Key Results From an International Study of Handwriting Experts

Mara L. Merlino, PhD\*, Kentucky State University, Frankfort, KY 40601; Veronica B. Dahir, PhD\*, University of Nevada, Reno, Reno, NV 89557; Derek L. Hammond, BA\*, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297-5205; La'Quida Smith, MA\*, Kentucky State University, Frankfort, KY 40601; Chandler D. Al Namer, BA, Kentucky State University, Frankfort, KY 40601; Taleb A. Al Namer, BA, Kentucky State University, Frankfort, KY 40601; Mauricio Alvarez, PhD, University of Nevada, Reno, Reno, NV 89557; J. Guillermo Villalobos, MA, University of Nevada, Reno, Reno, NV 89557; Charles Edwards, MA, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will understand some of the principles of cognitive human factors, cognitive psychology, and the use of eye-tracking technology to study attention and feature-matching processes as they relate to decision-making processes in forensic document examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the relationship between cognitive human factors such as context effects, information about the measurement characteristics of the currently used nine-position authorship opinion scale, and findings about sufficiency in the number and complexity of handwriting samples available in signature comparison tasks.

The International Ergonomics Association defines human factors as “the scientific discipline concerned with the understanding of interactions among humans and other elements of a system, and the profession that applies theory, principles, data, and methods to design in order to optimize human well-being and overall system performance.”<sup>1</sup> Cognitive ergonomics is a subfield of human factors in which cognitive processes, such as memory, perception, reasoning, decision making, skilled performance, and human reliability, are examined in the context of work and operational settings. The goal of cognitive ergonomics is to improve task performance by the systematic study of the interaction between human cognitive functioning and the systems or environments in which tasks are performed.

Forensic science is produced and consumed in the context of various systems developed by human actors. At the “Examiner Action” level, error may be based on examiner decision (e.g., failure to recognize exemplars or standards as inadequate, or insufficient data to support conclusions); examiner perception (e.g., not all data are perceived, or data are inadequately compared); examiner skill (e.g., data are misinterpreted or misunderstood); or examiner violations (e.g., disregarding procedures, or misrepresenting information).<sup>2</sup>

“Conditions that Affect Performance” are adverse mental states of the examiner (e.g., anger, haste, mental fatigue, stress, or other cognitive factors); adverse physiological states (e.g., illness, lack of sleep, eyestrain); physical or mental limitations of the examiner (e.g., inadequate training, limited experience, color vision deficiency); communications (e.g., confusing or conflicting directions or demands, inadequate communication among examiners, inadequate report-writing skills); physical environment (e.g., clutter, inadequate lighting, poor workplace design); or the technical environment (e.g., defective, inadequate, or outdated software, tools, or equipment).

Interdisciplinary research encompassing expertise from forensic practice, social and cognitive psychology, vision science, and other areas is needed to establish the basis and extent of expertise, to develop rigorous protocols and measures, and to establish education and training programs that consistently and comprehensively address the knowledge and skills required to establish expertise in forensic fields. A human factor approach to understanding issues of reliability, validity, proficiency, expertise, and sources of bias involves an examination of multiple sources of information, and it is important to address the production of forensic science from multiple perspectives. This international multidisciplinary research program (National Institute of Justice Award No. 2015-90606-KY-DN) extended previous research exploring the reliability, measurement validity, and accuracy of established Forensic Document Examiner (FDE) procedures. The three experiments in this research investigated the following questions: (1) What is the relationship between the context established by presentation order of questioned and known writing and the examination process?; (2) How do examiners apply the currently used bipolar continuum of certainty (Elimination through Identification with a center position of Inconclusive) when expressing their opinions about the authorship of questioned writings?; and (3) How much writing constitutes “sufficient” information upon which to base an opinion?

This series of four papers will report on the results of: (1) a telephone survey about the training, education, and background of project participants, as well as their opinions about the strengths and weaknesses of professional training; (2) an eye-tracking experiment investigating the relationship between position of the questioned and known writings and the visual inspection of available writing features; (3) examiners’ use of the nine-position “authorship” scale; and (4) an eye-tracking experiment investigating examiner call accuracy given varying numbers of writings and writing complexity.

#### Cognitive Human Factors, Empirical Measurement, Sufficiency and Complexity

### J7 A Methodology for the Removal of Adhesives

*Kevin P. Kulbacki, MSFS\*, Internal Revenue Service, National Forensic Laboratory, Chicago, IL 60607*

---

**Learning Overview:** After attending this presentation, attendees will understand a basic methodology for the removal of adhesives, such as packaging tape.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a case study for when the removal of an adhesive substance may be required. Additionally, this presentation will include a basic methodology for conducting the removal.

Forensic document examiners occasionally conduct examinations on documents that have adhesive products, such as tape. This presentation arises from casework in which the evidence consisted of makeshift address labels. The makeshift address labels were consistent with cut-out sections that were subsequently taped onto the envelope. During the investigation, sheets of paper with an assortment of addresses were recovered with sections cut out, consistent with address labels. Research was undertaken to determine the reliability of using un-du® Sticker, Tape and Label Remover to remove tape from envelopes without damaging the underlying paper labels to allow for subsequent fracture match examinations.

Test samples were designed recreating the circumstances surrounding the evidence in question. Initial testing was conducted under a fume hood using the shovel-like tool that is built into the un-du® bottle. Following the included directions, a small amount of un-du® was applied to the built-in tool near the corner of the tape. The tool was then used to scrape underneath the tape. While following this procedure, it was determined that the bottle would continue to drip more solution than what was needed, thereby leading to saturation of the document. Additionally, it was determined that if an excess of un-du® solution was applied, it would possibly stain the document.

The methodology was then refined to remove the use of the built-in tool to prevent saturation of the document. Under the modified methodology, a spoonula was used to apply the un-du® solution at a slower pace and in a more refined manner. Using this method, it was possible to apply smaller amounts of the un-du® solution directly underneath the tape as it was being removed. Through careful application of this methodology, it was possible not only to separate the tape from the envelope, but also to separate the makeshift label from the tape at the same time.

It was determined that under controlled circumstances, un-du® was effective at allowing the removal of tape with little-to-no staining of the documents in question.

---

#### Methodology, Removal, Adhesives

### J8 Analysis of Black Toners Using Scanning Electron Microscopy (SEM)

*Anna Lasinska\*, Forensic Bureau Internal Security Agency, Warszawa, AE, POLAND*

---

**Learning Overview:** After attending this presentation, attendees will understand some principles of printed matter examination and identification. The goal of this study was the estimation capabilities of the verification of toners on printouts made by using laser printing devices and laser multifunctional devices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a novel method for the identification of laser printing. The proposed method could prove crucial for forensic casework and could run parallel to predominant document analysis methods. Hence, the present technique can be utilized for building a large database of various toner references for future considerations. The classification of the toner samples can be further studied using other analytical methods, such as Fourier Transform Infrared (FTIR) and Raman spectroscopy. These methods may help the forensic science community to characterize and classify the toners and present the data as additional information to the judicial system for the verdict.

The universal availability of printers and multifunctional devices has resulted in a decrease in handwritten documents. Since we currently have a choice of different types of printers, multifunctional devices, and copiers, the research to identify a printing device is a relevant problem.

To date, a few reports have indicated the possibilities of varying the available toners in Poland, based on studies by Infrared (IR) spectroscopy and Scanning Electron Microscopy (SEM). However, based on this study, it was not clear how to relate the toner to the appropriate device (printer, copier).

Therefore, the identification of printing and copying devices was performed within the framework of a research project by the Forensic Bureau of the Internal Security Agency. The goal of the study was to determine if a laser printer or multifunctional laser device could be identified by an examination of the toner on a printout from that device. The research materials used were printouts from ten different companies.

An analysis of the toners on printouts made from 134 models of laser printing devices was conducted. This analysis showed that the implementation of a more sensitive method such as SEM created new opportunities for the identification of laser printing. Group selection has been made and, in some cases, individual printouts. The present technique can be utilized for building a large database of various toner references for future consideration. However, the classification of the toner samples can be further studied by using other analytical methods such as FTIR and Raman spectroscopy. These methods may help the forensic science community to characterize and classify the toners and present the data as additional information to the judicial system for the verdict.

### **J9 An Interdisciplinary Study: Alcohol and Its Influence on Breath Alcohol Concentration (BrAC), Blood Alcohol Concentration (BAC), and Handwriting**

*Andrea Ledic, BS\*, Croatian Forensic Science Centre "I. Vucetic," Zagreb, Europa 10000, CROATIA*

---

**Learning Overview:** After attending this presentation, attendees will better understand the influence that alcohol may have on a writer's handwriting signature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a unique interdisciplinary case study in which handwriting was analyzed and the results compared to BrAC and BAC, as well as by teaching attendees about the effects alcohol has on the brain and nerves that may result in the writer's handwriting and signature containing characteristics of distortion.

Alcohol is a substance that is toxic to the human body, primarily the brain, and it directly influences human behavior. Ethanol can be found in alcoholic beverages. It is a modern poison that has an effect on the body's Central Nervous System (CNS) similar to that of anesthetics, such as ether or chloroform.

Previously published papers were primarily based on the analysis of the characteristics of handwriting and signatures of persons under the influence of alcohol with no significant statistical analyses. The goal of this research was to establish the significance of measuring the influence of alcohol in relation to blood, breath, and handwriting to carry out a statistical analysis of the collected data.

To verify the collected data, a controlled drinking study was conducted with 63 healthy volunteers (21 male and 42 female participants between the ages of 26 and 61 years) with a body mass index lower than 30. The participants consumed alcoholic beverages to simulate real drinking conditions.

Handwriting samples were taken before, immediately after, and an hour following alcohol consumption. They were examined under the VSC 6000 HS and Leica® stereo microscope.

The Dräger Breath Alcohol Analyser, model 6810Za, was used for breath analysis before and 15 minutes after alcohol consumption. Blood samples taken before and an hour after alcohol consumption were analyzed using the Perkin® Elmer® Gas Chromatograph with an ionization detector (Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID-HS)) and TurboMatrix Headspace Auto Sampler.

The BrAC is the amount of alcohol in breath, while the BAC is the amount of alcohol in blood. No significant differences were found between the BrAC and BAC results obtained from a single participant. However, the same amount of the same alcoholic beverage shows different BACs in taller and heavier individuals as opposed to shorter and lighter individuals because the organism of taller and heavier persons contains more water, which dilutes the alcohol they consume.

Taking practice and theory into consideration, the changes visible in the handwriting of persons who are under the influence of alcohol are proportionate to BAC, but the effects of alcohol on handwriting may vary depending on the individual's health and their physical traits. Regarding the handwriting, the results obtained indicate that, in certain cases, handwriting characteristics, such as the size of the letters/words, length of syllables/words, space between letters/words, tremor, as well as others, significantly increase under the influence of alcohol. Handwriting was also compared to the results obtained by the Dräger test and blood sample analysis with the aim of establishing whether handwriting can be used for obtaining an accurate measurement of BAC of the person writing.

The results of this research may also be used in certain cases for establishing the effects of alcohol on a person's ability to drive, considering that the same part of the brain is responsible for writing and driving.

---

**Handwriting, Breath Alcohol Concentration, Blood Alcohol Concentration**

### J10 The Classification of Raman Patterns From Inkjet Printer Inks Using Visual Comparisons of Spectra and Different Statistical Methodologies

Patrick Buzzini, PhD\*, Sam Houston State University, Huntsville, TX 77340; James M. Curran, PhD, University of Auckland, Auckland 1142, NEW ZEALAND; Carrie Polston, BA, Sam Houston State University, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will understand the criteria to differentiate Raman patterns measured on inkjet-printed documents from different sources and the ability of different multivariate statistical methods to classify the collected Raman spectra.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the comparison between traditional visual inspection and different statistical methods to differentiate and classify spectroscopic patterns in an investigative context.

Inkjet printers are devices that are commonly encountered in society. Therefore, it is not surprising that they are likely to be involved in different types of illicit activities, such as threats or extortions by means of anonymous letters, fraud in the context of disputed contracts, alterations to or counterfeit of ID documents, or counterfeit of currency. The printing process used in inkjet technology involves the production of a constellation of ink dots of micrometric size that are projected without contact to the receiving surface (i.e., paper). When coupled with a microscopical approach, Raman spectroscopy has been demonstrated to be a suitable method for obtaining a chemical signature *in situ* from the three main colored components (cyan, magenta, and yellow) of inkjet printer inks. Although the Raman technique is already a relatively well-established method for the characterization of colorants (both dyes and pigments), this study highlights the contribution of minor peaks within Raman spectra to improve the discriminating capabilities of the technique.

In the present phase of this project, 231 Raman spectra were collected from the cyan, magenta, and yellow color components of 11 inkjet printer ink samples provided by the Counterfeit Forensic Section of the United States Secret Service, using a Near-Infrared (NIR) laser wavelength at 785nm. Spectra were first compared visually, and groupings were formed for each individual color and for the three colors jointly considered. Since the overall goal of this project is to evaluate if Raman data gathered from these three components constitute, together, a chemical signature of sufficient discriminating quality to provide reliable investigative leads, many spectral comparisons need to be carried out. However, visual comparisons are impractical and tedious for this purpose, and a sensible statistical classifier is then required for conducting spectral comparisons. To facilitate the implementation of a statistical approach, two main problems need to be considered. The first is that most differentiations between spectra of different inkjet printer ink samples are made by consideration of minor peaks since most of the Raman bands present in a spectrum are shared by multiple samples. This is due to the prevalent use of few colorants in the inkjet manufacturing industry and/or to the higher scattering property of these colorants compared to other present within the ink formulation. The second problem is that Raman spectra often exhibit large intra-source variation with regard to the absolute intensity of the signal, although their relative intensities and wavenumber positions present high repeatability. This implies that appropriate data pre-treatment and feature selection must be carefully investigated.

In this study, spectra have been submitted to baseline correction, and four normalization methods have been investigated: normalization to the same frequency, normalization to area unity, normalization to unit sum, and Standard Normal Variate (SNV). Data dimension reduction techniques of Principal Component Analysis (PCA) and t-Stochastic Node Embedding (t-SNE) have been utilized for visualizing the collected high-dimensional spectral data. The potential of the classification methods of Linear Discriminant Analysis (LDA), random forests, and Naïve Bayes classifiers were evaluated. At this stage, none of the selected combinations of statistical methods resulted in the classifications observed by visual inspection of spectra. For example, for random forests (applied after normalization to area unity and t-SNE), ten-fold repeated cross-validation with three repeats per fold were used to achieve an overall accuracy of the model of approximately 75% for the cyan color. A following step of this study will consist of selecting lower portions of the spectral range that are expected to yield less inter-sample redundancy.

This research is funded by an award from the National Institute of Justice.

#### Questioned Documents, Raman, Inkjet

### J11 Writing Speed and Fluidity and Accuracy of Calls in High and Low Complexity Signature Comparisons

Mara L. Merlino, PhD\*, Kentucky State University, Frankfort, KY 40601; Mauricio Alvarez, PhD, University of Nevada, Reno, Reno, NV 89557; Taleb A. Al Namer, BA, Kentucky State University, Frankfort, KY 40601; J. Guillermo Villalobos, MA, University of Nevada, Reno, Reno, NV 89557; Charles Edwards, MA, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will understand the relationship between writing speed and fluidity, writing complexity, and the accuracy of decisions made by forensic document examiners about whether the signatures are genuine or simulated.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of engaging in theoretically based, multidisciplinary research to an understanding of the nature of the methodology and expertise in forensic document examination.

The extensive scrutiny of the methods and findings of numerous areas of expert testimony has prompted acrimonious debate among academicians, forensic practitioners, and legal professionals concerning what has been referred to by the Forensic Science Committee of the National Academy of Sciences (“Committee”) as “faulty forensic science analyses.”<sup>1</sup> While acknowledging the importance and utility of the forensic disciplines, the Committee also addressed the perceived flaws in such evidence. For example, advances in technology in various forensic disciplines, especially in the field of DNA testing, show that erroneous or misleading forensic evidence has contributed to the wrongful conviction of innocent individuals.<sup>1</sup> The Committee called for improvements in forensic science practices, arguing that increased and demonstrated reliability and validity in forensics will help law enforcement investigations by improving the reliability of identifications, and homeland security efforts will also improve as improvements are made in the methods and procedures of the forensic disciplines.<sup>1</sup>

The Committee specifically identified several important issues, including practitioner certification, accreditation, and the availability of skilled, well-trained personnel.<sup>1</sup> Many areas of forensic science lack uniformity in training, accreditation, and practice standards. The Report stated that operational principles and procedures for many disciplines are not standardized between or within jurisdictions; attempts at standardization are not viewed favorably in many instances; and that protocols such as Scientific Working Group (SWG) standards “often are vague and not enforced in any meaningful way ... These shortcomings obviously pose a continuing and serious threat to the quality and credibility of forensic science practice.”<sup>2</sup>

The Committee also discussed the lack of demonstrated validity and reliability within the interpretation-based disciplines, stating “... no forensic method has been rigorously shown to have the capacity to consistently, and with a high degree of certainty, demonstrate a connection between evidence and a specific individual or source ... The simple reality is that the interpretation of forensic evidence is not always based on scientific studies to determine its validity. This is a serious problem. Although research has been done in some disciplines, *there is a notable dearth of peer-reviewed, published studies establishing the scientific bases and validity of many forensic methods.*”<sup>3</sup>

Among the writing characteristics identified by professional document examiners as indicators of genuine writing are the speed and fluidity of the questioned writing when compared to the known writings of an individual. This presentation reports empirical information about the accuracy of results of forensic document examiner comparisons of genuine-to-genuine and genuine-to-simulated signatures when considering the handwriting dynamic information obtained from digitizing tablets using Movalyzer<sup>®</sup> software. Results comparing high-complexity and low-complexity signature samples will also be reported.

#### Decision Accuracy, Writing Speed, Signature Complexity

### J12 Trends in Forensic Document Examination in Québec, Canada

*Mylene A. Signori, BSc\*, LSJML, Montreal, PQ H2K 3S7, CANADA; Richard K. Van Gheluwe, BSc, Montreal, PQ H2G 2X8, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand the types of criminal cases which are submitted to the Québec Forensic Provincial (state) Laboratory, over the past ten years. Some questions had arisen concerning the shift in the types of analysis that may have taken place in recent year in forensic document examinations in relation to police investigative practices and judicial practices. Ultimately, some changes were observed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting an overview of the capacities of a francophone forensic document examination unit in North America, over a period of ten years.

Over the past ten years, there seems to have been a rising pressure on the Canadian justice system in terms of delays. These delays may be attributed to different factors: the lack of rooms for the trials, the shortage of staff in the judicial system, the prosecutors, the defense lawyers, and the overload of the judges' agendas. These delays have also been ascribed to the forensic analyses.

The Laboratoire de Sciences Judiciaires et de Médecine Légale wanted to find out if this intangible pressure would result in a shift in police investigators' requests for analysis in the forensic document examination unit. In all, several individual investigative requests (in forensic document examination only) were examined, pertaining solely to criminal cases over a period of ten years (2006 to 2017). The Statistical Package for Social Sciences data-collecting software was used to compile the studied elements. Civil and private cases were not retained for this study.

The cases were assessed under different criteria, including the time of year the request was received and completed, the type of offenses, the number of documents to analyze in each case, the time taken to entirely process the case, the complexity of the examinations, etc.

Originally, approximately 30 different criminal offenses were listed. These had to be grouped into main categories for this research: financial crimes, misdemeanor and threats, crimes against the persons—major crimes, crimes against property, organized crime, terrorism, and other infractions.

In July 2016, the Canadian Supreme Court rendered a judgement, *R. v. Jordan*, which stated new delays under which criminal and civil cases had to be dealt with diligently—from the beginning to the end of the judicial process—before being detrimental to the accused.<sup>1</sup> Although this judgement is fairly recent, a shift in requests has already been observed, resulting in more pressure being imposed upon all forensic analysts.

This research ultimately demonstrated that a slight change in forensic document examination requests has been observed during recent years, in the type of cases submitted, the complexity of the cases submitted by the combined investigations joint task forces, and the gravity of the offenses.

### J13 The Examination of Crossed Lines for the Determination of Sequence of Strokes Using Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) and X-Ray Fluorescence (XRF)

Samiah Ibrahim, BSc\*, Ottawa, ON K1S 1R1, CANADA; Julie Binette, BS\*, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA; Mario Larouche, BS, Ottawa, ON K2E 7M6, CANADA

---

**Learning Overview:** The goal of this presentation is to provide information about a novel approach to the determination of sequence of stroke for crossed ink lines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to the present knowledge base concerning the determination of sequence of strokes for crossed ink lines.

During the course of forensic examinations of documents, the question of sequence of strokes is common. Determining which ink or printed line was produced first, second, third, etc. may play an important role in answering questions about the genuineness or veracity of the document or its content. Furthermore, this problem is growing in scope as the number of writing instrument types, ink formulations, and printing devices and media expands. Forensic Document Examiners (FDEs) may be presented with line crossings of any kind, and so need in their arsenal the best fit analysis for the possible mixed-media before them.

Over the years, many destructive and non-destructive techniques have been developed for or applied to the examination of crossed lines; Rodrigues e Brito et al. have published a comprehensive review of the research to date in this regard.<sup>1</sup> The methods outlined in this compendium include microscopy, lifting techniques, the use of electrostatic detection devices, chemical analyses, chemometric, and advanced imaging techniques. While this presentation outlines the use of XRF techniques to resolve problems of crossed lines, there is little research on the application of LA-ICP/MS.

This research explores the use of LA-ICP/MS and XRF as semi-destructive and non-destructive techniques, respectively. LA-ICP/MS is a highly sensitive analytical chemistry technique used to determine the trace element concentration and elemental distribution of a wide range of solid samples. This technique can be considered semi- or micro-destructive in that, with an appropriate stage, a document need not be cut or otherwise destructively manipulated. However, the technique uses a laser to directly ablate, or burn, the sample surface for a total volume of <1µg, thereby ensuring the integrity of the sample and allowing for other measurements using different techniques. XRF is a non-destructive analytical technique in which a primary X-ray beam is used to excite fluorescent radiation from the sample, yielding an elemental map of the region of interest.

Twenty-five writing instruments of various ink formulations were used to create intersecting lines with printed matter from five devices and with paper designed for use with the printing devices (e.g., inkjet, photocopy, laser papers). The crossed lines were created such that the sequence was cataloged and blinded from the rest of the study team. The samples were imaged, observed microscopically and macroscopically, then run using both techniques. The resultant analytical output and crossed lines were examined by 5 FDEs and 20 non-examiners to determine if: (1) the individuals could easily and reliably determine the sequence of strokes based on the output, and (2) there was a difference between the results from the FDEs and laypeople. Notwithstanding the complexity of intersecting line problems, this study adds to the body of research to determine reliable techniques for use by FDEs in casework.

### J14 The Comprehensive Analysis of Counterfeit Currency

*Irina Geiman, MS\*, United States Secret Service, Washington, DC 20223*

---

**Learning Overview:** After attending this presentation, attendees will understand the need for a comprehensive examination of highly deceptive counterfeit currency and the timely dissemination of the findings to key stakeholders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing the understanding of chemical and instrumental analysis techniques as they pertain to the examination of counterfeit currency. This presentation will discuss analysis and comparison of materials found in counterfeit Federal Reserve Notes originating on three different continents.

Counterfeit United States currency is found throughout the world but is often of poor quality and is easily detected by cash handlers and banknote scanning equipment. However, highly deceptive counterfeit Federal Reserve Notes occasionally appear in circulation and provide an excellent opportunity to study the techniques used by criminal elements to reproduce currency components, such as paper, inks, and security features. Understanding the materials and methods employed by the counterfeiters allows the United States Secret Service (USSS) to investigate the relevant supplies, manufacturing, and distribution networks.

Depending on the sophistication level of the counterfeiting efforts, the notes may contain printing inks of the types found in genuine Federal Reserve Notes. The intaglio inks, metallic inks, and optically variable inks are of particular interest to USSS as they may provide information about the intended distribution routes of the counterfeit notes. For example, the presence of optically variable ink with a well-simulated color change indicates intent for person-to-person distribution, while the presence of magnetics indicates intent to deceive banknote scanners. Counterfeit notes may also contain custom paper incorporating counterfeit security fibers, security threads, and watermarks.

Access to a full suite of analytical instrumentation allows the USSS Counterfeit Forensic Section Document Analysts to conduct in-depth profiling of the materials found in counterfeit United States currency. For example, Fourier Transform Infrared (FTIR) spectroscopy may be utilized to analyze polymers of counterfeit security fibers, security threads, and security ribbons. X-Ray Fluorescence (XRF) spectrometry may provide valuable information about the elemental composition of the paper and ink while Microspectrophotometry (MSP) is essential for examination of the color gamut of counterfeit materials.

Examination of the individual counterfeit currency components provides information on the types and the consistency of the employed materials plus allows the USSS to build an overall picture of the counterfeiter's skills and potential motivations. Such information is then disseminated to the key stakeholders to be able to forensically link counterfeit notes and cases and to assist investigators in developing timely leads. It also helps the United States Currency Program members study the reliability and effectiveness of the current genuine security features.

---

#### Currency Analysis, Counterfeit Currency, Federal Reserve Note

### J15 Assessing the Impacts of Induction Spatial Effects on Magnetic Flux Measurements of Toners

*Carrie Polston, BA\*, Sam Houston State University, Huntsville, TX 77341; David E. Thompson, PhD, Sam Houston State University, Department of Chemistry, Huntsville, TX 77341; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX 77340*

---

**Learning Overview:** After attending this presentation, attendees will understand: (1) the potential for the use of a quantitative magnetic flux measuring device to differentiate between black-and-white toner-printed documents from different sources, and (2) the magnetic characteristics exhibited by toner printed documents and how to employ magnetic flux measurement techniques during comparative examinations between questioned and reference printed texts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a method for quickly screening black-and-white toner-printed documents, reducing the need for more time-consuming or destructive methodology.

This study expands on questions raised by previous research into magnetic properties of toner. Specifically, this research investigates the effects of the external biasing unit on the repeatability of magnetic flux measurements of toner-printed documents. The hypotheses advanced were that: (1) the sample does not reach saturation magnetization for all particles if the sample distribution is abnormally shaped and the surface area of the toner exposed to the induction current is less than one-fourth of the total sample surface area, and (2) hysteresis effects can enhance or suppress the native magnetic flux of the sample depending on the sensor orientation relative to the native flux field of the sample. Both phenomena could lead to aberrant measurement values which are not representative of the true value for the sample and can increase the apparent sample inhomogeneity and measurement uncertainty if not controlled.

To test these hypotheses, measurements were conducted on five samples collected from different printing devices. The samples were printed with controlled grids of square, rectangular, and elongated rectangular blocks that all had the same area as well as line grids of differing densities. Thirty measurements were conducted on each sample and on each grid type, with the sensor oriented so the rectangles or lines were parallel to the induction current. The measurements were repeated in planes of rotation of 90°, 180°, and 270° counter to this original position. The values obtained for each sample in the different planes of rotation for the square grid were compared with a *t*-test to evaluate the presence and impact of hysteresis effects. The values obtained for each sample in the different planes of rotation for the rectangular grids were compared to those obtained for the square grids using the *t*-test to determine the impact of the induction current orientation effects.

It was found that both hysteresis and induction current orientation effects had a significant effect on the results obtained when comparing the measurements taken from one sensor orientation to those taken from another orientation (*p* value <.01). However, the magnitude of the hysteresis effects was smaller (<20% enhancement or suppression) than the magnitude of the induction orientation effects (up to 90% suppression). The hysteresis effects were also found to be reciprocal, with enhancement values mirrored by equal and opposite suppression values in another plane of orientation. This indicates that the hysteresis effects can be controlled via sampling methodology. New quantitative methods are needed to anticipate and correct for orientation-induced variation in the measured magnetic flux. Important inputs for such methods will include the surface area of the toner and its orientation relative to the induction current.

These findings have identified orientation effects as a significant source of variability in magnetic flux data and the need for new quantitative models that correct for this variability. The ability to recognize and correct for orientation-induced variations will be critical to the future implementation of a method using magnetic flux measurements in forensic laboratory settings, where there is a need for rapid, non-destructive screening of toner-printed documents.

---

#### Questioned Documents, Toner, Magnetic Flux

### J16 Contested Estates: A Bloody Mess

*Khody R. Detwiler, BS\*, Lesnevich & Detwiler, Roaring Spring, PA 16673*

---

**Learning Overview:** After attending this presentation, attendees will better understand how blood differs from writing ink formulas within the scope of the forensic document examination field, and why many certain writing production methods and instrumentation are simply not compatible with materials such as blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) showing the intricacies of conducting an analysis of extended handwritten entries produced entirely in blood, and (2) providing a unique perspective into the limitations that blood may impose upon certain production methods and writing instruments.

From examining letters and notes in homicide cases to identifying authors of forged checks, Forensic Document Examiners (FDEs) are often called upon to provide opinions in a variety of complex situations. Many of these cases unfold through a unique web of interesting facts and circumstances. Some of the most captivating cases seen in the forensic document examination field arise when family members become embroiled over money and assets in highly contentious estate matters. This presentation focuses on one such case involving the authenticity of a handwritten codicil, which determined the true heirs of a multi-million dollar estate. Although this may have seemed like a straightforward forensic handwriting case, it was anything but, as this codicil was written entirely in blood.

To make matters even more interesting, opposing counsel took the position that if the writing was deemed genuine, then the codicil was nothing more than a fabrication produced with the aid of an autopen or some other similar mechanical writing instrument. In addition to completing a forensic handwriting analysis to determine the authenticity of the writing at issue, counsel's position required further research to be conducted into identifying how or why certain methods of production would, or would not, be plausible due to the writing at issue having been produced with blood. This stage of the analysis revealed quickly that very little information is available within the scientific community pertaining to the examination of writings produced with blood.

This presentation will walk attendees through the entire examination and testimony process, highlighting the specifics of the actual analysis and research conducted, and will further discuss how the evidence was presented at trial, leading to a successful outcome.

---

#### **Handwriting, Blood, Fountain Pen**

### J17 A Comparative Study of Generation Y and Generation Z Signatures

Nina A. Harnarine, BSc\*, Forensic Examiners, Inc, Toronto, ON M4W 3H1, CANADA

---

**Learning Overview:** After attending this presentation, attendees will understand the handwriting characteristics observed in Generation Y and Generation Z signatures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing handwriting characteristics observed in the younger generations' signatures, those that are shared within Generations Y and Z, and if differences exist between the generations.

Before 1980, writing was taught in North American schools using copybooks from published writing systems. After 1980, there was a shift in the North American public schools for students to copy their teacher's writing on the chalkboard.<sup>1</sup> The North American educational curriculum over the years has had less focus on penmanship and writing instruction. As of 2006, some Provinces in Canada have eliminated cursive writing as a learning expectation in the curriculum.<sup>2</sup> As of 2013, approximately 45 states in the United States have removed cursive writing instruction from the curriculum.<sup>2</sup>

Generation Y or the Millennial Generation was born between the early 1980s and the mid-1990s. Generation Y was one of the first generations to grow up with computers, the internet, and cell phones. They were exposed to technology and many became technologically savvy. Several individuals from Generation Y were exposed to cursive writing instruction but have reverted to hand printing.

Generation Z or the Post-Millennial Generation was born between the mid-1990s and the mid-2000s. At a very young age, Generation Z was exposed to technologies, such as computers and tablets. They have become highly proficient in the use of technology. Some individuals within the younger generation have had no formal cursive writing instruction and are unable to write or even read cursive writing.

The younger generations often prefer to type on an electronic device versus writing with pen and paper. Speech-to-text is also a popular option. Video chat, text, or direct messaging is favored over handwritten correspondence.

This project sets out to compare the signatures of Generation Y and Generation Z. Participants from this study ranged in age from 18 to 39 years (born 1980 to 2001) and learned to write in North America. The Generation Y participants ranged in age from 24 to 39 years (born 1980 to 1995). The Generation Z participants ranged in age from 18 to 23 years (born 1996 to 2001). Ten specimen signatures were collected from each participant. Handwriting features that were assessed include: type of writing, style of writing, skill, case of writing, letter construction, connections, punctuation, initial and terminal strokes, size, flourishes, line quality, alignment, positioning, and range of variation.

It is hypothesized that Generation Z writers will have less connections, introduce more hand printed forms, have poorer line quality, and have a lower skill than Generation Y.

Signatures are important in authenticating documents. Do Generation Y and Z still value pen-and-paper signatures? The educational and societal changes that distinguish Generations Y and Z from past generations include: the lack of formal penmanship training in cursive writing and the shift toward electronic communication. Are there unique features in Generations Y and Z signatures that set them apart?

### J18 A Social Science Paradigm for Forensic Handwriting Identification

Carole E. Chaski, PhD\*, ALIAS Technology, LLC, Georgetown, DE 19947

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the possibility of applying a social science paradigm to forensic handwriting identification using the model presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing: (1) principles for applying the social science research paradigm to forensic handwriting identification and other pattern-recognition forensic sciences, and (2) ways that this paradigm could shift current practices.

Forensic handwriting identification is practiced within governmental crime laboratories and independent consultancies and was the first forensic science to come under the scrutiny of the *Daubert* factors for scientific evidence.<sup>1</sup> In the past 20 years, there have been *Daubert* challenges, generally with mixed results: some exclusions, some inclusions, and some restricted inclusions of testimony.<sup>2,3</sup> The forensic document examination community, the legal community, and the academic research community have offered multiple solutions for meeting the *Daubert* factors, including the development of software for fully automated handwriting identification, such as CEDAR-FOX and FLASH-ID, proficiency experiments, and consensus-based standards in groups such as Technical (Scientific) Working Group on Questioned Documents and the Organization of Scientific Area Committees subcommittee for forensic document examination.<sup>4,5</sup> All of these solutions stem from the desire to provide forensic document examination, and especially handwriting identification, with an acceptable and feasible scientific foundation, objectivity, and mitigation of confirmation bias.

This presentation focuses on a social science research paradigm that can be applied to handwriting identification as well as other pattern recognition techniques. This social science paradigm is already accepted within major social sciences (e.g., psychology, linguistics, sociology).<sup>6-9</sup> While social sciences (e.g., psychology, linguistics, sociology) are known for strong quantitative analysis and laboratory experimentation, they also provide research guidelines for qualitative assessment based on educated judgments. The main purpose of this paradigm within the social sciences is to produce objective results when the analysis is based on qualitative assessment. This paradigm involves an administrator and a small team of at least three experts. The experts work independently (“blindly”) using a checklist as well as unstructured notes for the analysis of items, performing a qualitative assessment of the data. This paradigm provides a measure of reliability for the assessment using well-known and standard statistical procedures for inter-rater reliability (i.e., agreement among qualitative assessments).<sup>10</sup> The paradigm’s experimental design or workflow can easily be replicated. Finally, this paradigm can be adopted in both governmental laboratories and independent consultancies, which could lead to standardization in the field.

The social science paradigm has already been employed in forensic linguistics for the qualitative analysis of suicide notes and threat letters.<sup>11</sup> The workflow for this paradigm in forensic linguistics has been implemented in software to insure that: (1) the administrator manages the team objectively, (2) the team members actually do work independently (“blindly”) and cannot be influenced by each other’s assessment (thus avoiding group-induced confirmation bias), and (3) the administrator runs the automated quantitative assessment of the team’s collective decision and inter-rater reliability. The report based on this paradigm includes both the collective decision and the inter-rater reliability so that the strength of the decision can be evaluated using statistical information.

This social science paradigm differs in several important ways from current practices in both governmental crime laboratories and independent consultancies. Thus, there may be cultural resistance to adopting this paradigm. On the other hand, if adopted by the forensic document community, forensic handwriting identification could align with standard social sciences.

#### Forensic Handwriting Identification, Social Science, Inter-Rater Reliability

### J19 Seen and Unseen Evidence of the Shroud of Turin and Use of the VP-8 Image Analyzer

*Janis Winchester, MS\*, Fort Myers, FL*

---

**Learning Overview:** After attending this presentation, attendees will understand the Shroud of Turin and the use of the scientific instrument, the VP-8 Image Analyzer, that assists with demonstrating the apparent 3D-relief image on the Shroud of Turin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining the Shroud of Turin and the methods and materials used with the VP-8 Image Analyzer to show the apparent 3D-relief image on the XYZ axis as the brightness information of the grayscale.

The Shroud of Turin documents an image of a man consistent with the events leading up to the crucifixion and death of Jesus of Nazareth, approximately two thousand years ago. It is believed to be the burial cloth which wrapped Jesus Christ when he was laid in the tomb, after he was taken down from the cross. Of interest today is that the linen cloth documents these historical events. The bodily image on the cloth indicates that the body was placed supine on half of the approximately 14-foot linen fabric, and the other half was pulled over the head, then laid on top of the body. Today this linen cloth is maintained in Turin, Italy, in a specially made environmental case.

Although the VP-8 Image Analyzer is no longer in production, other technologies may show the apparent 3D-relief image. The VP-8 provided one of the early analog image projections in the 1970s. This was of interest to the distinguished scientists, representing a vast range of scientific expertise, who were involved with the initial Shroud of Turin Research Project (STURP). The use of the VP-8 Image Analyzer was one of the deciding factors used by the scientists prior to their traveling to Turin, Italy, to examine the original linen cloth in 1978. The scientists examined the fabric, performed various tests and experiments focusing on what may have caused the image formation, and noted the other evidence they found on the cloth. They issued a scientific report of their findings in 1981 and described additional areas of research. The most comprehensive data on the Shroud of Turin is available on the website at [www.shroud.com](http://www.shroud.com). It is available to scientists and anyone interested in learning more about this unique mystery.

The VP-8 uses the input of a 2D photograph of the Shroud of Turin, from an image analysis camera, to visualize an apparent 3D relief image. What appears is that of a relief image of the Man of the Shroud, not seen on the normal 2D photograph. This unique phenomenon may indicate radiating energy, possibly photons from a possible blast of radiation parallel to gravity. The VP-8 records the data that is then imaged on the display monitor.

Given the uniqueness viewed on the display monitor of the possible photons from a potential source such as radiation, the VP-8 Image Analyzer assists in this visualization of the photographic grayscale. This characteristic, along with the fact that the image of the man of the Shroud of Turin is found on the inside of the folded linen, indicates the radiating energy came from the body of the man within the folded cloth. Additional research is ongoing.

This case study describes a unique phenomenon on the linen of the Shroud of Turin along with references for further investigations. Additional research, such as the examination for possible letter forms, pollen, body fluids, and other areas for forensic research is intriguing, along with how the image was formed on the burial cloth of the Shroud of Turin.

---

#### **Shroud of Turin, VP-8 Image Analyzer, Evidence**

### **J20 The Discrimination of Primary and Secondary Impressions on the Second Page of a Two-Part Carbonless Copy Paper Using VSC40: A Case Study**

*Muneeb H. Khan, MPhil, Punjab Forensic Science Agency, Lahore, Punjab 54700, PAKISTAN; Khurram W. Mahmood, MPhil, Punjab Forensic Science Agency, Lahore, Punjab 53700, PAKISTAN; Muhammad Irfan Ashiq, PhD\*, Punjab Forensic Science Agency, Lahore, Punjab 54500, PAKISTAN; Mohammad A. Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, PAKISTAN*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the importance of performing examinations on an original questioned document instead of its photocopy and the need for the examination of all areas of the document instead of examining only a requested area of the document. A better understanding among the partner departments and agencies will be recognized with the goal of facilitating evidence-based justice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a reference for the examination of questioned items beyond the scope of requested examinations.

In Pakistani banks, customers are required to fill out bank-issued, two-part, carbonless copy paper “Bank Deposit Slips” to deposit cash in their bank accounts. The depositor submits filled slips to the bank officer along with the cash deposit. The bank officer then verifies details and mentions the total cash amount received along with the number and denomination of bills. After all verifications, the bank officer cross-signs and dates the “Bank Deposit Slip” and returns the 2<sup>nd</sup> page (i.e., Depositor’s Copy) to the depositor. In normal practice, each set of “Bank Deposit Slips” is not placed as a separate set but in the form of booklet. This case study involves one such instance in which the depositor used a “Bank Deposit Slip” to deposit a cash amount of PKR 849,500 to the account of a seller for the purchase of some goods. However, he did not realize that it already contained secondary impressions on the 2<sup>nd</sup> page due to the pen pressure used on the previously filled “Bank Deposit Slip” in the booklet. Later, the seller registered a complaint with the local police station that the depositor has submitted a copy of a deposit slip after altering the amount from PKR 849,500 to PKR 8,049,500 and received goods against the altered amount. The case was submitted to the Questioned Document Department for analysis to examine suspected tampering on the questioned copy of the deposit slip.

To analyze the evidence for tampering, an examination was conducted utilizing the Foster & Freeman Video Spectral Comparator 40 (VSC40) and all fields on the questioned depositor’s copy of the “Bank Deposit Slip,” including the account title, account number, date, total amount in words, amount, total amount, depositor’s signature, and contact number, were examined. Denominations, quantity, and amount were examined by using the spot fluorescence filter in the range of 560nm–680 nm with a long-pass barrier filter 725nm in front of the camera of the VSC40. This report discusses quite unusual findings from this optical examination. Multiple primary and secondary impressions were deciphered. Based on the observations recorded by the use of the above-mentioned settings on VSC40, if only the requested fields were tested, it would have resulted in the false identification of tampering in the fields account title, account number, date, total amount in words, amount, total amount, depositor’s signature, and contact number. Complete examination of the questioned “Bank Deposit Slip” along with the firsthand knowledge of common banking procedures for depositing cash into an account in Pakistan, helped reveal the fact that the questioned “Bank Deposit Slip” did not contain any indications of tampering, but only contained the secondary impressions due to the previously placed two-part carbonless copy paper above it.

### J21 Contemporary Challenges, Expert’s Insights, and Judicial Perspectives on Forensic Document Examination Testimony

*Jan Seaman Kelly, BA\*, Forensic Dynamics LLC, Las Vegas, NV 89147; Stephanie Domitrovich, JD, PhD\*, Sixth Judicial District of PA, Erie, PA 16501*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the challenges encountered in providing testimony in a *Daubert* or *Frye* hearing and the perspectives of the judiciary who oversee the hearings.

**Impact on the Forensic Science Community:** The presentation will impact the forensic science community by showing the challenges faced in contemporary *Daubert* or *Frye* hearings as well as understanding the perspectives of the judiciary.

Prior to the 1993 decision in *Daubert vs. Merrill Dow Pharmaceuticals*, state and federal courts heard challenges to expert testimony relying on Federal Rules of Evidence 702 or *Frye v. United States*.<sup>1,2</sup> The Federal Rules of Evidence 702 states an expert who possesses the knowledge, skill, experience, training, or education may testify in the form of an opinion if it will assist the trier-of-fact. In *Frye v. United States*, the admissibility of scientific evidence is based on general acceptance.<sup>1</sup> Seventy years later, *Daubert v. Merrell Dow Pharmaceuticals* stated the judge, as the “gatekeeper,” is responsible in determining whether the scientific evidence the expert will testify to meets the five *Daubert* criteria.<sup>2</sup> The five criteria that are to be applied to determine if the expertise meets scientific rigor are as follows: (1) whether a method can or has been tested, (2) the known or potential rate of error, (3) whether the methods have been subjected to peer review, (4) whether there are standards controlling the technique’s operation, and (5) the general acceptance of the method within the relevant community. The *Daubert* Court also emphasized that these five factors be applied by trial judges in a flexible manner. Trial judges have great discretion in deciding on the admissibility of evidence; appeals from *Daubert* rulings are subject to a very narrow abuse-of-discretion standard of review.

Moreover, Federal Rule of Evidence 702 requires the following for expert testimony: A witness who is qualified as an expert by knowledge, skill, experience, training, or education may testify in the form of an opinion or otherwise if: (1) the expert’s scientific, technical, or other specialized knowledge will help the trier-of-fact to understand the evidence or to determine a fact in issue; (2) the testimony is based on sufficient facts or data; (3) the testimony is the product of reliable principles and methods; and (4) the expert has reliably applied the principles and methods to the facts of the case.

Also, under Federal Rule of Evidence 403, the trial judge may exclude relevant evidence if its probative value is substantially outweighed by the danger of unfair prejudice, confusing the issues, misleading the jury, undue delay, wasting time, or needlessly presenting cumulative evidence. Federal case law recognizes that certain situations call for exclusion of evidence that is of unquestioned relevance. These situations entail risks ranging from inducing decisions on purely emotional bases to confusing or misleading jurors. Trial judges must balance the probative value of and need for this evidence against the harm likely to result from admitting said evidence.

Several state courts, such as New York and Pennsylvania, still apply the *Frye* standard instead of the *Daubert* standards. Trial judges in *Frye* jurisdictions, in essence, defer to the scientists and admit expert opinion based on scientific techniques only where the techniques are generally accepted as reliable in the relevant scientific community.

Forensic document examiners have offered testimony in *Daubert* and *Frye* challenges for more than 20 years. A few of those challenges resulted in limited testimony or exclusion based on the gatekeeper’s determination that the profession lacked published standards and testing to establish reliability. As a result, the forensic document profession responded by drafting and publishing standards for various examinations, training, and conclusions, as well as participating in research studies conducted by academia.

This presentation will discuss the impact of testimony describing the profession’s work in publishing standards and the results of testing on the *Daubert* and *Frye* challenges that have occurred over the past several years in numerous state and federal jurisdictions. After attending this presentation, attendees will have a better comprehension of the trial court’s admissibility standards regarding expert testimony as to forensic document examination.

The importance of explaining in detail the basis for the issued conclusions, the established reliability of the field of forensic document examination as well as the practitioner through testing and research, and the work of the Organization of Scientific Area Committees (OSAC) subcommittee in drafting or revising current standards in the field of forensic document examination will all be discussed.

### J22 Photo-Polymer Stamps: Their Examination and Identification

*F.L. Jim Lee, Jr., MS\*, Summit Forensic Document Examination Lab, Eden, UT 84310*

---

**Learning Overview:** The goal of this presentation is to introduce attendees to the examination of defects in a stamp impression made from a photo-polymer stamp for the purpose of identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing awareness of the forensic document examination of photo-polymer stamps that the questioned document examiner may encounter.

Questioned document examiners may encounter diversity in the makeup of the stamps in this class of devices. “The diversity is not limited to classification based upon makeup. The actual material from which the stamp is constructed, and its mode of manufacture adds to the possible verities.”<sup>1</sup> A forensic document examiner must not only be aware of the many factors that can cause individual or unique features in a photo-polymer stamp and its impression, but also must be able to evaluate and interpret the significance of any specific characteristic and the relevance it may have to the question or problem under examination. The Scientific Working Group for Forensic Document Examination (SWGDOC) has produced standards that supersede the *ASTM E 2289-03 Standards*, published by the American Society for Testing and Materials, International. These published standards provide the procedures that should be used by forensic document examiners when conducting examinations and comparisons involving rubber stamps and their impressions. These standards are of great importance to the questioned document examiner for it is the questioned document examiner who must be “able to interpret the significance of any particular feature, the relevance it has to the problem in hand, the weight of opinion it merits and the depth of knowledge that can be gained from it.”<sup>2</sup> Of consideration to the forensic document examiner should always be the possibility of the existence of a duplicate stamp. Because of the existence of this possibility, often the forensic document examiner should maintain a conservative approach when rendering his or her opinion on examinations. Oftentimes, an inconclusive finding will need to be rendered instead of a positive identification of a specific stamp.

This presentation will provide an overview of the process involved in the manufacture of photo-polymer stamps. Additionally, this presentation will discuss the results of research conducted by the presenter in evaluating the results of the attempt of several forensic document examiners to examine and compare stamped impressions from a specific photo-polymer stamp manufactured for this purpose and the accurateness of their opinions in comparison with the ground truth solution of the problem provided.

### J23 Invisible Migration of Luminescent Components in Inks in Crossed-Line Intersections

*Rhett Williamson, PhD, Florida International University, Miami Beach, FL; Daniela Djidrovaska, MS, Interpol Lyon, Lyon, FRANCE; Andrea Ledic, BS\*, Croatian Forensic Science Centre "Ivan Vucetic," Zagreb, Europa 10000, CROATIA; Vesna Antikj, MS, Forensic Department, Skopje, MACEDONIA; Stjepan Brzica, BS, Forensic Science Centre "Ivan Vucetic," Zagreb, CROATIA; Rolf Hofer, PhD, Forensic Science Institute Zurich, Zurich, SWITZERLAND; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the interactions of luminescent inks in crossed-line intersections.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping determine the chemical identity of the luminescent compounds present in the formulation of inks to better understand the interaction of different inks in crossed-line intersections.

Characterizing the fluorescent components of inks, most commonly dyes, is very useful in document examination for association, discrimination, and intelligence purposes. Optical methods such as fluorescence, infrared luminescence, and spectroscopic methods such as Fourier Transform Infrared (FTIR) spectroscopy, and Ultraviolet/Visible (UV/VIS) spectroscopy rely on these properties. In addition, chromatographic, spectroscopic and mass spectrometric techniques such as High-Performance Liquid Chromatography (HPLC), Gas Chromatography (GC), paper chromatography, Nuclear Magnetic Resonance (NMR) spectroscopy, and Liquid Chromatography/Mass Spectrometry (LC/MS), and Gas Chromatography/Mass Spectrometry (GC/MS) have been applied to the analysis of dyes and pigments.

In recent years, laser desorption has been applied to the analysis of inks, with success in characterizing the dye, pigment, and, more limitedly, the polymeric content of the inks on paper in combination with other techniques such as Thin-Layer Chromatography (TLC) and Raman spectroscopy.

This study involved independent analyses of several inks by three laboratories in Croatia, Macedonia, and the United States. A combination of TLC, GC/MS, HPLC, Matrix-Assisted Laser Desorption Mass Spectrometry (MALDI-MS), Direct Analysis in Real-Time Mass Spectrometry (DART<sup>®</sup>-MS), and LC/MS were implemented by the three laboratories in order to characterize the luminescent components of inks present in crossed-line intersections. A combination of luminescent compounds, including crystal violet and methyl violet, were characterized and identified to be present in mixtures in the ink formulations utilizing each of the analytical techniques included in this study. When inks interact in crossed-line intersections, invisible migration may occur. This migration is a result of the intersection of the liquid inks with one another, causing a solvation effect. This causes the luminescent compounds, in this case crystal violet and derivatives. However, the temporal sequence of deposition of inks present in crossed-line intersections could not be determined. The protocol described here allows for the isolation and characterization of luminescent compounds present in the formulation of inks to varying degrees, and the information presented here can be used in the future establishment of a standard protocol for the identification of luminescent compounds in inks.

---

#### **Ink, Crossing-Line Intersection, Crystal Violet**

### J24 Reasons for Qualified Opinions in Forensic Document Examination

Jane A. Lewis, MFS\*, Milwaukee, WI 53202

---

**Learning Overview:** After attending this presentation, attendees will be familiar with the current reasons for qualified opinions in forensic document examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by developing an appreciation for the major causes of less-than-definite findings in the reports of forensic document examiners resulting from their casework examinations of disputed handwriting.

This study was motivated by recent questions from attorneys asking why less-than-conclusive opinions were necessary in reports. When submitters deliver questioned handwriting evidence for analysis, they expect that the resulting opinion will be an identification or an elimination. The use of electronically saved documents at low resolution and the tendency of individuals and businesses to scan and destroy original documents imposes limitations on the examinations of forensic document examiners. This study was conducted to determine the main reasons for questioned handwriting cases resulting in qualified opinions. Scales of opinions are typically used by forensic document examiners to convey the level of confidence that the evidence in the case will support. The goal of each examination is to determine the origin or authenticity of the questioned material. Limitations of the evidence will lead to a less-than-definite conclusion expressed as a qualified opinion. Appreciation for the reasons behind qualified opinions will help spur attorneys and investigators to search for the best quality case evidence. Original questioned and known documents will provide the most detailed information to allow document examiners to properly do their work.

Case files from 2015–2017 and the first half of 2018 were reviewed to determine the reasons for qualified opinions in each case. Ten specific reasons for qualified opinions were discovered from studying 49 cases. Evaluation of each case and the reasons for the qualified opinions generated were tallied. The three main reasons for qualified opinions in the case files were: (1) the lack of contemporaneous known writing, (2) the lack of known writing comparable to the questioned writing, and (3) the submission of poor clarity copies. The submission of poor clarity copies was the most common reason for a qualified opinion in a questioned handwriting case. A substantial number of cases displayed two reasons for reaching a qualified opinion.

The study sought to specify the precise reasons that forensic document examiners rendered qualified opinions in questioned handwriting cases. The study pointed to three significant reasons and seven other important reasons for the findings. The study suggests that informing submitters of the specific reasons for qualified opinions in questioned handwriting cases will lead investigators and attorneys to strive for the best evidence submissions in each case, which will include original questioned and known documents or good quality first-generation copies.

---

#### Handwriting, Qualified Opinion, Copies

### J25 The Admissibility of Hand Printing Identification in the United States Courts

Karen J. Nobles, BA\*, Forensic Document Services, LLC, Pensacola, FL 32591-0411

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the admissibility of hand printing identification in the courts in the United States.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information and tools to improve the success rate of hand printing testimony.

Both federal and state courts in the United States have generally treated expert testimony from a forensic document examiner about the identification of handwriting and the identification of hand printing in the same manner. Logically, this seems to be the correct approach because the methodology for the comparison of questioned and known handwriting samples and the comparison of questioned and known hand printing samples is the same. In fact, the *Standard for Examination of Handwritten Items*, published by the Scientific Working Group for Forensic Document Examination (SWGDOC) in 2015 defined the type of writing covered by the standard as, “hand printing, cursive writing, numerals, symbols, or combinations thereof ....” In addition, most of the historical and current literature that discusses handwriting identification does not differentiate between cursive handwriting and hand printing when discussing the methods and procedures for examination and comparison. However, in some legal cases, the court has addressed hand printing identification separately from handwriting identification. In those courts where the identification of hand printing has been evaluated individually, hand printing identification has been subjected to numerous inconsistent decisions. Expert testimony about hand printing identification has been randomly admitted, excluded, and limited in court districts across the United States. After conducting both legal and non-legal research and reading through all the publications and the opinions in the relevant cases, there is a notable anomaly in the decisions regarding hand printing evidence in the United States courts. If expert hand printing testimony is proffered, the court generally admits the testimony for the trier-of-fact to consider in making their decision. In fact, prior to *Daubert*, research for this study was unable to find a single instance in which hand printing testimony was excluded. However, post-*Daubert*, if the admission of the hand printing testimony is challenged, the testimony of the handwriting expert is generally limited, or even excluded. If a challenge is not filed, the handwriting expert can testify to the identification of hand printing as routinely as any other examination.

This study looks at the reasoning of the court in each of these cases, especially considering the criteria developed in the landmark case of *Daubert v. Merrell Dow Pharmaceuticals*, and provides both historical and current supplemental publications and legal decisions that can be used by forensic document examiners to support the reliability of hand printing identification.<sup>1</sup> This supplemental information can be utilized to satisfy the court’s requirements, whether it applies the *Frye v. United States of America* standard (general acceptance) or the *Daubert* standard, in which the judge is tasked with determining if the science meets each of the five criteria.<sup>2</sup>

### J26 Pairwise Comparison Scores for Handwritten Questioned Documents

Danica Ommen, PhD\*, Iowa State University Department of Statistics, Ames, IA 50011; Cami Fuglsby, MS, Department of Mathematics and Statistics, Brookings, SD 57007; Christopher P. Saunders, PhD, Brookings, SD 57006; Michael Caligiuri, PhD, University of California, San Diego, CA 92093; Linton Mohammed, PhD, Forensic Science Consultants, Inc, Burlingame, CA 94010-2017; JoAnn Buscaglia, PhD, FBI Laboratory, CFSRU, Quantico, VA 22135

**Learning Overview:** After attending this presentation, attendees will better understand the value of pairwise comparison methods for designing tests of scientific validity for forensic feature comparison methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating an alternative use for pairwise comparison methods beyond automated source identification applications.

**Hypothesis Statement:** Methods resulting in pairwise comparison scores can be used in designing tests of scientific validity for a variety of forensic feature comparison methods, specifically in the case of validating questioned document examiners' conclusions.

In 2016, the President's Council of Advisors on Science and Technology released a report that advocated for further research into the scientific validity of all forensic feature comparison methods, including methods for handwriting evidence.<sup>1</sup> One of the research initiatives identified by the Organization of Scientific Area Committees, overseen by the National Institute of Standards and Technology, in response to this report seeks to validate the conclusions expressed by forensic document examiners regarding the weight or the value of the evidence in a particular comparison. To design the experiments needed to test examiners' conclusions, it is often necessary to pair handwritten documents with various levels of correspondence for the test comparisons performed by the examiners. In this way, the document examiners' conclusions will not be skewed by receiving, for example, only very easy comparisons. Since this pairing needs to be done quickly and effectively, we have been developing an automated method of comparing two documents that would produce a "score" indicating the level of similarity between two documents. Scores that are high indicate writing that is visually similar, and scores that are low indicate writing that is visually dissimilar. This score can then be used to provide the examiners with a range of difficulty in the test comparisons. The idea is that the person designing the test comparisons can pick out test comparisons that are from different writers with a high score to provide examiners with difficult exclusions, and test comparisons that are from the same writer with a low score to provide examiners with difficult inclusions. The test designer may also want to select easier test comparisons for both inclusions and exclusions, and a variety of pairs for comparison with moderate levels of difficulty.

In this presentation, a pairwise comparison score for images of scanned handwritten questioned documents using both open-source and proprietary automated image feature-detection methods will be developed. The Scale-Invariant Feature Transform (SIFT) and the Speeded-Up Robust Features (SURF) algorithms have demonstrated potential to identify important features of images for the purpose of comparing two general images of any content.<sup>2</sup> Woodard et al. demonstrated the use of these open-source algorithms for automated writer identification systems in the case of Arabic handwriting.<sup>3</sup> Gannon Technologies Group developed the proprietary FLASH ID algorithm to perform a similar writer identification task, regardless of the written language.<sup>4</sup> However, the algorithms first need to be trained on a set of images to create a dictionary/codebook of similar features to look for in the test images. Once the algorithm is trained, a single image is provided as the input, then a numerical representation of the important features in that image is output to the user. A method of comparing these numerical outputs to produce a similarity score indicating the level of correspondence between two scanned images of handwriting (cursive or print) will be demonstrated. The use of the scores on a collection of handwritten and handprinted English-language documents collected as part of an ongoing research effort will also be presented.

### J27 The Evolution of Security Features in International Travel Documents

*Carolyn Bayer-Broring, MFS\*, Immigration & Customs Enforcement, McLean, VA 20598-5116*

---

**Learning Overview:** After attending this presentation, attendees will have a more thorough understanding of how the construction of international travel documents evolves to meet new standards and thwart counterfeiters.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of the more common security elements and features that appear in international travel documents, showing how those elements evolve as needs arise.

For international travel, a person is usually required to provide documentary proof of citizenship for their home or adopted country before being allowed to board a train, boat, or plane, or to cross a country's border. In most cases, the required travel document is a passport or similar booklet that contains personalized data, which normally includes the date of birth and image of the bearer, to establish identity.

In the early 20<sup>th</sup> century, when passport use first came into the lexicon, the documents were not very sophisticated and were, in fact, sometimes very rudimentary. As their use became more widespread, the information contained in passports became more valuable and, thus, more susceptible to fraud and theft. Recognizing the valuable nature of that information, passport producers understood the need to secure the personalized data against misuse and counterfeiting. In earlier documents, that security was most often achieved using one or two security features of varying degrees of sophistication. As international travel became more popular, affordable, and more widely available, the documents evolved to become more sophisticated and secure.

In the 1940s, the International Civil Aviation Organization (ICAO) was formed by the United Nations to govern practices and standards regarding air navigation, including aspects such as flight inspection and facilitation of border-crossing procedures. As the ICAO developed and grew, among its many duties, it became the de facto dictating body for passport security. The ICAO was responsible for developing standards for the advancement and use of machine-readable travel documents, and more recently (in 2015) has developed standards for the design and use of biometric passports, which utilize Radio Frequency Identification (RFID) chips to store the valuable personalized data and information.

In this presentation, attendees will see a selection of international travel documents, showing how the documents evolved and advanced from the days prior to ICAO conformity through the progression of adding security features over the years to bring them into compliance. As travel documents continue to hold high value for criminals, such as terrorists and human smugglers, the necessity remains for passport designers to stay one step ahead of the counterfeiters. To meet these demands, document security designers are now developing more sophisticated and expensive features to thwart criminals. Savvy document designers recognize not only the need to utilize these sophisticated security features and safeguards, but to continue to meet financial demands that often limit how much can be spent on each booklet. This presentation will allow viewers to see how passport designers use a layered approach of security features of varying cost and sophistication to meet these goals.

### J28 Adding an Objective Approach to Questioned Document Examination Using Principal Component Analysis (PCA) and Mahalanobis Distance

Loren M. Williams, BS\*, Bethlehem, PA 18020; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104; Morgan Mills, MSFS, Burlington, NC 27215

**Learning Overview:** After attending this presentation, attendees will better understand the potential role that statistical analysis can play in helping to support subjective determinations of authorship in questioned document examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a simplified way to incorporate statistics into questioned document examination.

Document examiners have a skill that lay people do not. Studies have shown that professional examiners make fewer mistakes and are more accurate than laypeople when determining authorship of writing.<sup>1,2</sup> This skill, which is based on experience and expertise, is essential in helping to determine fraudulent writing and to correctly assign the writing origin of documents.

However, after the release of the National Academy of Science's Report on strengthening forensic science in 2009, it was made clear that objective measures of comparison are needed to augment and strengthen conclusions that are essentially subjective in nature.<sup>3</sup> One possible approach is to couple the skill of questioned document examiners with statistics to create a more objective methodology, allowing stronger conclusions to be made. Since questioned documents offer measurable characteristics such as the height of letters, the ratio of heights of adjacent letters, and the distance between words, the potential to use some form of multivariate statistical analysis in questioned document examination exists. To this end, this study incorporated the use of PCA and Mahalanobis distance to classify groups of known writing. In addition, the potential of using this method to compare an unknown with exemplar writing was explored.

To test this, 20 handwriting samples were collected from 50 individuals. The handwriting samples were all the same and taken on four different days. Writing was in script and the template used was a bank check. Various known features, such as height of capital and lowercase letters, distances between words, and ratios of letter heights, were measured using Adobe® Photoshop® 2017. Measurements were placed into a spreadsheet and used to perform PCA to attempt discrimination of handwriting between individuals. Of the 50 individuals, 32 were able to be distinguished visually when examining the principal components in a 3D plot. Unknown writing samples taken from 10 participants in the original 50 were collected and compared to the dataset. Using PCA, it was determined that each unknown could be visually placed into the correct data set. In addition, Mahalanobis distances were also calculated. Results from this statistical test showed that 8 of the 10 unknowns were able to be correctly classified into their respective data sets. An additional 10 unknowns were collected from individuals not in the original group of 50 and were compared to the dataset. The visual analysis using PCA indicated 9 of the 10 unknowns were not classified into any of the original 50 datasets, although the Mahalanobis distances placed several of the unknowns into one of the original 50 datasets based on criteria used in the study.

Results from the study seem to indicate that PCA offers the potential of objectively confirming conclusions reached in traditional questioned document examinations. Going forward, results reached in this study should be confirmed by the subjective examination of a trained document examiner. If results in this manner are consistent with the statistical analysis, it will lend credence to the use of statistical analysis (PCA in particular) to be used in tandem with traditional handwriting examination. This could help alleviate the criticisms often levied on handwriting comparisons as being too reliant on subjective analysis. Finally, PCA could be a tremendous tool in showing the variability in handwriting exemplars taken from individuals. Objective determination of this variability can be helpful in assessing the validity of particular exemplars used in writing comparisons.

### J29 An Exploratory Analysis of Handwriting Features: Investigating Numeric Measurements of Writing That Are Important for Statistical Modeling

*Amy M. Crawford, MS\*, Center for Statistics and Applications in Forensic, Ames, IA 50011; Alicia L. Carriquiry, PhD, Center for Statistics and Applications in Forensic, Ames, IA 50011*

---

**Learning Overview:** The goal of this presentation is to provide insights into which features of handwritten documents are important for statistical modeling with the task of writer identification and to discuss how these features overlap with features that questioned document examiners typically examine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing ongoing forensic statistics research to practitioners in the field. Collaboration and communication is fundamental to the success of emerging research.

In recent years, researchers have begun to uncover the process that document examiners follow when conducting a visual analysis of documents. This has been done using several approaches. One of the most fascinating is eye movement tracking, where a device tracks where the eyes are drawn and how long they stay fixated at certain locations on writing samples. This provides insight into which features are seemingly important to examiners when making decisions of writership. There has also been a significant emphasis on the use of data and statistical methodologies to assist in comparison of handwritten documents. For us, data are numeric measurements extracted from handwriting that has been scanned and processed. This research conducts a statistical analysis of measurements that have the power to discriminate between writers and will be important to a statistical model.

Decomposing a document to focus on smaller, meaningful bits of writing at a time lends nicely to an algorithmic approach to writer identification. These pieces of writing, often corresponding to letters, are treated as small graphs with nodes and edges and collect measurements from the graphs. Measurements such as curvatures, lengths, and slants of edges, relative heights of graph nodes, the diameter and shapes of loops, and many more are taken into consideration.

An exploratory analysis with a multitude of measurements is conducted. This is done by comparing features of graphs with similar structures across writers to investigate their ability to discriminate between writers. Measurements that separate writers well in a numeric capacity will be useful for statistical models. Such models are designed to complete the task of writer identification. The results of this feature analysis are discussed with relation to features of writing that document examiners typically consider important in casework as well as results from eye-tracking studies.

Since writing is a realization of a physical action and one cannot expect measurements taken from a single writer to be identical for every repetition of writing, a within-writer analysis is conducted. The writing samples used as data for this analysis were collected from a variety of individuals across the country. Participants were asked to complete writing tasks on a few occasions, each one month apart. The results of the within-writer analysis with respect to samples taken from a single writer with the same content and differing content will be discussed. These comparisons are conducted for writings in a single day, one month apart, and two months apart. These statistical analyses will provide numerical insights into how variable writing is for a single writer over varying periods of time.

#### Document Examination, Statistics, Writing Features

## Questioned Documents – 2019

---

**J30**    **WITHDRAWN**

### J31 A Comparison of Gaze Behavior in Sequential Versus Simultaneous Presentation of Signatures in a Handwriting Comparison Task

Mara L. Merlino, PhD\*, Kentucky State University, Frankfort, KY 40601; Chandler D. Al Namer, BA, Kentucky State University, Frankfort, KY 40601; Derek L. Hammond, BA, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297-5205; Robert S. Olson, Kentucky State University, Frankfort, KY 40601; Pierre Easley, BA, Kentucky State University, Frankfort, KY 40601

**Learning Overview:** After attending this presentation, attendees will understand some of the principles of cognitive psychology and the use of eye-tracking technology to study attention and feature-matching processes as they relate to the presentation of writing information in forensic document examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating different methods of unmasking information contained in writing samples on the visual behavior and decision accuracy in a signature comparison task.

A substantial body of research addresses the cognitive mechanisms involved in attention and visual search. Relational models of visual search demonstrate that visual attention can be guided by attending to specific feature values, such as color, size, or intensity, by inhibiting attention to irrelevant features, or by directing attention to how stimuli differ. Many current theories of attention propose that attention is based on “the interplay of a bottom-up, saliency-based attentional system and a top-down, feature-specific selection mechanism.”<sup>1</sup> According to Becker, another type of information that guides attention is relational information about the target, or information about how the irrelevant information of a non-target differs from the features of the target.<sup>1</sup> Relational models place the target in relation to its context, offering more specific (e.g., directional) information about differences.<sup>1</sup> This relational aspect of attention may also be influenced by the presentation formats of signature specimens.

Research on eyewitness testimony and studies on the use of sequential vs. simultaneous lineups in criminal investigations provide a conceptual framework for studying the effects of method of presentation on the deployment of attentional resources and the examination and weighting of signature specimens. Although simultaneous lineups are the most common procedure used in the United States, researchers argue that simultaneous lineups, which are relational in nature, result in biased judgments.<sup>2</sup> Witnesses are required to use “relative judgments” by comparing lineup members to each other, rather than relying on their memory for such comparisons. This method is problematic because if the true perpetrator is not in the lineup, then the witness will often implicate the lineup member who most closely resembles the perpetrator, resulting in a false identification.<sup>3</sup> Much of the laboratory research in this area indicates that sequential lineup procedures are less likely to be biased than are simultaneous lineups.

Subsequent field research using the double-blind sequential method of lineup presentation indicates that, in practice, the simultaneous procedure may produce fewer false identifications than the sequential procedure. The sequential lineup forces witnesses to resort to “absolute judgment” in which they can compare each photograph in the lineup only to their memories of the offender, but field studies of this phenomenon have demonstrated either equivocal or contrary results to lab studies.<sup>4</sup>

Kassin et al. stated, “Examiners should work ‘linear’ rather than ‘circular,’ thus initially examining the evidence from the crime scene and documenting their findings before making comparisons against a target. This will eliminate the potential influence of the target on how information is processed and the weight assigned to it.”<sup>5</sup>

The use of sequential rather than simultaneous presentation of signatures during a handwriting identification task has been discussed in the Forensic Document Examiner (FDE) community in Australia, but this procedure has not been empirically tested. This presentation reports the results of an empirical experiment investigating the differences in examination processes and the accuracy of signature comparison decisions when signatures are presented simultaneously or sequentially during a signature comparison task.

Sixteen signatures were presented during an experimental eye-tracking procedure (NIJ Award # 2015-DN-BX-K069). Signature comparisons were counterbalanced so that all 16 signature comparisons were viewed either simultaneously or sequentially. Participant gaze behavior was recorded using a Tobii X2-60 eye-tracking system. Results will be discussed in the context of current discussions about sequential unmasking of forensic evidence features.

#### Decision Accuracy, Presentation Context, Presentation Order

### J32 Forensic Characterization and Discrimination of Manila Envelopes

*Maria I. Sanchez-Melo, MS\*, West Haven, CT 06516; Virginia M. Maxwell, DPhil, Department of Forensic Science, West Haven, CT 06516; Irina Geiman, MS, United States Secret Service, Washington, DC 20223; Brooke W. Kamrath, PhD, University of New Haven, West Haven, CT 06516*

---

**Learning Overview:** After attending this presentation, attendees will understand the meaningful physical and chemical differences among manila envelopes produced by different manufacturers that can be used to discriminate and/or identify several brands of this type of envelope.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by evaluating commonly employed physical and chemical analytical techniques to determine which offers the greatest discrimination potential, thus developing an analytical protocol for the forensic analysis of manila envelopes.

Envelopes are important probative items of evidence that are analyzed by forensic document examiners as they can be found at crime scenes when ransom, threat letters, or potentially harmful substances are sent to victims in an envelope through the mail. The use of manila envelopes in the United States is quite common because they are made of thick and durable manila paper; thus, they are frequently used to transport or send documents. There does not exist previously published research on the physical or chemical characterization of manila envelopes. Although there are many studies on the forensic analysis of office paper and paper-based banknotes, and only a few on white envelopes, a gap in the research has been identified. The ability to offer a way to systematically analyze manila envelopes, starting with the non-destructive techniques and using the most discriminating techniques, will be useful for the document examiner and the investigation.

The purpose of this research was to analyze manila envelopes using analytical methods commonly used for the analysis of paper and adhesives to be able to characterize and compare those sold by different manufacturers as well as the envelopes included in the same and different batches from the same manufacturer. Thus, this study investigated whether there are meaningful differences among them, and if these can be used for forensic discrimination and/or identification of the manufacturer. Samples from five manila envelopes, size 9"x12", from three boxes purchased from ten different brands were analyzed to evaluate the commonality between brands and determine the best methods for the discrimination of the envelopes. The analytical methods studied in this research included physical measurements of the envelopes and their folds, color examination using a colorimeter, the use of Alternate Light Sources (ALS), and chemical analysis using Thin-Layer Chromatography (TLC), Attenuated Total Reflection/Fourier Transform Infrared (ATR/FTIR) Spectroscopy, Raman Spectroscopy, X-ray Fluorescence (XRF), and X-ray Powder Diffraction (XRD).

Results indicate that IR spectroscopic analysis of the manila paper did not show meaningful differences; however, it was able to discriminate the adhesive between several of the various brands. Significant differences between brands were observed based on Raman spectra of the manila paper, as well as several physical measurements, including weight and thickness. Thus, it was concluded that detectable chemical and physical differences in the paper and adhesives of manila envelopes can be used for brand discrimination and have the potential to be used for brand identification.

### J33 An Examination of the Influence of Various Parameters on the Quality of Laser Printer Printouts

*Jasna Galekovic\**, Forensic Science Centre Ivan Vucetic, Moi, Zagreb 10000, CROATIA

---

**Learning Overview:** The goal of this presentation is to show attendees how variable print parameters of laser printers and various file formats can affect the print quality of laser printers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness that print quality of laser printers, apart from other parameters such as substrates, replacement toners, etc., are greatly influenced by the variable parameters of the printer itself as well as the file format being printed.

Forensic document examiners are often asked to determine whether two or more laser-printed documents were produced by the same laser printer. The examination of questioned documents can be performed using multiple techniques, such as microscopic examination, physical examination, and chemical examination (Fourier Transform Infrared Spectroscopy (FTIR), X-ray microanalysis, etc.). The physical analysis includes examinations of toners (type, fusion methods, etc.), possible printer identifying characteristics (roller marks, repetitive defects marks, etc.), and printout quality.

The goal of this study was to determine in which way the variable printer's parameters, such as print resolution, color or black/white printing, etc., as well as different file format (.txt, .pdf, .jpg, .png), have influence on printout quality. In the present study, more than 200 printout samples were taken from five different color laser printers. The number of printed samples on each printer depended on the number of their predefined variable parameters. Several files were used for printing on each of the printers; one file was created in MS Word® (letters and numbers in Arial and Times New Roman font), then saved in different file formats (.txt file, high-compressed .pdf file, low-compressed .pdf file); another file was a .pdf file containing letters, numbers, graphics, vectors, and images. Standard office paper (A4, 80g/m<sup>2</sup>) was used for preparing these samples. The examinations of samples were performed using non-destructive methods, such as video-spectral and stereomicroscopic analysis.

This study has shown that changing the parameters of the printer itself and changing the file format that is printed on the same printer causes significant differences in print quality. For example, there is a significant difference in letter size and the shape of the same letters and numbers between the print samples of a file saved as a high-compressed PDF file and a file saved in plain TXT format. Furthermore, changing the printer resolution and other available parameters, such as color balance, edge control, halftone options, RGB graphics, etc., also have a great effect on the printout quality.

Based on the results obtained, it is possible to conclude that the document experts should know that the differences in the printing quality of two or more of the questioned documents do not necessarily mean that they are manufactured on different laser printers and that other available test methods are needed to provide more reliable conclusions.

---

#### Laser Printers, Variable Parameters, Printout Quality

### **J34 Understanding the Impact of Human Factors on Forensic Examinations: Recommendations From the Expert Working Group for Human Factors in Handwriting Examination**

*Melissa K. Taylor, MA\*, Gaithersburg, MD 20899; Ted M. Burkes, BS\*, FBI Laboratory, Quantico, VA 22135; Emily J. Will, MA\*, Raleigh, NC 27658; Reinoud D. Stoel, PhD\*, Laan van Ypenburg 6, Den Haag, NETHERLANDS*

---

**Learning Overview:** After attending this presentation, attendees will better understand: (1) the general themes of human factors and organizational theory, and (2) the findings and recommendations of the Expert Working Group on Human Factors in Handwriting Examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping forensic professionals understand the impact of human factors on the handwriting examination process.

Much has been written in recent years about the role of human factors in forensic science. Human factors research examines the interactions between humans and other elements of a system—technology, training, decisions, products, procedures, workspaces, and the overall environment—with the goal of improving both human and system performance. Human factors analysis can be used to advance our understanding of the true nature of errors in complex work settings such as crime laboratories. Research in this area has identified factors that contribute to inefficiencies and quantified the effects of human and organizational factors on the performance of critical tasks. Causes of error include fatigue, workload, cognitive overload, poor interpersonal communications, imperfect information processing, team mistakes, and flawed decision making. Error management requires an understanding of the nature and extent of error so that appropriate changes can be made to the conditions that induce error, actions that prevent or mitigate error can be employed, and personnel can be properly trained to avoid error traps. The forensic science community can benefit from the application of lessons learned from human factors work in aviation and medicine to reduce the consequences and likelihood of human error in the scientific interpretation of evidence. While in most instances the results of human error are harmless and correctable, in circumstances such as forensic analysis where errors may lead to the loss of life or liberty, error prevention is imperative.

The National Institute of Justice and the National Institute of Standards and Technology have partnered to sponsor a series of expert working groups to examine the effects of human factors in forensic analyses and recommend approaches to improve practices and reduce the likelihood of errors. This presentation will focus on human factor issues in the handwriting examination process; interpretation and evaluation of handwriting evidence; reporting and testimony; quality assurance and quality control; education, training, and certification; and management. The Expert Working Group on Human Factors in Handwriting Examinations met eight times over the course of two-and-one-half years and heard presentations from experts in the areas of human factors; the weight of evidence in law, statistics, and forensic science; decision making and formulation of propositions; probabilities and likelihood ratios; and other relevant topics. With illustrative examples, this discussion will provide general themes of human factors research, a description of the current handwriting examination process, and present the recommendations of the Working Group.

---

**Handwriting Examination, Human Factors, Managing Error**

### **K1 An Improvement for High Sensitivity of Drug Screening by Thermal Desorption and Pyrolysis Combined With Direct Analysis in Real Time-Mass Spectrometry (TDP/DART®-MS)**

Hiroko Abe, MA, University of Chiba, Inohana, 1 8 1, Chuo-ku, Chiba-shi 260-0856, JAPAN; Chikako Takei\*, BioChromato Inc, 1 12 19, Honcho, Fujisawa-shi, Kanagawa-ken 251-0053, JAPAN; Motoshi Sakakura, PhD, AMR, Inc, 2 13 18, Nakane, Meguro-ku 152-0031, JAPAN; Teruhisa Shiota, AMR, Inc, 2 13 18, Nakane, Meguro-ku 152-0031, JAPAN; Kayako Suga, AB Sciex, 4 7 35, Kitashinagawa, Shinagawa-ku 140-0001, JAPAN; Daisuke Yajima, MD, University of Chiba, 1 8 1, Inohana, Chuo-ku, Chiba-shi 260-0856, JAPAN; Hirotaro Iwase, PhD, University of Tokyo, 7 3 1 Hongo, Bunkyo-ku 113-0033, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the value of TDP/DART®-MS for the rapid identification and screening of forensic drugs in biological and autopsy specimens (e.g., urine and blood).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how TDP/DART®-MS can be effectively applied as an identification and screening technique for the forensic drugs present in biological and autopsy specimens.

**Introduction:** Drugs present in biological and autopsy specimens cannot be detected without first selecting the pretreatment and analytical conditions appropriate for the drugs. However, in recent years, the situation in which new substances appear one after another, including New Psychoactive Substance (NPS) that threaten society, makes it very difficult to optimize the analytical conditions for each new substance. Thus, there is a need for a comprehensive analysis system that requires minimal investigation of pretreatment and analytical conditions. So, an analytical method for directly analyzing drugs in blood that does not require any pretreatment is being investigated. In a previous study, TDP/DART®-MS was used to separate and detect drugs in urine.<sup>1</sup> The detected ions were correctly identified according to their measured accurate mass and product ion spectra. Moreover, for the quantitative analysis, urine calibrator curves were prepared at concentrations ranging 0.01 µg/ml–1 µg/ml and the curves were linear in that range. However, the detection sensitivity was not satisfactory, so the current investigation aims to improve the detection intensity of drugs.

**Materials and Method:** The samples were standard drug mixture solutions and drug mixture-fortified blood and urine. The standard drug mixture solution consisted of 38 kinds of illegal drugs (e.g., cationics, cannabinoids, and phenethylamines). Mass spectra were obtained by using a quadrupole Time-Of-Flight (qTOF) mass spectrometry equipped with a DART® ion source and a TDP unit. The TDP unit was mounted between the DART® ion source and the mass spectrometry. Mass spectra were measured in positive-ion mode after the samples were heated from room temperature to 300°C. Additionally, to improve the detection intensity, the following two methods were considered: the solvent extraction for deproteinization treatment, and modifications to the analysis systems. In the former case, ethanol (EtOH), methanol (MeOH), and acetonitrile (ACN) were used and in the latter case, the glass tee-tube (the HOOD) was attached between an ion source and the qTOF. This glass tee-tube can work for preventing the diffusion of volatilized drugs from the blood samples.

**Results and Discussion:** Each drug was separated and detected through thermal gradient heating for all samples, and thermal desorption profiles were highly reproducible for individual drugs. The detected ions were correctly identified according to their measured accurate mass and product ion spectra. ACN was the best for deproteinization treat for this investigation, since ACN was attained the highest sensitivity. In addition, when using the HOOD, the peak area of the extracted ion current gram of each drugs was more intense, and it was thought that the volatilized drugs had been ionized more efficiently by attaching the HOOD. Moreover, the calibration curve was linear regardless of the presence or absence of HOOD. Finally, it was confirmed that the heating rate of the TDP device was also effective for improving the detection intensity of drugs, as increasing the heating rate has improved the separation of the peaks and improves the peak intensity.

#### **Drug Screening, TDP/DART®-MS, Urine and Blood**

## K2 New $\beta$ 2-Agonists in Sports Doping

Anil Aggrawal, MD\*, Maulana Azad Medical College, New Delhi 110002, INDIA

**Learning Overview:** After attending this presentation, attendees will gain insight into new  $\beta$ 2-agonists that are being used in sports doping. Attendees will also learn about the investigational aspects of these new doping agents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stimulating further inquiry and research into the investigational aspects of new  $\beta$ 2-agonists being used in sports.

$\beta$ 2-Agonists are derivatives of phenyl- $\beta$ -ethanol amines with different substituents on the aromatic ring and on the terminal amino group. The exact positions of different substituents further characterize  $\beta$ 2-agonists as catecholamines, resorcinols, or saligenins.

The  $\beta$ 2-agonists exist as two drug classes: the Short-Acting  $\beta$ 2-Agonists (SABA) (first generation, e.g., salbutamol, terbutaline, fenoterol, isoproterenol), and the Long-Acting  $\beta$ 2-Agonists (LABA) (second generation, e.g., salmeterol, formoterol). Recently, the term “Ultra-LABA” has been used to describe the third-generation products of this drug class. In addition to novel Ultra-LABAs, Long-acting Antimuscarinic Agents (LAMAs), phosphodiesterase inhibitors, and Inhaled Corticosteroids (ICSs) are utilized in combination therapy. Using drugs in combination may lower doses of individual agents, decrease adverse effects, simplify medication regimens, and improve compliance.

The most prominent representatives of  $\beta$ 2-agonists are clenbuterol and salbutamol. They are used primarily for the treatment of asthma and related bronchial spasms. Because about 10%–15% of Olympic athletes exhibit asthma syndromes, the use of  $\beta$ 2-agonists is relatively high among them.  $\beta$ 2-agonists exhibit muscle anabolic and lipolytic properties not as their intended effects, but as side effects. Because of relatively low adverse effects of the  $\beta$ 2-agonists, they are considered by some athletes as a “safe” alternative to anabolic androgenic steroids.

Interestingly, although demonstrable in animal experiments, there is little evidence that  $\beta$ 2-agonists can really improve performance in trained athletes. Despite this, in recent years several new  $\beta$ 2-agonist molecules have emerged. Some of these are AZD-3199, AZD-9708, carmoterol, indacaterol, LAS-100977, milveterol, olodaterol, PF-610355, trantinterol, and vilanterol.

In some countries,  $\beta$ 2-agonists are even used to increase the muscle mass of animals, so they can yield more meat. Thus, athletes visiting these countries either for training or simply for tourism may inadvertently consume meat derived from such animals. This may cause them to test positive for  $\beta$ 2-agonists. The German national anti-doping agency has even published a clenbuterol (the most controversial  $\beta$ 2-agonist) warning for athletes traveling to Mexico or China recommending particular vigilance with food.

This presentation discusses the use of  $\beta$ 2-agonists in sports doping, in particular, the new molecules as mentioned above, as well as their use in cattle fattening.

### Doping, Sports, Toxicology

## K3 Screening and Quantitation of Pesticides in Biological Specimens

Muhammad Taimoor Chaudhary, MPhil\*, Punjab Forensic Science Agency, Lahore, Punjab, PAKISTAN; Mohammed Sarwar, PhD, Cuyahoga County Coroner's Office, Cleveland, OH 44106; Sardar Ali Wattoo, MPhil, Punjab Forensic Science Agency, Lahore, Punjab 53700, PAKISTAN; Mohammad A. Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab, PAKISTAN

**Learning Overview:** After attending this presentation, attendees will be able to understand: (1) the ongoing potential of Gas Chromatography (GC) coupled with Mass Spectrometry (MS) in the detection of common pesticides, (2) suitable single-step Liquid-Liquid Extraction (LLE) procedures, and (3) the current misuse of different types of pesticides used in Pakistan. The objective of this study was to develop a simultaneous screening and quantitation method for the detection of pesticides by using a suitable solvent combination (for LLE) in the absence of a color test.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the results of the case studies regarding the use of pesticides for suicidal and homicidal purposes. Rapid GC/MS run with Selected Ion Monitoring (SIM) and scan mode for the analysis of common pesticides has not been previously reported and may be highly valued in clinical and forensic settings.

Pesticides are a common source of oral and inhaled poisoning in Pakistan. Cases have been reported regarding accidental and/or intentional poisoning of some commonly used pesticides. Rapid identification of pesticides in biological samples is not only necessary for early treatment decisions but also important for forensic toxicology cases.<sup>1</sup> Analytical methods devised for the determinations of pesticides in food and plant items are not directly useful for biological matrices as sample clean up pours are a major hindrance.<sup>2-10</sup> Despite the benefits of Solid Phase Extraction (SPE), Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS), pressurized liquid extraction and Solid Phase Microextraction (SPME), LLE is still the most commonly used extraction technique for the past two decades.<sup>11</sup>

Basified postmortem samples (2mL) were extracted in a single step by using ethyl acetate and dichloromethane (5mL of 1:1 v/v). Caffeine was used as the internal standard in this study. All extracts were reconstituted with ethyl acetate and hexane in (1:1 v/v), and 1 $\mu$ L was injected in GC/MS. Electron Impact Mass Selective Detector (MSD) was used on Selected Ion Monitoring (SIM) and scan mode whereby DB-5ms capillary column (30m x 250 $\mu$ m x 0.25 $\mu$ m) was installed in GC. The method was validated for screening and quantitation of carbofuran, atrazine, chlorpyrifos, buprofezin, bifenthrin, pyriproxyfen, lambda-cyhalothrin, cypermethrin, deltamethrin, acephate, acetamiprid, and imidacloprid.

The method was validated by using spiked synthetic blood samples with five-point calibration (calibration range 0.50mgL–3.75mg/L). Limit Of Detection (LOD) ranged from 0.202mgL–0.657mg/L, while the Limit Of Quantitation (LOQ) varied from 0.50mgL–1.00mg/L. Accuracy (82.0%–115.20%) and precision (as %CV; 2.14%–17.50%) at three different concentration levels (1.0mgL, 2.5mgL, and 3.75mg/L of pesticides) were within acceptable ranges (80%–120% and < 20%, respectively). Postmortem samples of homicide and suicide cases submitted were analyzed for the presence and quantitation of pesticides. Various cases were found to be positive for the stated pesticides in whole blood, gastric contents, and liver tissues.

### **K4 Elemental Analysis of Hair and Tissue by Open Vessel Digestion and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) Analysis**

*Beth M. Slaybaugh, MPS\*, NMS Labs, Willow Grove, PA 19090; Donna M. Papsun, MS, NMS Labs, Willow Grove, PA 19030; Riley Murphy, PhD, NMS Labs, Willow Grove, PA 19090; Joan Schemmer, NMS Labs, Willow Grove, PA 19090; Lee M. Blum, PhD, NMS Labs, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will have gained knowledge about a newly developed sample preparation method for the analysis of hair and tissue samples using an open vessel acid digestion method followed by ICP/MS analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a method of acid digestion that provides the opportunity for greater sample throughput and the potential for less contamination compared to closed vessel microwave systems.

Trace metal analysis is highly important in both forensic and clinical toxicology. Metals analysis can play a key role in death and poisoning investigations as well as in environmental and workplace exposure monitoring. Blood, serum, and urine are typical matrices used for analysis. However, in some cases, it is necessary to analyze non-aqueous matrices, such as hair, nails, and tissues. This study introduces a method in which non-aqueous samples are digested into an aqueous solution utilizing a series of chemicals and a heating block, and then analyzed by ICP/MS. Approximately 0.3–1.0 grams of solid sample is weighed into pre-cleaned disposable tubes for the digestion process. Minimization of contamination is key in trace metals analysis for proper identification of toxicological results without the influence of pre-analytical variables and, in this method, digestion tubes are pre-cleaned to remove possible contaminants. These digestion vessels are not recycled as in microwave procedures. An acid digestion mixture composed of 4% hydrochloric, 23% nitric, and 1% hydrofluoric acids is added to each tube, followed by the addition of hydrogen peroxide. The sample is then placed into the heating block that has a 47-sample capacity for digestion, which runs 3 hours and 35 minutes. Upon completion, the sample is diluted to a final volume of 25 milliliters with 2.0% nitric acid. A quantitative method using quadrupole ICP/MS with collision cell technology is used to detect 14 elements. These elements are chromium, manganese, cobalt, nickel, arsenic, selenium, molybdenum, cadmium, tin, antimony, barium, thallium, lead, and bismuth. This presentation will focus solely on barium, arsenic, lead, and cadmium in hair.

Precision and bias estimates were tested for all elements using certified reference materials, including hair, mussel, scallion, celery, dogfish liver, and synthetic urine and blood. Precision as % Coefficient of Variation (CV) for the total digest procedure was less than 15% for all certified reference materials. The accuracy for the total digestion procedure was determined to be within +/-15%. The method uses aqueous standard calibration curves for each analyte of interest. The curves for all elements pass an acceptance criteria in which the slope of the back-calculated concentrations to the target concentrations during validation fell between 0.85 to 1.15 and the bias was within 20%. The relationship between the measured and expected values was also plotted and established to be linear for all elements within the analytical measurement range.

Cases where this method was used include hair analyses over a period of one year from individuals with unknown histories of metals exposures. The findings were: for cadmium ( $n=10$ ), results ranged from 0.018mcg/g to 0.57mcg/g with a median of 0.10mcg/g and average of 0.20mcg/g; for barium ( $n=13$ ), results ranged from 1.6mcg/g to 8.4mcg/g with a median of 4.9mcg/g and average of 4.8mcg/g; for arsenic ( $n=5$ ), results ranged from 0.22mcg/g to 1.2mcg/g with a median of 0.85mcg/g and average of 0.78mcg/g; and for lead ( $n=36$ ), results ranged from 0.14mcg/g to 3.8mcg/g with a median of 0.68mcg/g and average of 0.90mcg/g. Results from hair analysis can help differentiate between baseline levels of trace metals and overexposure or poisoning situations.

In conclusion, open vessel hot block digestion provides a suitable process in which non-aqueous matrices are prepared for ICP/MS analysis. The results from these analyses may assist with the assessment of trace metal determinations in alternative specimens of toxicological interest.

Brian Joseph Waters, MS\*, Fukuoka University, Department of Forensic Medicine, Fukuoka 814-0180, JAPAN; Kenji Hara, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Natsuki Ikematsu, BPharm, Fukuoka University, Fukuoka 814-0180, JAPAN; Mio Takayama, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Aya Matsusue, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Masayuki Kashiwagi, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN; Shin-ich Kubo, PhD, Fukuoka University, Fukuoka 814-0180, JAPAN

**Learning Overview:** After attending this presentation, attendees will better understand the toxicological findings that indicate death due to ingestion of GBL, a metabolic precursor to Gamma-Hydroxybutyrate (GHB).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating an efficient and robust method for the determination of GBL and GHB from biological fluids.

In May of 2018, a man (Case 1) in his early forties went missing from the hospital room where he was staying. He left a handwritten will stating he would die in the backyard of a former male coworker (Case 2) in his late sixties. The note included the name and address of the coworker. Both men were found dead lying side by side on a blue tarp in the backyard of the address written on the will. Near their feet were many empty packages of sleep medication, wine and whisky bottles, unlabeled brown bottles containing an unidentified liquid, and other trash.

Blood and gastric samples from both men were obtained for toxicological analysis. Prior to analysis, ethanol quantitation and screening by Liquid Chromatography/Mass Spectrometry (LC/MS) had been performed by another laboratory. Routine GC/MS screening revealed the presence of GBL, a colorless liquid with a characteristic odor that is often used as a precursor to other chemicals. GBL undergoes rapid enzyme-mediated hydrolysis or oxidation to GHB *in vivo*. The presence of GHB was confirmed by GC/MS analysis after Trimethylsilyl (TMS) derivatization.

For quantitation, duplicate aliquots of 200 $\mu$ L of blood or diluted gastric contents were added to 10-mL headspace vials with an equal volume of distilled water. Sodium chloride was added along with an internal standard, GBL-d<sub>6</sub>; 20 $\mu$ L of 5N hydrochloric acid was added to one sample and 20 $\mu$ L of water was added to the other. The vials were capped and pre-heated for 5min at 70°C. An HS/SPME fiber was used to extract the GBL from the samples. The SPME fiber was inserted and exposed to the headspace and continued to be heated at 70°C for 10min. After adsorption, the fiber was inserted into the GC inlet and desorbed for 2min at 250°C. In the vial containing acid, any GHB in the sample was converted to GBL. In the vial omitting the acid, the GHB was not converted. The difference between the GBL quantitation in the acid sample and the non-acid sample represented the amount of GHB in the specimen.

Separation was performed on a Shimadzu® TQ8030 GC/MS with tandem columns consisting of a Rtx®-200 (5m x 0.15mm x 0.25 $\mu$ m df) pre-column connected serially to an Rtx®-200 (8m x 0.18mm x 0.4 $\mu$ m df) separation column. Injection was in the split mode at 1:15. Helium was the carrier gas with an initial pressure of 259.7kPa. The interface and ion source temps were 260°C and 230°C, respectively. The initial column temp was 60°C for 0.8min, ramped to 250°C at 70°C/min, and held for 3min. The MS was operated in the scan-SIM mode (scan: *m/z* 40-550; SIM: *m/z* 42, 86 for GBL, *m/z* 48, 92 for GBL-d<sub>6</sub>) with electron impact ionization at 70eV.

Case 1 had absolute GBL concentrations in the blood and gastric contents of 75 $\mu$ g/mL and 695 $\mu$ g/mL, respectively. Absolute GHB concentrations (as total GHB-absolute GBL) in the blood and gastric contents of Case 1 were 404 $\mu$ g/mL and 103,955 $\mu$ g/mL, respectively. Absolute GBL concentrations in the blood and gastric contents in Case 2 were 64 $\mu$ g/mL and 782 $\mu$ g/mL, respectively. Case 2 had absolute GHB concentrations in the blood and gastric contents of 367 $\mu$ g/mL and 43,436 $\mu$ g/mL, respectively.

The GBL and GHB levels were consistent with other fatalities attributed to GHB/GBL intoxication in the literature. Both men had several different compounds in their system, including sleep medication and alcohol, in various amounts.

## K9 Validation of the Neogen® Enzyme-Linked Immuno-Sorbent Assay (ELISA) Cocaine/Benzoyllecgonine-2 Kit for Whole Blood and Urine Specimens

Nicholas B. Tiscione, MS\*, West Palm Beach, FL 33406

**Learning Overview:** After attending this presentation, attendees will understand the performance of the Neogen® ELISA Cocaine/Benzoyllecgonine-2 kit for screening whole blood and urine specimens as evaluated by a validation based on the Scientific Working Group for Forensic Toxicology (SWGTOX) Standard Practices for Method Validation in forensic toxicology laboratories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the validation of an ELISA method based on the SWGTOX standard.

**Objective:** The validation of a semi-quantitative method for the rapid screening of whole blood and urine specimens by a Dynex DSX® Automated ELISA System using the Neogen® Cocaine/Benzoyllecgonine-2 kit.

**Method:** Whole blood samples were diluted 1:5 with manufacturer-provided buffer before being loaded onto the instrument, then further diluted 1:2 by the instrument. Urine samples were diluted 1:20 with buffer by the instrument. The diluted sample volume added to each well was 15µL and 10µL for whole blood and urine, respectively. For all other parameters (e.g., incubation times, reagent volumes), the manufacturer assay instructions were followed. Performance of the assay was evaluated at decision points of 50ng/mL and 25ng/mL for whole blood and 300ng/mL, 150ng/mL, and 50ng/mL for urine. The validation included the evaluation of sensitivity, precision, specificity, carryover, plate drift, ruggedness/robustness, and a case sample comparison.

**Results:** Carryover was evaluated by running three replicates of a blank matrix control following a positive matrix control at 10µg/mL for both blood and urine. Carryover was not detected in the assay. The sensitivity was evaluated by replicate analysis of a blank matrix control to determine the theoretical Limit Of Detection (LOD) and by the analysis of standards at successively lower levels to determine an experimental LOD. The theoretical LOD was determined to be 16ng/mL for blood and 23 ng/mL for urine. The experimental LOD was determined to be 25ng/mL for both blood and urine. Precision was evaluated at 0ng/mL, 12.5ng/mL, 25ng/mL, 37.5ng/mL, 50ng/mL, 75ng/mL, and 100ng/mL for blood and 0ng/mL, 25ng/mL, 50ng/mL, 75ng/mL, 150ng/mL, 225ng/mL, 300ng/mL, and 450ng/mL for urine with three replicates at each level over five separate runs ( $n=15$ ). The Coefficient of Variation (CV) was less than or equal to 6.1% for blood and urine at all studied concentrations. The mean response  $\pm 2$  Standard Deviations (SD) at each decision point for both blood and urine at 50ng/mL and 300ng/mL, respectively, did not overlap with the mean response  $\pm 2$  SD of standards prepared at  $\pm 50\%$  of the concentration of the decision points. Overlap was observed at decision points of 25ng/mL in blood and 150ng/mL and 50ng/mL in urine. Specificity was evaluated for cocaine and cocaethylene in blood by the analysis of negative matrix samples fortified at 10µg/mL, 100ng/mL, 70ng/mL, and 50ng/mL. In urine, concentrations of 10µg/mL, 600ng/mL, 400ng/mL, and 300ng/mL were employed. Observed cross reactivity was lower than that reported by the manufacturer. Cocaine cross reactivity was estimated to be 44% for whole blood and 40% for urine. Cocaethylene cross reactivity was estimated to be 46% for whole blood and 43% for urine. No interference was observed from screening known authentic samples, which contained 22 commonly identified drugs and metabolites. Two out of five positive blood specimens and one out of five urine specimens were identified as being negative by the assay, with responses just above the cutoff. These specimens had benzoyllecgonine concentrations near the cutoff and had been in storage for 1–35 months. Plate drift was evaluated by analyzing 24 replicates at the validated decision point for each matrix. The number of replicates analyzed was greater than the number of samples run in routine casework. Plate drift was not observed.

Whole Blood ( $n=15$ )	Level (ng/mL)	Mean O.D.	SD	CV (%)	Mean + 2 SD	Mean – 2 SD
	0	0.898	0.038	4.2	0.974	0.822
	25	0.693	0.031	4.5	0.755	0.631
	50	0.568	0.026	4.6	0.620	0.516
	75	0.460	0.028	6.1	0.516	0.404
	100	0.408	0.023	5.6	0.454	0.362

Urine ( $n=15$ )	Level (ng/mL)	Mean O.D.	SD	CV	Mean + 2 SD	Mean – 2 SD
	0	1.166	0.044	3.8	1.254	1.078
	150	0.579	0.030	5.2	0.639	0.519
	300	0.407	0.017	4.2	0.441	0.373
	450	0.310	0.019	6.1	0.348	0.272

**Conclusion:** The Neogen® Cocaine/Benzoyllecgonine-2 ELISA kit is a precise, specific, and rapid screening procedure to detect benzoyllecgonine in blood and urine.

### Cocaine, Validation, Enzyme-Linked Immuno-Sorbent Assay

### K10 The Detection of Various Drugs in Human Urine Samples Via Total Vaporization-Solid Phase Microextraction (TV-SPME)

*Kymeri E. Davis, BSc\*, Indiana University-Purdue University Indianapolis, Indianapolis, IN 46202; John V. Goodpaster, PhD, FIS Program, Indiana University-Purdue University Indianapolis, Indianapolis, IN 46202*

**Learning Overview:** After attending this presentation, attendees will understand: (1) TV-SPME and how it may be used to detect drug analytes, and (2) the ability of Gas Chromatography/Mass Spectrometry (GC/MS) and TV-SPME to detect drugs in toxicological samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how TV-SPME may be implemented in laboratories.

While GC/MS is a frequently used technique in forensic science laboratories, there are limitations, such as the need for compounds to be thermally stable as well as volatile. Some compounds must undergo derivatization prior to being injected into the gas chromatogram to satisfy these requirements. SPME is a technique in which analytes are absorbed onto a fiber that is then placed inside the GC inlet for desorption. TV-SPME utilizes the same technique as standard SPME but vaporizes a sample extract that is then absorbed onto the fiber. The Polydimethylsiloxane-Divinylbenzene (PDMS-DVB) fiber is first exposed to a vial containing the derivatization agent. The SPME fiber is then exposed to a new vial containing the analyte of interest. A study was conducted to determine the optimal time needed for the fiber to absorb the derivatization agent so that both the solvent (e.g., water) and the analyte were fully derivatized with no underivatized compounds detected. This study indicated that 50 minutes was the optimal time needed to adequately saturate the fiber. TV-SPME is beneficial because it allows for the analyte to be derivatized during the extraction process, which reduces analysis time. TV-SPME requires little sample preparation and small sample sizes.

It was hypothesized that TV-SPME could be used to analyze drugs and drug metabolites in human urine samples. The GC temperature program was set to an initial temperature of 60°C with a 15°C/min oven ramp. The inlet temperature was 250°C using splitless mode. The MS scan range was 40m/z–550m/z. Drugs of interest included methamphetamine and amphetamine. Each drug was spiked into a human urine sample known to be free of any illegal substances. Concentrations were at ng/mL levels. Each sample was then analyzed using a TV-SPME GC/MS method after being exposed to the proper derivatization agent for a sufficient amount of time. After exposing the SPME fiber to Trifluoroacetic Anhydride (TFAA) for 50 minutes, methamphetamine (28.6ng/mL) and amphetamine (19.0ng/mL) derivatives were both successfully detected in a urine sample.

Currently, this method shows that methamphetamine and amphetamine can be detected at ng/mL levels in human urine with no prior sample preparation aside from placing the sample into a headspace vial. Future work will include a recovery analysis and future compounds may include benzoylecgonine,  $\gamma$ -Hydroxybutyric Acid (GHB),  $\gamma$ -Butyrolactone (GBL), and 11-Nor-9-Carboxy- $\Delta^9$ -Tetrahydrocannabinol (THC-COOH). There are currently numerous methods and techniques available for the analysis of controlled substances. However, these methods often require sample preparation such as an extraction. This TV-SPME method requires little-to-no sample preparation and utilizes a simple GC/MS method.

#### Gas Chromatography, Solid-Phase Microextraction (SPME), Drugs

## K11 The Postmortem Distribution of 3,4-Methylenedioxyamphetamine (MDMA) and 3,4-Methylenedioxyamphetamine (MDA) From an Accidental Death Due to MDMA Intoxication

Danylle Kightlinger\*, Office of the Chief Medical Examiner, Washington, DC 20024; Victor W. Weedn, MD, JD, The George Washington University, Washington, DC 20007; Lucas W. Zarwell, MFS, Washington, DC 20011

**Learning Overview:** After attending this presentation, attendees will understand the postmortem distribution of MDMA and MDA from an accidental death due to MDMA intoxication.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an evaluation of the postmortem distribution of MDMA and MDA, as well as the ratio of MDA to MDMA, in various matrices, which could aid in the approach and analysis of other MDMA intoxication cases.

A 29-year-old female was found kneeling, facedown on her bedroom floor approximately two hours after her last known communication and was pronounced dead on scene roughly 40 minutes later. The scene was unremarkable. Approximately 18 hours after the decedent was pronounced dead, a medicolegal autopsy was performed, and specimens were submitted for toxicological analysis.

An expanded panel was conducted on the priority sample (Femoral Blood 1), and electrolyte's testing was conducted by biosensor analysis on vitreous humor. After completion of the expanded panel, all other specimens were analyzed using a confirmatory, quantitative Gas Chromatography/Mass Spectrometry (GC/MS) method for amines.

Medicolegal autopsy findings included: pulmonary edema (1,300 grams combined lung weight); zonal necrosis of the liver; approximately 25mL of green material in the stomach with gastric mucosal hemorrhage; and a contusion on the inner lower lip (a possible indication of agonal seizure activity). Electrolytes results were determined, and from the expanded panel, seven compounds were reported in Femoral Blood 1: MDMA, MDA, cocaine, benzoylecgonine, diphenhydramine, alprazolam, and naloxone. Furthermore, MDMA and MDA postmortem concentrations and ratios for all submitted specimens were as follows:

**Table 1:** MDMA and MDA Postmortem Concentrations and Ratios by Specimen

Specimen	MDMA (mg/L or mg/kg) <sup>^</sup>	or	MDA (mg/L or mg/kg) <sup>^</sup>	or	MDA:MDMA	Fluid or Tissue MDMA: Blood 1 MDMA	Fluid or Tissue MDA: Femoral Blood 1 MDA
Femoral Blood 1	16.3		0.31		0.01	1.00	1.00
Femoral Blood 2	15.1		0.26		0.01	0.92	0.83
Heart Blood 1	18.0		0.33		0.01	1.10	1.06
Heart Blood 2	18.1		0.28		0.01	1.11	0.90
Urine	5.89		ND*		--	0.36	--
Vitreous Humor	10.3		0.12		0.01	0.63	0.38
Liver	45.9		1.05		0.02	2.81	3.38
Brain	39.7		0.74		0.01	2.43	2.38
Gastric Content	774		ND*		--	47.4	--

<sup>^</sup>Fluids were reported in mg/L; tissues were reported in mg/kg.

\*ND – Not Determined

The official cause and manner of death were ruled as an accident due to MDMA intoxication, although it was recognized that suicide was a distinct possibility. Other drugs detected were not significant in quantity and all electrolyte levels were within normal postmortem limits. The extremely high level of MDMA present in the gastric content suggests the route of administration was ingestion. However, no tablets were found in the stomach and the formulation in which the MDMA was ingested—suspected tablet or liquid form—is unknown. MDMA and its active metabolite appear to exhibit similar pharmacokinetics, showing a seemingly consistent ratio with respect to the MDA/MDMA concentrations (0.01–0.02) in all specimens. The liver and brain concentrations were substantially higher than the femoral blood. The low MDMA concentration present in the urine suggests death occurred soon after ingestion. The MDMA postmortem concentrations in this case are some of the highest reported. While femoral blood remains the preferred sample, this data suggests that heart blood concentrations are comparable to femoral blood, indicating heart blood may be used when necessary.

### MDMA, MDA, Postmortem Distribution

### K12 The Detection and Quantitation of Ten Synthetic Cannabinoid Metabolites in Human Urine Using High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS)

Cassandra A. Swart, BS\*, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Daniel Lee, MS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Mikayla Caldwell, BS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Katherine N. Moore, MS, Research Triangle Park, NC 27709; Nichole D. Bynum, MS, RTI International, Johnson Building, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118

**Learning Overview:** After attending this presentation, attendees will be able to use the method described, or develop their own singular method, for analysis of urine for selected synthetic cannabinoid metabolites.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the analysis of selected synthetic cannabinoid metabolites.

**Background/Introduction:** Synthetic cannabinoids remain in the top 25 drug-encountered analytes in seized drug evidence based on the United States Drug Enforcement Administration's National Forensic Laboratory Information System 2017 mid-year report. Despite efforts to control synthetic cannabinoids, illicit manufacturers continue to modify their structures to avoid legal regulations, creating an ever-changing analytical target for forensic laboratories. In addition, due to structural modifications of these synthetic cannabinoids, many of these compounds can bind to endogenous CB1 and CB2 receptors with greater affinity, causing severe adverse and life-threatening effects. Because of their structural dissimilarity to  $\Delta^9$ -Tetrahydrocannabinol (THC), combating the rapid growth and emergence of synthetic cannabinoids with conventional THC-based methods is often not effective.

**Objective:** With a focus on synthetic cannabinoids of different core structures such as naphthoylindole, adamantoylindole, quinoliny, and carboxamide, the purpose of this research was to develop and validate a robust and reliable method to accurately identify and quantify ten synthetic cannabinoid metabolites in human urine.

**Method:** Using HPLC with a 4000 QTRAP® Electrospray Ionization Tandem Mass Spectrometry (ESI/MS/MS) in positive ionization mode, samples were extracted using supported liquid extraction using ISOLUTE® cartridges. The method was validated in accordance to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for quantitative analysis using the following analytes: UR-144 degradant N-pentanoic acid, UR-144 N-(5-hydroxypentyl), PB-22 N-(5-hydroxypentyl), MDMB-FUBICA metabolite 3, JWH 250 N-pentanoic acid, ADB-PINACA pentanoic acid, ADB-PINACA N-(4-hydroxypentyl), AB-FUBINACA metabolite 3, 5-fluoro PB-22 3-carboxyindole, and 5-fluoro MDMB-PICA metabolite 7.

**Results:** With this developed method, total analysis time was eight minutes with samples eluting within 3.26 to 4.47 minutes. Calibration curves for each analyte had accepted  $R^2$  values  $> 0.99$ . The calibration model was established to be linear using a weighting factor of  $1/x$ . A linear dynamic range of 5ng/mL – 40ng/mL was used for all analytes. Extraction of analytes using Supported Liquid Extraction (SLE) cartridge improved sample-prep time by more than half, compared to traditional solid phase extraction methods. Percent recovery of analytes using the SLE was determined to be from 68.4% to 90.7%. Bias and precision was assessed at 5ng/mL, 25ng/mL, and 30ng/mL for all analytes. Samples had acceptable calculated percent bias and percent coefficient of variation within  $\pm 20\%$ . No carryover was observed. No interference was observed for other commonly encountered drugs clonazepam, diazepam, (+) methadone, morphine, fentanyl, cocaine, amphetamine, 3,4-methylenedioxymethamphetamine (MDMA), 25I-NBOMe, and Phencyclidine (PCP) at 2,000ng/mL.

**Conclusion/Discussion:** The overall development and validation of this method demonstrates a sensitive and reliable way to positively identify ten different synthetic cannabinoid metabolites in human urine in rapid time.

#### Synthetic Cannabinoids, Supported Liquid Extraction, Metabolites

### K13 The Detection and Quantitation of 17 Synthetic Cannabinoids in Human Whole-Blood Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Following Supported Liquid Extraction

*Daniel Lee, MS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Shawn Foley, BS, Boston University, Biology Department, Boston, MA 02118; Erika Phung, BS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Cassandra A. Swart, BS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Nichole D. Bynum, MS, RTI International, Research Triangle Park, NC 27709; Katherine N. Moore, MS, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS\*, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118*

**Learning Overview:** After attending the presentation, attendees will have information on the validation of a detection and quantitation method of select synthetic cannabinoids in human whole-blood with the use of LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the analysis of select naphthoylindole, adamantoylindole, quinolinyl, and carboxamide synthetic cannabinoids in human whole-blood by LC/MS/MS.

**Background/Introduction:** Synthetic cannabinoids have become a growing concern in society. The extensive list of synthetic cannabinoids and the abuse rate has drawn the attention of government agencies throughout the world. These synthetic cannabinoids can adopt several different structures, while still acting on endogenous cannabinoid (CB1 and CB2) receptors. In addition, due to structural modifications of these synthetic cannabinoids, many of these compounds can bind to CB1 and CB2 receptors with greater affinity, causing severe adverse and life-threatening effects. Because of their structural dissimilarity to the phytocannabinoid  $\Delta^9$ -THC, combating the rapid growth and emergence of synthetic cannabinoids with conventional THC-based methods has become an ongoing struggle.

**Objective:** The purpose of this research was to develop and validate a robust and reliable method to accurately identify and quantify 17 synthetic cannabinoids in human whole-blood using LC/MS/MS. The method was validated in accordance to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for quantitative analysis using the following analytes: 4-cyano CUMYL-BUTINACA, 5-fluoro-3,5-ABPFUPPYCA, 5-fluoro ADB-PINACA, 5-fluoro PY-PINACA, ADB-PINACA, APP-PICA, CUMYL-THPINACA, EMB-FUNICACA, JWH-250, MDMB-FUBICA, MEP-CHMICA, MO-CHMINACA, NM2201, PB-22, RCS-8, UR144, and XLR11.

**Method:** Using High Performance Liquid Chromatograph (HPLC) with a 4000 QTRAP® Electrospray Ionization Tandem Mass Spectrometry (ESI/MS/MS) in positive ionization mode, the total analysis time was 8.013 minutes with samples eluting within 3.8 to 5.8 minutes. Calibration curves for each analyte had accepted  $R^2$  values  $> 0.99$  using a weighting factor of  $1/x$ . A linear dynamic range of 0.5ng/mL – 25ng/mL was used for all analytes, except for MO-CHMINACA and NM2201, which were quantifiable at lower (0.1ng/mL) levels. Extraction of analytes was performed using ISOLUTE® Supported Liquid Extraction (SLE) cartridges, which improved sample-prep time by more than half, compared to traditional methods.

**Results:** Percent recovery of analytes using the SLE was determined to be from 54.92% to 83.36%. Bias and precision was assessed at 1ng/mL, 3ng/mL, 7ng/mL, and 20ng/mL for all analytes. All samples had accepted calculated percent bias and percent coefficient of variation within  $\pm 20\%$ . No signs of carry-over were observed with this method. Ionization suppression and enhancement was observed at various levels, from -4.47% to 76.67%, but had little effect on other validation parameters. Analysis of other commonly encountered drugs (clonazepam, diazepam, (+) methadone, morphine, fentanyl, cocaine, amphetamine, 3,4-methylenedioxymethamphetamine (MDMA), 25I-NBOMe, and Phencyclidine (PCP)) at 2,000ng/mL showed false identification for ADB-PINACA.

**Conclusion/Discussion:** The overall development and validation of this method demonstrates a sensitive and reliable way to positively identify 17 different synthetic cannabinoids in human whole-blood in rapid time.

#### Synthetic Cannabinoids, Supported Liquid Extraction, Forensic Toxicology

### **K14 An Analysis of Carboxyhemoglobin in Postmortem Blood and Epidemiology Data of Suicide Autopsy Cases From 2011–2016 in Taiwan**

*Chu-An Yang, MS\*, Institute of Forensic Medicine, New Taipei City 23548, TAIWAN, REPUBLIC OF CHINA; Hsiu-Chuan Liu, MS, Institute of Forensic Medicine, Taipei, TAIWAN, REPUBLIC OF CHINA; Ray H. Liu, PhD, Forensic Science Review, Vancouver, WA 98685; Dong-Liang Lin, PhD, Institute of Forensic Medicine, New Taipei City 23548, TAIWAN, REPUBLIC OF CHINA*

**Learning Overview:** After attending this presentation, attendees will gain insights regarding: (1) factors that are important to the analysis of Carboxyhemoglobin (COHb) in postmortem blood specimens, and (2) trends and epidemiological data of Carbon Monoxide (CO) poisoning deaths in Taiwan during the 2011–2016 period.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving forensic laboratories' analysis of COHb in postmortem blood specimens and helping medical examiners' determination on cause of death in CO poisoning cases.

Poisoning-related death statistics in Taiwan, regularly provided by the Ministry of Justice's Institute of Forensic Medicine, indicated the number of CO-poisoning cases has been consistent and significant in recent years. The most common cases were suicidal deaths facilitated by coal burning. The measurements of COHb in postmortem blood specimens could be unreliable and difficult due to putrefaction and other factors. The purpose of this study was to evaluate whether test results could be affected by: (1) blood from different sources (heart, pelvis, and thoracic cavity); and (2) specimen storage temperature (–20°C, 4°C, 25°C, and 40°C). In addition, suicide cases (with autopsy) were studied to reveal the trend of CO-poisoning deaths in Taiwan during the 2011–2016, six-year period to aid in the formulation and administration of suicide prevention policies in Taiwan.

The ABL80 FLEX CO-OX blood gas analyzer was used to determine COHb concentration in test specimens, following the operation guide provided by the manufacturer. It was found to be easy to operate, requiring a short test time and small sample volume (around 70µL). Test results indicated: (1) the ranges of intra-/inter-day precision and accuracy were 0.00%–6.37% and 98.1%–104.7%, respectively; (2) the best results for postmortem blood specimens came with two-fold dilution (with deionized water and 0.9% sodium chloride aqueous solution), as specimens provided were often too thick with a small volume; (3) no significant difference was found among specimens collected from different parts of the same person; and (4) COHb concentration was stable through 28 days when specimens were refrigerated at –20°C or 4°C.

This method was successfully applied to the analysis of postmortem blood specimens from forensic cases in Taiwan for the 2011–2016 period. Statistics of autopsy cases (404 total) during this six-year period revealed: (1) the number of suicidal deaths beginning with 2011 were: 17, 19, 18, 30, 18, and 18 (120 total); (2) there were 108 CO-poisoning suicides by coal burning—nearly 90% of the total number of suicide cases; (3) the number of male victims was significantly higher than female (272 vs. 132); (4) most victims (71) were 31–40 years old; (5) the peak periods were January/February and September/October; and (6) most cases were found in residence. The range, mean, and median of COHb concentrations found in the 120 suicide case specimens were 10.1%–91.1%, 59.9%, and 62.9%, respectively. Alcohol, sedatives, and antidepressants were the most commonly found drugs in these specimens, but with concentrations below their respective lethal levels.

#### **Carboxyhemoglobin (COHb), Postmortem Blood Specimen, Epidemiology**

### K15 An Imidacloprid Insecticide Fatal Poisoning: Gas Chromatography/Mass Spectrometry (GC/MS) Detection in Alternative Biological Matrices

*Antonella Sorrentino, MD, Istituto Medicina Legale, Bari 70124, ITALY; Biagio Solarino, PhD, Università degli Studi di Bari, Bari 70125, ITALY; Silvia Trotta\*, Institute of Legal Medicine, Bari 70124, ITALY; Quintino Mita, BS, Laboratory of Forensic Toxicology, Bari 70124, ITALY; Giuseppe Strisciullo, BES, University of Bari, Bari 70124, ITALY; Lucia Aventaggiato, Policlinico, Bari 70100, ITALY*

**Learning Overview:** After attending this presentation, attendees will better understand the chloronicotinoid compounds, including its intended uses, toxic effects, and, because of its availability in certain communities, its use as a suicide modality.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stressing the importance of scene investigation, autopsy findings, and toxicology results to determine the cause of death in imidacloprid (pesticide) intoxication.

Imidacloprid (1-(6-chloro-3-pyridylmethyl)-N-nitroimidazolidin-2-ylideneamine) is a neonicotinoid insecticide in the chloronicotinyl nitroguanidine chemical family, rapidly and almost completely absorbed after ingestion. It is subsequently metabolized to 6-chloronicotinic acid, which is conjugated with glycine, then eliminated or reduced to guanidine. About 70% to 80% of an administered dose is excreted unchanged in the urine and 20% to 30% in feces. Imidacloprid acts on the Central Nervous System (CNS) as an agonist at the nicotinic acetylcholine receptor. It causes initial stimulation followed by fatigue of the agonized neurons and ultimately interferes with the transmission of neuronal impulses. Insecticide products containing imidacloprid are used worldwide; therefore, occasionally, accidental intoxication or intentional self-intoxication occurs throughout the world. Despite the original belief that imidacloprid has low mammalian toxicity, there is increasing evidence that imidacloprid may cause heart, kidney, and other organ damages and even death in addition to gastrointestinal irritation and neurological symptoms.

**Case:** A 55-year-old man was found dead lying prone on the grass near his summerhouse. No signs of traumatic injury were on the body surface and the parents denied serious systemic disorders. A plastic bottle of insecticide containing a little quantity of thick, white liquid was in the kitchen, while close to the body there were traces of this substance, apparently vomited by the victim. A medicolegal autopsy was required. The man's length was 171cm and he weighed 79kg. There were no signs of traumatic injury on the body. His face showed congestion, and there was some viscous, white fluid in his mouth. A fluid material with the same organoleptic features was at a section in the upper airways, esophagus, in the stomach (ca. 300cc), and in the duodenum. No other macroscopic alteration of the inner organs was observed. Microscopic examinations revealed pulmonary edema, fragmentation of myocardial fibers, and slight pancreatic hemorrhage. Full scan GC/MS analyses were performed on an Agilent® 6890 GC coupled 5973 inert mass spectrometer, previous liquid-liquid extraction of the biological specimens by organic mixture solvents (n-heptane; 1,2-dichloroethane; dichloromethane; 2-propanol) at pH 1.5. Both imidacloprid (IMI) and its metabolite 6-chloronicotinic acid (6-CNA) were quantified: the retention time was respectively 11, 14, and 5.64 minutes, while the ions spectrum was 211, 126, 99 (IMI) and 214, 170, 140 (6-CNA). For the detection of the metabolite, the derivation procedure BSTFA-1% TCMS was needed. Analytical results showed: inferior vena cava blood (IMI: 35µg/ml; 6-CNA: 0.6µg/ml), femoral blood (IMI: 55µg/ml; 6-CNA: 0.76µg/ml), urine (IMI: 14µg/ml; 6-CNA: 0.79µg/ml), vitreous humor (IMI: 18µg/ml; 6-CNA: 0.11µg/ml), abdominal adipose tissue (IMI: 28µg/g; 6-CNA: 0.39µg/g), and Total Gastric contents (IMI: 105mg; 6-CNA: 5.1mg).

**Discussion:** Acute toxicity is generally measured by LD50 and LC50 but these values are unknown for imidacloprid. Hence the presence of this substance in the plastic bottle and its distribution in all the alternative biological matrices here analyzed suggest an uncommon fatal intoxication of imidacloprid. Regarding the manner of death, no farewell letter was near the cadaver and the parents denied any kind of trouble so difficult as to explain suicide. However, the thorough scene investigation coupled with external examination and autopsy are in accordance with an intentional ingestion of pesticide.

#### Imidacloprid, Alternative Biological Matrices, Suicide

### K16 An Impaired Driving Case Involving Xylazine

*Ilene K. Alford, MS\*, Palm Beach County, West Palm Beach, FL 33406; Nicholas B. Tiscione, MS, West Palm Beach, FL 33406*

**Learning Overview:** After attending this presentation, attendees will be aware of the appearance of xylazine in combination with fentanyl, cocaine, and other drugs in a specimen collected as part of an impaired driving investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the rapidly evolving trends in drug use and abuse.

**Objective:** To describe an impaired driving case involving xylazine identified in a urine specimen in combination with fentanyl, cocaine, and other drugs.

**Background:** Xylazine is an alpha2 adrenergic agonist used in veterinary medicine for sedation, anesthesia, muscle relaxation, and analgesia. Recreational use of xylazine has been reported in Connecticut, Puerto Rico, Texas, and in Europe. Xylazine has been previously reported in cases involving heroin and fentanyl in Philadelphia, PA. Recently, xylazine in combination with fentanyl has also been identified in Palm Beach County, FL, and Ohio in drug seizure cases.

**Method:** A urine specimen was collected and submitted as part of an impaired driving investigation after a Breath Alcohol Analysis (BrAC). The urine specimen was screened using a basic extraction with scan Gas Chromatography/Mass Spectrometry (GC/MS) and a nine-panel Enzyme-Linked Immunosorbent Assay (ELISA) for barbiturates, benzodiazepines, buprenorphine, carisoprodol, cocaine/benzoylecgonine, fentanyl, opiates, oxycodone/oxymorphone, and cannabinoids. All positive results were confirmed with GC/MS and/or Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

**Results:** The incident occurred at approximately 5:00 p.m. on a Saturday evening. The subject was a 29-year-old White male. Witnesses observed him running in front of cars in a parking lot and beating on vehicles. An officer in a marked patrol vehicle arrived on the scene and observed the subject behind the wheel making a couple of failed attempts to back into parking spaces. The officer made successive efforts to stop the suspect's vehicle by activating her emergency lights, air horn, and Public Address (PA) system giving verbal instructions to stop the vehicle, all of which were initially unsuccessful. The suspect finally stopped after the officer's second use of the air horn. When the officer approached the subject's vehicle on foot, the subject was sweating profusely, had red, glassy eyes, miosis, stuttering and excited speech, and could not stop fidgeting and flailing his arms. The subject had difficulty turning off the vehicle when requested, attempting to do so with the gear shifter and wipers switch before the officer advised him to use the ignition switch. Upon exiting the vehicle, the subject was unsteady on his feet. Field sobriety exercises were administered. During the horizontal gaze nystagmus task, the subject closed his eyes several times leaving them closed for several seconds while his head fell backward. Lack of smooth pursuit was observed in both eyes. During the other tasks, the subject had difficulty maintaining his balance and completing the tasks as instructed. A brown powder that field tested positive for heroin and a syringe was in the vehicle.

The BrAC did not detect ethanol. Cocaine, fentanyl, codeine, morphine, buprenorphine, xylazine, delta-9-carboxy-tetrahydrocannabinol, lidocaine, and tramadol were identified in the urine specimen. Benzoylecgonine was indicated but not confirmed due to the presence of cocaine.

**Conclusion:** Recent submissions to the Palm Beach County Sheriff's Office Drug Chemistry Unit involving xylazine have included a counterfeit M30 oxycodone tablet containing methamphetamine, fentanyl and xylazine, and a tan powder containing heroin, fentanyl, and xylazine. Xylazine was tentatively identified by library match in both cases. This is consistent with previously reported cases involving concurrent detection of xylazine with heroin and fentanyl and indicates xylazine may be an additive in samples involving heroin and opioids.

#### Xylazine, Impaired Driving, Case Report

## K17 Liquid Chromatography/Quadrupole Time-Of-Flight (LC-QTOF) Screening for Fentanyl Analogs in Whole Blood and Oral Fluid

Kaitlyn B. Palmquist, BS\*, Huntsville, TX 77340; Madeleine J. Swortwood, PhD, Sam Houston State University, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will better understand the role of high-resolution Mass Spectrometry (MS) in the identification of novel fentanyl analogs in biological samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a unique screening methodology for the detection of fentanyl analogs in blood and oral fluid.

Fentanyl analogs are responsible for an increasing number of opioid related deaths in the United States. Routine forensic analyses are often unable to detect these analogs due to the low concentrations and similar molecular structures. To address this problem, a comprehensive screening method was developed and validated according to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for 14 fentanyl analogs in whole blood and oral fluid using LC-qTOF/MS.

Blood (0.25mL) or oral fluid (1mL containing 1:3 oral fluid: Quantisal® buffer) were fortified with deuterated internal standards, diluted with phosphate buffer, and extracted with a polymeric solid-phase extraction column. After washing, analytes were eluted with 5% ammonium hydroxide in ethyl acetate, dried, and reconstituted in mobile phase. An Agilent® Technologies 1290 Infinity® LC coupled to an Agilent® Technologies 6530 Accurate Mass TOF/MS was used for analysis in two separate acquisition modes: TOF mode and All Ions Fragmentation (AIF) mode. Personal Compound and Database Libraries (PCDLs) were produced in-house containing all analytes of interest ( $n=14$ ), as well as other drugs of abuse ( $n=53$ ). Both matrices were validated according to SWGTOX Standard Practices for Method Validation in Forensic Toxicology guidelines. For proof of applicability, authentic postmortem blood ( $n=30$ ) and antemortem oral fluid samples ( $n=18$ ) were extracted and analyzed as described above.

Chromatographically, all analytes eluted before seven minutes. Baseline resolution was achieved for most analytes. Butyrylfentanyl and isobutyryl fentanyl were unable to be distinguished by the LC system, which is a common issue encountered in toxicological analyses. To address this problem, certified reference standards were analyzed using an Agilent® Technologies 6890N Gas Chromatograph (GC) coupled to an Agilent® Technologies 5975B MS equipped with an Agilent Technologies DB-5 (30m x 0.25mm x 0.25 $\mu$ m) column. The GC was able to fully separate these isomeric compounds 12.5min method.

The Limits Of Detection (LOD) for all analytes in blood were 0.1-0.25ng/mL and 0.1-1.0ng/mL in TOF and AIF modes, respectively. In oral fluid, the LOD were 0.25ng/mL and 2.5ng/mL in TOF and AIF modes, respectively. No carryover or interferences (exogenous or endogenous) were observed. Matrix effects in blood were considered acceptable for most analytes with minor ion enhancement of 1%–14.4%, while the nor- analytes (metabolites) exhibited ion suppression >25%. Matrix effects in oral fluid were considered acceptable for all analytes with ion suppression and enhancement ranging from -11.7%–13.3%. Stability was assessed after 24 hours in the autosampler (blood at 22°C and oral fluid at 4°C) and refrigerator (blood at 4°C). All analytes were determined to be stable under each condition, except alfentanil in OF (>25% loss in autosampler). Authentic postmortem blood samples ( $n=30$ ) were positive for: furanyl fentanyl ( $n=16$ ), 4-ANPP ( $n=15$ ), cis-methyl fentanyl ( $n=4$ ), fentanyl ( $n=3$ ), and valeryl fentanyl ( $n=1$ ). Additional drugs of abuse detected included methamphetamine ( $n=2$ ), cocaine ( $n=2$ ), ketamine ( $n=2$ ), 6-MAM ( $n=7$ ), alprazolam ( $n=5$ ), morphine ( $n=8$ ), codeine ( $n=7$ ), hydrocodone ( $n=2$ ), etizolam ( $n=3$ ), amitriptyline ( $n=1$ ), buprenorphine ( $n=1$ ), zolpidem ( $n=1$ ), meperidine ( $n=1$ ), and U-47700 and its metabolites (n-desmethyl-U47700 and n,n-didesmethyl-U47700) ( $n=15$ ). Oral fluid samples ( $n=18$ ) collected from arrestees under an Institutional Review Board (IRB) -approved protocol did not contain any fentanyl analogs. However, additional drugs of abuse detected included methamphetamine ( $n=15$ ), amphetamine ( $n=7$ ), cocaine ( $n=4$ ), 6-MAM ( $n=4$ ), morphine ( $n=2$ ), codeine ( $n=1$ ), alprazolam ( $n=1$ ), and mephedrone ( $n=1$ ).

This research presents two validated screening methods for fentanyl analogs in whole blood and oral fluid using LC-qTOF analysis with low limits of detection. In addition, this research presents an alternative GC/MS application for the separation of fentanyl analogs, specifically, butyryl and isobutyryl fentanyl.

This research was funded by the Forensic Science Foundation Lucas Grant Award and a grant from the National Institute of Justice (NIJ).

### Fentanyl Analogs, Postmortem Blood, Oral Fluid

### K18 Kava Impairment in Drivers

Ashley A. Gilbert, BS\*, Sam Houston State University, Huntsville, TX 77340; Justin Grodnitzky, PhD, Iowa Division of Criminal Investigation Criminalistics Laboratory, Ankeny, IA 50023; Jonna Berry, PhD, Iowa Division of Criminal Investigation Criminalistics Laboratory, Ankeny, IA 50023

**Learning Overview:** After attending this presentation, attendees will better understand the impact of kava on Driving Under the Influence of Drugs (DUID) cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by strengthening the evidence that chronic or larger dosages of kava have detrimental effects on driving performance. To date, few reports investigate the impact of recreational use of kava on the cognitive and motor skills related to driving ability.

Kava, or *Piper methysticum*, is an Oceanic plant that is often consumed as a beverage. When consumed in therapeutic doses, kava has anti-anxiety effects. However, when consumed at high dosages, kava has been reported to produce sedation, tremors, and even a few cases of choreoathetosis. According to drug forums, recreational use of kava gives users a feeling of euphoria and heavy limbs. Despite being native to the Pacific islands, kava is becoming more and more popular in the United States, with kava bars popping up in various cities throughout the country. Kava teas, capsules, and powders are available for purchase at supermarkets and drug stores. Reports have shown that there does not appear to be significant impairment on cognition at acute, therapeutic doses of kava. However, there is evidence of the impairment of motor coordination and visual attention at larger chronic doses.

The psychoactive properties of kava have been attributed to lactone molecules primarily found within the root. Six kavalactones contribute to most of the pharmacological activity: kavain, 7,8-dihydrokavain, methysticin, 7,8-dihydromethysticin, yangonin, and desmethoxyyangonin. Many different modes of action have been suggested for the kavalactones. The main modes of action reported are the interaction of kavain on Gamma-Aminobutyric Acid (GABA) receptors, the interaction of yangonin on cannabinoid receptors, and blockage of voltage-gated Na<sup>+</sup> and Ca<sup>2+</sup> ion channels. It is these interactions that result in an effect similar to that of Central Nervous System (CNS) depressants and cannabis.

The Iowa Division of Criminal Investigation (DCI) Criminalistics Laboratory examined the data collected from suspected kava-impaired drivers. Four cases between November 2011 and April 2018 were reported by Drug Recognition Experts (DREs) for suspected kava use. Of the four cases, two urine samples were positive by Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for the kavalactones yangonin and methysticin. Ethanol was detected in one case, but at <0.02g/dL. No blood samples were available for testing. DRE reports were provided for all four cases. Each of the four drivers admitted to drinking kava prior to driving and no other drugs were found during the toxicology analysis. In all four cases, DRE reports revealed that the kava-inhibited drivers did not pass the standardized field sobriety tests, and horizontal gaze nystagmus was present. The DRE officers in each case deemed the driver under the influence of a CNS depressant and unable to safely operate a motor vehicle. Until recently, no quantitative method was available in this laboratory for kavalactones. However, a new quantitative method was developed for yangonin and methysticin in urine by LC/MS/MS. The administrative cutoff was set to 10ng/mL, which was above the limit of quantification for both yangonin and methysticin in this study. The most recent kava case was analyzed with the new method, but significant degradation of kavalactones was noted, indicating possible instability within a urine sample. Analysis of the DRE and toxicology reports suggest that kava has an impairing effect on the motor skills required for driving.

#### Kava, Drug Recognition Expert (DRE), DUID

## K19 A Comparison of Multiple Extraction/Purification Methods for Novel Psychoactive Substances (NPS) From Biological Matrices

Ashley N. Kimble, BS\*, Miami, FL 33172; Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, Miami, FL 33199

**Learning Overview:** The goal of this presentation is to demonstrate the results of comparing multiple extraction/purification methods for NPS in biological fluids (urine and whole blood).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by optimizing an extraction technique that is capable of handling high throughput and NPS of many different classes, which could greatly benefit forensic toxicology laboratories.

This research was designed to develop/optimize an extraction method capable of isolating a wide variety of NPS from biological fluids. This was accomplished by comparing multiple extraction methods, including online Solid Phase Extraction (SPE), classical SPE, crash/dilute and shoot, and (Quick, Easy, Cheap, Effective, Rugged, and Safe) QuEChERS. The focus of this work was to statistically compare the extraction/purification methods based on drug recovery, drug retention, reproducibility, minimization of matrix effects, time, and overall cost. Although extraction techniques for common drugs of abuse are well studied, developing extraction methods specifically targeting NPS is needed due to the increasing prevalence of NPS in forensic casework.

Dilute-and-shoot was accomplished by diluting urine samples with High-Performance Liquid Chromatography (HPLC) water using a 1:5 dilution followed by Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS) analysis. For crash-and-shoot, 600 $\mu$ L of cold acetonitrile (-20°C) was added to 200 $\mu$ L of whole blood, vortexed, and centrifuged for 5min at 7,000rpm. After being centrifuged, the supernatant was removed and added to an LC vial, evaporated to dryness under a gentle flow of nitrogen, then reconstituted in 200 $\mu$ L of methanol for analysis. Classical SPE was performed following a method previously developed in the laboratory using a positive-pressure SPE apparatus and Agilent® Bond Elut Plexa PCX cartridges. Online SPE utilized an Agilent® 1290 Flex Cube LC unit with a Bond Elut (BE) online polymeric sorbent material (PLRP-S) cartridge.

QuEChERS has been shown to be a successful technique for extracting common drugs of abuse from biological fluids, but also has potential for extracting NPS. QuEChERS is an appealing alternative due to fewer transfer steps, quick extraction time, and decreased cost when compared to other approaches. This work used an in-house developed mini one-pot QuEChERS kit. Samples were added to pre-weighed components (MgSO<sub>4</sub>, NaCl, PSA, C18), shaken by hand, vortexed, and centrifuged at 7,000 rpm for 5min. After centrifugation, the acetonitrile layer was removed and added to an LC vial, dried, and reconstituted in 200 $\mu$ L of methanol. An Agilent® 1290 Infinity® HPLC system and Agilent® 6460 QqQ/MS with Jet Stream Technology Electrospray Ionization (ESI) operated in positive mode was used for analysis, along with an Agilent® Zorbax® Rapid Resolution HD Eclipse Plus™ C18 column for chromatographic separation. All samples were analyzed using a triggered Multiple Reaction Monitoring (tMRM) method that is validated for the detection of multiple NPS. All methods were tested using a mix of 36 NPS, which included compounds and metabolites from different drug classes, at three different concentrations (5ng/mL, 20ng/mL, and 80ng/mL). The four different extraction procedures for NPS in blood and urine were evaluated and compared using two-way Analysis Of Variance (ANOVA) to assess significant differences. If the ANOVA showed a significant difference, a Tukey Honest Significant Difference (HSD) test was completed to determine which specific methods were significantly different.

Findings demonstrated that NPS recoveries from urine with QuEChERS and dilute-and-shoot were not statistically different, while recoveries from blood were significantly higher with QuEChERS than with crash-and-shoot. For example, most synthetic cannabinoids demonstrated recoveries from urine above 75% with QuEChERS. QuEChERS, when used for both blood and urine, showed a decrease in matrix effects for all classes of NPS when compared to crash/dilute-and-shoot. While online SPE is an efficient option, it provided low recoveries for many classes of NPS, especially synthetic cannabinoids. Total time required from extraction start to analysis varied from 5min (dilute-and-shoot) to 3h (classical SPE), while costs varied from relatively inexpensive (dilute-and-shoot and QuEChERS) to expensive (online SPE and classical SPE, due to instrumentation and consumable costs, respectively). Although dilute-and-shoot was the quickest and most cost effective, it is a crude method that can leave matrix components, which can damage instrumentation and lead to unwanted ion suppression and enhancement. In conclusion, results showed that QuEChERS provided the best combination of extraction capability, elimination of matrix effects, time, and cost for application to NPS analysis.

### K21 The Detection and Quantification of 23 Drugs in Blood and Urine Following Solid Phase Extraction (SPE) Using Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS)

Courtney McGowan, BS\*, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Kelsie L. Jenquine, BS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Michael Moretto, BS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118; Shawn Foley, BS, Boston University, Biology Department, Boston, MA 02118; Nichole D. Bynum, MS, RTI International, Johnson Building, Research Triangle Park, NC 27709; Katherine N. Moore, MS, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Biomedical Forensic Sciences, Boston, MA 02118

**Learning Overview:** After attending this presentation, attendees will be able to use the method presented, or develop their own singular method, for both blood and urine analysis of selected amphetamines, antidepressants, anesthetics, opioids, designer, and hallucinogenic drugs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a method that will provide the ability to analyze different drug groups in one method for both blood and urine matrices.

**Background/Introduction:** In forensic toxicology, analysis of drugs in biological fluids is performed to determine cause of death, suspected drug use, drug-facilitated crimes, or whether someone was driving under the influence. Determining what analytes are present and the concentration of those compounds in a variety of matrices (e.g., blood, urine, or oral fluid) can be complex. It is therefore necessary to have optimal sample preparation and instrumental conditions that work for all matrices of interests. Determining the best approach can be challenging due to the amount of time and resources to perform expansive evaluations of sample preparation, stationary/mobile phases, LC conditions, and MS operating parameters.

**Objective:** This project developed and validated an SPE and UPLC-MS/MS method using both human whole blood and urine to identify and quantify selected amphetamines, antidepressants, opioids, anesthetics, designer drugs, and hallucinogenic drugs.

**Method:** Calibration curves and Quality Controls (QCs) were prepared for SPE in 200 $\mu$ L of either drug-free whole blood or donated urine. All donated samples were collected following approved Institutional Review Board requirements. Analytes were spiked at varying concentrations using certified reference standards. Deuterated internal standards were also spiked at a concentration of 200ng/mL. QCs were prepared at 20ng/mL, 125ng/mL, 450ng/mL, and 950ng/mL. SPE was performed with mixed-mode copolymeric Clean Screen<sup>®</sup> DAU columns. Samples were reconstituted in 400 $\mu$ L of Millipore<sup>®</sup> water containing 0.1% formic acid.

The samples were run by UPLC with a 4000 QTRAP<sup>®</sup> Electrospray Ionization Tandem Mass Spectrometry (ESI/MS/MS) in positive ionization mode. Separation was achieved using a Kinetex<sup>®</sup> F5 2.6 $\mu$  100 $\text{Å}$  50mm x 3.0mm column.

**Results:** Bias, precision, Limit Of Detection (LOD), Limit Of Quantitation (LOQ), calibration model, carryover, and dilution integrity, ion suppression and enhancement, and processed stability validation parameters were assessed. All analytes in both matrices had quadratic fit with 1/x weighting, LOQs were 0.5ng/mL, 5ng/mL or 10ng/mL, and no observed carryover. Calibration ranges of 10ng/mL to 1,000ng/mL, 0.5ng/mL to 1,000ng/mL, and 0.5ng/mL–500ng/mL were used. For the 23 drugs in blood, the bias ranged from -18.10% to 11.87%, precision ranged from 0.24% to 14.33%, and recovery in matrix ranged from 85% to 119%. In urine, the bias ranged from -5.40% to 7.67%, precision ranged from 0.09% to 11.99%, and recovery in matrix ranged from 80% to 119%.

**Conclusion/Discussion:** The method containing 23 drugs, including selected amphetamines, antidepressants, anesthetics, opioids, designer, and hallucinogenic drugs, was successfully validated in both blood and urine using the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for method validation. SPE provided clean extracts for analysis by positive ESI-UPLC-MS/MS for both matrices.

#### Solid Phase Extraction, Forensic Toxicology, Multi-Drug Analysis

## K22 Driving Under the Influence of Drugs (DUID) in Different Countries: An Overview

Aldo Di Nunzio\*, Magna Graecia University, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Michele Di Nunzio, BS\*, Biogem scarl, Via Camporeale, area PIP, Ariano Irpino (AV) 83310, ITALY; Antonello Crisci, MD, University of Salerno, Salerno 84084, ITALY; Ciro Di Nunzio, PhD\*, Magna Graecia University Legal Medicine, Viale Europa, Germaneto, Forensic Genetics Laboratory, Catanzaro 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand different countries' policies regarding DUID and how they differentiate from Driving Under the Influence of Alcohol (DUIA).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how different nations/states are fighting the issue of DUID and the importance of synergistic cooperation between police, medical professionals, and forensic toxicologists.

Driving a motor vehicle is not easy. It is a skills-required task and drivers should be aware of their own safety and that of others. Hence, taking substances, such as alcohol or other drugs (also prescribed), before driving is a bad idea. The effects of alcohol on performance and behavior and the clinical tests for drunkenness are widely documented. Indeed, blood alcohol concentration—set as 0.5g/L—is a value internationally recognized by most countries. Studies show that a person's demeanor is altered at this concentration.<sup>1</sup> On the other hand, the situation for drugs is deeply different. While alcohol is just one molecule, drugs represent a class of molecules, totally different from each other (depressants, stimulants, hallucinogens, etc.). Moreover, there are different responses, inter-individuals and intra-individuals, to drugs. Some “drug naïve” subjects can experience dissimilar feelings from drug addicts.<sup>4</sup> Therefore, in this complicated scenario, an arbitrary drug level cannot be set or, at least, driving impairment cannot be defined only on “a laboratory outcome.” There are two main approaches to legislating against drivers who drive while under the influence of drugs. The first is an impairment standard, under which a driver is guilty of the crime of Driving Under the Influence (DUI) if it can be shown that their driving ability is affected by drug or alcohol use. This is the so-called “affected by” approach and it is the most straightforward and relates the person's behavior to the crime of impaired driving. Evidence to support these charges may include appearance, speech, divided attention and balance, etc. The second approach to prosecuting impaired driving behavior is the so-called “per se approach.” Under this construction, the government, based on its obligation to preserve public health and welfare and in consideration of the risks to its citizens of sharing the roadways with impaired drivers, has moved to outlaw driving after having consumed a drug with potentially intoxicating properties. This approach is called per se if a quantitative standard in blood, oral fluid, or urine is set above which driving is prohibited.<sup>2</sup> Today, countries/states are adopting different policies. In Europe, only a few nations (Belgium, Czech Republic, Republic of Ireland, Luxembourg, Norway, United Kingdom) out of 26 set limit values for some drugs (THC, amphetamines, cocaine, morphine).<sup>5</sup> By contrast, in the United States, Nevada and Ohio show a straightforward law, where limits were set also for drugs' metabolites.<sup>3</sup> Other countries (Australia and Russia) have a “zero tolerance;” they did put the limits at the cut-off levels. Italy, as other countries (Lithuania, Malta, etc.), has established no drug limits. In these cases, the offended impairment level is defined when the drug is detected in the blood. Furthermore, it is important for countries/states with no per se law (Alabama, New Jersey, Argentina, etc.) to train police officers to recognize impaired drivers throughout several tests such as a walk-and-turn test, a one-legged-stand, and the assessment of Horizontal Gaze Nystagmus (HGN).

In conclusion, it is significant to understand how drugs affect individual components of the task of driving and how they can affect their overall performance. To consider the extent of the impairment, an overall consideration about behavioral domain analysis, epidemiological monitoring, and empirical toxicological assessment should be performed. To achieve this, a synergistic cooperation among police officers, medical professionals, and forensic toxicologists is extremely important.

### Forensic Science, Driving Impairment, Drugs

### K23 The Impact of Storage Conditions, Sample Volume, and Collection Technique on Blood Alcohol Concentration (BAC) in Non-Decomposed Defibrinated Sheep's Blood

Christian T. Pascual\*, Emporia State University, Emporia, KS 66801; S. Sharee Lambert, BA, Emporia State University, Emporia, KS 66801; Carrie Hodges, MLS, Kansas Bureau of Investigation, Topeka, KS 66604; Melissa M. Bailey, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the effects of the collection technique, time, temperature, sample volume, and presence of excess glucose on the BAC in non-decomposed whole blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the percentage of ethanol is affected when the blood sample is collected and stored under various conditions over a five-month period. This study also investigated how the presence or absence of excess glucose (>240mg/dL) affects the BAC over time, given that blood is often collected from suspects or victims with diabetes or metabolic disorders. The results of this longitudinal study could springboard to policy reforms in terms of the process of collection, storage, handling, or testing of samples taken from suspects of Driving Under the Influence (DUI) cases.

The forensic science community worldwide has no standardized procedures for the collection, storage, handling, or testing of samples for blood alcohol analysis. Degradation of ethanol in blood alcohol samples can be caused by storage temperature, time of storage, and sample volume.<sup>1</sup> If samples need to be re-analyzed or if significant time elapses between evidence receipt and analysis, the samples must be stored correctly to ensure accurate results.<sup>2</sup>

Two sets of aliquots of seven different ethanol concentrations were prepared in defibrinated sheep blood (Hemostat Laboratories): 0g/dL, 0.05g/dL, 0.08g/dL, 0.10g/dL, 0.15g/dL, 0.20g/dL, and 0.30g/dL. D-glucose from Fisher Scientific was added to one set of aliquots in sufficient quantity to result in a blood glucose measurement of at least 240mg/dL. The appropriate sample from each of the aliquot was then added to 10mL gray-stoppered BD Vacutainer® blood collection tubes (GST) in varying amounts: 2.5mL, 5mL, 7.5mL, and 10mL, either by drawing under vacuum (method 1) or by removing the stopper and adding the blood via syringe (method 2). For each ethanol concentration, four groups of samples were made. Group 1 had tubes of each volume as described, with and without excess glucose, collected using method 1 and stored at room temperature (25°C)—8 tubes in total. Group 2 had 8 tubes as in group 1 but were refrigerated at 4°C. Group 3 had 8 tubes as in group 1 but collected using method 2 and stored at room temperature. Group 4 had 8 tubes as described in group 3 but refrigerated at 4°C. All four groups were made at each BAC for monthly analysis (months 0–5), for a total of 1,344 tubes. All the tubes were aliquoted at the beginning of the study. Room temperature was chosen to study the effects of improper storage conditions that could be encountered if samples are not appropriately refrigerated in a timely manner. Each month, samples were analyzed in duplicate with an internal standard of 0.002% 1-propanol in water by an Agilent® 7820A GC and 5977E MS with headspace after instrument calibration; with 0.10g/dL standards run every 46 vials.

The data in the study were analyzed using Analysis of Variance (ANOVA) in which the level of significance was tested with the *p*-value of 0.05. The study discovered that over time, samples with lower volume had a greater ethanol loss than samples with higher volume (0.014g/dL vs 0.006g/dL). Additionally, the samples collected through method 1 had more ethanol loss than those collected through method 2 (0.01g/dL vs 0.008g/dL). Samples that were stored at room temperature had a higher percentage of ethanol loss as compared to those that were refrigerated (0.016g/dL vs 0.004g/dL). However, the presence of excess glucose does not significantly affect ethanol loss. These findings show that storage temperature, collection technique, and sample volume may affect ethanol concentration in blood samples and these factors should be considered when drawing conclusions about data obtained from case samples.

## K24 *In Silico* Simulation of Fentanyl Raman Spectra

Madison R. Schackmuth, BS\*, Huntsville, TX 77340; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX 77340; Darren L. Williams, PhD, Sam Houston State University, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will be familiar with the use of Gaussian modeling for the simulation of fentanyl Raman spectra.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging preemptive characterization of novel fentanyl structures with Gaussian modeling of Raman spectra.

Fentanyl and its analogs (fentologs) are mu ( $\mu$ ) receptor agonists capable of causing severe respiratory depression in conjunction with the typical opioid toxidrome.<sup>1</sup> The number of deaths associated with fentanyl and its analogs has increased, particularly in North America, and cases involving seized fentologs more than doubled from 2015 to 2016.<sup>2,3</sup> Potential hazards to law enforcement, emergency responders, and forensic scientists have also drawn concern. Screening methods that can keep pace with the fentolog development are in high demand. Raman spectroscopy is non-destructive and capable of elucidating chemical structures of substances through packaging in solution, in all states of matter.<sup>4</sup> Due to safety concerns and licensure requirements for obtaining powdered forms of Schedule I controlled substances, modeling of fentolog structures was performed *in silico*. Predictive modeling of Raman spectra can be used to explore the properties of novel synthetic structures and create libraries prior to their appearance on the illicit drug market.

Gaussian 09 software package and density functional theory calculations were used to simulate Raman spectra for the fentologs. The fentanyl structure was modeled in GaussView 5.0 software. The geometry of the structure was optimized, and the vibrational frequencies determined through simulation with the Gaussian 09W software. Four levels of theory were used to optimize the geometry including molecular mechanics, semi-empirical, Hartree-Fock (HF), and Density Functional Theory (DFT). The simulation excluded solvation as a parameter and was optimized at room temperature. Fentanyl was optimized at a vibration theory/geometry optimization of B3LYP/6-311G(d)/B3LYP/6311G(d). The structures of seven fentologs ((+)-Cis-3-methylfentanyl, 4-ANPP, acetylfentanyl, butyrylfentanyl, furanylfentanyl, isobutyrylfentanyl, and norfentanyl) were modified in GaussView 5.0 from the optimized fentanyl structure. The analogs were simulated through three levels of theory and basis sets: HF STO-3G, DFT B3LYP 6-31G(d), and DFT B3LYP 6-311G(d). The total energies (Hartree) of the simulated structures were compared to assist in selecting the lowest energy structure. The transition wavenumbers and intensities calculated by Gaussian were plotted in a spreadsheet. A normal distribution was plotted around each transition wavenumber (spectral line) considering the spectral resolution (transition width) as the standard deviation. The normal distribution was multiplied by the transition intensity. The area under the normal distribution curve at each increment wavenumber value along the x-axis was summed to graph the simulated intensity. Elevated baseline and baseline slope parameters were simulated by adding a user-defined value to the spectral intensities. Spectral resolution was administratively set at 8  $\text{cm}^{-1}$ . The fentolog spectra are consistent across modification groups with the presence or absence of bands corresponding to specific vibrations that can be utilized for differentiation.

**Learning Overview:** After attending this presentation, attendees will be able to show how the toxicological examination remains a crucial scientific piece of evidence in cases of death from thermal energy, especially when the autopsy does not clarify all aspects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the role of toxicological investigation and the circumstantial data in order to investigate the correct sequence of events in a fire.

Traumatic injuries due to thermal energy include all the effects produced by exposure of the human body to temperatures that are too high or too low compared to the body's adaptability. The type of lesions sustained depends on the temperature level. Heat injuries can be determined by the increase in temperature, electricity, radiation, nuclear energy, or corrosive or caustic substances. The contact between a heat source and the body surface determines the production of burns on the skin. In some cases, the affected area is large, so that in addition to local effects, a systemic syndrome occurs that affects various organs and systems. Burns are a serious public health problem. Burns generally occur in domestic or work environments, but also as a result of traffic accidents, self-harm, or assaults.<sup>1</sup> Burns are classified, according to the depth of the lesion, as: first degree—epidermis; second degree—superficial dermis; third degree—deep dermis; fourth degree—deep soft tissues; and fifth degree—bones and joints.<sup>2,3</sup>

The analysis of thermal energy lesions is fundamental to establish the therapy and the prognosis for the patient. In the forensic field, the main purpose is understanding the cause and the modality of death. The injuries can be caused by a murder, an accident, or a suicide. In cases of death related to a fire, the autopsy is not always sufficient to establish the diagnosis and the manner of death. This study will demonstrate the determinant contribution of toxicological analysis in the diagnosis and reconstruction of the mode of death, in accordance with other data collected.

Reported here is the case of two boys found dead inside a commercial premise destroyed by fire. At the entrance to the room, it was noted that the interior had been destroyed by the flames, with evidence of an intense smell of flammable liquid. The 3D Computed Tomography (CT) excluded the presence of gunshots in both cases. In the first case, the autopsy showed deep burns, especially on the arms and legs, with black smoke spots on the palate. In the second case, superficial burns and the presence of soot in the glottis were detected. The percentage of carboxyhemoglobin and the presence of alcohol, drugs, or psychoactive drugs by mass spectrometry were investigated. The toxicological analysis showed in both cases that death was due to carbon monoxide poisoning in different percentages: 40.75% in the first case; 24.18% with presence of ecgonine and benzoylecgonine in the urine in the second case. In the first case, death was also due to burns spread by burning highly inflammable material.

The analysis of the cause of death in victims of fires is a great forensic enigma. In these cases, death may have occurred before, during, or after the fire. To reconstruct the event, the forensic pathologist must evaluate the circumstantial data during the inspection and investigate the signs of vitality at autopsy. Among these is highlighted the discovery of the soot in the glottis, in the trachea, and in the lungs, with the presence of extensive burns on the corpse. Often the signs present at the autopsy are not sufficient for diagnosis. In literature, a retrospective study on 107 firefighters showed that only about 65% of cases show signs of viability in the airways at autopsy. In the remaining cases, the signs are not significant or are even absent.<sup>4</sup> In these events, the role of toxicological investigation is crucial. Carbon monoxide levels are indicative that the victim was still alive at the time of the fire.<sup>4-7</sup> In this case, the toxicological data has been decisive for determining the cause of death, but has also contributed to defining the modalities of the event. This investigation, in agreement with the circumstantial data, suggested that the disaster had been caused by arson. The performing of 3D CT and autopsy remains essential to rule out other possible causes of death.<sup>8</sup>

### K27 Metabolic Profiling of the Synthetic Cannabinoid AB-FUBINACA Using an Electrochemical Cell, Human Liver Microsomes, Cryopreserved Hepatocytes, and Liquid Chromatography/High Resolution Mass Spectrometry (LC/HRMS)

Eduardo M. Cardoso, MSc\*, Federal Police of Brazil, Minas Gerais 30441-170, BRAZIL

**Learning Overview:** After attending this presentation, attendees will better understand the challenges associated with Synthetic Cannabinoids (SCs) analyses and the different approaches to tackle the problem. The goal of this presentation is to assess electrochemical cell forced oxidation as a suitable tool for metabolite investigation and to identify major and specific biomarkers to unequivocally confirm intake of the synthetic cannabinoid AB-FUBINACA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting an unusual tool as a complementary technique for the characterization of metabolic pathways of new chemical entities.

In the present research, the goal is to characterize the phase I metabolism of the SC AB-FUBINACA, chosen due to recent prevalence studies.<sup>1</sup> *In vitro* metabolism was investigated using Human Liver Microsomes (HLM), Cryopreserved Human Hepatocytes (CHH) and forced electrochemical oxidation assays, and the metabolic entities separated and identified using LC/HRMS.

One of the main issues of SC analysis is the emergence of new compounds with unknown metabolic profiles, which means no urinary marker metabolites are known. Since the clandestine chemists' strategy is to make minor alterations on the pharmacophore core of the molecule, it is not uncommon to have the same metabolites coming from different parent SCs. For instance, 5'-OH-JWH-018 can derive from hydroxylation of the JWH-018 pentyl chain, but also from oxidative defluorination of AM-2201.<sup>2</sup> This is even more problematic when isomeric compounds are present with similar metabolic pathways, with one drug scheduled while its pair is not, such as the case with BIM-2201 (FUBIMINA) and THJ-2201 (each scheduled in the United States on different dates).<sup>3</sup>

With the data gathered in this research, a metabolic pathway was proposed. The incubation of AB-FUBINACA with HLMs in the presence of Nicotinamide Adenine Dinucleotide Phosphate (NADPH) resulted in the formation of six metabolites, including two mono-hydroxylations (M1.1 and M1.2), the amide hydrolysis (M2), a dehydrogenation (M3), and two mono-hydroxylations of the amide hydrolysis (M4.1 and M4.2). The hepatocytes yielded similar results, but the prevalence of the metabolites changed, being mainly dominated by the amide hydrolysis and some related by-products. The Electrochemical Cell (EC) -forced oxidation displayed a range of multiple hydroxylations (mono, di, and tri), carbonylations/ epoxylation, and carboxylations, although no amide hydrolysis could be detected. Authentic urine samples confirmed that the hepatocytes displayed the closest correlation between *in vivo* and *in vitro* investigations. The electrochemical cell-forced oxidation proved to be a fast and cost-effective tool for the prediction of new chemical entities. However, it was not able to predict the main *in vivo* metabolic pathway, probably due to the conditions used in the experiment (low buffer strength, room temperature, and duration of the assay). Optimization of the EC assay conditions may lead to better results.

It seems that the amide hydrolysis (M2) and the glucuronidation of the amide hydrolysis (M5) are suitable urinary markers, but these are not specific markers for intake of AB-FUBINACA, since they can be formed by ester hydrolysis from AMB-FUBINACA or EMB-FUBINACA. A better biomarker would be a metabolite with intact terminal carboxamide groups, like M1.2, but it was only found in the *in vitro* experiments and not in the urine samples. Further *in vivo* investigations are suggested to confirm or refute M1.2 as a suitable marker and evaluate the influence of inter-individual variability.

## K28 Methadone Overdose in Patients Following Methadone Maintenance Treatment: An Italian Issue

Matteo Favia\*, Laboratory of Forensic Toxicology, Bari 70124, ITALY; Ilaria Santoemma, Laboratory of Forensic Toxicology, Bari 70124, ITALY; Quintino Mita, BS, Laboratory of Forensic Toxicology, Bari 70124, ITALY; Giuseppe Strisciullo, BES, University of Bari, Bari 70124, ITALY; Francesco Introna, MD, Dim Sezione Di Medicina Legale, Bari 70124, ITALY; Antonio De Donno, PhD, Laboratory of Forensic Toxicology, Bari 70124, ITALY

**Learning Overview:** The goal of this presentation is to increase awareness of the problem of overdose deaths in patients following Methadone Maintenance Treatment (MMT) in Italy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the importance of developing new guidelines in methadone maintenance treatment for opioid-addicted patients in order to avoid overdose deaths.

Methadone is an opioid like heroin or opium. MMT is recognized as a reference treatment for opioid dependence. Cases of methadone overdose in patients following MMT are already described in the existing scientific literature.

According to Italian law, at the beginning of the treatment, patients must receive medication under the supervision of a physician to avoid an overdose. After a period of stability, patients are allowed to take methadone at home in pre-arranged and personalized concentrations to empower their self-responsibility.

It has been estimated that plasma methadone levels should be at least 0.05mg/L–0.10mg/L (50ng/ml–100ng/ml) to prevent withdrawal symptoms in narcotic maintenance patients.

In methadone maintenance subjects, the mean blood level of methadone is around 110ng/ml. Detected average concentration of methadone was 280ng/ml in 59 victims of fatal methadone overdose. Methadone is largely metabolized by mono and di-N-demethylation, with spontaneous cyclization of the resulting unstable metabolites to form 2-ethylidene-1,2-dimethyl-3,3-diphenylpyrrolidine (EDDP) and 2-ethyl-5-methyl-3,3-diphenylpyrrolidine (EMDP). In some cases, it may be useful to quantitate EDDP concentrations, as the presence of the metabolite in substantial amounts may indicate prior usage of the drug and therefore tolerance to its effects, although the organs' relative amounts of methadone and EDDP would of course also depend on survival times after administration.

In the past year, five forensic autopsies on corpses of regular opioid users were performed at the Institute of Legal Medicine of Bari, Italy. Four were found dead in their homes. In two of those cases, there were empty and loaded syringes next to their bodies and multiple track marks over the bodies. In one case, the subject died from a stabbing, but she was following MMT.

In all these cases, very high methadone concentrations in blood were found (785ng/ml, 1,356ng/ml, 1,188ng/ml, 626ng/ml, 983ng/ml). Toxicological analysis also showed very high concentrations of EDDP in blood (respectively 1,494ng/ml, 2,790ng/ml, 1,565ng/ml, 1,23 ng/ml, 490ng/ml). The average blood level of methadone in these cases was 987.6ng/ml, against 1,514.4ng/ml of EDDP. Both Methadone (MTD) and its metabolite 2-Ethylidene-1,5-dimethyl-3,3-diphenylpyrrolidine (EDDP) were identified and quantified by Gas Chromatography/Mass Spectrometry (GC/MS) analysis on an Agilent® 6890 GC coupled 5973 inert mass spectrometer, following Liquid-Liquid Extraction (LLE) from cadaveric blood by organic mixture solvents at pH 9.0. The amount of sample for analysis was 1ml.

Overdose with methadone is characterized by stupor, muscle flaccidity, respiratory depression, cold and clammy skin, miosis, hypotension, coma, and circulatory collapse. After performing an autopsy and ancillary analysis, it was possible to conclude that the cause of death was respiratory depression by overdose of methadone in four cases. In the cases described in this study, no other substance of abuse was found, apart from the fifth case that showed both methadone and cocaine abuse. All five subjects were following an MMT in a public health institute.

Fatalities in adults from methadone overdose have increased significantly in many urban areas because of the widespread availability of the drug, both from licit and illicit sources. An improvement of the MMT's guideline is needed to reduce future methadone overdose deaths. This study suggests delivering methadone under strict medical control, not only to avoid cases of overdose, but also the possibility that opioid users following MMT are selling methadone on the black market. A strict monitoring of the drug concentration in the blood of the addict attending MMT to assess adherence to the medical plan is also recommended.

### Methadone, Overdose, Methadone Maintenance Treatment

## K29 Yohimbine Quantification in Postmortem Specimens: Two Case Reports

Matthew N. Newmeyer, PhD\*, Office of the Chief Medical Examiner, Baltimore, MD 21223; Rebecca Jufer Phipps, PhD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Barry S. Levine, PhD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Zabiullah Ali, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; John Stash, DO, Office of the Chief Medical Examiner, Baltimore, MD 21223; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to describe two postmortem cases in which yohimbine was identified during routine analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding valuable data for improved interpretation of yohimbine-positive postmortem cases.

Yohimbine is an indole alkaloid, approved in the United States to treat erectile dysfunction. It is also abused on the streets and used as a nutritional supplement among body builders.<sup>1</sup> Yohimbine is a potent  $\alpha$ -adrenoreceptor antagonist, leading to an increase in noradrenaline and dopamine.<sup>2</sup> Yohimbine was identified in two postmortem cases during routine analysis and quantified via a validated Gas Chromatography/Nitrogen Phosphorus Detection (GC/NPD) method.

In the first case, the decedent was a 53-year-old male found alone in his residence. The decedent had no significant medical history; however, he was a known Phencyclidine (PCP), cannabis, and ethanol user. Heart blood, subclavian blood, urine, bile, liver, and kidney were submitted for toxicological analysis. The second case involved a 47-year-old male who was reported missing. The decedent's car was located parked on a bridge, and the decedent was later found 2,000 yards from shore. According to the decedent's mother, the decedent was depressed with previous suicide attempts. He was a known methadone and cocaine user. Cavity blood, urine, bile, liver, and kidney were submitted for analysis. Routine toxicological analysis included volatiles, an acidic/neutral drug screen, an alkaline drug screen, and Enzyme-Linked Immuno-Sorbent Assay (ELISA) for morphine, benzodiazepines, and oxymorphone.

In case 1, the urine drug screen detected PCP and yohimbine; ethanol and other volatiles were not detected in the heart blood. PCP was quantified in the heart blood at 0.1mg/L. Yohimbine in the heart and subclavian blood were 7.3mg/L and 5.3mg/L, respectively (central/peripheral ratio 1.4); additionally, yohimbine in the urine, bile, liver, and kidney were 34mg/L, 11mg/L, 47mg/kg, and 10mg/kg, respectively (liver/central ratio 6.4, kidney/central ratio 1.4). The cause and manner of death were yohimbine intoxication and undetermined, respectively. In the second case, the urine drug screen was positive for several substances; on subsequent analysis, the cavity blood contained cocaine <0.05mg/L, benzoylecgonine, methadone 1.0mg/L (liver methadone 3.4mg/kg), dextromethorphan 0.1mg/L, and mirtazapine 0.06mg/L. Ethanol and other volatiles were not identified. Yohimbine was only identified in the cavity blood and urine at 0.1mg/L and 0.2mg/L, respectively. The cause and manner of death were multiple injuries and drowning and suicide, respectively.

There are few reported postmortem yohimbine data in the literature. In one report of two fatal overdoses, yohimbine was identified in iliac blood at 7.4mg/L (case 1) and heart blood at 5.4mg/L (case 2).<sup>3</sup> In another report, a patient presented to the hospital following ingestion of a large amount of yohimbine and was successfully treated; 3h after ingestion the blood yohimbine concentration was 5.2mg/L.<sup>1</sup> The central and peripheral blood yohimbine concentrations from case 1 presented agree with postmortem concentrations previously reported, while the cavity blood yohimbine concentration in case 2 falls in the range of maximum concentrations observed in controlled administration studies reported elsewhere.<sup>2</sup> Care must be taken when interpreting and comparing postmortem drug concentrations, and postmortem redistribution must always be considered. The data presented indicated yohimbine may be susceptible to redistribution. These data are a valuable addition to the toxicological literature and will help improve interpretation of postmortem yohimbine concentrations.

### **K30 Validation of an Assay for Amphetamines in Postmortem Samples Using Supported Liquid Extraction (SLE) and Biotage® Extrahera™ Automation Followed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Analysis**

*Heidy P. Rivera, BA\*, Elizabeth, NJ 07202; Kristen M. Bailey, MS, Office of the Chief Medical Examiner, Charleston, WV 25302; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701; James C. Kraner, PhD, Office of the Chief Medical Examiner, Charleston, WV 25302*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the importance of integrating automation in the forensic toxicology laboratory for the purpose of reduced analyst time and improved assay consistency.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the Biotage® Extrahera™ robotic platform for automated drug extraction is capable of efficiently and reliably processing up to 96 samples in a single batch. This method validation demonstrated that the automated method was capable of successfully performing extractions at the intended use level and can be used to replace the current manual extraction for casework involving amphetamines.

The Biotage® Extrahera™ is an automated robotic instrument that can perform an extraction on up to 96 samples, allowing for an increase in time efficiency and minimization of error by increasing pipetting precision and reducing the risk of contamination between samples. The Biotage® Extrahera™ utilizes an interchangeable platform that can be customized for SLE, SPE, Phospholipid Depletion (PLD), and Protein Precipitation (PPT)-based methods.

In this study, an SLE method for amphetamines in postmortem whole blood using the Biotage® Extrahera™ and LC/MS/MS analysis was validated in accordance with the Scientific Working Group for Forensic Toxicology (SWGTOX) Standard Practices for Method Validation in Forensic Toxicology published in 2013. A 200µL aliquot of calibrators, controls, and whole blood samples were manually pipetted onto a Thomas Scientific 1mL, 96-well plate that was loaded onto the Biotage® Extrahera™ where the samples were extracted utilizing a Biotage® Isolute® SLE+ 400µL 96-well plate and a Waters® 2mL 96-well square collection plate. Deuterated analogs of the analytes of interest were used as internal standards. A 100µL aliquot of the eluate was evaporated to dryness and reconstituted on the Biotage® Extrahera™ with 1000µL of Optima-grade water for injection onto a Waters® LC/MS/MS system. Samples were then analyzed by electrospray ionization in positive-ion Multiple Reaction Monitoring mode with optimized collision energy for the precursor ion selected, monitoring two or three transitions for each analyte of interest. The validation plan consisted of studies for various interferences, calibration model, ionization suppression/enhancement, carryover, bias and precision, Limit Of Detection (LOD), and Limit Of Quantitation (LOQ). The analytes of interest were amphetamine, methamphetamine, phentermine, ephedrine/pseudoephedrine, phenylpropanolamine, MDA, and MDMA.

This method produced data that met the acceptance criteria established for the validation. The internal standard, analyte, and matrix interference studies revealed that no deuterated internal standard, commonly encountered non-target analytes, or matrix components produced a signal for any of the target analytes. The method was free from carryover at 3,000ng/mL for each analyte. Ionization suppression or enhancement was less than ±25%. The proper calibration model and weighting function was chosen for each analyte using a Microsoft® Excel® spreadsheet. The method also produced the following quantitative data: the LOD and LOQ for amphetamine, methamphetamine, phentermine, ephedrine, phenylpropanolamine, MDA, and MDMA were 20ng/mL, 10ng/mL, 40ng/mL, 10ng/mL, 10ng/mL, 10ng/mL, and 10ng/mL, respectively. For all compounds, bias and precision were within 20%.

### **K31 Method Validation for Simultaneous Identification and Quantification of Postmortem Volatiles in Whole Blood (WB), Vitreous Humor (VH), and Cerebrospinal Fluid (CSF) Using Gas Chromatography/Headspace/Flame Ionization Detector (GC/HS/FID)**

*Supriya Krishna, MSc\*, All India Institute of Medical Sciences, Department of Forensic Medicine & Toxicology, New Delhi 110092, INDIA; Om P. Murty, MD, All India Institute of Medical Sciences, Department of Forensic Medicine & Toxicology, New Delhi 110092, INDIA; Ashok K. Jaiswal, PhD, Forensic Medicine, New Delhi 110029, INDIA; Tabin Millo, MD, All India Institute of Medical Sciences, Department of Forensic Medicine & Toxicology, New Delhi 110092, INDIA*

**Learning Overview:** After attending this presentation, attendees will gain appreciation for the application of a validated GC/HS/FID methodology for simultaneous detection and quantification of seven volatiles as detected in stored whole blood, vitreous humor, and cerebrospinal fluid.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping toxicologists understand the intricacies and significance of analyzing many volatiles in single run using acetonitrile as an internal standard. This will also help attendees better understand the correlation of ethanol concentration between each body fluid.

Determination of blood alcohol content is a frequently requested assay in forensic toxicology laboratory. Although determination of alcohols in blood is a routinely used procedure, the results and methodologies are constantly improving. A highly sensitive, reproducible, and rapid GC method was validated for the analysis of seven volatiles frequently encountered in stored samples and samples collected within hours of autopsy. The extensive review of literature in this field yielded methods with extensive instrumentation and method preparation. Although the use of GC for the determination of blood alcohol concentration is a routinely used procedure, its validation for the use for stored and postmortem samples is an emerging research field. This presentation covers a method, using GC/HS/FID, capillary column (DB-624) and carrier gas-Nitrogen, validated to analyze ethanol, methanol, acetone, acetaldehyde, N-propanol, I-propanol, and N-butanol in different postmortem matrices such as femoral blood; vitreous humor and cerebrospinal fluid; with acetonitrile as an internal standard. Addition of an internal standard (acetonitrile) was ensured to authenticate results and compensate for any matrix changes. A good peak resolution between volatiles and internal standard was achieved. Linear correlation was achieved for peak area and concentration across the range of 3.95mg to 316mg/100ml with a correlation coefficient within the range of 0.988–0.999 for all matrixes. Limit of Quantitation (LOQ) and Limit of Detection (LOD) were within the range of 0.1mg%–1mg% for all matrixes. Reproducibility of samples and standards, inter- and intra-day, resulted in precision and accuracy within the range of acceptance as prescribed by validation guidelines. The sample volume required for validation was 1ml. With the developed method, no sample preparation or pre-treatment was required for volatile estimation. The total run time of the GC and HS cycle was 24.68min after sample sealing. The advantage of simultaneous screening of volatiles is important in forensic toxicology because of the possibility of identification of volatiles in single run, less sample utilized, and easy results for interpretation.

In conclusion, the proposed methodology serves to analyze the compounds, quantitatively and qualitatively utilizing minimum sample volume, and analysis of different biological fluids with the same method resulted in a methodology competent enough to be used in research and forensic samples.

### K32 Ethylenediamine Opioid Analogs, AH-7921, and U-47700 and Their Actions on Cloned Human OPRM1 Receptors

John L. Krstenansky, PhD\*, Keck Graduate Institute School of Pharmacy, Claremont, CA 91711; Alexander C. Zambon, PhD, Keck Graduate Institute, Claremont, CA 91711; Thomas Hsu, PhD, Keck Graduate Institute, Claremont, CA 91711; Jayapal Mallareddy, PhD, Keck Graduate Institute School of Pharmacy, Claremont, CA 91711

**Learning Overview:** After attending this presentation, attendees will learn about the development of an *in vitro* human mu-opioid receptor assay (hOPRM1) and the testing of analogs related to emerging synthetic opioids AH-7921 and U-47700.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing attendees to see how human receptor data compares to literature data that had only been performed in animals for some important emerging opioids of abuse.

The published pharmacology for the AH-7921 and U-47700 is more than 35 years old and was performed using non-human receptor systems.<sup>1-5</sup> While animal data and data using non-human receptors suggest similar action in humans, it is clearly more desirable to use human receptors to more accurately predict activity in humans. Considering the recent abuse of these opioids, this study sought to assess their pharmacology using a cloned human  $\mu$ -opioid receptor (hOPRM1) in an *in vitro* stable human cell line.

Analogs within the AH-7921 and U-47700 series were synthesized and characterized by Nuclear Magnetic Resonance (NMR), Gas Chromatography/Mass Spectrometry (GC/MS), Infrared (IR), and Raman (1,064nm and 785nm). In the U-4770 series, the stereochemically pure R,R and S,S isomers were synthesized from single isomer intermediates.

An amino terminal HA-tagged hOPRM1 receptor was stably expressed using lentiviral transduction in human fibrosarcoma HT1080 under control of the EF1a promoter. Agonists acting at the hOPRM1 receptor activate  $G_{ai}$ , which in turn suppresses cAMP levels. Therefore, to characterize hOPRM1 pharmacology, analogue-mediated suppression of forskolin-induced cAMP accumulation was measured. In addition, to determine if changes in cAMP were mediated by hOPRM1 receptors, a treatment group containing 1mM naloxone in addition to the highest dose of the test analogue was assessed. The levels of cAMP were measured using a commercial kit, ELISA-based Catchpoint assay. Optimization of the assay involved dose ranging the amount of naloxone needed to show complete agonist reversibility, buffer optimization to maintain cell adherence and minimize cell loss during the assay, and optimizing the sequence of reagent introduction to obtain consistent results.

The optimized assay was used to run full-concentration response curves for morphine, AH-7921, and U-47700 (R,R stereochemistry). The EC<sub>50</sub> values were 39nM, 16nM, and 10nM, respectively. These values are in agreement with the potencies reported in earlier literature. The (S,S) isomer of U-47700 had significantly less potency at this receptor. The literature suggests these analogs bind to both mu- and kappa-opioid receptors (OPRM1 and OPRK1) but with differing affinities based on their stereochemistry.<sup>3</sup> In a variety of series related to AH-7921 and U-47700, the 3,4-dichlorobenzoyl substitution consistently demonstrated the greatest potency relative to other substitutions on the benzoyl group.

In conclusion, an *in vitro* assay that can assess the human abuse potential of emerging opioids has been developed and the stereochemistry of the U-47700 stereoisomer more liable for abuse, (R,R), has been confirmed.

**THIS ABSTRACT WAS NOT PRESENTED.**

### **K34 An Analysis of Alcohol Metabolites Ethyl Glucuronide and Ethyl Sulfate in Human Umbilical Cord Samples**

*Marykathryn Tynon Moody, MSFS\*, NMS Labs, Willow Grove, PA 19090; Joseph Homan, MS, NMS Labs, Willow Grove, PA 19090; Denise Nicole Schiller, MSFS, Bristol, PA 19007; Wendy R. Adams, PhD, NMS Labs, Willow Grove, PA 19090; Frederick Strathmann, PhD, NMS Labs, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/Center for Forensic Science Research and Education, Willow Grove, PA 19090; Robert A. Middleberg, PhD, NMS Labs, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will be able to discuss a method for detecting ethyl glucuronide in human umbilical cord samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the capability of an analytical method that can be used to analyze ethyl glucuronide in umbilical cord samples as a biomarker of alcohol use during pregnancy.

Alcohol is the most popular legal psychoactive drug used in the United States. Due to its use and abuse across a variety of ages, races, and genders, the concern for prenatal exposure to ethanol is one to be taken seriously. While approximately 90% of pregnant women between the ages of 15 and 44 years old report they are abstaining from alcohol, maternal self-report is not always reliable. Many women do not want to self-incriminate or face the social stigma of reporting alcohol use; also many women reporting data may inadvertently have recall bias skewing the overall percentages. A more reliable and objective method to identify prenatal ethanol exposure would be beneficial to allow more timely intervention if needed.

The two alcohol metabolites focused on in this project are ethyl glucuronide and ethyl sulfate. These metabolites are formed by ethanol undergoing conjugation with either a glucuronide or a sulfate group, respectively. The detection of ethyl glucuronide has been reported in multiple newborn specimen types; however, there is very little data on ethyl sulfate.

This presentation describes a screening and confirmation method for the analysis of ethyl glucuronide and ethyl sulfate using a homogenizing-crash extraction with Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

The method was validated according to a Scientific Working Group for Forensic Toxicology (SWGTOX) -compliant procedure for a qualitative assay including experiments that evaluated precision around the decision concentration (cut-off), sensitivity and specificity, robustness, evaluation of interfering compounds, matrix effect, and extraction efficiency and stability of the analyte in extract and post-extraction stability.

Sample preparation for both the screening and confirmation methods consisted of an external cleaning process to remove contamination from the samples, followed by homogenizing the sample coupled with a protein precipitation. The extract was then diluted prior to instrumental analysis. The analytical method was performed on an AB SCIEX™ 6500+ triple quadrupole mass spectrometer equipped with an Electrospray Ionization (ESI) source for both methods. Separation was achieved using a Waters® CSH C18 (3mm x 100mm, 3.5micron) column coupled with 2 Phenomenex Security Guard Cartridges Polar-RP for the screening assay and a Waters® HSS T3 (3mm x 100mm, 3.5micron) column coupled with 2 Phenomenex Security Guard Cartridges Polar-RP for the confirmation assay.

These methods produced data that met the acceptance criteria established for the validation. Both methods produced 94% sensitivity and 100% specificity during the validation. It was also determined that there was no significant carry over after a sample of high concentration, and that there were no interferences when looking at 39 related compounds and common drugs of abuse. The analyte was stable in the extract for seven days, and stable in the auto-sampler vial for three days post-initial analysis. During development and validation, 138 patient cases were analyzed for ethyl glucuronide, and 124 cases for ethyl sulfate, and it was determined the estimated positivity rate for ethyl glucuronide was 4.35% and 100% for ethyl sulfate. Due to the 100% positivity rate for ethyl sulfate, it was removed from the scope while more information can be obtained.

#### **Ethyl Glucuronide, Umbilical Cord, Forensic Toxicology**

### K35 2,4-Dinitrophenol (2,4-DNP)—An “Old New Drug”: A Gas Chromatography/Mass Spectrometry (GC/MS) Method for Screening and Quantitation of 2,4-DNP in Postmortem Blood Specimens and Three Fatal Poisoning Cases Reports

Eduardo G. de Campos, MSc\*, Center for Forensic Science Research and Education, Willow Grove, PA; Melissa Friscia, MSFS, Center for Forensic Science Research and Education, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/Center for Forensic Science Research and Education, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will be able to describe a GC/MS method for the toxicological analysis of 2,4-DNP in blood and its concentration in authentic postmortem specimens.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel method for the analysis of 2,4-DNP in whole blood specimens and by reporting concentrations of 2,4-DNP found in authentic postmortem blood samples for future reference.

**Introduction:** 2,4-DNP is a substance that has been used as a pesticide and for manufacturing explosives and dyes. In 1933, 2,4-DNP was initially used as a weight-loss drug, but it was prohibited for human consumption in 1938 due to its serious adverse effects, including extreme loss of weight, hyperthermia, fatigue, respiratory depression, and death. In recent years, there have been reports of 2,4-DNP reemerging as a weight-loss drug and of associated lethal intoxication induced by this compound.

**Methods:** Sample preparation was performed by Liquid-Liquid Extraction (LLE). The samples were pretreated with a clean-up basic extraction using 0.1 N NH<sub>4</sub>OH, followed by an acidic extraction using 0.1 N HCl to target the 2,4-DNP, using n-butyl-chloride as the extraction solvent. 4-nitrophenol was used as the internal standard. Samples were rotated for 15min and centrifuged for 10min at 4,600rpm. After the final acidic extraction, the organic layer was collected and dried under nitrogen flow at 35°C for 30min. The extract was reconstituted in N,O-Bis(Trimethylsilyl)Trifluoroacetamide (BSTFA) -1% Trimethylchlorosilane (TMCS) and derivatized for 30min at 80°C. Analysis was performed by GC/MS, with electron impact ionization, and using hydrogen as the carrier gas. An HP-5MS column (30m x 0.2mm x 0.25um) was used and the total run time was 8.5min. Injector, MS source, and MS quadrupole temperatures were set to 265°C, 230°C, and 150°C, respectively.

**Results/Discussion:** A method with no derivatization was first evaluated using GC/MS with hydrogen and helium as carrier gases. However, underivatized-2,4-DNP was only detected at elevated concentrations using helium as the carrier gas. This study further evaluated a BSTFA derivatization step to increase the sensitivity. A recovery of 84% for 2,4-DNP was achieved with the LLE method. The method also showed good linearity in the range of 1.0mg/L–100mg/L (R<sup>2</sup>=0.9979).

Postmortem blood samples collected during autopsies from three suspected 2,4-DNP-related cases were analyzed. Case 1 was a 21-year-old male who was admitted to the emergency room after allegedly ingesting about 3mL of wintergreen oil. He presented with shortness of breath, increased body temperature, sweating, and increased heart rate. A family member stated that he had been consuming a thermogenic supplement, and a bottle of 2,4-DNP with an Aldrich® label was found at his house. The concentration of 2,4-DNP in his blood collected at the time of autopsy was 48mg/L. Case 2 was a male who presented with a 2,4-DNP concentration in postmortem iliac blood of 13mg/L. Case 3 was a female who was found dead and had a weight-loss supplement in her purse containing 2,4-DNP. A concentration of 3.3mg/L was found for 2,4-DNP in femoral blood.

**Conclusions:** 2,4-DNP is a highly polar phenolic compound and its detection by GC is an analytical challenge because 2,4-DNP shows a strong interaction with the stationary phase. In addition, 2,4-DNP derivatization by silylation with BSTFA seems to be very sensitive to reaction medium—better results were achieved when the derivatization was promoted with no solvent in the reaction medium (as acetonitrile). In this work, a GC/MS-based method, using hydrogen as carrier gas, for 2,4-DNP detection and quantitation was successfully developed, presenting a high potential to be easily implemented and performed in routine toxicological analysis. As the 2,4-DNP seems to be reemerging as a weight-loss drug, the method can detect and quantify 2,4-DNP in authentic human whole blood samples.

#### 2,4-Dinitrophenol, Gas Chromatography, Postmortem Toxicology

### K36 Quantitation of Fentanyl and Metabolites From *Lucilia Sericata* Larvae and Liver Tissue Using a Modified Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) Extraction With Analysis by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Joseph A. Cox, MS\*, Pasadena, TX 77504; Colby Ott, BS, Shippensburg, PA; Luis E. Arroyo, PhD, Department of Forensic and Investigative Sciences, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will better understand a modified QuEChERS extraction combined with a sensitive method for determining concentrations for fentanyl and two known metabolites, norfentanyl, and despropionyl fentanyl (4-ANPP), in tissue toxicology specimens using LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relaying a novel procedure that utilizes the unique extraction properties of a QuEChERS extraction with modifications to allow for the extraction of drugs from challenging matrices. Analytical separation and detection was conducted on a Triple Quad LC/MS/MS that provides the required sensitivity and selectivity of the target analytes.

The opioid crisis in the United States has a serious impact on our society. According to the National Institute on Drug Abuse (NIDA), more than 100 people die every day of opioid overdose. Even more concerning is the increase of overdose deaths involving synthetic opioids (e.g., fentanyl and fentanyl analogs), with increases from 3,105 deaths in 2013 to 19,413 deaths in 2016 (625% increase). Under special circumstances (e.g., when blood or urine are not available due to decomposition or exsanguination), liver samples are regularly the first choice for toxicological analysis, mainly due to the organ's ease of collection at autopsy and homogenization for drug extraction. On the other hand, fly larvae have been used as a toxicological analysis matrix when traditional matrices are not available due to skeletonization or to corroborate findings in extremely decomposed tissues. The succession that occurs on a corpse after death is a relatively confined and closely packed ecosystem that is typically restricted to the remains and close proximity. If xenobiotics are present in the body, they will be ingested by the organisms feeding on the corpse. Therefore, any concentrations identified in insect tissue can be indicative of drugs present in the tissue they were feeding on.

Common practices for tissue extraction involve a Solid Phase Extraction (SPE) or Liquid-Liquid Extraction (LLE), but the process for these techniques can be time consuming and often involve tissue homogenizers using blenders that could allow cross contamination. In recent years, the QuEChERS extraction protocol was introduced in the market to deal with samples with high a content of fatty materials, especially for food analysis. This sample preparation technique avoids the risk of cross contamination by producing a homogenized sample into a single disposable tube. QuEChERS has been reported as a rugged sample preparation method in blood analysis and more recently in liver tissues. This study proposed using a simple sample homogenization system consisting of a high-speed mixer mill with disposable stainless-steel balls contained in a homemade plastic holder. This setup helped to reduce the sample size to a few grams and improve the homogenization steps. A modified QuEChERS extraction was used with a 0.2g sample (liver and larvae) amount. Homogenization was achieved using a high-speed mixer mill (Retsch MM 200) with a homemade attachment for 1.5mL centrifuge tubes and 4.5mm stainless steel balls. The quantification method was performed on an Agilent® 6470 Triple Quad LC/MS/MS system. Chromatographic separation was achieved on a ZORBAX® Eclipse Plus™ C18 RRHD 3.0mm x 100mm, 1.8µm column with 0.1% formic acid and 5mM ammonium formate in water (mobile phase A) and 0.1% formic acid in methanol (mobile phase B). *Lucilia sericata* eggs (250) were placed to feed on beef liver tissue homogenate (200g) with four concentrations of fentanyl (0µg/Kg, 2. µg/Kg, 50µg/Kg, 250µg/Kg) and allowed to develop to third instars. Thirty specimens from each treatment were heat killed in water, rinsed to remove any potential residual drug, then dried, measured (weight, length, and width) and stored at -80°C for toxicology analysis.

A validation of the LC/MS/MS method for fentanyl, norfentanyl, and 4-ANPP was performed with a Limit Of Detection (LOD) of 0.1ppb and an Analytical Measurement Range (AMR) of 0.5ppb to 250ppb. Accuracy for all three compounds at the lowest calibrator were above 82 (±0.88) % with a %RSD of less than 5% and for the highest calibrator above 94 (±0.47) % accuracy with a %RSD less than 0.5%. Linearity was acceptable for all three compounds as they were all better than 0.995. The average recovery for the liver extraction was greater than 75 (±1.4) % and the average recovery for the larvae extraction was greater than 71 (± 1.6) %.

The method was validated, and the calibration curves reconcile well with forensic toxicology criteria. The extraction and LC/MS/MS method developed for analysis of larvae and liver tissue for fentanyl, norfentanyl, and 4-ANPP is precise, sensitive, and reproducible at forensically relevant concentrations.

#### QuEChERS, Fentanyl, *Lucilia sericata*

## K37 Study of the Mu-, Kappa-, and Delta-Opioid Receptor Models and the Kratom Alkaloids

Reba E. Chamblee\*, Fulton, MS 38843; Caroline Spencer, BS, Oxford, MS 38655; Pankaj Pandey, PhD, University of Mississippi, University, MS 38677; Robert J. Doerksen, PhD, University of Mississippi, University, MS 38677; Murrell Godfrey, PhD, University of Mississippi, University, MS 38677

**Learning Overview:** After attending this presentation, attendees will better understand the interactions of kratom and its various alkaloids with the mu-, kappa-, and delta-opioid receptors.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the understanding of complex interactions between substituents of specific kratom alkaloids with the mu-, kappa-, and delta-opioid receptors. Understanding these key interactions can help lead to improved knowledge of the effects these alkaloids produce.

Kratom, *Mitragyna speciosa*, is a plant indigenous to countries of southeast Asia and has traditionally been used for medicinal treatments.<sup>1</sup> However, the popularity of the drug has significantly increased recently due to its euphoric effects, leading it to being used as an alternative to illegal opioids. Several alkaloid compounds have been isolated from the leaves of the plant. The main alkaloids seen are the following five alkaloids: mitragynine, 7-hydroxymitragynine, speciociliatine, speciogynine, and paynantheine. Two alkaloids, mitragynine and 7-hydroxymitragynine, have exhibited high potencies and are potentially even more potent than morphine.<sup>2</sup> Previous studies have indicated that the main mediator of the psychoactive effects is the opioid receptor system, specifically the mu-, kappa, and delta-opioid receptors.<sup>3</sup> Agonistic activity has been seen by mitragynine and 7-hydroxymitragynine at the mu-opioid receptor while antagonistic activity has been seen by all five of the above alkaloids at the kappa- and delta-opioid receptors. The highest binding affinities occur at the mu-opioid receptor and lesser affinities at the kappa- and delta-opioid receptors. Expanding concern of kratom has led to more research into its mechanism of binding with target receptors and how its growth of use impacts the forensic science and criminal justice community.

In this study, mu-, kappa-, and delta-opioid receptor models were used to establish the ligand-receptor interactions between the receptors and the constituents of specific kratom alkaloids. This was accomplished using Schrodinger's Maestro molecular modeling software. The major natural alkaloids of the plant were selected for this study because of their high abundances as well as their binding affinities. Maestro employs the technique known as molecular docking to study the binding of a ligand to the active site of a known 3D protein model. The docking of the ligands to proteins is used to determine the most accurate orientation of the ligand in the active site and the specific interactions that take place between the ligand and the protein. Maestro determines a "docking score" that is not the same as the experimental binding affinity but is related in terms of ranking the binding of the ligands to the receptor. Docking of the ligands to the receptors took place after both the alkaloid ligands and the opioid receptor models were prepped for docking and a grid of the active sites was generated. Data generated from each docking yielded information on the best poses/positions of the alkaloids for binding to the receptors, interactions between the ligands and receptors, and the estimated binding affinities.

The results of this study provide a better understanding of the interactions that take place between kratom alkaloids and the opioid receptors. Specific structural characteristics of the alkaloids studied were found to influence key residue interactions with the receptors. This study looked at structural characteristics, such as: length of the alkyl chain; presence or absence of function groups, including ketone, ester, and hydroxyl; and amine groups. Some residues were present consistently throughout the studies, including Asp147, Tyr148, and His297 in the mu-opioid receptor, Tyr129 in the delta opioid receptor, and Asp138 in the kappa opioid receptor. All these residues have been found to be important residues in activation of the opioid receptors.<sup>4</sup> The next step of this research will include comparing the docking studies with the different receptors to the known binding affinities to gain a better understanding of what is influencing the binding affinities and the adverse reactions of the kratom alkaloids. The results from this study will aid in the understanding of the influence specific structural characteristics have on the binding and pharmacology of these drugs. Future results from this study will lead to a new understanding of the effects kratom and its alkaloids have within the human body and help determine its potential for abuse.

### Kratom, Opioid Receptors, Molecular Modeling

### **K38 Electrochemical Tools for the Rapid Detection of Opioids and Novel Psychoactive Substances (NPS) With Confirmatory Analysis by Liquid Chromatography/Triple Quadrupole/Mass Spectrometry (LC/QqQ/MS)**

*Colby Ott, BS\*, Shippensburg, PA; Joseph A. Cox, MS, Pasadena, TX 77504; Hugo Cunha-Silva, MS, University of Burgos, Burgos, SPAIN; Julia Arcos-Martínez, PhD, University of Burgos, Burgos, SPAIN; Luis E. Arroyo, PhD, Department of Forensic and Investigative Sciences, Morgantown, WV 26506-6121*

**Learning Overview:** After attending this presentation, attendees will be able to explain the theory and use of electrochemical techniques as screening tools in forensic science and understand their implications in the testing of NPS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing toward an electrochemical sensing method that will provide qualitative and quantitative information to enhance workflow in laboratories to speed up screening and analysis, reducing costs and backlogs. The proposed approach will allow on-site testing of unknown substances enabling for non-invasive roadside testing of Driving Under the Influence of Drugs (DUID) suspects and as a rapid on-site detection system on drug seizures.

Due to the growing number of cases involving fentanyl and fentanyl-analogs, opioid abuse poses a significant threat to the United States. Opioid-related overdose deaths have increased over the past several years, leading to a public health emergency declared by the Department of Health and Human Services. NPS have compounded the issue due to having similar or increased potency. NPS are synthetic analogs to known controlled substances designed by making modifications to the core chemical structure in most cases, and include fentanyl-analogs and synthetic cannabinoids, among others. Electrochemistry can provide a rapid, sensitive, and selective screening technique to overcome the limitations faced by other methods in the field. Electrochemistry offers a versatile platform that is sensitive, portable, and low cost, which can be modified to suit a variety of needs and detection requirements.

Cytochrome P450 enzymes represent a class of enzymes suited to work with controlled substances due to their role in the metabolism of the many xenobiotics within the body. Modification relies on the ability to transfer electrons from the working electrode to the heme center of the enzyme to stimulate the enzyme's metabolism of the drug in solution. Additional modification with gold nanoparticles provides a good metal platform that can be used for attachment strategies not possible on carbon, as well as a different electrode surface. Such modification is demonstrated in this study.

Screen-Printed Electrodes (SPEs) allow for a portable and straightforward testing platform due to containing all three needed electrodes within a small area. SPEs are made by depositing alternating layers of conductive material for the electrode surfaces with insulating material and plastic to create a small (~1.5 x 0.5 inches) strip-like testing surface. SPEs are desirable testing platforms due to being low cost and disposable, having high-throughput, and requiring small sample volumes. These SPEs then act as sensors, recording the electrochemical process taking place and can provide qualitative and quantitative data about an analyte in solution. The most common of these SPEs are carbon-based, which provide a large window of potential and possible modifications. These electrodes can be modified with many materials, including enzymes and nanoparticles/nanomaterials. Modifications allow for the activity, sensitivity, and specificity to be controlled for the desired application. Traditional electrochemical testing methodologies also allow for modifications to the electrode surface as well as various types of electrode materials.

Three target drugs were tested: codeine, fentanyl, and PB-22 (a synthetic cannabinoid NPS). Cytochrome P450 enzymes were immobilized on the surface of the electrodes for analysis of codeine. Cyclic voltammetry and chronoamperometry were utilized for the analysis and characterization of the drug in Phosphate-Buffered Saline (PBS). Standard curves from successive additions were generated to determine potential limits of detection. Analysis of fentanyl in PBS via deposited gold nanoparticles on the working electrode was tested to determine its viability as a testing method. Finally, a traditional electrochemical cell approach was utilized with a platinum working electrode for the analysis of PB-22 in acetonitrile containing tetrabutylammonium perchlorate. Additionally, a method using dynamic multiple reaction monitoring with LC/QqQ/MS was developed for confirmatory analysis as part of the development of a pain-management panel containing 28 drugs. This method was designed for use in oral fluid.

Codeine was characterized in PBS buffer, and the limit of detection was found in the low  $\mu\text{g/mL}$  levels. Similar ranges of detection were obtained for fentanyl. Detection of fentanyl was possible utilizing only gold nanoparticles on the SPE. Excellent linearity ( $>0.999$ ) was seen between  $3\mu\text{g/mL}$  and  $1\mu\text{g/mL}$  concentrations tested. The limit of detection of PB-22 was determined to be approximately  $208\text{ng/mL}$  with linearity greater than  $0.999$ .

### K39 A Comprehensive Analysis of Synthetic Cannabinoids and Metabolites in Oral Fluid (OF) By Online Solid Phase Extraction (SPE) and Liquid Chromatography/Triple Quadruple/Mass Spectrometry (LC/QqQ/MS)

Carmen T. Mulet, BS\*, Florida International University, Miami, FL 33199; Anamary Tarifa, PhD, Florida International University, Miami, FL 33199; Anthony P. DeCaprio, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** The goal of this presentation is to demonstrate the comprehensive analysis of 30 synthetic cannabinoids and metabolites in OF by LC/QqQ/MS using online SPE for sample pretreatment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how to detect and quantify Synthetic Cannabinoid (SC) parent drugs, as well as metabolites, in a non-invasive matrix using a relatively swift analytical technique that is sensitive enough to be able to detect low levels of structurally diverse SCs.

According to the National Institute on Drug Abuse, the emerging class of novel psychoactive substances known as SCs include man-made, mind-altering chemicals that are sprayed on dry, shredded plant material and can either be smoked or sold as liquids to be vaporized in e-cigarettes. SCs are often marketed as “synthetic marijuana” and may not be detected by traditional drug screening tests for marijuana, as they do not have the same structure as  $\Delta^9$ -THC, the main active ingredient in marijuana. Due to the typically rapid metabolism of SCs and their instability in biological matrices, fast analytical methods are needed for the detection and confirmation of parent drugs, as well as metabolites, at very low levels.

SCs are transferred from the blood into OF primarily by diffusion. The detection of these drugs in an OF matrix is advantageous because there is no need for same-sex collection, it is a non-invasive technique that has little risk of adulteration, and collection can be done onsite. OF is a viscous aqueous matrix composed of electrolytes, small molecules, and higher molecular-weight compounds, including proteins and enzymes. Therefore, a sample pretreatment step, typically Liquid-Liquid Extraction (LLE) or SPE, is required prior to sample analysis. Unfortunately, both procedures are time-consuming and involve large amounts of solvents for cleanup.

This study demonstrates the comprehensive analysis of 30 synthetic cannabinoids and metabolites in OF by LC/QqQ/MS using online SPE for sample pretreatment. The aim is to be able to detect and quantify SC parent drugs, as well as metabolites, in a non-invasive matrix using a relatively swift analytical technique that is sensitive enough to be able to detect low levels of structurally diverse SCs. OF specimens are collected using a Quantisal<sup>®</sup> device consisting of a cotton pad that is placed in the mouth and turns blue upon collection of an approximate 1mL OF sample. This is transferred to a plastic collection tube containing 3mL buffer, provided by the manufacturer, for drug extraction and stability during storage. An aliquot from this sample is spiked with an internal standard SC mix and compared against a six-point calibration curve created using synthetic or authentic pooled OF and buffer (1:3, v:v). An Agilent<sup>®</sup> 6470 triple quadrupole MS equipped with Jet Stream Electrospray Ionization (ESI) technology is used in positive mode with dynamic Multiple Reaction Monitoring (MRM) (3 MRM repeats) for the characterization of the analytes (1 $\mu$ L injection). Binary gradient elution is performed on a ZORBAX<sup>®</sup> Eclipse Plus<sup>™</sup> C18 Rapid Resolution HD (3.0 x 100mm x 1.8 $\mu$ m) column using MeOH + 0.1% formic acid as organic phase and 5mM ammonium formate + 0.1% formic acid as phase modifier with a total run time of 15min. Online SPE is carried out on an Agilent<sup>®</sup> 1290 Infinity<sup>®</sup> Flexcube using ACN, MeOH, and water for cleanup and reconditioning.

Initial results demonstrate calibration curve linearity from 0ng/mL–100ng/mL ( $R^2 >0.99$ ), with Limit Of Detections (LODs) in the range of 0.5ng/mL–1ng/mL. In addition, better analyte ionization was noted with authentic pooled OF as compared to synthetic OF for calibration curves. Determination of Matrix Effects (ME), Process Efficiency (PE) and Recovery (RE) showed data for most analytes to be within acceptable limits according to the Scientific Working Group for Forensic Toxicology (SWGTOX) and other relevant validation guidelines. An exception was noted in the case of PB-22 metabolites, which showed ME >198%, PE >283% and RE >135%. Following full validation and inclusion of additional SCs and metabolites, this method is expected to facilitate rapid and reliable screening of SCs in forensic toxicology applications.

### K40 Investigating the Binding of Fentanyl and Fentanyl Analogs to the Opioid Receptors

Marissa A. Teske\*, Olive Branch, MS 38654; Caroline Spencer, BS, Oxford, MS 38655; Pankaj Pandey, PhD, University of Mississippi, University, MS 38677; Robert J. Doerksen, PhD, University of Mississippi, University, MS 38677; Murrell Godfrey, PhD, University of Mississippi, University, MS 38677

**Learning Overview:** After attending this presentation, attendees will better understand the interactions between fentanyl and its various analogs with the mu-, kappa-, and sigma-opioid receptors in the brain.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the understanding of the interactions between fentanyl, fentanyl analogs and the mu-, kappa-, and sigma-opioid receptors, and of the specific interactions that are related to the adverse effects of these drugs.

Fentanyl was synthesized in 1960 by Dr. Paul Janssen of the Janssen Company to act as a rapid-acting analgesic that, unlike similar analgesics around that time, did not have negative cardiovascular effects.<sup>1</sup> Fentanyl overdoses were first reported around 1972 with subsequent increases in overdose cases reported as additional methods of administration became available.<sup>1</sup> From 1999 to 2011, the number of fatal opioid analgesic overdoses quadrupled and, for the year 2015, the death toll in the United States totaled 33,091.<sup>2</sup> The lacing of heroine with fentanyl by drug dealers in order to increase the client's opioid high is one major reason for this spike in overdose deaths. Fentanyl and its analogs are all agonists of the opioid receptors.<sup>2</sup> There are several physical effects of opioid binding at the  $\mu$ -opioid receptor, including respiratory and central nervous system depression.<sup>2</sup> Fentanyl-related deaths are increasing rapidly, and more potent fentanyl analogs are found laced in heroine and cocaine every day. It is therefore imperative that scientists stay ahead of the illegal drug trade. One way this goal can be accomplished is by using cutting-edge technology to investigate ligand binding and molecular docking of illegal substances before they even enter the market.

This study examined the interactions that take place between fentanyl, and its analogs, and the opioid receptors they interact with in the body. The molecular modeling software, Maestro, was used to study these specific interactions. Fentanyl and its analogs were sketched and prepped for docking to the receptors using Maestro. The opioid receptors were chosen for this study from available, active-state crystal structures. The data from this study identified specific interactions that take place between these drugs and the binding site of corresponding opioid receptors. Key residue interactions included aromatic stacking interactions, hydrophobic interactions, polar interactions, and hydrogen bonding. These interactions corresponded to varying structural changes between fentanyl and its analogs. The interactions and structural changes were used to help better understand the potency and toxicity of fentanyl and fentanyl analogs. Future work will include using the results of this study to help predict potential new analogs of fentanyl before they appear on the drug market. Scientists and law enforcement will have advanced knowledge on various fentanyl-related substances to improve both detection and treatment of fatal overdose cases.

**K41 WITHDRAWN**

## K42 Serum Albumin Binds Synthetic Cannabinoids and Model Compounds and Drugs

Oluseyi A. Vanderpuye, PhD\*, Albany State University, Forensic Science, Albany, GA 31705; Alexius K. Lampkin, Headland, AL 36345; Johnathan Jones, BS, Albany State University, Forensic Science, Albany, GA 31705

**Learning Overview:** After attending this presentation, attendees will learn: (1) how agarose gel electrophoresis and spectroscopy can be applied to detect binding of certain synthetic cannabinoids, prescription drugs, and compounds with serum albumin; and (2) that interactions of synthetic cannabinoids and drugs with serum albumin are a consideration for the pharmacokinetics of synthetic cannabinoids and other compounds.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how serum proteins affect drug bioavailability and methods of characterizing drug-serum protein interactions. Additionally, the community will become more aware of the use of spectroscopic methods for characterizing interactions of different compounds with albumin. Interpretation of toxicological data may be influenced by agents that affect the blood concentration of free drugs and compounds and their lifetimes.<sup>2,3</sup> Albumin has demonstrated relevance for these parameters for many compounds of toxicological interest; therefore, consideration of its effects on pharmacokinetics of synthetic cannabinoids warrants more investigation.

Serum albumin is known to bind a diversity of non-polar organic compounds and drugs.<sup>1-4</sup> It was hypothesized that human and bovine serum albumin would bind to synthetic cannabinoids such as Bay 59-3074 and JWH-015, which are non-polar molecules with ring structures that are practically insoluble in aqueous solution.

For this study, binding to albumin was tested for the synthetic cannabinoids and as controls, model compounds such as the dye Nile Red, eosin, bromophenol blue, coumarin, the drugs tobramycin, colchicine, and a brand name mixture of brimonidine tartrate and dexamethasone to further advance knowledge of compounds that bind serum albumin.

Agarose gel electrophoresis was one method used for assessing binding of the synthetic cannabinoids and other compounds to albumin. Ultraviolet/Visible (UV-Vis) and fluorescence spectroscopy were other applicable methods.<sup>3,4</sup> The compounds used can be visualized by their color or by their UV-induced fluorescence. In the absence of BSA, non-polar synthetic cannabinoids and model compounds would not be expected to migrate in agarose gels or be visible after electrophoresis. If any of these compounds bind to albumin, then their complexes would migrate in agarose gel electrophoresis bound to the albumin and be visible by their intrinsic color or fluorescence under UV-light.

It was found that in agarose gel electrophoresis in the presence but not in the absence of albumin, fluorescent bands at the position of albumin were observed for mixtures with Bay 59-3074 and JWH-015 and for mixtures of albumin with Nile Red, eosin, coumarin, the drugs tobramycin, colchicine and mixture of brimonidine tartrate and dexamethasone. In the absence of these compounds, albumin was not fluorescent or colored. It was also observed that in the presence of albumin, compounds such as eosin, bromophenol blue and Nile Red changed color. In the presence of albumin, under UV-light, Bay 59-3074, JWH-015 and Nile Red became more fluorescent. This suggested that interaction of these and other compounds would be detectable by changes in the UV-Vis and fluorescence spectra.

In conclusion, it was observed for the first time that the synthetic cannabinoids Bay 59-3074 and JWH-015 bind serum albumin. This could affect their bioavailability and allow these drugs to attain higher concentrations in blood than permitted by their non-polar character and allow them to circulate longer. The use of agarose gel electrophoresis to detect albumin binding to synthetic cannabinoids and other compounds has not been previously reported and is applicable to the study of albumin interaction with compounds of pharmacological significance that are fluorescent or colored.

### Cannabinoids, Albumin, Electrophoresis

## K43 Postmortem Distribution of Nicotine and Cotinine in Suicidal Overdoses Following Transdermal and Oral Administration

Rebecca Jufer Phipps, PhD\*, State of MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Saffia Ahmed Sakinedzad, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Mary G. Ripple, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Ling Li, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the postmortem distribution of nicotine and cotinine following transdermal and oral administration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing medical examiners and toxicologists with postmortem concentrations for nicotine and cotinine in suicidal overdoses following transdermal and oral administration.

Nicotine is a toxic alkaloid present in tobacco at concentrations (w/w) of 0.5%–8%. In addition to cigarettes and smokeless tobacco products, nicotine is commercially available in lozenges, sublingual tablets, chewing gum, nasal sprays, inhalers, transdermal patches, and solutions for electronic smoking devices. Nicotine produces stimulation of nicotinic receptors in the autonomic ganglia and central nervous system. Nicotine overdose produces symptoms ranging from nausea, dizziness, tachycardia, and hypertension to convulsions, coma, and death. Blood nicotine concentrations ranging from 1.0mg/L to >100mg/L have been reported in nicotine associated fatalities.<sup>1</sup>

The Office of the Chief Medical Examiner (OCME) of the State of Maryland recently investigated two deaths due to nicotine intoxication; one involving transdermal administration and the other involving oral ingestion of a vape liquid.

**Case 1 History:** A 60-year-old female was found unresponsive in her residence during a welfare check (requested by friends who had received suicide letters mailed by the decedent). She was lying in a supine position on her bed with a suicide note located on the bedside table. Two empty, unlabeled pill bottles and a taped recording of the decedent were also located in the bedroom. Due to case history, an inspection at OCME was performed. External examination revealed 14 21mg/24hr nicotine patches on her body (ten on her chest, one on each arm and leg). Other than the nicotine patches, inspection findings were unremarkable. Comprehensive toxicology testing was performed, and the results are summarized in the table below.

**Case 2 History:** A 34-year-old female was found unresponsive in the driver's seat of a vehicle parked in a residential neighborhood. She had been reported missing two days earlier by her mother who reported that the decedent indicated that she was going to kill herself by "poisoning." Five empty bottles of Big Heart 555 vape liquid (12mg/34mL) and an empty water bottle were present in the vehicle. A full autopsy was performed, and findings were unremarkable. Comprehensive toxicology testing was performed, and the results are summarized in the table below.

Comprehensive toxicology testing included volatiles, an acidic neutral drug screen, an alkaline drug screen and Enzyme-Linked Immuno-Sorbent Assay (ELISA) for morphine, benzodiazepines, and oxycodone. Nicotine was confirmed and quantitated by liquid-liquid extraction, followed by Gas Chromatography/Mass Spectrometry (GC/MS). Briefly, internal standard (d<sub>4</sub>-Nicotine; 0.2 mg/L) was added to specimens (5.0mL) that were alkalized with 0.1N sodium hydroxide and extracted with n-butyl chloride, then back extracted into 0.1N sulfuric acid, and finally alkalized with ammonium hydroxide and extracted into methylene chloride. Isopropanol (100µL) was added and the extract was evaporated to the isopropanol layer which was injected into the GC/MS for analysis. The method was linear from 0.12mg/L to 2.0mg/L for nicotine and cotinine. A five-point calibration curve and two control concentrations (0.30mg/L and 1.25mg/L) were used for quantitation. An administrative reporting limit of 0.12mg/L for both analytes was used. Toxicology results (mg/L or mg/kg) for the two cases are summarized below.

Case	Heart Blood	Peripheral Blood	Liver	Kidney	Vitreous Humor
1	Nicotine: 0.20	Nicotine: 0.22	N/A	N/A	Nicotine: 0.12
	Cotinine: 0.36	Cotinine: 0.48			Cotinine: 0.32
	Alprazolam: 0.033				
	Dextromethorphan: 0.5				
	Diphenhydramine: 0.6				
	Fluoxetine: 1.1				
	Hydroxyzine: 0.4				
Oxycodone: 1.2					
2	Nicotine: 34	Nicotine: 21	Nicotine: 170	Nicotine: 31	Nicotine: 9.9
	Cotinine: 0.40	Cotinine: 0.30	Cotinine: 1.2	Cotinine: 0.35	Cotinine: <0.6
	Diphenhydramine: 0.05				

For Case 1, the medical examiner ruled that the cause of death was nicotine, oxycodone, fluoxetine, and dextromethorphan intoxication; the manner of death was suicide. For Case 2, the medical examiner ruled that the cause of death was nicotine intoxication; the manner of death was suicide. The nicotine concentrations detected in these two cases are significantly elevated from what would be expected with appropriate use of the products involved. In Case 1, it is likely that higher nicotine concentrations were not observed due to the presence of additional drugs at toxic concentrations and the slower transdermal route of administration. In Case 2, the nicotine concentration was very high with lower concentrations of cotinine, suggesting that death occurred quickly after administration of an excessive dose.

### K44 Surface Enhanced Raman Scattering (SERS) Analysis for Synthetic Opioids

Xuyang He\*, University of Southern Mississippi, Hattiesburg, MS 39406

**Learning Overview:** After attending this presentation, attendees will understand: (1) how sensitive and useful the SERS technique is in forensic drug/toxicological analysis, (2) how to optimize the signal enhancement to various degrees by using different metal substrate/solvent/aggregating reagents, and (3) how to do a quantitative measurement with SERS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by elucidating the application of SERS in forensic investigations regarding synthetic opioids. In most cases, SERS was deemed a rapid and sensitive screening test, but SERS can also work as a reliable confirmatory test if used properly.

Presented here is the study of identifying and quantifying certain synthetic opioids using SERS. In recent years, the abuse of opioids, especially the powerful synthetic opioids such as fentanyl and its analogs, has become America's leading cause of overdose deaths, which is the so-called opioids crisis. Hence the rapid detection, identification, and quantification of these psychoactive substances emerge as a critical need for forensic scientists. Usually it is not feasible to analyze fentanyl and its analogs using traditional techniques because of their superior potency, leading to very low concentration present in samples. As a valuable analytic tool for the detection and identification of various chemical compounds of forensic interest, Raman spectroscopy attracts increasing attention over the past decades due to its non-destructive nature, wide application range, and capability of providing rich structural information. The Achilles' heel of general Raman spectroscopy is its weak signal, resulting from the fact that only one scattered photon out of ten thousand is Raman active. One of the solutions to this is the SERS technique, which boosts the signal by placing the sample in the vicinity of or on rough metal/semiconductor substrates. The signal enhancement factor of SERS can reach up to  $10^{11}$ , improving the detection limit to  $10^{-12}$  M. In addition, SERS has proven to be a great means to quench unwanted luminescence for fluorescent molecules while enhancing the Raman signal at the same time.

This study analyzed synthetic opioids, especially those potent ones such as ohmefentanyl, tetrahydrofuranlylfentanyl, etc. Multiple research efforts have been focused on qualitative detection and identification of forensic drugs by SERS. However, quantitative SERS measurements are scarce, owing to the complexity of the system and the spectra. Ideally, when SERS peaks of interest are unique and not overlapped with other peaks, quantification is possible by calculating peak areas/heights after appropriate calibration. In fact, an analyte is always within a complex background such as blood/urine/saliva plus metallic colloidal solutions and we often need to perform quantitation for multiple analytes simultaneously. One way to overcome these issues is the Standard Addition Method (SAM), by spiking the standard to both blank and real samples. Therefore, first this work systematically studied the dependence of SERS signal enhancement on difference experiment conditions. The results reflect how the signal enhancement varied with different substrates, solvents, and aggregating reagents. Also, the quantitative measurements of certain potent synthetic opioids under optimized SERS conditions are conducted using the standard addition method.

#### SERS, Opioids, Quantitation

**K45 WITHDRAWN**

### **K46 The Interplay Between Forensic Analysis of Seized Drug and Medicolegal Death Investigation Toxicology in the Investigation of Clinical Intoxications to Support Public Health Preparedness and Response**

*Barry K. Logan, PhD\*, NMS Labs/Center for Forensic Science Research & Education, 3701 Welsh Road, Willow Grove, PA 19090; Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Amanda L.A. Mohr, MSFS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will be able to evaluate the benefits of an integrated approach to early identification of toxic Novel Psychoactive Substances (NPS) in forensic toxicology and seized drug casework and the rapid communication of these findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the interconnectedness of forensic analysis of seized drug and medicolegal death investigation casework, with investigation of clinical intoxications in support of public health functions.

There are increasing demands from public health and public safety agencies for better data regarding the extent, trends, and impacts of adverse reactions to the current opioids being abused. Comprehensive chemical analysis, market awareness to inform scope of testing, data collection and management, and rapid sharing of information are all key components of ensuring that both clinical and forensic practitioners remain aware of the most current threats from novel opioids. Data from drug identifications made in seized drugs directs the generation and updating of mass spectral libraries for both point of contact screening devices, seized drug laboratories, and toxicology screening protocols. Confirmation of positive findings from toxicological testing in clinical and forensic populations can alert seized drug testing labs of the need to perform additional testing.

This study has envisioned a model of using data from seized drug testing obtained from samples at ports of entry into the United States, with data from the sample-mining and data-mining of toxicological samples from medicolegal death investigation cases, and data from comprehensive toxicological testing of intoxications in the emergency room, to rapidly identify threats to public health and prepare the relevant stakeholder groups to respond.

In July 2018, there was a mass outbreak of apparent opioid overdoses in Philadelphia, PA, on Saturday and Sunday, with more than 1,000 cases being reported. This was associated with an opioid stamp design “Santa Muerte.” Three deaths were attributed to the outbreak by the media. The cases were unusual in that once the subjects were reversed with naloxone, they displayed an uncharacteristic agitation, shaking, and tachycardia, which apparently responded to treatment with physostigmine, an antidote to anticholinergics such as scopolamine or atropine. Consequently, health alerts were sent out through the public health network about this threat from a combined opioid with anticholinergic.

The following Tuesday, a sample of the Santa Muerte product was submitted to the laboratory for testing. Analysis was performed the same day by Liquid Chromatography/quadrupole Time Of Flight/Mass Spectrometry (LC/qTOF/MS), and Gas Chromatography/Mass Spectrometry (GC/MS) using the Automated Mass Spectral Deconvolution and Identification System (AMDIS) developed by the National Institute of Standards and Technology (NIST). The material was found to contain heroin, fentanyl, and 5F-ADB, a potent cannabinoid CB1 receptor agonist. No anticholinergic drug was present. 5F-ADB can co-elute with heroin under some chromatographic conditions and use of AMDIS can be key to identifying these minor components in complex drug mixtures.

On that Wednesday, samples from one of the intoxications was retrieved and was submitted to the laboratory for testing. Those samples were tested the following day and confirmed the presence of 6-monacetylmorphine, fentanyl, and 5F-ADB. Those results were returned to the hospital, and the Philadelphia Public Health Department was notified of the findings. The findings were also communicated to the National Drug Early Warning System (NDEWS), the Drug Enforcement Administration (DEA) SYNTH-OPIOIDS list, and a pre-established list of other key national and international stakeholders.

This early alert enabled public health agencies to share this information about the toxicity of this batch of drugs with the drug-using community to assist in harm reduction and reduce the risk of further adverse events, and it allowed local crime laboratories to re-examine their chromatographic data and identify 5F-ADB in prior cases. It alerted toxicology laboratories to consider including synthetic cannabinoid testing in their investigation of apparent drug injection deaths or intoxications. It also raised awareness among medical toxicologists of the potential for synthetic cannabinoid drugs to manifest as anticholinergic intoxications, improving the potential for future treatments.

This case study showcases the importance of the interplay between toxicology and seized drug analysis, clinical and forensic stakeholders, and public health and public safety organizations in the investigation of NPS intoxications. It also reinforces the critical need for rapid and timely testing in emergent outbreaks to maximize the value of this resource.

#### **Synthetic Cannabinoids, Novel Opioids, Early Warning Systems**

## K47 The Identification of Synthetic Cannabinoids in Forensic Toxicology Casework Using an Archived High Resolution Mass Spectrometry Data System

Amanda L.A. Mohr, MSFS\*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Alex J. Krotulski, MS, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/Center for Forensic Science Research & Education, 3701 Welsh Road, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will be able to describe a rapid Liquid Chromatography (LC) high resolution Time-Of-Flight Mass Spectrometry (TOF/MS) method for the analysis of synthetic cannabinoids and workflow for the retrospective datamining of previously acquired sample extracts and TOF data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel approach for creating a historical data archive for biological specimens that will be continually re-interrogated as new synthetic cannabinoids and their metabolites are discovered to determine retrospectively the date of first appearance and spread of new compounds as they appear on the drug market.

Since 2008, synthetic cannabinoids have continued to infiltrate the drug market and have been implicated in an increasing number of emergency room admissions, death investigations, and high-profile intoxication events in corrections populations. Understanding the scale and scope of these events requires the availability of comprehensive analytical testing, which is currently lacking due to the speed with which new compounds appear. From a laboratory standpoint, the challenges of remaining current with synthetic cannabinoids stem from the diversity of compounds in the class, the large number of analogs and configurations, and delays in availability of analytical standards.

For the extraction of synthetic cannabinoids and their metabolites, blood samples (0.5mL) were prepared using liquid-liquid extraction with Tris hydrochloride buffer (pH 10.2) and MTBE. Urine samples (1mL) were prepared using Solid Phase Extraction (SPE) with ammonium carbonate buffer (pH=9.3) and elution with formic acid in methanol. All sample extracts were evaporated to dryness and reconstituted in 200µL of mobile phase.

Samples were acquired using a SCIEX® TripleTOF® 5600+ quadrupole TOF/MS coupled to a Shimadzu® Nexera® ultra high-performance liquid chromatograph. A reverse phase gradient using ammonium formate (10mM, pH 3) and methanol/acetonitrile (50:50) was employed for chromatographic separation on a Phenomenex® Kinetex® C18 analytical column (50mm x 3.0mm, 2.6µm) at a flow rate of 0.5mL/min. The total run time for analysis was seven minutes. Precursor ions were acquired by TOF/MS scan (100m/z–550m/z) via positive electrospray ionization. Precursor isolation was performed using SWATH® acquisition with overlapping windows from 10-25 Da in width, and fragmentation was achieved using a rolling collision energy of 35eV±15eV.

Data processing was performed using PeakView software with an Extracted Ion Chromatogram (XIC) list containing 262 synthetic cannabinoid parent compounds, metabolites, and internal standards. New standards are continually being added to the library as they become available. All previously analyzed casework data files are reprocessed using PeakView to investigate if other synthetic cannabinoids are present that were not known about at the time of initial testing.

This synthetic cannabinoid screening method was qualitatively validated for 19 parent compounds in blood and 19 metabolites in urine. These compounds were determined to be representative of the overall library database ( $n=262$ ), spanning a range of generations and diverse chemistries based on standard availability, and reflected the most currently prevalent drugs and their metabolites. Following three days of qualitative validation, all analytes met method validation performance criteria for precision/accuracy, limits of detection, interferences, processed sample stability, and carryover.

To date, 227 extracts from NMS Labs have been analyzed for synthetic cannabinoids. In total, 44 extracts were positive for at least one synthetic cannabinoid (parent or metabolite) for a positive rate of 19.4%. Table 1 shows all positive parent compounds identified and their rates of occurrence. This initial analysis has resulted in the identification of newly emergent synthetic cannabinoids, including 4-cyano-CUMYL-BUTINACA, 5F-EDMB-PINACA, and 5F-MDMB-PICA, which were not previously included in the scope at the time of testing.

**Table 1: Synthetic Cannabinoid Parent Positivity (June and July 2018)**

Parent Compound	Occurrence
5F-ADB (5F-MDMB-PINACA)	20
MMB-FUBINACA (FUB-AMB)	9
ADB-FUBINACA	8
5F-MDMB-PICA	6
AB-PINACA	2
4-cyano-CUMYL-BUTINACA	2
5F-EDMB-PINACA	2
5F-PB-22	1
AB-CHMINACA	1
5F-AMB	1

A rapid method for analysis of synthetic cannabinoids has been developed, validated, and successfully applied to forensic sample extracts. Additional populations, such as corrections and emergency room patients, are also being tested. As new synthetic cannabinoids appear on the market, they will be added to the library database and all previously acquired data will be re-interrogated for the new analyte. Data will be continually tabulated to create timelines and trend reports within these populations.

### Synthetic Cannabinoids, LC/qTOF, 5F-ADB

### **K48 Sample Mining: The Identification of Emerging Novel Psychoactive Substances (NPS) Through Reanalysis of Biological Extracts From Forensic Toxicology Casework**

Alex J. Krotulski, MS\*, Center for Forensic Science Research & Education, 2300 Stratford Avenue, Willow Grove, PA 19090; Susan Varnum, PhD, Temple University, 1801 N Broad Street, Philadelphia, PA; Barry K. Logan, PhD, NMS Labs/Center for Forensic Science Research & Education, 3701 Welsh Road, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will understand the value of real-time sample analysis and retrospective data analysis for the identification of emerging NPS present in toxicological extracts, but not within the initial scope of analytical testing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing novel workflows and approaches for the identification of emerging NPS and providing information regarding NPS currently being detected, or undetected, in forensic casework.

NPS continue to pose health and safety threats to drug users and various clinical, forensic, public health, and public safety communities within the United States. Medical and forensic toxicologists are now tasked with the difficulty of interpretation of clinical and analytical findings, but this interpretation is dependent on the scope of testing, the availability of standard reference material, and the ability to characterize novel substances. This study sought to evaluate innovative methodologies for the identification of emerging NPS timely to first incident or detection using an NPS-rich dataset.

Discarded sample vial extracts from a large forensic toxicology laboratory (NMS Labs) were acquired for re-analysis against an extensive in-house library database. Sample extracts were collected from initial testing procedures for the directed analysis of select novel stimulants, novel opioids, and designer benzodiazepines, as well as other drug classes. Sample extracts were de-identified prior to inclusion in this study.

In-house re-analysis of sample extracts was performed via Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry (LC/qTOF/MS) using a SCIEX™ TripleTOF™ 5600+ coupled with a Shimadzu® Nexera® XR UHPLC. Chromatographic separation was achieved by a standard reverse phase gradient using ammonium formate (10mM, pH 3), methanol/acetonitrile (50:50), and a Phenomenex® Kinetex C18 analytical column (50mm x 3.0mm, 2.6µm). The total runtime was 15.5 minutes. Precursor ion mass acquisition was achieved by TOF/MS scan from 100-510 Da. Product ion mass acquisition was achieved following isolation using SWATH™ acquisition. Fragmentation occurred using a rolling collision energy of 35eV±15eV for the generation of mass-window specific fragment ion spectra. Resulting datafiles were compared against an extensive in-house library database containing precursor ion exact mass, retention time, fragment ion accurate masses ( $n=5$ ), and library mass spectra for more than 700 drugs, including a clear majority of NPS.

To date, 2,136 sample extracts have been re-analyzed using the described workflow. Comprehensive data processing has resulted in the identification of a wide-variety of NPS across several categories, some of which were incorporated into initial testing procedures. The most common novel opioids detected included cyclopropylfentanyl, methoxyacetylfentanyl, and fluoro-isobutyrylfentanyl; the most common novel stimulant detected was N-ethyl pentylone; and the most common designer benzodiazepines detected were flubromazepam and etizolam.

This novel workflow has resulted in the identification of NPS for the first time in toxicological specimens, including isopropyl-U-47700 and 3,4-methylenedioxy-U-47700. In addition, novel opioid precursors have been identified in the extracts, including N-methylnorfentanyl, benzylfentanyl, despropionyl-ortho-methylfentanyl, despropionyl-3-methylfentanyl, and benzylfurylfentanyl. While many of these fentanyl analogue precursors are believed to be inactive, their presence in toxicological extracts can provide useful information to pinpoint a likely route of manufacture or possibly novel opioid active agent.

NPS continue to emerge on the drug market. Based on the results of this study, biological extracts for sample mining and archived datafiles for data mining proved to be a rich dataset for the identification and discovery of emerging NPS. Forensic laboratories not currently utilizing updated broad-based screening methodologies or retrospective data analysis workflows should be aware that NPS in toxicological specimens could go undetected.

#### **NPS, Novel Opioids, Isopropyl-U-47700**

## K49 Fringe Analogs: The Emergence of New Synthetic Drugs in Postmortem Cases in Miami

Elisa N. Shoff, BS\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; George W. Hime, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Diane Boland, PhD, Miami-Dade Medical Examiner Department, Miami, FL 33136

**Learning Overview:** After attending this presentation, attendees will better understand new synthetic compounds that are becoming more prevalent in postmortem casework, specifically in Miami-Dade County, FL. Attendees will also gain an understanding of the difficulty in detecting these compounds, especially if they are not normally targeted in traditional drug screens.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing novel compounds that for the first time have been implicated in the cause of death in decedents in Miami-Dade County and Collier County, FL. Furthermore, this presentation will inform the forensic science community of the potential increase in dissociative hallucinogens and analogs of methylphenidate as drugs of abuse.

Since 2011, the Miami-Dade County Medical Examiner Department (MDME) has been detecting synthetic drugs in postmortem cases, specifically synthetic cathinones, cannabinoids, benzodiazepines, and most importantly, fentanyl/opioids. In recent years, analogs of compounds not frequently abused in Miami, such as arylcyclohexylamines (ketamine, phencyclidine) and methylphenidate, have emerged throughout the United States. To improve the detection of these various fringe analogs, the MDME has implemented a targeted drug screening/confirmation method into routine postmortem casework using an Ultra High-Performance Liquid Chromatograph (UHPLC), coupled to an Ion Trap-Mass Spectrometer (Ion Trap-MS). This data-dependent method utilizes a Scheduled Precursor List (SPL), retention time matching, and an in-house library built with certified reference materials for the purposes of identification. The SPL contains both a targeted molecular ion and daughter ion for each compound for the purposes of MS<sup>2</sup> and MS<sup>3</sup> spectral fragmentation. In addition, all library entries contain a full-scan MS, MS<sup>2</sup>, and MS<sup>3</sup> spectral profile for each compound.

Currently, three analytes that can be classified as fringe analogs—3-Methoxy-PCP, 4-Methoxy-PCP, and 4-Fluoromethylphenidate—were added to a previously validated method that targets designer analogs. Limits of detection in extracted whole blood were established for these three analogs, at 0.5ng/mL, 1ng/mL, and 1ng/mL, respectively. All case samples analyzed using this method were postmortem whole blood specimens, extracted using mixed-mode solid phase extraction columns. All case samples were initially screened on a Gas Chromatograph coupled to a Mass Selective Detector (GC-MSD). Since the beginning of 2018, three cases screened positive for at least one of the three fringe analogs added into the targeted method. Further detail of the analog detected, and other case information, is shown in the table below.

Case #	History	Analog(s) detected via LC-Ion Trap-MS	Analog(s) detected via GC-MSD	Cause of Death	Manner of Death
1	Found unresponsive in bed by family members. Had history of illicit drug use.	3-Methoxy-PCP	3-Methoxy-PCP	Multiple Drug Toxicity (3-Methoxy-PCP included)	Accident
2	Unrestrained driver that collided with a bus. Had used illicit drugs in the past.	3-Methoxy-PCP	None	Blunt Injuries of Torso	Accident
3	Found unresponsive. History of illicit drug use.	3-Methoxy-PCP, 4-Fluoro methylphenidate	4-Fluoro methylphenidate	Pending Toxicology	Pending

Because potency and potential toxic concentrations are unknown for these compounds, sensitive and targeted methods are ideal. The increased presence of these new synthetic drugs has led to the development of additional methods at the MDME, both for the purposes of quantifying these compounds, and adding other related analogs to the current UHPLC-Ion Trap-MS targeted screening method. With further studies and testing, more definitive conclusions can be drawn from this handful of unique compounds emerging in the Miami synthetic drug scene.

### 3-Methoxy-PCP, 4-Fluoromethylphenidate, Postmortem Toxicology

## K50 A Carfentanil Outbreak in Florida in 2016

*Chris Delcher, PhD, University of Florida College of Medicine, Gainesville, FL 32608; Yanning Wang, MS, University of Florida, Gainesville, FL 32610; Russell S. Vega, MD, District 12 Medical Examiner's Office, Sarasota, FL 34239; Jessica Hvozdoch, BS\*, University of Florida, Gainesville, FL 32608; Chris W. Chronister, PhD, University of Florida, Gainesville, FL 32608; Bruce A. Goldberger, PhD, University of Florida College of Medicine, Gainesville, FL 32608*

**Learning Overview:** After attending this presentation, attendees will understand the sociodemographic information, geographic and temporal patterns, and prescription histories associated with a fatal overdose outbreak caused by the introduction of carfentanil to a local illicit drug supply. Deaths concentrated in the Sarasota, FL, area were compared to other carfentanil-involved fatal overdoses in Florida from June to December 2016 as this synthetic opioid spread throughout the state.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing outbreak details and warning signs for more targeted, rapid responses to emerging novel psychoactive substances. Illicitly manufactured fentanyl analogs pose a serious public health threat and have changed the way the opioid overdose epidemic must be approached in the United States. Accelerated reporting, reliable data sharing systems, and proactive pharmacovigilance are needed when combating this dynamic crisis.

**Methods:** Data sources for this study included the Florida drug-Related Outcomes Surveillance and Tracking (FROST) System and the Electronic-Florida Online Reporting of Controlled Substance Evaluation Program (E-FORCSE), which acts as the Florida Prescription Drug Monitoring Program (PDMP). Date-of-death information was provided by the District 12 Medical Examiner's Office. Descriptive statistics, chi-square tests, and epidemic curves compared characteristics of the Sarasota area with the remainder of the state.

**Results:** Of the 548 statewide carfentanil deaths in 2016, 114 (20.8%) occurred in the Sarasota area, a region that only accounts for 4.0% of Florida's population. The Sarasota overdose epidemic began with four deaths in June 2016, peaked with 37 deaths in July, and declined substantially by November. In July, more carfentanil deaths occurred in this area than the rest of the state combined ( $n=17$ ). The height of the outbreak did not occur for the rest of Florida until October (137 deaths, 25.0% of the state total), demonstrating an approximate two-month lag. Most decedents in Sarasota were White males (73.7%) and over one-third of all decedents were between 25 and 34 years old. Concomitant drugs in both Sarasota and the rest of Florida included cocaine (50.9%), oxycodone (9.6%), and alprazolam (23.7%). However, carfentanil-positive decedents in Sarasota were less likely to test positive for heroin (7.9% v. 23.5%), fentanyl (7.0% v. 22.6%), and other fentanyl analogs (1.8% v. 25.8%). According to statewide PDMP data, at least one controlled substance was dispensed within two years prior to death in 94 decedents (82.5%), and half ( $n=47$ ) filled the prescription within one year of death. Approximately 21.1% of decedents had no or insufficient evidence of a prescription.

**Discussion/Conclusion:** Timing and concomitant substance patterns suggest Sarasota was a point of entry for carfentanil in the state of Florida. This study demonstrates that rapid, geographically targeted responses are necessary to mitigate similar incidents during their early stages and additional steps are necessary to prevent similar outbreaks in the future. For example, Florida medical examiners now have access to the state PDMP, strengthening the medicolegal death investigation process with clinical data, for improved surveillance and response to fatal overdoses. However, this incident demonstrated that additional efforts are needed to determine how pharmacovigilance signals, such as unusual prescribing patterns, can initiate early intervention. Further, new "listening platforms" (e.g., drug-focused social media) and data systems (e.g., emergency medical services transports) may assist authorities with the rapid identification of emerging drugs in communities. In this incident, law enforcement and the media were the first entities to caution the public of the carfentanil outbreak in Florida, emphasizing the need for local, interagency data-sharing and more effective, standardized communication among stakeholders. The forensic toxicology backlog and the resulting delay in cause-of-death reporting by medical examiners are often the rate-limiting steps for such communication. Establishing routine methods for fentanyl analog analysis and identifying novel substances remains a significant challenge for laboratories across the country. The Centers for Disease Control and Prevention's (CDC's) Enhanced State Opioid Overdose Surveillance (ESOOS) Program provides funding to support more timely and comprehensive data acquisition, including toxicology for both non-fatal and fatal opioid overdoses, as well as the assessment of risk factors associated with fatal overdoses. In the future, these data will alert public health and safety organizations to changes in the illicit drug market that have the potential to develop into fatal outbreaks, facilitating efforts for more effective responses.

### Carfentanil, Epidemiology, Fatal Drug Overdoses

**K51 Examining Demographics and Emerging Drug Trends on Accidental Deaths Due to Intoxication in Washington, DC**

*Samantha Tolliver, PhD\*, Office of the Chief Medical Examiner, Washington, DC 20024; Lucas W. Zarwell, MFS, Washington, DC 20011*

**Learning Overview:** After attending this presentation, attendees will understand how the proliferation of laced heroin has impacted intoxication deaths from 2013 to 2017 within the District of Columbia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining drug trends and the demographic information of the decedent population within the District of Columbia.

At the District of Columbia Office of the Chief Medical Examiner (DC OCME) between the years of 2003 and 2012, the combination of natural (55%) and accidental (25%) deaths accounted for 80% of the case load. On average, accidental deaths were largely comprised of blunt injury, followed by intoxication. In the order of prevalence, cocaine, ethanol, and heroin were routinely detected among those cases. However, fentanyl was not commonly detected at that time, as it was only listed in 2010, as being identified in 3% of the cases. Fentanyl reappeared in 2013, when it was identified in 1% of the accidental death cases. This presentation will focus on accidental deaths that were specifically due to drug intoxications between the years of 2013 and 2017.

Table 1 lists the most commonly encountered analytes and/or analyte classes identified within the accidental drug intoxication population in the District of Columbia from 2013 to 2017. A review of the data indicated that deaths attributed to heroin usage were the most prevalent. Within that time, heroin deaths peaked in 2015, which is the same year that fentanyl analogs (4%) began to emerge within the decedent population. An examination of the race and gender demographics (Table 2) revealed that, on average, those most impacted by accidental drug intoxications were Black males (57%); followed by Black females (23%), White males (13%) and White females (3%).

Year	Cocaine & metabolites	Heroin & metabolites	Ethanol	Opioids	Fentanyl	Fentanyl Analogs	PCP
2013	25.34%	26.03%	15.75%	9.59%	1.37%	0.00%	8.22%
2014	22.86%	23.33%	15.71%	13.81%	3.81%	0.00%	4.76%
2015	14.39%	32.20%	15.15%	9.09%	7.58%	4.55%	2.65%
2016	15.37%	22.09%	14.78%	7.31%	13.88%	8.51%	6.27%
2017	16.39%	17.45%	12.03%	4.48%	20.05%	9.43%	4.13%

**Table 1:** Commonly Encountered Drugs in Accidental Intoxication Deaths between 2013–2017

Year	Black Male	Black Female	White Male	White Female
2013	54.64%	24.74%	17.53%	1.03%
2014	50.43%	24.35%	18.26%	4.35%
2015	53.33%	21.33%	20.00%	5.33%
2016	64.38%	18.30%	10.78%	2.61%
2017	56.59%	27.47%	9.07%	3.57%
Average	57.34%	23.17%	12.93%	3.38%

**Table 2\*:** Race and Gender Demographics from 2013–2017

\* All other race/ gender combinations that averaged less than 2% of the cases were excluded.

When compared to 2015, 2016 saw a decrease in the detection of heroin. However, this was met with an increase in fentanyl and its analogs. As a result, Black males, who accounted for 64% of the accidental intoxications, reached a record high within this cause of death. Conversely, Black females, White males, and White females all saw decreases within their populations. This seems to be in stark contrast to the demographic information generated throughout the United States, as reportedly White adults (aged 25–54 years old) are those most affected by the opioid crisis.<sup>1,2</sup>

As compared to 2016, 2017 continued the pattern of decreased identification of heroin with an increase in fentanyl and its analogs. Cases containing any combination of heroin, fentanyl, or fentanyl analogs accounted for nearly half (46%) of the intoxication deaths in the District of Columbia. Although Black males saw a 12% decrease in intoxication deaths during this time, they remained the most affected demographic. At 27%, Black females had their largest amount of intoxication deaths (range: 18%–27%) for the years examined. Conversely, accounting for 9% of these cases, White males had their lowest (range: 9%–20%) amount of intoxication deaths. White females, at 3% (range: 1%–5%), had the least amount of intoxication deaths among the race/gender demographics with 2% or more of the cases.

The impact that fentanyl and its analogs have had on drug deaths cannot be denied. The District of Columbia has experienced record highs among its intoxication deaths, as well as within the Black male population. These increases moved in parallel with the proliferation of laced heroin, thus further emphasizing how critical it is for a forensic toxicology laboratory to be able to provide analytical testing that is in line with the current drug market.

## K52 Long-Term Phencyclidine (PCP) Usage Trends in the District of Columbia

Kristin Jones, BS, Egg Harbor Township, NJ 08234; Charis Wynn, MSc\*, Office of the Chief Medical Examiner, Washington, DC 20024; Lucas W. Zarwell, MFS, Washington, DC 20011

**Learning Overview:** After attending this presentation, attendees will understand: (1) PCP use specific to the District of Columbia population based on a retroactive study observing poly-drug use and sample concentrations, and (2) the effects of PCP based on a review of published literature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a statistical resource on how the longstanding use of PCP has historically affected the community. Nationally, PCP is not a common drug of abuse and is often overlooked in trend reports. However, it is among one of the most prevalent illicit drugs abused specific to the District of Columbia.

PCP was developed in the 1950s as an intravenous anesthetic for both human and veterinarian use. It is known illicitly under a variety of names such as Angel Dust; is found in many forms, such as powder, crystal, tablet, and liquid; and can be injected, snorted, ingested, or smoked. PCP is a non-competitive antagonist for N-Methyl-D-aspartic (NMDA) receptor resulting in the high variance in effects observed in users. PCP's continuous resurgence in the community is possibly a result of a phenomenon called "generational forgetting" in which there was a continuous flow of new drugs onto the scene and older ones being rediscovered and reinvented by younger generations, such as combining phencyclidine with marijuana.

A retrospective study on Driving Under the Influence (DUI) and postmortem cases at the District of Columbia Office of the Chief Medical Examiner (OCME) were conducted to demonstrate and draw conclusions regarding trends. This study reviewed 145 postmortem cases from 2003 to 2017 in which PCP was listed in the cause of death, and 868 DUI cases from 2010 to 2017 in which PCP was present. Data was generated based on key components of the cases, such as poly-drug use and sample concentrations. Statistics were analyzed to determine correlation in specimen source, antemortem and postmortem concentrations, and any increasing or decreasing trends over the years.

The number of postmortem cases in which PCP was listed increased from 2003 to 2017 by a factor of ten. Manner of death in the 145 PCP postmortem cases were mostly accidental with only five homicides, three of which were while in police custody. The most common drugs, in order of prevalence, used with PCP in postmortem poly-drug cases were cocaine, ethanol, and heroin. The number of DUI cases in which PCP was present increased from 2010 to 2017 by 14%. The most common drugs, in order of prevalence, used with PCP in DUI poly-drug cases were marijuana, benzoylcegonine, and codeine. There was no correlation between femoral, heart, or hospital blood PCP concentrations for postmortem or antemortem cases. Table 1 compares the findings within the District of Columbia population to that of established literature:

	Postmortem Blood	Antemortem Blood (DUI)
Reference <sup>1</sup> Average	1.1mg/L	0.075mg/L
Reference <sup>1</sup> Range	0.5-3.3mg/L	0.007-0.240mg/L
In-house Average	0.072mg/L	0.023mg/L
In-house Range	0.01-0.37mg/L	0.01-0.15mg/L

**Table 1:** Phencyclidine Concentrations in Postmortem and Antemortem Blood

Over the past 15 years, the District of Columbia has seen an increase in PCP postmortem cases, possibly due to a policy change that increased reporting and decreased inconsistencies with listing specific drugs in case reports. Generally, over the past seven years, PCP prevalence in DUI casework has increased. Regionally, our concentrations across postmortem and antemortem populations tend to be lower than what is suggested in literature sources surveying other areas. When analyzing OCME casework from 2003 to 2017, data demonstrates that accident cases are most likely the cause of death associated with most PCP-related postmortem cases. However, there is no correlation in blood concentration of PCP use and the manner of death. At higher doses of PCP, users tend to be more aggressive and display increased strength, which possibly explains homicide cases accounting for the second most common cause of death associated with PCP intoxication due to restraints in police custody.

### K53 Determining the Prevalence of Gabapentin Abuse Among Opioid Users in Northern Virginia

Alexa Genalo, MSc\*, Fairfax, VA 22030

**Learning Overview:** The goal of this presentation is to provide insight on the specific trend of gabapentin abuse among opioid users in the Northern Virginia region.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new information on a specific drug trend in Northern Virginia directly related to the ongoing opioid crisis in the United States. The research covered in this presentation complements similar studies that have been previously conducted and proves gabapentin is an abused substance that should be federally controlled.

Gabapentin is an Anti-Epileptic Drug (AED) used in the treatment of epilepsy and postherpetic neuralgia. It was first approved for use in 1993 and is not a scheduled drug under the Controlled Substances Act due to its perceived low abuse potential and little to no drug-drug interactions. Today, gabapentin is also used off-label to treat a variety of conditions, including chronic pain and substance-dependence disorders. More often than not, gabapentin is prescribed to patients in conjunction with opioid compounds to treat their chronic pain. However, recent studies have shown that when this combination of drugs are used together, gabapentin enhances the effects of the opioid compounds, leading to increased levels of sedation and respiratory depression. These heightened effects have led to a trend of abuse of gabapentin with both licit and illicit opioid compounds across the United States. This study serves to explore the presence of this gabapentin abuse among opioid users in the counties of Northern Virginia serviced by the Virginia Department of Forensic Science (VA DFS) Northern Laboratory.

The goals of this research were to establish the presence of gabapentin in opioid-positive samples, to determine the percentage of gabapentin-positive cases, and to examine the gabapentin-positive cases for the type of opioid compounds present to determine whether illicit or prescription opioids were used more. For the purposes of this research, illicit opioid compounds were defined as heroin, fentanyl, and fentanyl derivatives. It was hypothesized that gabapentin would be present in a high percentage of opioid-positive samples and that gabapentin would be abused more commonly with illicit opioid compounds.

Blood samples received by the Toxicology Section of the VA DFS Northern Lab that were confirmed to contain opioid compounds were tested for the presence of gabapentin using a liquid-liquid extraction method and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) instrumentation. Chromatograms collected from the instrument were analyzed to determine the presence or absence of gabapentin in the selected samples. Gabapentin was present in 9% of the total number of samples tested. There was insufficient data to determine whether prescription or illicit opioids were used with gabapentin more, as the gabapentin-positive samples contained both prescription opioid compounds and illicit opioid compounds. The results of this study demonstrate the presence of this drug trend within our community and complement similar studies conducted on a broader scale in proving that gabapentin has an abuse potential and should be a federally controlled substance.

#### Gabapentin Abuse, Opioids, Anti-Epileptic Drugs

## K54 The Use of Molecular Modeling to Investigate the Influence of Structural Characteristics on the Binding of Synthetic Cannabinoids to the CB1 Receptor

Caroline Spencer, BS\*, Oxford, MS 38655; Pankaj Pandey, PhD, University of Mississippi, University, MS 38677; Robert J. Doerksen, PhD, University of Mississippi, University, MS 38677; Murrell Godfrey, PhD, University of Mississippi, University, MS 38677

**Learning Overview:** After attending this presentation, attendees will better understand the interactions between synthetic cannabinoids and the CB1 receptor and how structural changes of these compounds influence the interactions taking place within the binding pocket.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the understanding of essential interactions between specific substituents of synthetic cannabinoids with CB1 receptor residues through molecular modeling. The knowledge of these key interactions can help lead to a better understanding of the effects of these compounds and aid in the discovery of possible new synthetic cannabinoids.

Synthetic cannabinoids have emerged onto the drug scene as an alternative to illegal marijuana.<sup>1</sup> Like  $\Delta$ -9 Tetrahydrocannabinol ( $\Delta$ -9 THC), the main psychoactive ingredient in marijuana, synthetic cannabinoids interact with G-coupled protein receptors found in the brain, immune system, and peripheral organs.<sup>2</sup> There have been two cannabinoid receptors identified—CB1 and CB2. The binding of THC and synthetic cannabinoids to the CB1 receptors located in the brain is believed to induce the psychoactive effects. Even though there are similarities between  $\Delta$ -9 THC and synthetic cannabinoids, many synthetic cannabinoids have been determined to be full agonists for the CB1 receptor whereas  $\Delta$ -9 THC is only a partial agonist.

In this study, an active-state CB1 receptor model, proposed by the Doerksen lab, was used to compare the ligand-receptor interactions between the JWH synthetic cannabinoids, developed by John W. Huffman, and the CB1 receptor.<sup>3</sup> This study focused on the naphthylindole group of JWH synthetic cannabinoids. This group includes JWH-007, 018, 073, 116, 122, 182, and 210. This study was accomplished using Schrödinger's Maestro molecular modeling software. JWH ligands were selected based on their affinity for binding to the CB1 receptor. The docking of the ligands to the receptor took place after both the ligands and CB1 receptor model were prepped for docking and a grid of the active site was generated. Parameters were set to give the five best possible poses, or positions, for the ligands. Once the ligands were docked to the CB1 receptor model, the interactions were thoroughly analyzed. The information collected from this study includes the amino acid residues interaction with the ligands and the bond distances of these interactions, the docking score of each ligand and each pose, estimated binding affinities, and ligand  $K_i$  values. Once the known synthetic cannabinoids were analyzed, new structures were designed based on specific structural characteristics. The new structures were studied in the same way as the known synthetic cannabinoids to determine how these structural changes influence the binding and interactions of these compounds to the CB1 receptor.

The results of this study show the influence structural characteristics have on the docking score and relative binding affinity of the synthetic cannabinoids to the CB1 receptor. One structural characteristic examined in this study was the increasing alkyl chain length on the naphthalene group present in these ligands. The results were able to show a trend in docking score when increasing the alkyl chain length by one carbon on the naphthalene from no alkyl chain to a pentyl chain. The trend in docking scores was also shown to be dependent on the length of the alkyl chain (butyl or pentyl) that was on the nitrogen of the indole portion of the compound. However, when the structural characteristic of the carbonyl group was removed from the structures, the trend in docking scores was found to be reversed. A correlation was also seen with the docking score trend and the number of aromatic stacking interactions taking place in the binding pocket. Examining the JWH ligands docking revealed key interactions that were seen consistently in the active site. These interactions included Trp 279, Trp 356, Phe 177, and Phe 200. Identifying the key interactions between the synthetic cannabinoids and the CB1 receptor, and how their structural components influence the interactions, can lead to a better understanding of the effects of these drugs, including toxicity and potential for abuse. Future research will include the development of a database consisting of known synthetic cannabinoids, as well as newly designed synthetic cannabinoids, and pharmacological information of these compounds to aid in the rapid identification and understanding of synthetic cannabinoids as they appear in the drug market.

### K55 Can Synthetic Urine Replace Authentic Urine to Cheat Drug Testing?

*Victor J. Kim, BBA\*, Tripler Army Medical Center, Honolulu, HI 96859; Catherine K. Okano, PhD, Tripler Army Medical Center, Tripler Army Medical Center, HI 96859; Caroline Osborne, BS, Tripler Army Medical Center, Honolulu, HI 96859; Deanna Frank, BS, Tripler Army Medical Center, Honolulu, HI 96859; Christopher Meana, BS, NCIS Hawaii Field Office, Honolulu, HI ; Marisol Castaneto, MS, Ewa Beach, HI 96706-6430*

**Learning Overview:** After attending this presentation, attendees will understand what Synthetic Urine (SU) is, if it can really beat workplace drug testing, and its negative effect to our community and society.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that drug testing can be fooled with the substitution of SU products, which could bring about meaningful changes to make workplace drug testing as effective as possible.

**Background:** Urine is still the most common matrix utilized in workplace drug testing. Workplace drug testing in the United States Department of Defense was established to deter service members from illicit drug use and ensure personnel readiness. Federal civilian employees in drug testing positions also undergo Urine Drug Testing (UDT) before and during employment. Attempts to obscure illicit drug use have been observed in UDT programs with excessive hydration, urine adulterants, and urine substitutions with or without the use of prosthetic sex part (e.g., “Whizzinator”). SU is utilized by drug testing laboratories as a matrix for quality control preparations. However, SU products are now commercially sold as “novelty” and/or “fetish urine.”

**Objective:** To determine if SU can pass as authentic urine, this study challenged Army UDT collection and testing procedures using eight different commercial SUs.

**Material and Methods:** Eight SU products purchased from local smoke shops or online vendors were poured in plastic collection urine bottles. Adulterated/substituted samples such as 10% bleach in water (1:5 dilution), 10% bleach in urine (1:5 dilution), 10% hydrogen peroxide in urine (1:5 dilution), apple cider vinegar, and apple juice were also individually poured in collection bottles. These samples were placed randomly in boxes with other negative urine specimens. Three laboratory technicians were instructed to process the samples and pour sample aliquot to undergo immunoassay screening per standard operating procedures. Aliquots were screened in the Beckman AU5800 analyzers for cannabinoids, cocaine, amphetamines, codeine/morphine, hydrocodone/hydromorphone, oxycodone/oxymorphone, benzodiazepines, and synthetic cannabinoids. All SU, five adulterated urine samples, and two donor urine specimens were sent to a separate drug testing laboratory for specimen validity testing. None of the technicians in either laboratory had prior knowledge of which were adulterated or SU samples. Additionally, on-site SU (Synthetic UrineCheck™) and adulteration strips (Sciteck® AdultaCheck® 6) provided by Sciteck® were challenged with SU, adulterated urine, and negative authentic urine. Water and donor urine samples were used as controls for the Synthetic UrineCheck™. The Sciteck® AdultaCheck® 6 strips tested for oxidant, creatinine, nitrite, glutaraldehyde, pH, and chromate.

**Results:** Drug laboratory personnel identified five of eight SU products during accessioning. All SU products screened negative in the drug immunoassay and additionally passed the specimen validity testing as valid urine. The SU detection test strips were able to discriminate between authentic urine and SU products, although the test strip was not able to distinguish between diluted urine and SU. When the diluted urine and SU samples were tested with the Sciteck AdultaCheck® 6, all passed the adulteration test strips and were identified as authentic urine.

**Conclusion:** Direct observation during the collection process is critical to deter donors from adding or substituting their own urine specimens. In the civilian UDT, temperature strips may be affixed to the collection bottles or placed on the bottles immediately after collection to measure urine temperature. The specimen’s temperature must read between 90°F–100°F (32°C–38°C). In contrast, military UDT do not use temperature strips and rely on randomly selected observers to monitor any foul play during the collection process. In either circumstance, the use of “Whizzinator,” a prosthetic penis, has become an option for drug users. The prosthetic penis is attached to a bladder with a temperature strip. To deter SU use, UDT programs need to enforce optimal environment and direct observation during the collection process.

#### Synthetic Urine, Workplace Drug Testing, Urine

### K56 Detection of *In Utero* Ethanol Exposure Via Ethyl Glucuronide and Ethyl Sulfate Analysis in Placenta

Jennifer Hanna, New York, NY 10019; Ana De Castro, PhD, Universidade de Santiago de Compostela, Santiago de Compostela 15782, SPAIN; Elena Lendoiro, MD, University of Santiago de Compostela, Santiago de Compostela 15782, SPAIN; Angelines Cruz-Landeira, PhD, MD, Universidade de Santiago de Compostela, Santiago de Compostela 15782, SPAIN; Manuel Lopez-Rivadulla, PhD, University of Santiago de Compostela, Santiago de Compostela 15782, SPAIN; Marta Concheiro-Guisan, PhD\*, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** This presentation will demonstrate to attendees the value of utilizing placenta as an alternative matrix to meconium for the determination of *in utero* ethanol exposure, and the extent to which the two matrices can be compared.

**Impact on the Forensic Science Community:** This research will impact the forensic science community by providing a sensitive and specific method employing an alternative matrix to improve the interpretation of *in utero* ethanol exposure that will help toxicologists, legal personnel, and clinicians understand the newborns' outcomes and the medical and legal consequences of this exposure.

According to the 2016 National Survey on Drug Use and Health, ethanol was the second most prevalent substance (8.3%) after tobacco (10%) among pregnant women in the United States, with the ethanol prevalence being higher among 26- to 44-year-old pregnant women than in the 18- to 25-year-old group (9.1% vs. 6.5%). Alcohol consumption during pregnancy may happen due to preconceived notions among the population that a minor amount of alcohol during pregnancy can be harmless. However, there is no amount of ethanol deemed safe for consumption during pregnancy. Alcohol exposure during pregnancy constitutes one of the leading preventable causes of birth defects, mental retardation, and neurodevelopmental disorders in exposed children. Objective analytical methods are necessary to monitor this exposure.

A method for the determination of *in utero* ethanol exposure utilizing the direct minor metabolites of ethanol, Ethyl Glucuronide (EtG), and Ethyl Sulfate (EtS), has been developed, validated, and applied to authentic placenta samples from newborns whose meconium tested positive for EtG (>5ng/g). A 0.1g of placenta was mechanically homogenized in methanol and extracted using weak anion exchange solid phase cartridges and analyzed via Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Chromatographic separation was performed by Kinetex® Polar C18 column using a gradient elution of 0.1% formic acid in water and 0.1% formic acid in acetonitrile. Each compound was quantified and confirmed using its respective internal standard and two transitions in Multiple Reaction Monitoring (MRM) mode. Validation results demonstrated a linear range of 10ng/g–500ng/g with a limit of quantification of 10ng/g for both EtG and EtS, with residuals within  $\pm 20\%$  and a coefficient of determination greater than 0.99. Imprecision was maintained below 12%, and accuracy was within 83.1%–112.4%. Matrix effects (-69.9%– -15.2%), extraction efficiency (75%–92.7%), process efficiency (22.5%–76.3%), and interferences and autosampler stability at 10°C were also assessed during validation.

The validated method was applied to 59 authentic placenta samples. EtG and/or EtS was detected in 8 out of 59 samples with ranges of 26.5ng/g–266.5ng/g and 11ng/g–24.3ng/g, respectively. Results from placenta were compared to different EtG meconium cutoffs from the literature in paired samples to establish relative rates of agreement between the two matrices. The highest agreement of 50% was achieved at EtG cutoff of 444ng/g in meconium, and the lowest agreement of 13.6% at EtG analytical cutoff of 5ng/g in meconium.

A sensitive and specific method for the determination of EtG and EtS in placenta was developed. Comparing meconium and placenta, meconium showed a higher sensitivity, but placenta could be employed as alternative sample if meconium is not available. To date, this is the first study to compare placenta and meconium to detect ethanol exposure during pregnancy.

#### Ethanol, Ethyl Glucuronide, Ethyl Sulfate

## K57 Co-Reaction of Lactate/Lactate Dehydrogenase in an Enzymatic Ethanol Assay

Julia C. Liebl, BA\*, University of New Haven, West Haven, CT 06516; Robert H. Powers, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will understand how an enzymatic ethanol assay can produce false positives or falsely elevated results for samples containing elevated levels of lactate and Lactate Dehydrogenase (LDH) due to trauma or illness. Attendees will also understand threshold levels of lactate and LDH necessary for interference to occur and the magnitude of potential effects on ethanol results.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying the potential for interference by lactate/LDH in an Alcohol Dehydrogenase (ADH)-based ethanol assay and providing an understanding of the physiological parameters that could reasonably cause such an interference. The results of this project can be used to facilitate the interpretation of enzymatic ethanol results by pathologists, medical personnel, and toxicologists.

Enzymatic assays are commonly used to determine blood alcohol content in clinical settings. In some instances, this data may be used as evidence in legal settings (e.g., Driving Under the Influence (DUI) cases). The enzymatic assay measures the amount of ethanol indirectly as  $\Delta$  NADH. It is theoretically possible that interference from the oxidation of lactate to pyruvate could occur and produce a falsely positive or elevated result.<sup>1</sup> While addressed sporadically over the past 30 years, questions of the conditions under which such interference may occur remain unresolved, particularly in the LDH range of 4,000U/L–10,000U/L. While abnormally elevated levels of lactate and LDH are not routinely present in clinical samples, nor are erroneous “false positive” ethanol results considered to be a common problem, there has been persistent concern regarding the potential for such interference affecting some samples of legal significance.<sup>2-9</sup> Further, no information regarding the combination of ethanol, lactate, and LDH in an ADH assay has been provided.

To determine if the presence of lactate and LDH in a serum sample could impact the ethanol level observed in the assay, varying amounts of lactate and/or LDH were added to an enzymatic ethanol assay. The concentrations of lactate and LDH utilized were chosen to reflect elevated levels reasonably observable in living individuals (normal lactate: 0.5mM–2.2mM, elevated lactate: 5mM–50mM; normal LDH: 122U/L–225U/L, elevated LDH: 200U/L–10,000U/L) suffering from a combination of trauma, shock, hypoxia, hepatic disease, or other conditions producing leakage of hepatic enzymes and lactic acidosis.<sup>5, 10,11</sup>

The results indicate that elevated levels of lactate and LDH can result in false positive and falsely inflated results from the ADH assay, most notably at higher concentrations. In a system with no ethanol, the lower threshold of response was detected with a combination of 4,000U/L LDH and 50mM lactate. This indicates that interference occurs far above physiologically normal levels of LDH and explains the rarity of this interference. On the upper end, 10,000U/L LDH and 50mM lactate produced a signal of 92mg/dL, which may have significant legal implications.

When lactate and LDH were added to a system with ethanol present, a signal increase of up to 350% was observed, with greater effects noted with low (30mg/dL) and medium (60mg/dL) levels of ethanol in the system. These results indicate that lactate/LDH interference, while rare, can conceivably cause a significant false positive or falsely inflated “ethanol” result.

## K58 The Application of Statistical Design of Experiments (DoE) to Assess External Decontamination Methods in Forensic Hair Analysis

Jennett M. Chenevert, MS\*, Florida International University, Miami, FL 33199; Anthony P. DeCaprio, PhD, Florida International University, International Forensic Research Institute, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will understand how statistical DoE can help optimize highly variable forensic methodologies, particularly in forensic hair analysis, with the ultimate goal of working toward standardization of these techniques.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that this work will contribute to a body of research aimed at determining the most effective method(s) for decontaminating hair samples for forensic analysis and subsequently isolating drugs of abuse from these samples.

It was hypothesized that statistical DoE could be used to determine which conditions of a discrete set of levels of defined parameters would result in the most effective removal of amphetamine from the surface of human head hair, deposited by means of external environmental exposure. As a complex solid sample matrix, hair requires pretreatment measures, including decontamination, homogenization, and extraction, to remove the drug from the hair matrix components to allow for analysis. Optimizing pretreatment parameters is essential to accurately identify and quantify drugs present in a hair sample. One of the most challenging issues faced in hair testing analysis and interpretation is the differentiation between a drug that is detected due to superficial deposition onto the surface of the hair and a drug incorporated into hair from intake and systemic distribution. This interpretive challenge necessitates effective removal of the drug on the surface of hair deposited by means of contamination from an individual's environment prior to analysis. The Society of Hair Testing (SoHT) recommends at least one wash step with an aqueous solvent and one with an organic solvent. These guidelines are general, and thus a variety of decontamination methods have been published to date without a systematic comparison of these different techniques.

The major goal of this work was to conduct a comprehensive DoE analysis of decontamination parameters and their effect on the removal of drug from the surface of hair. A 2<sup>4</sup>-fractional factorial block design followed by Analysis Of Variance (ANOVA) and Tukey's Honestly Significant Difference (HSD) analysis were used to compare the main factors: wash time, aqueous and organic decontamination solvent identities, and order of wash (i.e., organic wash first vs. aqueous wash first). The blocking factors were the number of sequential washes with both the aqueous and organic solvents. Neat amphetamine powder was superficially applied to blank human head hair. The hair was decontaminated following the 2<sup>4</sup>-fractional factorial block design matrix.

A 30mg aliquot of hair was weighed into a stainless steel milling jar with 200µg of amphetamine sulfate. The samples were agitated using a BioSpec® Mini-Beadbeater™ 24 ball mill, without milling beads present. The samples were then washed with the aqueous or the organic solvent first for either 30s or 30min. The aqueous wash was performed by adding 1mL of chromatography-grade water or 1% Sodium Dodecyl Sulfate (SDS) and agitating on an orbital shaker. The organic wash was performed by adding 1mL of 2-propanol or dichloromethane and agitating on an orbital shaker. There were 1–3 washes of the aqueous and organic washes performed, depending on the two blocks of the experimental unit. The hair was then dried for 24h at 40°C in an oven. Once dried, the samples were homogenized using the ball mill with chrome-steel milling beads at 3,800rpm for 30s. The drug was extracted by means of enzymatic hydrolysis of the hair proteins, with a pre-incubation in 12mg/mL aqueous Dithiothreitol (DTT) for 2h at 37°C, followed by incubation with 2mg/mL proteinase K. Extracted samples and wash solutions were purified by spin filter centrifugation (3 KDa MW cut-off) and Solid Phase Extraction (SPE) before Liquid Chromatography/Triple quadrupole/Mass Spectrometry (LC/QqQ/MS) analysis. Three replicate samples for each design point were analyzed.

Analysis of Variance (ANOVA) results indicated that 3- and 4-factor interactions (i.e., the parameters associated with combinations of 3 and 4 parameters under study) were significant. The percent of drug recovered from the hair to which amphetamine was superficially applied was highest, at 46%, for samples that were washed for 30s during each wash step, employed dichloromethane as the organic wash solvent, and were washed with the organic solvent before the aqueous solvent. When expanded to additional drugs, it is expected that this work will contribute to a body of research aimed at determining the most effective method(s) for decontaminating hair samples for forensic analysis and subsequently isolating drugs of abuse from these samples.

### Forensic Hair Analysis, External Contamination, Statistical Design of Experiments

### K59 An Evaluation of a Presumptive Screen in Urine as a Rapid Method of Determining Fentanyl-Related Deaths

Aaron M. Shapiro, PhD\*, British Columbia Provincial Toxicology Centre, Vancouver, BC V5Z 4R4, CANADA; Andrew Tu, PhD, British Columbia Coroners Service, Burnaby, BC, CANADA; Michael Moss, MBBS, Interior Health Authority, Kelowna, BC V1Y 1T2, CANADA; Jatinder Baidwan, MBBS, British Columbia Coroners Service, Burnaby, BC V5H 4N2, CANADA

**Learning Overview:** After attending this presentation, attendees will: (1) appreciate the challenges faced by coroner/medical examiner systems considering the recent opioid crisis, (2) learn the differences between presumptive immunoassay and confirmatory mass spectrometry, and (3) understand the relationship (or lack thereof) between drug concentrations in the blood and urine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential benefits and detriments of using presumptive screening to limit the number of autopsies performed in suspected overdose deaths.

**Background/Introduction:** The province of British Columbia, Canada, has seen an unprecedented increase in the number of opioid-related deaths in recent years. In 2017, there were 1,156 fentanyl-related deaths, which represent 81% of all illicit drug deaths in the province. The British Columbia Coroners Service stratifies decision-making on postmortem examination prior to autopsy and releases bodies in cases in which fatal drug findings are identified. In cases in which an immediate toxicological cause of death cannot be identified, decedents undergo full postmortem examination. There is a limited timeframe in which a body can be stored prior to autopsy. Toxicology results must therefore be performed within days of collection. To expedite fentanyl testing, the implementation of urine screen immunoassay has been proposed.

**Objective:** The purpose of this study is to evaluate the robustness of presumptive urine drug screening in suspected fentanyl-related deaths by establishing the relationship between fentanyl and norfentanyl in blood and urine.

**Method:** Suspected drug-related deaths that occurred within the Interior Health Region of the Province of British Columbia were included in this study if blood and urine were available for testing. One aliquot of urine was sent to clinical laboratories within the Interior Health region for presumptive testing using the SureStep™ urine fentanyl drug test (cutoff concentrations: >20ng/mL norfentanyl, >100ng/mL fentanyl). Blood and a second aliquot of urine were sent to the Provincial Toxicology Centre for complete toxicology testing by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Concentrations of fentanyl and norfentanyl in blood and urine were then compared to the presumptive results. A concentration of 3ng/mL was the minimum concentration at which fentanyl could be associated with death.

**Results:** Preliminary results from 29 cases found that 72% of presumptive urine screen results coincided with blood fentanyl results. There were five false negatives, in which the presumptive screen did not detect fentanyl but the concentration in the blood exceeded 3ng/mL, and three false positives (Se=72%; Sp=73%; PPV=81%; NPV=62%). Urine fentanyl and norfentanyl concentrations determined by LC/MS/MS in acute overdose deaths did not strongly correlate to those of blood (correlation coefficient=0.12 and 0.65 for fentanyl and norfentanyl, respectively). All presumptive screen results in which fentanyl was detected contained norfentanyl; however, 25% of those cases were below the reported cutoff. In contrast, 8% of cases in which the presumptive screen did not detect fentanyl were above the reported cutoff. Urine carfentanil concentrations ranged from 0.2ng/mL to 2.0ng/mL. No carfentanil-only cases were detected by the presumptive screen.

**Conclusion/Discussion:** In the majority of cases, urine presumptive screening coincided with blood fentanyl concentrations of at least 3ng/mL. Comparison of urine concentrations to presumptive screen results suggest that the high false negative rate is related to the absence of norfentanyl in the urine following acute death, rather than a sensitivity issue associated with the presumptive screen. False negative results carry minimal risk as they are followed up by complete toxicology testing and postmortem examination. However, false positives would result in the release of a body prior to autopsy in cases in which no cause of death has been determined. Further investigation into this study will provide valuable insight into whether the false positive rates constitute an acceptable risk.

#### Fentanyl, Urine Screening, Postmortem Toxicology

## K60 Distinguishing Cyclopropylfentanyl From the Analogs Crotonylfentanyl and Methacrylfentanyl in Two Dimensions: The Utilization of Liquid Chromatography and Mass Spectrometry

Svante Vikingsson, PhD\*, National Board of Forensic Medicine, Linköping 58758, SWEDEN; Markus Roman, BS, National Board of Forensic Medicine, Department of Forensic Genetics and Forensic Toxicology, Linköping 58758, SWEDEN; Robert Kronstrand, PhD, National Board of Forensic Medicine, Department of Forensic Toxicology, Linköping 58758, SWEDEN

**Learning Overview:** After attending this presentation, attendees will: (1) be aware of two fentanyl analogs that could potentially be mistaken for cyclopropylfentanyl, and (2) have the tools to distinguish them.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) providing modes of separation for cyclopropylfentanyl and closely related analogs, and (2) identifying potential pitfalls involving isobaric analogs in New Psychoactive Substances (NPS) identification.

**Background:** In 2017, Sweden experienced a series of 72 deaths involving the fentanyl analog cyclopropylfentanyl. Identification was complicated by the two isobaric analogs crotonyl- and methacrylfentanyl, which produced similar high-resolution Mass Spectrometry (MS) -spectra and similar retention times in the screening assay.

**Goal:** The goal of this study was to establish methodology that could distinguish the three analogs by Liquid Chromatography (LC) and/or MS to verify the presence of cyclopropylfentanyl in autopsy cases.

**Methods:** A screen for chromatographic selectivity was conducted. Five different Ultra High-Performance Liquid Chromatography (UHPLC) columns (50x2.1, <math><2\mu\text{m}</math>) including Waters® HSS T3, CSH Phenyl Hexyl, Protein BEH C4 and BEH C8 as well as Kinetex® PFP from Phenomenex, were screened using two different organic modifiers as B-phase (either acetonitrile or methanol with 0.05% formic acid) and two different A-phases (0.05% formic acid in either water or 10mM ammonium formate) using a generic gradient from 5%–65% organic modifier over 8min at 0.7ml/min. A 2min gradient was optimized based on the results of the screen.

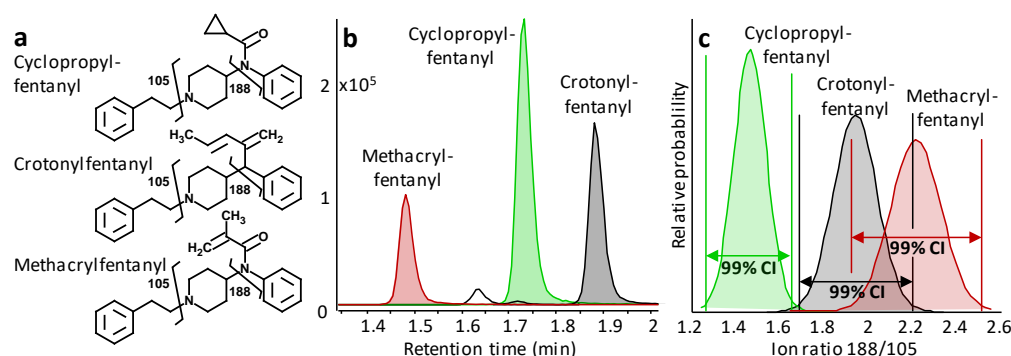

As fragmentation of the analogs was very similar (major fragments in Figure 1a), ion ratios of major fragments were investigated to distinguish the analogs. Reference ion ratios were established as the average of ten replicates analyzed by Multiple Reaction Monitoring (MRM) on an AB SCIEX® API 4500 LC/MS/MS. The separation was performed using a Waters® BEH Phenyl column (50x2.1mm, 1.7 $\mu\text{m}$ ) with 0.05% formic acid in 10mM ammonium formate and methanol as mobile phases.

The stability of ion ratios over time was investigated by analyzing data from 68 cyclopropylfentanyl autopsy cases analyzed over seven months. The standard deviation and the 99% confidence interval ( $\pm 2.6$  SD) were calculated. As no case data was available for crotonyl- and methacrylfentanyl, the same Relative Standard Deviation (RSD) was assumed.

**Results:** The best separation was obtained on a Waters® Protein BEH C4 column using 0.05 formic acid in 10mM ammonium formate and 0.05% formic acid in methanol as mobile phases. Separation with an optimized 2min gradient from 15-30% methanol is shown in Figure 1b.

Average ion ratios (m/z 188/105) for cyclopropyl-, crotonyl-, and methacrylfentanyl were 1.46, 1.94 and 2.21, respectively. The RSD for the cyclopropyl ion ratio was 5.1%. Probability profiles were plotted in Figure 1c including the 99% confidence interval ( $\pm 2.6$  SD). Cyclopropylfentanyl could be distinguished from the other analogs while an overlap existed between crotonyl- and methacrylfentanyl.

Analogues with closely related isobaric analogs is a growing concern given the increasing number of NPS, especially as laboratories may not be aware of potential analogs at the time of method validation. By utilizing selective chromatographies and carefully selecting acceptance criteria for ion ratios, the confidence in NPS identification can be increased.

**Figure 1** – Structures of the fentanyl analogs (a), optimized chromatography (b), and Confidence Intervals (CI) of m/z 188/105 ion ratios (c).

**Conclusion:** This study illustrates that even though cyclopropyl-, crotonyl-, and methacrylfentanyl have the same nominal mass and are structurally similar, it was possible to distinguish them by their retention time on a BEH C4 column.

It was also possible to distinguish cyclopropylfentanyl from crotonyl- and methacrylfentanyl by the difference in their respective m/z 188/105 ion ratios. However, crotonyl- and methacrylfentanyl could not be distinguished from each other using only ion ratios. These approaches could potentially be used to distinguish other NPS drugs from isobaric analogs and provide more reliable identifications in toxicological casework.

---

### **Cyclopropylfentanyl, Crotonylfentanyl, Methacrylfentanyl**

## K61 Method Optimization for the Derivatization of 35 Drugs Commonly Reported in Driving Under the Influence of Drugs (DUID) Cases

Lexus R. Rutter, BS\*, Arcadia University, Glenside, PA 19038; Jody Searfoss, BA, Glenside, PA 19038-3215; Kristina Fanning, MS, United Chemical Technologies, Bristol, PA 19007; Danielle A. Mackowsky, MS, United Chemical Technologies, Bristol, PA 19007; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038

**Learning Overview:** After attending this presentation, attendees will have an increased understanding of which derivatizing agent and technique are best suited for the analysis of a variety of common drugs of differing chemistries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing forensic laboratories with a derivatization and Gas Chromatography/Mass Spectrometry (GC/MS) method for Tier 1 drugs and metabolites associated with DUID cases.

DUID encompasses prescription, over-the-counter, and controlled substances that cause impairment of one's judgment and motor skills. A series of recommendations has been published that describes two tiers of drugs that are commonly seen in DUID cases.<sup>1</sup> Screening and confirmatory cutoff limits have been recommended for the Tier 1 drugs to create better consistency across laboratories.<sup>1</sup>

Typical casework for many forensic toxicology laboratories for DUIDs includes blood and urine screenings. There is a move internationally from GC to Liquid Chromatography (LC) techniques, but many laboratories still lack instrumentation such as a triple quadrupole LC/MS/MS. For most laboratories, derivatization is therefore a critical step for certain drugs to be suitable for GC/MS analysis.

The Tier 1 drugs consist of four classes of drugs. The Central Nervous System (CNS) stimulants include methamphetamine, amphetamine, 3,4-methylenedioxymethamphetamine (MDMA), 3, 4-methylenedioxyamphetamine (MDA), cocaine, benzoylecgonine, and cocaethylene. The CNS depressants consist of carisoprodol, meprobamate, zolpidem, alprazolam,  $\alpha$ -hydroxyalprazolam, clonazepam, 7-aminoclonazepam, lorazepam, diazepam, nordiazepam, oxazepam, and temazepam. Codeine, 6-acetylmorphine, buprenorphine, norbuprenorphine, fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone, oxymorphone, tramadol, and o-desmethyltramadol make up the narcotic analgesic category. The cannabis category includes Tetrahydrocannabinol (THC), carboxy-THC, and 11-hydroxy-THC. Differences in the functional groups associated with these drugs often require different derivatizing reagents such as silylation, acylation, and alkylation reagents. This research aims to determine a single GC/MS method for the analysis of all 35 recommended Tier 1 drugs and metabolites.

A test mix was prepared by adding 1mL of a 10 $\mu$ g/mL solution for each of the 35 drugs in acetonitrile. Seven derivatizing reagents, Pentafluoropropionic Acid Anhydride (PFPA), Trifluoroacetic Acid Anhydride (TFAA), Heptafluorobutyric Anhydride (HFAA), N, O-Bis (Trimethylsilyl)Trifluoroacetamide with 1% Trimethylchlorosilane (BSTFA with 1% TMCS), N-Methyl-N-Trimethylsilylfluoroacetamide (MSTFA), N-methyl-N-(tert-butyltrimethylsilyl) trifluoroacetamide with 1% Tert-Butyltrimethylchlorosilane (MTBSTFA with 1% TBDMCS), and Trimethylanilinium Hydroxide (TMAH) were assessed. Triplicate samples of 100  $\mu$ L of the test mix were derivatized for each reagent changing the temperature and time of incubation followed by GC/MS analysis.

Separation of all 35 drugs was achieved on an Agilent® 6890 GC 5975 MS using an Agilent® DB-5MS Ultra Inert (30m x 0.25mm x 25 $\mu$ m) capillary column with a temperature program starting at 60°C and ending at 325°C. MSTFA and PFPA yielded the most consistent results across the range of chemistries of the drugs and it was possible to obtain sharp, reproducible baseline-resolved peaks at concentrations equal to the cutoff values stated in the DUID recommendations for the 35 Tier 1 drugs and metabolites.<sup>1</sup>

### Derivatization, GC/MS Analysis, DUID

### K62 A Case Report: Driving Under the Influence (DUI) of Flubromazepam

Erin L. Karschner, PhD\*, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; George F. Jackson, PhD, Forensic Toxicology, Burlington Township, NJ 08016; Jeff Walterscheid, PhD, Armed Forces Medical Examiner System, Division of Forensic Toxicology, Dover Air Force Base, DE 19902

**Learning Overview:** After attending this presentation, attendees will be aware of the impairment effects demonstrated by an individual DUI of a benzodiazepine Novel Psychoactive Substance (NPS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing quantitative data from a single drug intoxication case that may assist toxicologists in future casework interpretation.

Benzodiazepines are a commonly prescribed class of drugs used to treat anxiety, seizures, and sleep disorders. Several decades ago, investigators synthesized a number of benzodiazepines as potential new treatment options. More recently, these substances have reemerged for sale on the internet as legal highs. Flubromazepam was first developed and patented in the 1960s and reappeared on the internet marketplace in 2012. Currently, few reports are available from single drug intoxications involving flubromazepam.

**Case History:** Police were notified of a vehicle driving erratically and swerving between lanes. The 23-year-old male driver was stopped after his vehicle hit a curb. The individual was unable to hold a steady conversation and had difficulty comprehending the questions asked by the officer. The officer administered Standardized Field Sobriety Tests (SFSTs) and observed indicators for lack of smooth pursuit in both eyes on the Horizontal Gaze Nystagmus (HGN) test and six clues on the Walk And Turn (WAT), including inability to maintain balance during the instruction phase, started too soon, missed heel-to-toe, raised arms, incorrect number of steps, and improper turn. No additional SFSTs were conducted due to the observations made during the HGN and WAT. An officer initiated a search of the vehicle and discovered empty prescription bottles of sertraline and oxycodone, a small bag of blue pills, a small bag containing traces of a white powder, and white powder located in the compartment above the gearshift. The individual threw himself to the ground while he was being detained and was injured. At that time, he was transported to a medical facility where blood was drawn and submitted to the Armed Forces Medical Examiner System Division of Forensic Toxicology.

Routine toxicological analyses included ethanol and additional volatiles, drugs of abuse immunoassay, and an alkaline-extractable drug screen. Blood volatiles were analyzed by headspace Gas Chromatography/Flame Ionization Detector (GC/FID). Immunoassays were performed for amphetamines, barbiturates, benzodiazepines, cannabinoids, cocaine, opioids, phencyclidine, and sympathomimetic amines. Alkaline drugs were extracted with a mixed-mode solid phase extraction procedure and analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) in full-scan mode. Identification criteria included retention time within  $\pm 2\%$  of the analyte in the control standard and a full-scan mass spectrum matching a reference spectrum with at least 70% confidence. Subsequent confirmation was conducted with a validated method for liquid-liquid extraction and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis. Two Multiple Reaction Monitorings (MRMs) were monitored for all analytes and deuterated internal standards. Qualitative identification was dependent on meeting MRM ratio, peak shape, and retention time criteria. Quantitative criteria included control bias within 20% of target and calibration curves with  $r^2 \geq 0.99$ .

The blood was negative for ethanol but was presumptively positive for benzodiazepines by immunoassay. An alkaline drug screen narrowed the benzodiazepine presumptive positive to flubromazepam with a 76% spectral library match. Confirmatory analysis revealed that the blood contained flubromazepam at 546ng/mL.

This study presents a DUID case where flubromazepam was the only substance identified in the blood. In addition to the erratic driving behavior, the individual displayed two clues on the HGN and six of eight clues on the WAT. Video evidence also showed the individual stumbling and hitting walls as he left his room 20min prior to the DUI incident. Lack of smooth pursuit, impaired divided attention, and other central nervous system depressant outcomes observed in this individual were similar to effects elicited by traditional benzodiazepines.

#### DUID, Flubromazepam, NPS

### K63 Toxicological Findings in Driving Under the Influence Cases in Northeast Ohio: A Six-Year Study

Amanda J. Jenkins, PhD\*, University of Massachusetts Memorial Medical Center, Worcester, MA 01605; Kimberly Yacoub, MS, Westlake, OH 44145; Douglas E. Rohde, MS, Lake County Crime Laboratory, Painesville, OH 44077

**Learning Overview:** After attending this presentation, attendees will have a better understanding of drug prevalence in a recent Driving Under the Influence/Driving Under the Influence of Drugs (DUI/DUID) population.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data on recent drugged drivers in the United States.

**Background:** There are more than six million motor vehicle accidents in the United States annually. Drug testing of operators of motor vehicles has become a routine occurrence, especially if serious injuries or fatalities occur. Knowledge of the prevalence of drugs in these individuals will provide evidence to assist policy makers in the public health effort to improve roadway safety.

**Objective:** The objective of this study was to review all driving cases submitted to the Lake County Crime Laboratory for toxicology testing by law enforcement during the period January 1, 2012, to December 31, 2017, in Lake and Ashtabula Counties, Ohio.

**Methods:** Blood and/or urine were submitted for each case and a standard protocol utilized to determine the tests to be conducted. Testing for volatiles by headspace gas chromatography in blood and urine was initially performed. If the ethanol concentration was below the per se level (per se=blood 0.08; urine 0.11 g%), the specimen was assayed by enzyme-linked immunosorbent assay screen for amphetamine, barbiturates, benzodiazepines, cannabinoids, carisoprodol, cocaine/metabolites, fentanyl, methadone, methamphetamine, opiates, oxycodone, phencyclidine, tramadol, tricyclic antidepressants, and zolpidem. Screening positive results were confirmed by Gas Chromatography/Mass Spectrometry (GC/MS). A general drug screen by solid phase extraction followed by GC/MS for alkaline, neutral, and acidic drugs was also performed based upon case history. Additional confirmatory testing was performed as indicated by the case narrative, further investigation, or law enforcement request.

**Results:** A total of 845 cases were identified. Blood and urine were submitted in 25% of the cases with 46% blood-only and 29% urine-only submissions. Only confirmed drug testing results are presented. No drugs, including ethanol, were detected in 30 cases (3%). The most common drug detected was ethanol ( $n=442$ ; 52%, range; mean and median (g%)- blood 0.010–0.410; 177, 174; urine 0.012–0.474; 210, 215) followed by opioids (36%), benzodiazepines (22%), and marijuana (21%). Other prevalent drugs included cocaine/metabolites, sympathomimetic amines, and carisoprodol/meprobamate. More than one drug were identified in 319 cases (37% of the total number of cases) with 93 cases (11% total) containing more than three compounds (62% of these occurred 2015–2016). Barbiturates and phencyclidine accounted for less than 3% of the positive cases. The highest number of individual drugs associated with a single case was 12. Codeine/morphine was the most prevalent opioid combination and alprazolam, clonazepam/7-aminoclonazepam, and diazepam/metabolites were prevalent for the benzodiazepines. Trends observed included the proportion of cases positive for ethanol decreased over the study period, from 66% of all cases in 2012 to 37% in 2017. The proportion of cases positive for opioids increased from 2012 (18%) to a high of 57% in 2016.

**Conclusion:** A six-year evaluation of potential drugged driving cases demonstrated that at least one drug was detected in more than 95% of cases. Furthermore, a noteworthy number of cases reflected poly drug use.

#### Driving Under the Influence, Impaired Driving, Toxicology

### K64 Inhalant Abuse: Cases Analyzed for Toluene Over a Three-Year Period

*Justine M. Titko, MSFS\*, NMS Labs, Willow Grove, PA 19090; Lee M. Blum, PhD, NMS Labs, Willow Grove, PA 19090; Dennis J. Miller, DeKalb County Coroner's Office, Sycamore, IL 60178; Ayako Chan-Hosokawa, MS, NMS Labs, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will understand the toluene blood concentrations in suspected overdose death cases and the benefits of pursuing an unknown chromatographic peak observed during the toxicological analysis of a postmortem specimen.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing statistical information associated with toluene findings in postmortem cases and provide insight into a specific case of toluene abuse.

This presentation focuses on a review of 56 cases over a three-year period in which toluene was detected via dual column headspace Gas Chromatography with Flame Ionization Detection (GC/FID) (RL=0.3mcg/mL). Of these cases, 52 provided information in the case history about the decedent's gender; 85% ( $n=44$ ) were males, while 15% ( $n=8$ ) were females. The 56 cases were then subdivided into three subcategories based on case history: Huffing or Solvent Abuse Suspected Deaths ( $n=11$ , 20%); Other Causes of Death ( $n=5$ , 9%); and No Case History Provided ( $n=40$ , 71%).

To assess toluene concentrations in postmortem cases, the 11 postmortem cases in which huffing or solvent abuse was suspected were examined. The mean ( $\pm$ SD) blood concentration of toluene in this subset of cases ( $n=11$ ) was  $16.8 \pm 36.2$ mcg/mL (median=3.1mcg/mL; range: 0.63mcg/mL–130mcg/mL). Of the 11 cases, 82% were male and 18% were female. The ages provided for 73% of the cases averaged 45.5 years old (range; 22–62 years old) with the median and mode both at 50 years old. Additional findings observed in these cases included other volatile organic compounds, ethanol, acetone, isopropanol, methanol, prescribed medications, and drugs of abuse.

There was one specific case that illustrated the importance of pursuing an unidentified chromatographic peak during a toxicological examination. The case involved a 63-year-old male found unresponsive at his residence after his mother called the police to perform a welfare check on him. He was found in the basement with a plastic bag over his head and a jar nearby containing a clear liquid that smelled like paint thinner. The decedent had a history of huffing paint thinners for approximately 13 years, and toluene is a known ingredient in some types of paint thinners. Autopsy findings included, but were not limited to, a decomposed body with autolysis of organs, pulmonary edema and congestion, and prostatic hypertrophy.

A routine postmortem toxicology drug panel indicated non-lethal amounts of ethanol and caffeine in cavity blood and a non-lethal amount of ethanol in vitreous fluid. However, the investigation of an unknown substance in an analysis for alkane constituents of solvents resulted in supplemental testing in the cavity blood. First, the blood specimen was analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) using full-scan mode that identified toluene and isovaleraldehyde. Then, the presence of these findings was quantitated by dual column headspace GC/FID. The toluene measured, 2.53mcg/mL, was likely an underreported value because of the volatility of the substance and the handling of the specimen multiple times prior to the analysis for toluene. The cause of death was determined to be toluene intoxication.

Toluene has been abused through the years (e.g., glue sniffing and huffing) because of its ease of accessibility and low cost. Specimens from individuals suspected of inhalant solvent abuse require specialized handling and testing due to the volatile nature of these compounds. Such considerations need to be considered when investigating these types of cases.

#### Toluene, Inhalant, Overdose

### **K65 The Detection and Quantification of Amphetamine and Norephedrine in Rat Brain, Heart, and Liver Tissues at Different Stages of Decomposition After Internment**

*Christina Rose Mendralla, BS\*, Arcadia University, Glenside, PA 19038; Jolene Bierly, MSFS, NMS Labs, Willow Grove, PA 19090; Heather L. Harris, JD, Glenside, PA 19038; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038*

**Learning Overview:** After attending this presentation, attendees will be aware of the possible relationship between antemortem amphetamine dose and the concentration of amphetamine and its metabolite norephedrine in buried remains at various stages of decomposition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information regarding the effect of decomposition on the identification and quantification of amphetamine and norephedrine in postmortem tissue samples. This will aid death investigators in determining a possible drug contribution to cause of death when amphetamine is present.

In forensic toxicology casework, the primary matrices include biological fluids, such as blood and urine. However, some forensic casework includes the testing of decomposed postmortem tissue samples. Forensic toxicologists, therefore, need to know if decomposition has an effect on the identification and quantification of a drug because any analysis completed by the toxicologist assists the forensic pathologist in determining the impact of the drug(s) on the cause of death. This involves the understanding of taphonomy and its effects. Due to this intersection of toxicology and taphonomy, this research aims to determine the relationship between antemortem amphetamine dose, the concentration of amphetamine, its metabolite norephedrine, and the stage of decomposition of buried remains.

This relationship is important for amphetamine as it is a drug that is seen in fatal drug cases, so a possible relationship between decomposition and the concentration detected could have an impact on its interpretation in postmortem samples. To determine this relationship, 17 male Long Evans rats were dosed with amphetamine at concentrations of 10mg/kg, 6mg/kg, 2mg/kg, 1mg/kg, 0.6mg/kg, and 0.2mg/kg once a day for ten days. The rats dosed at the 10mg/kg, 6mg/kg, and 2mg/kg concentrations were euthanized with CO<sub>2</sub> ten days after the final injection while the other doses were euthanized with CO<sub>2</sub> immediately following the final dose. The rats were then interred in the New Jersey Pine Barrens, then later exhumed at different stages of decomposition in accordance with the Megyesi method. Following exhumation, liver, heart, and brain tissue samples were collected during dissection, but when decomposition was more advanced, samples were collected from the general location at which the organ would have been found. The samples were stored at -20°C until analysis. During analysis, the samples were tested for amphetamine and its metabolite norephedrine.

The samples were prepared by homogenizing the tissues with saline using a Biotage® Bead Ruptor 24 (1:1 for brain and liver, 2:1 for heart) and performing a protein precipitation with acetonitrile followed by a Liquid-Liquid Extraction (LLE) for amphetamine and norephedrine. The LLE method involved an initial organic extraction using dichloromethane/ethyl-acetate/isopropyl alcohol (3:1:1), a back extraction using a 1M phosphate buffer at pH 2.5, and a final organic extraction using dichloromethane/isopropyl alcohol/ammonium hydroxide (78:20:2). The analytes were identified and quantified using a Perkin Elmer Clarus® SQ 8T Gas Chromatograph/Mass Spectrometer (GC/MS) in Selected Ion Monitoring (SIM) mode with amphetamine-D11 (m/z 194) and norephedrine-D3 (m/z 283) as the internal standards. The SIM ions for amphetamine are 190, 118, and 91; the SIM ions for norephedrine are 280, 190, and 91. The column used in this research is an Agilent® DB-5ms Ultra column (30m, 0.25mm ID, 0.25µm df). This method was validated using the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines for method validation.

The analysis of the postmortem tissue samples showed that amphetamine and norephedrine can be detected in soft tissue through the different stages of decomposition. A dose-related concentration was seen within the two groups of rats.

#### **Amphetamine, Buried Remains, Postmortem Tissue**

## K66 The Stability of Antidepressants and Antipsychotics in Dried Blood Spots (DBS) in Postmortem Cases

Matteo Moretti, MD\*, University of Pavia, Section of Legal Medicine and Forensic Sciences, Pavia 27100, ITALY; Francesca Freni, MSc, Arma Di Taggia, ITALY; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Claudia Vignali, University of Pavia, Pavia, ITALY; Angelo Groppi, University of Pavia, Pavia 27100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY; Luca Morini, University of Pavia, Pavia 27100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the reliability of the analysis of blood collected in postmortem cases and dried on a paper substrate (i.e., DBS), particularly for the detection and quantification of antidepressants and antipsychotics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new information about the use of DBS in forensic toxicology and the possibility of employing this technique as a good, simple, reliable, and complementary method of sample storage during autopsy.

**Background and Goals:** The analysis of blood collected and dried on a paper substrate (DBS) represents an alternative blood sample collection that is currently routinely used in neonatal screening. The analysis of DBS provides several advantages: (1) it requires a small volume of blood; (2) it needs easier sample handling and simple storage for a longer time periods at room temperatures; and (3) the dried blood matrix could limit or even avoid the postmortem changes, such as putrefaction or autolysis. The goals of this study were: (1) to develop a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for the determination of 22 antidepressants and 19 antipsychotics in DBSs; (2) to establish the diagnostic reliability of DBS with the routine blood analyses of these substances; and (3) to prove the stability of these analytes on DBS within a three-month period of storage.

**Method:** Aliquots of blood were pipetted on a five-spot filter paper (85µL of blood for each spot) in triplicate (so that further testing is possible). The cards were allowed to dry overnight in the dark at room temperature. For each analysis, a whole bloodstain was cut out and placed in a plastic tube containing 1mL phosphate buffer at pH 6 and deuterated internal standards, extracted using Solid Phase Extraction (SPE) cartridges, and injected into the LC/MS/MS system. The analytes were separated through a reverse phase chromatography on a C18 column and detected on a triple quad operating in Multiple Reaction Monitoring mode and positive polarization. A calibration curve was prepared in the range of Limit of Quantitation (LOQ) 500ng/mL.

Validation parameters (linearity, selectivity, specificity, accuracy, imprecision, recovery, matrix effects, and carry over) were tested. The procedure was applied to 60 authentic postmortem cases. For each case, 15 DBS were collected at T0. Four DBS were analyzed in triplicate within four consecutive weeks. The last samples were analyzed after three months.

**Results:** The analytical procedure is simple, sensitive, and specific. Limits of Detection (LODs) were detected in a range of 0.1ng/mL(g) to 4.1ng/mL(g) for antidepressants, and 0.1ng/mL to 2.7ng/mL for antipsychotics. LOQs varied from 0.3ng/ml to 13.6ng/ml for antidepressants and 0.3ng/ml to 9.1ng/mL for antipsychotics. Validation parameters fulfilled all the acceptance criteria. Eighteen different molecules were detected and quantitated in 22 out of 60 cases.

Four cases were positive for citalopram (42ng/ml–408ng/mL) and quetiapine (84 ng/ml –2309ng/mL), 3 for desvenlafaxine (479ng/ml–686ng/mL) and venlafaxine (25ng/ml–362ng/mL), 2 for paliperidone (17ng/ml–56ng/mL) and trazodone (91ng/ml–162ng/mL), while amisulpride (527ng/mL), clotiapine (25ng/mL), dibenzepine (483ng/mL), dixyrazine (126ng/mL), fluoxetine (56ng/mL), fluvoxamine (4,300ng/mL), haloperidol (20ng/mL), maprotiline (340ng/mL), mirtazapine (134ng/mL), and N-desmethylmirtazapine (112ng/mL), paroxetine (671ng/mL) and pimozone (130ng/mL) were found only once.

The concentrations on DBS stored at room temperature were in good agreement with the ones obtained on blood samples analyzed with routine methods (<30% CV, both at T0 and after three months).

The degradation percentage for most of the substances was lower than 20% within the three-month period. Citalopram, trimipramine, and paliperidone were stable for the first month, while a degradation higher than 50% was observed after three-month storage. Quetiapine was found to be stable into two samples, while a significant degradation was noticed in two other cases.

**Conclusions:** A method for the detection and quantitation of antidepressants and antipsychotics in DBS was successfully developed and validated. Preliminary results on 22 authentic positive postmortem cases suggested that DBS can be used as routine sample storage during autopsy. More cases will be analyzed to support the preliminary outcomes of this study.

### Dried Blood Spot, Antidepressants, Antipsychotics

### K67 A Rare Case Report on Sedative-Hypnotic Drug Screening in Homicidal Carbon Monoxide (CO) Poisoning

Linchuan Liao\*, Sichuan University, Chengdu, Sichuan 610041, CHINA

**Learning Overview:** After attending this presentation, attendees will understand a rare case of deliberate homicide via CO poisoning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of sedative-hypnotic drug screening in the case of CO poisoning.

CO has been considered the number one “Silent Killer.” In forensic practice, deaths due to CO poisoning are usually suicidal or accidental; homicidal CO poisoning is very rare. The current report presented an ingenious crime of homicidal CO poisoning, which is expected to emphasize the importance of sedative-hypnotic drug screening in the case of CO poisoning.

**Case:** Two men (Decedent A and B) in their fifties were found dead in a car parked in an open parking area in winter. Decedent A was lying on the reclining driver’s seat and Decedent B was lying prostrate on the reclining passenger seat. All doors and windows were locked. The ignition key was in the “ON” position, but the engine was not running. There was neither a suicide note in the car nor at the home of the victims. In the meantime, it was discovered that about \$75,000 cash carried by the decedents was missing. Autopsies were subsequently conducted as requested by both decedents’ wives.

**Autopsy Findings:** There were no notable injuries on the surface of the two bodies. The sclera and palpebral conjunctivae showed some petechiae in both bodies. Both of the decedents exhibited cherry-pink lividity, which did not fade upon finger pressure. Internal examination revealed that the musculature and internal organs were bright red in color. Sporadic petechiae were present on the surface of the heart, liver, lungs, and spleen.

**Toxicological Analyses:** Cardiac blood samples from both decedents were obtained at the autopsy for toxicological analyses of carbonyl hemoglobin (COHb), alcohol, and benzodiazepines. Blood COHb saturation of Decedent A and Decedent B determined by visible spectrophotometry were found to be 70.5% and 69.5%, respectively. Concentrations of alcohol in the blood samples of Decedent A and Decedent B determined by Headspace/Gas Chromatography (HS/GC) method were found to be at 0.20mg/ml and 1.02mg/ml, respectively. For analyses of benzodiazepines, blood samples were treated by liquid-liquid extraction with ethyl acetate, followed by identification and quantification analysis using Ultra-Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS). Estazolam was detected in the blood of both decedents at 0.31µg/ml and 0.10µg/ml in Decedent A and Decedent B, respectively.

**Discussion:** Since fatalities can take place when the CO saturation of blood rises above 40%, it seemed reasonable to judge that the cause of the deaths was CO poisoning. However, there were two questionable points in this case: (1) \$75,000 cash was missing; (2) estazolam was detected in both decedents (both decedents had no medical history of estazolam). Decedent A’s wife told the police that her husband had an appointment with his business partner C and never came back after that. After repeated interrogation, C eventually confessed that he put estazolam in the decedents’ drinks and drove the two sleeping persons to the suburb; then he locked them in his car and poisoned them with a prepared CO bottle, followed by moving the bodies back to Decedent A’s car, reclining the seats and turning on the ignition key, making it look like an accident. Although homicidal CO poisoning is very rare in forensic practice, this current case emphasizes the importance of additional screening for sedative-hypnotic drugs in the case of CO poisoning.

#### Homicidal CO Poisoning, Toxicological Analysis, Case Report

### K68 Medicinal Drug Suicide: A Six-Year Forensic Survey

Asit Kumar Sikary, MD\*, ESIC Medical College & Hospital, Faridabad, Haryana 121001, INDIA; Anu Sasidharan, MD, Amrita School of Medicine, Department of Forensic Medicine, Kochi 682026, INDIA; V.V. Pillay, MD, Amrita Institute of Medical Sciences, In-charge, Poison Control Centre, Kochi 682026, INDIA; Chittaranjan Andrade, MD, National Institute of Mental Health & Neuroscience, Department of Psychopharmacology, Bangalore 560029, INDIA

**Learning Overview:** After attending this presentation, attendees will better understand the increasing trends of medicinal drug abuse for suicidal purposes in a metro city of India due to the easy availability of over-the-counter drugs and prescriptions for others.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making attendees aware of the increasing problem of suicide by medicinal drugs that are prone to being missed if detection is not suspected.

Medicinal drug abuse has increased in recent years across the United States, Europe, and Australia and has acquired the top position along with other drugs of abuse. The most commonly abused medicinal drugs are opioids, followed by tranquilizers and psychotropic drugs. Medicinal drugs are easily available at home, are easy to obtain from a pharmacist on other people's prescriptions or even without a prescription (over the counter), are not illegal or expensive, are associated with less social stigma, are easily available over the internet, and have fewer side effects than street drugs.

The abuse is increasing in India, too, as reported by the United Nations Office on Drugs and Crime. According to the report, pharmaceutical drugs can be procured easily over the counter without any prescription. These are mainly synthetic opioids, tranquilizers, sedatives, and stimulants. These drugs are cheap compared to usual abusive drugs and are within the reach of the lower class. The National Crime Record Bureau of Government of India says that fatal medicinal drug abuses are mainly accidental overdoses used for various ailments and are procured over the counter from medical stores without any prescription.

In this study, cases of suicide with medicinal drugs from the South Delhi region of India were analyzed. Data on suicide by medicinal drugs were retrospectively analyzed. Drugs recovered from the scene of suicides were noted for their constituents and strength. Doses taken for suicide were estimated by considering the number of empty strips/vials of the drug that were used at the time of suicide. Relatives and friends of the deceased were interviewed at the time of the autopsy regarding the occupation of the victim, the source of the drug, and any history of abuse of that particular drug or any other drugs. The presence of the drug in the blood of these cases was confirmed through the reports from the Forensic Science Laboratory and from the departmental laboratory.

During this period of study, most of the suicides were due to hanging (~75%), followed by poisoning (~15%). Other causes of suicide were drowning, fall from height, and gunshot. There were 338 cases (201 males and 137 females) of suicidal poisoning; most of them were with pesticides used in agriculture (35%) and household chemicals (18%). Twenty males and seven females (8.0%) had committed suicide with medicinal drugs. The age range of males was 21-34 years while the age range of females was 22-32 years. Most of the males (45%) were students and the rest were mainly manual unskilled workers or unemployed. Among the females, most were housewives and students (43% each). The students had good knowledge of the various drugs available over the counter. Four victims were practicing doctors having access to various drug preparations. Out of 27 cases, 11 victims had consumed a drug having a combination of dextropropoxyphene (opioid analgesic) and dicyclomine (anticholinergic), mainly used as antispasmodic. Four victims consumed two drugs of different constituents, mainly combining alprazolam with others. The rest of the victims used drugs with a single constituent only. In three cases, drug constituents were not known. In 13 cases (48%), the drugs were obtained directly over the counter from the medical store without any prescription. In six cases, the drugs were prescribed by the treating physician for the victim or for a relative of the victim for various ailments. These legitimate prescriptions were mainly antispasmodics; one prescription was an antiepileptic and another prescription was an antidepressant. In three cases, the type of drug consumed was unknown, as the description of the content on the strip was not legible. How the victim acquired the drugs was not known. As per history, however, the drugs were not stored at home.

This study draws attention to the suicidal abuse of various medicinal drugs in an Indian metro city, which are easily available over the counter without any prescription or, with a prescription meant for oneself or for others. This method of suicide is easily preventable with the proper vigilance of prescribing doctors, dispensing chemists, and family members regarding suicidal abuse of various medicinal drugs.

#### Pharmaceutical Drugs, Over-the-Counter Drugs, Drug Overdose

## K69 Infant and Toddler Deaths Associated With Potent Opioid Exposure

*Robert Hargrove, BS\*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC; Sandra C. Bishop-Freeman, PhD\*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27607; Ruth E. Winecker, PhD, RTI International, Raleigh, NC*

**Learning Overview:** After attending this presentation, attendees will understand the dangers of potent medications as they relate to infants, toddlers, and young children. Case studies from the state of North Carolina will demonstrate what substances can harm an infant or child with environmental exposure—one swallow or pill.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the impact of the opioid epidemic on infants and toddlers and by educating forensic investigators, pathologists, and postmortem toxicologists.

While most ingestions of household products are benign, there are a handful of substances in which one pill or a small dose of medication will be sufficient to cause death in a small child, toddler, or infant. This concept is even more alarming with the modern-day opioid epidemic, which was initially fueled by generous prescribing habits and later gave rise to potent illicit fentanyl analogues. Unlike a typical adult ingestion for purposes of self-harm or pleasure, pediatric poisonings are usually the result of curiosity, exploration, a decreased or lack of sense of danger, or imitation of adults and older sibling behavior.

Due to body composition and size of an infant or toddler compared to an adult, it's not surprising to see that what may not cause death in an adult can easily cause a small child to succumb. Ingestions of a single dose of prescription medication can produce elevated concentrations in postmortem blood that may be confused with an intake of multiple doses. Without careful consideration and thorough investigations, these rulings may be considered intentional homicidal poisonings instead of accidental poisonings. Cases involving oxycodone, liquid methadone, and fentanyl will be discussed in detail. The popularity of highly potent opioids makes modern-day illicit substances far more dangerous to children. North Carolina has seen two cases of fentanyl analogue poisoning that have been certified as means of poisoning with undetermined manner by the pathologists.

Age/Sex	Weight	Toxicology	Select History
3 years/F	15 kg	Vena Cava Blood - 0.44mg/L Methadone Liver- 1.9mg/kg	A red substance was left in a food container in reach of the child, later confirmed to be methadone prescribed to the mother.
9 months/F	8.7 kg	Central Blood- 6-AM Present, 6.3ng/mL Acetyl Fentanyl, 23ng/mL Fentanyl	Infant was seen alive at 9:30 a.m. and found unresponsive at 2:25 p.m. A small piece of folded paper was recovered from gastric contents and was positive for 6-Acetylmorphine (6-AM) acetyl fentanyl, fentanyl, and morphine.

Multiple opioid case studies in toddlers and infants will be explained in detail to show incidents in which, after a thorough investigation, it was concluded that a child was exposed to a small amount of illicit substance or pharmaceutical preparation.

### Pediatric Poisoning Deaths, Postmortem, Forensic Toxicology

## K70 A Comparison of Cannabinoid Concentrations in Central and Peripheral Postmortem Blood Samples

Daniel S. Isenschmid, PhD\*, NMS Labs, Willow Grove, PA 19090; William H. Anderson, PhD, NMS Labs, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/ Center for Forensic Science Research & Education, Willow Grove, PA 19090

**Learning Overview:** The goal of this presentation is to provide toxicological evidence that demonstrates the limitations of interpreting postmortem cannabinoid concentrations in blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data demonstrating the variability of cannabinoid concentrations in blood collected from central and peripheral sites in medicolegal death cases.

**Introduction:** Variable concentrations of Delta-9-Tetrahydrocannabinol (THC) and its metabolites, 11-OH-Tetrahydrocannabinol (OH-THC) and Delta-9-Carboxy-Tetrahydrocannabinol (THCC), have been reported when comparing postmortem specimens collected at different times during the postmortem interval and from different sites in the body. This is the first study to compare central and peripheral blood cannabinoid concentrations in blood collected at the same time in a larger number of cases.

**Methods:** Central blood (identified as heart, chest, inferior vena cava, or subclavian) and peripheral blood (identified as femoral or peripheral) were collected during routine postmortem examinations. Peripheral blood was initially screened for cannabinoids using Enzyme-Linked Immuno-Sorbent Assay (ELISA) (cutoff concentration, 10ng/mL). Presumptive positive cases were subjected to confirmatory testing by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) for both peripheral and central blood samples. Additionally, antemortem samples were tested, when available. LC/MS/MS cut-off concentrations and Upper Limits Of Linearity (ULOL) were THC (0.5, 50ng/mL), OH-THC (1.0, 100ng/mL) and THCC (5.0, 500ng/mL). The ratio of the peripheral to central concentration of each analyte was determined for those analytes within the linear range of the assay. Additionally, a linear regression analysis between peripheral and central cannabinoid concentrations was performed. Analytes quantitating below the cutoff and greater than the ULOL were not included in the calculations.

**Results:** A total of 62, 65, and 39 pairs of blood samples were compared for THC, THCC, and OH-THC, respectively. As expected, the highest mean (3.16) and median (1.57) peripheral to heart blood ratio was for THC although the range was large (0.30–30) as reflected by a standard deviation of 4.91. The less lipophilic metabolites had ratios much closer to unity: THCC (mean 1.06, median 0.95, SD 0.61, range 0.28–4.05); OH-THC (mean 1.14, median 0.96, SD 0.55, range 0.51–3.18).

Linear regression analysis (r-squared) for peripheral vs. central THC, THCC, and OH-THC were 0.1943, 0.7443, and 0.9382, respectively. However, if the three highest concentrations of OH-THC (>20ng/mL) were deleted from the analysis, the r-squared value for this analyte fell to 0.4891. Additionally, there were five cases for which antemortem hospital blood samples were collected. The results for these cases are summarized in the table below:

Case	Date / Time	Blood	THC	THCC	OH-THC
1	11/17/2017 10:06	Antemortem	16	160	7.1
	11/18/2017 8:30	Central	18	100	5.4
	11/18/2017 8:30	Peripheral	>50	95	7
2	2/9/2018 14:30	Antemortem	0.94	7.5	ND
	2/10/2018 8:29	Peripheral	6.1	<5.0	ND
3	4/9/2018 21:35	Antemortem	26	94	7.3
	4/10/2018 10:50	Central	20	64	4.7
4	5/20/2018 unk	Antemortem	26	31	4.2
	5/21/2018 10:00	Central	12	40	6
	5/21/2018 10:00	Peripheral	11	23	3.3
5	7/3/2018 22:44	Antemortem	0.67	8.6	ND
	7/5/2018 9:45	Central	1.0	10	ND
	7/4/2018 18:10	Peripheral	3.9	6.2	ND

**Conclusions:** Postmortem peripheral blood THC concentrations exceeded central blood concentrations in 80% of cases studied. Additionally, in three out of four cases where antemortem blood was collected the day prior to peripheral blood, peripheral blood THC concentrations exceeded antemortem THC concentrations. Cannabinoid concentrations in postmortem blood can be subject to significant variability, and THC concentrations, in particular, should not be interpreted as if they were antemortem blood specimens.

### K71 A Comparison of Syringe Contents to Respective Biological Counterparts in 43 Medical Examiner Cases

*Sophia Brathwaite, BSc\*, Office of the Chief Medical Examiner, Washington, DC 20024; Lucas W. Zarwell, MFS, Washington, DC 20011; Samantha Tolliver, PhD, Office of the Chief Medical Examiner, Washington, DC; Chikarlo R. Leak, PhD, Office of the Chief Medical Examiner, Washington, DC 20024; Roger A. Mitchell, Jr., Office of the Chief Medical Examiner, Washington, DC 20024*

**Learning Overview:** At the end of this presentation, attendees will be better positioned to explore alternative strategies for determining the prevalence of New Psychoactive Substances (NPS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging toxicologists to evaluate scene paraphernalia in parallel with autopsy specimens from apparent accidental drug overdose cases. The correlation between the sets of data may provide toxicologically relevant information as well as prevalence information.

From March of 2017–present, the District of Columbia Medical Examiner has sought to preserve and solicit testing of syringe residues in an effort to identify emerging drugs of abuse. Results presented and discussed are from March 2017–March 2018.

Sixty-three syringes and other paraphernalia were collected from apparent accidental drug overdose investigative scenes in 43 medical examiner cases. In some instances, multiple syringes were collected per case. Two laboratories were employed. One laboratory analyzed the syringe residues for controlled substances and the second laboratory analyzed autopsy specimens for drugs of abuse.

First, a qualitative method developed to identify 21 fentanyl analogs, designer opioids, naloxone, and nalorphine by Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS) was validated in accordance with the Scientific Working Group for Forensic Toxicology (SWGTOX). In this method, postmortem blood and/or urine were subjected to liquid extraction. A reverse phase gradient was applied using ammonium formate (5mM, pH 3) and 0.1% formic acid in acetonitrile to achieve chromatographic separation by use of an Waters® Acquity® UPLC BEH C18 2.1mm x 50mm, 1.7µm analytical column coupled to a Waters® Acquity® UPLC I-Class system. Mass spectral identification was conducted via a Waters® Acquity® TQ Detector.

The second laboratory implemented analysis of syringe contents for controlled substances via Cobalt Thiocyanate color testing followed by Gas Chromatography/Mass Spectrometry (GC/MS) testing. Both methods are consistent with the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) protocol. Bulk liquids and/or residues were emptied into appropriate containers followed by a syringe wash using a small volume of methanol (~250µL–500µL). If blood was present in the syringe barrel, chloroform was the solvent of choice. The organic layers of the extracts were then used to perform cobalt thiocyanate color testing and GC/MS analysis.

Of the 63 syringes (43 cases) that were collected between the periods, 76% of syringe contents correlate to postmortem blood and/or urine that contained fentanyl, a fentanyl analog, designer opioid, and/or opioid receptor antagonists. Of these syringes, the most common substance was fentanyl (64%), followed by furanyl fentanyl (28%). Other fentanyl analogs detected include para-fluoroisobutyryl/FIBF (8%), U-47700 (8%), methoxy acetyl fentanyl (4%), and despropionyl fentanyl (4%). Additionally, opiates and cutting agents, such as noscapine, caffeine, and diphenhydramine, were detected as well.

The analysis of paraphernalia can yield information of toxicological importance when trying to gain understanding about the prevalence of NPS when little to no information is present. However, the detection of the same compound in both paraphernalia and autopsy specimen is not guaranteed. These types of surveys may help the community better understand the relationship between metabolites and parent compounds. Although evaluated on a small scale, fentanyl and furanyl fentanyl seem to be prevalent in the drug overdose cases involved and, similarly, conclusions can thus be made about prevalence in Washington, DC. Knowledge about these substances can be used as a public health tool for education regarding misuse of these substances.

#### Fentanyl Analogs, Postmortem, Paraphernalia

### K72 Suicide by Pesticide? A Case Study of Fenobucarb Ingestion

*Marissa J. Finkelstein, MS\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; Katherine L. Kenerson, MD, Miami-Dade Medical Examiner Department, Miami, FL 33136; George W. Hime, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Diane Boland, PhD, Miami-Dade Medical Examiner Department, Miami, FL 33136*

**Learning Overview:** After attending this presentation, attendees will better understand: (1) the pathological and toxicological findings that indicate death due to the ingestion of 2-(1-methylpropyl) phenyl methylcarbamate (fenobucarb), (2) the symptoms of carbamate poisoning, and (3) how the autopsy results of carbamate pesticide ingestion differ from bleach/hydrofluoric acid ingestion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for open lines of communication between pathologists and toxicologists to determine the cause of death in cases in which misleading information may be provided to investigators by family, hospital personnel, and first responders. This presentation will also impact the forensic science community by demonstrating the need for toxicologists to utilize antemortem clinical manifestations and autopsy findings to guide their route of analysis.

In December 2015, a 44-year-old Black male and his wife were involved in a heated, verbal and physical altercation at their residence. During the dispute, the intoxicated decedent discharged a handgun, causing his family to vacate the scene. He then went inside the residence and attempted suicide by ingesting an unknown caustic liquid. According to first responders, the liquid was hydrochloric acid, hydrofluoric acid, or bleach. Numerous attempts were made by the investigator to retrieve the unknown liquid from the terminal event scene. However, because the decedent was taken to the hospital, the bottle was never impounded by police or crime scene investigators.

The decedent was treated by fire rescue and taken to the hospital, where he expired three hours later. The decedent was conscious while being treated, but exhibited altered mental status, vomiting, and increased secretions. Upon arrival at the emergency room, the decedent presented with hypersalivation, respiratory failure, hypocalcemia, and increased potassium levels. The hospital staff consulted the Poison Control Center along with a hospital toxicologist. The toxicologist recommended aggressive calcium administration, a gastrointestinal endoscopy in less than 12 hours, and a calcium gel placement. Despite medical intervention, he went into cardiac arrest and expired in the emergency room.

Significant autopsy findings included the ingestion of 1.325L of a green-black, sludgy, granular fluid in the stomach, associated with staining of adjacent tissues, hemorrhage of retroperitoneal and mesenteric adipose tissues, hemorrhage of the soft tissues of the porta hepatis, left pleural effusion (140mL), and ascites (50mL). These findings were not characteristic of the ingestion of bleach or acid, which would have caused significant destruction of the stomach wall and soft tissues of the abdomen. Routine toxicological analysis detected ethanol (0.130%) in the antemortem blood, as well as diphenhydramine, lidocaine, ibuprofen, and naproxen in the gastric contents.

With no definitive cause of death, further toxicology testing was deemed necessary in this case. The pH of the gastric contents was tested to definitively rule out acid or bleach consumption, and the results indicated a physiologically normal pH of 2–3. Because of the autopsy findings and the decedent's symptoms prior to death, a screen to rule out organophosphate poisoning was performed. The gastric and small intestine contents were screened by Liquid-Liquid Extraction followed by Gas Chromatography/Mass Spectrometry (LLE-GC/MS) and 2-(1-methylpropyl) phenyl methylcarbamate (fenobucarb) was detected. Fenobucarb is a carbamate insecticide, and symptoms of carbamate poisoning include, but are not limited to, increased secretions, diarrhea, vomiting, confusion, respiratory depression, and cardiac arrest.

Based on the decedent's history, autopsy findings, and toxicology results, the forensic pathologist determined that the cause of death was ingestion of 2-(1-methylpropyl) phenyl methylcarbamate (fenobucarb), and the manner of death was suicide. This case demonstrates the necessity to consider all information, including clinical manifestations prior to death, autopsy findings, and toxicology results, in order to make an accurate determination as to cause and manner of death. This case also exemplifies that information provided to investigators from outside sources may not be accurate and may cause the investigation to head in the wrong direction.

#### Fenobucarb, Carbamate Pesticide Poisoning, Postmortem Toxicology

## K73 Death Due to Acute Nicotine Intoxication

Tiffany A. Hollenbeck, DO\*, Jackson County Medical Examiner's Office, Kansas City, MO 64108; Marius Tarau, MD, Kansas City, MO 64108; Lindsey J. Haldiman, DO, Jackson County Medical Examiner's Office, Kansas City, MO 64108

**Learning Overview:** After attending this presentation, attendees will be familiar with the toxic and lethal effects of nicotine, as well as the challenges in toxicological analysis of nicotine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the significant toxicity associated with liquid nicotine used to manufacture electronic cigarettes.

**Background:** Nicotine is a lipid soluble alkaloid substance that is extracted from the leaves of the *Nicotiana* plant.<sup>1</sup> Most commonly, nicotine is used in tobacco products such as cigarettes and chewing tobacco; it is found in some pesticides as well.<sup>2</sup> Nicotine is one of the most toxic and popular drugs of abuse; however, it rarely causes fatalities.<sup>1</sup> Electronic cigarettes were first introduced in 2004 and have gained significant popularity in recent years.<sup>3</sup> They are advertised to satisfy nicotine addiction without all the health hazards of inhaling tar and other carcinogens known to be present in traditional cigarettes. Liquid nicotine, the key ingredient in electronic cigarettes, poses a significant toxicological concern in that a very small ingested amount can be poisonous and life threatening.<sup>1-3</sup>

**Case:** A 23-year-old male was found by his roommate unresponsive, covered in vomit, in the bathroom of their residence. Emergency medical services were dispatched to the scene and resuscitative attempts were made for approximately 30 minutes before the subject was pronounced deceased. His roommate reported that he had seen the subject about 1 hour and 45 minutes prior and he did not appear to be intoxicated at the time. Of note, the subject had a bag which contained commercially available "stress relief-eucalyptus and spearmint" bath salts and three empty and apparently unused syringes that were, therefore, not collected for analysis. A nearly full package of cigarettes was found near the decedent, but no other nicotine products were identified at the scene. Autopsy revealed marked pulmonary edema and congestion of the kidneys and liver. There was no evidence of trauma identified. A drug screen performed on heart blood was positive for nicotine and amphetamines. Toxicological analysis of femoral blood revealed nicotine at a concentration of 2,400ng/ml and cotinine (a metabolite of nicotine) at a level of 210ng/ml, (limit of detection for nicotine and cotinine is 5.0ng/mL and 10.0ng/mL, respectively); these concentrations support the acute nature of the intoxication. Ethanol was also detected at a level of 13mg/dL. Amphetamines were not confirmed by liquid chromatography/mass spectrometry with a limit of detection at 10ng/mL. A novel psychoactive substances screen for bath salts was performed by National Medical Services (NMS) lab and was negative.

**Conclusion:** Liquid nicotine, used to fill electronic cigarettes, contains very high concentrations of nicotine, up to 36.6mg/mL in a refill solution, which can be toxic or lethal when consumed in even a small dose.<sup>4</sup> It is of great toxicological concern due to the ease of access to the substance with no strict control over distribution.<sup>1</sup> The estimated lethal dose of nicotine is about 30mg–60mg in an adult.<sup>5</sup> Effects of nicotine on the body are complex, with small doses causing a stimulatory effect (nausea, vomiting, dizziness, miosis, tachycardia, hypertension, sweating, and salivation) and lethal doses causing a depressive effect (prostration, convulsions, respiratory paralysis, and cardiac arrhythmias).<sup>5</sup> Other nicotine-related fatalities have been reported, primarily due to accidental exposure related to harvesting nicotine from the plant.<sup>2</sup> Few case reports have described ingestion of liquid nicotine to commit suicide, although the majority of these cases have other substances in addition to nicotine detected postmortem; most commonly a significant amount of alcohol and/or opioids, which contributes to the depressive effect on the central nervous system.<sup>1</sup> Although liquid nicotine was not located on scene, based on a literature review, the most likely method of sustaining such a high nicotine level in such a short period of time is either by ingestion or injection of a concentrated form of nicotine, as found in e-cigarette refills. This case is interesting in that the scene investigation suggests that the subject may have injected the nicotine (which is extremely rare), as opposed to ingesting it.

### K74 Validation of the Neogen® Enzyme-Linked Immuno-Sorbent Assay (ELISA) Benzodiazepine Kit Using Clonazepam as the Target Molecule for Blood and Urine

Grayce Behnke, BS\*, Export, PA 15632; Nicholas B. Tiscione, MS, West Palm Beach, FL 33406; John Rakus, PhD, Marshall University, Huntington, WV 25755; Lauren L. Richards-Waugh, PhD, Marshall University, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand: (1) the effectiveness of the Neogen® ELISA Benzodiazepine kit for screening whole blood and urine specimens using clonazepam as the target molecule, and (2) the challenges with following the Scientific Working Group for Forensic Toxicology (SWGTOX) Standard Practices for Method Validation in Forensic Toxicology Laboratories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the validation of an ELISA method for the screening of a broad range of benzodiazepines.

**Objective:** The validation of a semi-quantitative method for the rapid screening of whole blood and urine specimens by a Dynex DSX® Automated ELISA System using the Neogen® Benzodiazepine kit and clonazepam, rather than oxazepam, as the target molecule.

**Method:** Neogen® Benzodiazepine kit assay instructions for incubation times and reagent volumes were followed. The amount of sample added was increased from the recommended 10µL to 20µL. Whole blood samples were diluted 1:5 with Neogen® EIA buffer offline. Urine samples were diluted 1:10 with Neogen® EIA buffer online by the instrument. Performance of the assay was evaluated at one decision point for each matrix: 10ng/mL in whole blood and 25ng/mL in urine. An in-house validation protocol based on the SWGTOX standard practices was followed for the validation of the assay, which included the evaluation of sensitivity, precision, specificity, carryover, drift, ruggedness/robustness, and a case sample comparison.

**Results:** The theoretical Limit Of Detection (LOD) for clonazepam was calculated to be 2ng/mL in blood and 8ng/mL in urine. The experimental LOD for clonazepam was determined to be at least 5ng/mL in blood and 10ng/mL in urine. Precision was evaluated using the mean of three replicates from five separate runs ( $n=15$ ) at the decision point and at concentrations  $\pm 50\%$  and  $\pm 100\%$  of the decision point. Although the method was optimized, and precision was demonstrated at each level (coefficient of variation  $< 7.6\%$ ), the current SWGTOX validation requirements for a valid decision point were not fulfilled. Furthermore, the urine matrix did not meet the proposed revision of the SWGTOX requirements for determining a valid decision point promulgated by the Toxicology Subcommittee of the Organization of Scientific Area Committees for Forensic Science. Cross reactivity was observed with all 29 low- and high-dose benzodiazepines analyzed. If the cross reactivity of a compound was less than 100%, then the precision for the detection of that compound was evaluated. No carryover or drift was observed. The method proved to be both rugged and robust. Case sample comparison results were comparable to those obtained when the samples were initially screened using oxazepam as the target molecule. One false negative by both the original ELISA with oxazepam and reanalysis with clonazepam was identified by confirmation with liquid chromatography/tandem mass spectrometry.

**Conclusion:** The Neogen® Benzodiazepine kit using clonazepam as the target molecule exhibited high cross reactivity for 29 different low- and high-dose benzodiazepines and demonstrated excellent precision and sensitivity in both whole blood and urine, making it an efficient and reliable method to screen blood and urine specimens for benzodiazepines, even though it did not fulfill current SWGTOX validation requirements for a valid decision point.

**Validation, ELISA, Benzodiazepine**

### **K75 Quantitative Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Analysis of 39 Fentanyl Analogs and Metabolites in Blood, Urine, and Oral Fluid**

*Marilyn A. Huestis, PhD\*, Huestis & Smith Toxicology, LLC, Severna Park, MD 21146; Dominic Andrada, MS, Thermo Fisher Scientific, Sunnyvale, CA 94085; Rory M. Doyle, PhD, Thermo Fisher, Somerset, NJ 08873*

**Learning Overview:** After attending this presentation, attendees will know that many fentanyl analogs and metabolites can be identified and quantified in blood, oral fluid, and urine in a single sensitive and specific LC/MS/MS procedure.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how to identify and quantify fentanyl analogs in diverse biological matrices to document cause of death, the drugs involved with driving under the influence of drugs, and substance abuse.

Fentanyl and its novel psychoactive substance analogs are of strong interest due to increased potency, increased abuse liability, and the large number of intoxications and deaths occurring in the United States. Fentanyls are opioids with a rapid onset of effects that are injected or absorbed from a skin patch or oromucosally from an oral lollipop or buccal tablet. Fentanyls activate the  $\mu$ -opioid receptor and may be as much as 10,000 times more potent than morphine. Food and Drug Administration-approved synthetic fentanyls include pain medications and anesthesia agents. Recently, dozens of fentanyl analogs were introduced by clandestine laboratories located in China and other countries, resulting in many overdoses and deaths. Clinical hospital laboratories and local, state, and federal forensic toxicology laboratories need to identify the novel psychoactive substances responsible for these adverse events to alert public health authorities, first responders, and drug users about the presence of a new toxic drug, as well as to provide psychiatric follow up for the drug user. This fentanyl analytical method was developed and optimized for accurate and robust drug analysis, while also demonstrating the challenges associated with investigating multiple compounds of similar structure and physicochemical properties.

A Thermo Scientific™ Vanquish™ HPLC system and a Thermo Scientific™ TSQ Quantis™ tandem mass spectrometer in positive electrospray mode were utilized for the analysis. Sample size was only 100 $\mu$ L urine, oral fluid, or blood. The selected column was a Thermo Scientific™ Accucore™ C18 100mm x 2.1mm, 1.5 $\mu$ m column heated to 50°C, with 5 $\mu$ L injected. Mobile phase A was a water: methanol mixture containing 0.01% formic acid and 2mM ammonium formate and mobile phase B was methanol. The gradient began at 90% A and 10% B ending at 8.5min with 2% A and 98% B. Analyte elution occurred from 0.52min (NPP) to 7.2min (Valeryl Fentanyl). Baseline chromatographic separation was achieved for all analytes within a total run time of 10min.

Mass spectrometer settings were: vaporizer temperature: 475°C, ion transfer tube temperature 300°C, sheath gas: 70, aux gas: 10, sweep gas: 0, spray voltage: positive ion (V): 500, Q1/Q2 resolution: 0.7/0.7 (FWHM), cycle time (sec): 0.6, CID gas (mTorr) 2 and chromatographic peak width 6secs. Collision energies were optimized for each transition and ranged from 10V to 45V. Quantitative analysis was performed with Selective Reaction Monitoring (SRM) transition pairs for each analyte and internal standard. Reference materials for method validation were from UTAK.

Sample preparation techniques included protein precipitation for blood samples and simple dilution of urine and oral fluid samples, enabling high throughput analysis. Limits Of Quantification (LOQ) in blood ranged from 5pg/mL (acetyl norfentanyl) to 100pg/mL (remifentanyl), in oral fluid 10pg/mL (norfentanyl) to 100pg/mL ( $\beta$ -hydroxythiofentanyl), and in urine 25pg/mL (4-Anilino-4-piperidine) to 250pg/mL (N-methyl norcarfentanyl). Good linearity and reproducibility were obtained for all fentanyl analogs and metabolites with a coefficient of determination  $R^2 > 0.98$  or better for all drugs in the different matrices. Excellent imprecision and accuracy were achieved (CV < 15%) for all compounds in all matrices. The method achieved sensitive results for the analysis of 39 new fentanyl analogs with subtle structural differences and demonstrated the versatility of the mass spectrometer to consistently quantify multiple, closely related drugs at pg/mL concentrations.

#### **Fentanyl Analogs, LC/MS/MS, Blood, Oral Fluid, and Urine**

### K76 The Identification of Drug Metabolites in Adulterated Urine Samples Using Direct Analysis in Real Time-Time Of Flight/Mass Spectrometry (DART®-TOF/MS)

Bianca E. Olivieri\*, Lakeland, FL 33810; Mark Maric, PhD, Orlando, FL 32816; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816

**Learning Overview:** The goal of this presentation is to discuss complications that arise with adulteration of urine samples in drug analysis and how to analyze the samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new analytical technique to screen for drugs and their metabolites as well as detecting the presence of adulterants in urinalysis.

With the increased technology to identify drugs and their metabolites in urine screenings, more individuals are using forms of adulterants to evade positive results.<sup>1</sup> In a previous study, it was concluded that certain adulterants (e.g., bleach, Drano®, and eye drops) were able to create false-negatives when using a common screening procedure comprised of Enzyme-Linked Immunosorbent Assay (ELISA) and adulterant test strips (Intect® 7 and AdultaCheck® 6).<sup>2</sup> To circumvent false negatives using immunoassay techniques and to avoid subjectivity through color detection, this study proposes using DART®-TOF/MS to identify not only the drug of interest, but also any adulterants present within the sample. DART®-TOF/MS is an ambient ionization technique that has been shown through previous literature to have a high-resolution mass spectra and rapid analysis with minimal sample preparation.<sup>3</sup> DART®-TOF/MS has been used previously with bodily fluids and has shown to identify endogenous substances (e.g., creatinine) as well as exogenous substances (e.g., prescription drugs).<sup>3</sup>

For this study urine samples were collected anonymously by volunteers under Institutional Review Board (IRB) NO: SBE-16-12568. Volunteers also provided information on the study survey regarding drug use within the past week, which was then used to identify samples containing the drugs of interest and their metabolites. Samples collected contained tetrahydrocannabinol (11-nor-carboxy-delta-9-THC), cocaine (benzoyl ecgonine), amphetamines (d-amphetamine), and benzodiazepines (lorazepam, lorazepam glucuronide). These samples were then adulterated with bleach, vinegar, eye drops, Drano®, nitrite, table salt, and hand sanitizer at different concentrations (i.e., 5, 10, 25, 50% v/v or w/v). Adulterated samples were prepared for analysis using IonSense® SPE-it™ fiber kits, which uses a solid-phase micro extraction technique to isolate the analytes from components in the urine matrix. After sample preparation, Solid-Phase Microextraction (SPME) fiber strips were analyzed in the positive ionization mode on DART®-TOF/MS by placing the fiber into the ionization stream.

Initial data supports the use of DART®-TOF/MS as an analytical screening technique to identify drug metabolites and the presence of adulterants. The peaks observed during DART®-TOF/MS analysis indicated adulteration at low concentrations (i.e., 5% v/v) does not mask the presence of the drug/metabolite, unlike the combined immunoassay and adulterant test strip screening techniques, which were unable to detect adulteration at these low concentrations, as well the target drug/metabolite in some instances. Bleach was one adulterant that was easily observed in analysis, due to the presence of chlorinated peaks. A urine sample containing amphetamines and its metabolites was adulterated with bleach at the same five concentrations. As the concentration of bleach increased from the unadulterated amphetamine sample to a 50% v/v adulterant concentration, it was more difficult to observe the signal from the protonated amphetamine. However, the adulterant was still observed. Amphetamine was readily observed up to 10% v/v adulteration. Additional peaks, such as metabolites and fragments of the parent, were also observed in the resulting spectra. This trend was observed for the drugs in other urine samples that were exposed by different adulterants. Tampering of urine samples by adulteration requires the sample to be flagged and can lead to consequences for the individual; however, this cannot be achieved by current screening methods at low adulterant concentrations.

### K77 The Quantification of 4-Fluoroamphetamine, 4-Fluoromethamphetamine, 4-Chloroamphetamine, and 4-Chloromethamphetamine in Postmortem Blood and Urine by Ultra High-Performance Liquid Chromatography-Tandem Mass Spectrometry (UHPLC-MS/MS)

*Chu-An Yang, MS\*, New Taipei City 235, TAIWAN, REPUBLIC OF CHINA; Hsiu-Chuan Liu, MS, Taipei, TAIWAN, REPUBLIC OF CHINA; Ray H. Liu, PhD, Forensic Science Review, Vancouver, WA 98685; Dong-Liang Lin, PhD, Institute of Forensic Medicine, New Taipei City 23548, TAIWAN, REPUBLIC OF CHINA*

**Learning Overview:** The goal of this presentation is to provide insights of a highly sensitive UHPLC-MS/MS approach for the analysis of four New Psychoactive Substances (NPS)—4-fluoroamphetamine, 4-fluoromethamphetamine, 4-chloroamphetamine, and 4-chloromethamphetamine—in blood and urine specimens following a liquid-liquid extraction sample preparation protocol.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the development and validation of the UHPLC-MS/MS method to improve the identification and quantification of certain NPS in postmortem specimens.

4-fluoroamphetamine, 4-fluoromethamphetamine, 4-chloroamphetamine, and 4-chloromethamphetamine are substituted phenethylamine-type synthetic NPS, with amphetamine- and methamphetamine-like structural feature. Reportedly, 4-fluoroamphetamine and 4-fluoromethamphetamine produce mainly sympathomimetic effects and exhibit entactogenic properties, while 4-chloroamphetamine and 4-chloromethamphetamine stimulate the central nervous system, with a longer half-life than their fluoro-counterparts. These phenethylamine-type NPS have gained popularity on the illegal market and have been detected in specimens from many death cases in Taiwan during the past six years.

Blood or urine (0.5mL) were mixed with sodium hydroxide and extracted with ethyl acetate. The extracts were evaporated and reconstituted in the mobile phase (initial gradient composition) for injection onto the UHPLC-MS/MS system. Deuterated analogs of the analytes were used as internal standards. Chromatographic separation was achieved using an Agilent® ZORBAX® SB-Aq (100mm × 2.1mm i.d., 1.8-µm particle) analytical column at 50°C. The mobile phase included 0.1% formic acid (v/v) in water (A) and methanol (B), with a flow rate of 0.32mL/min. The initial gradient composition (A/B 90:10, v/v) was decreased to 0% A in 6min; then increased to 90% A in 1min. Parameters for mass spectrometric analysis included: (1) Agilent® Jet Stream Technology electrospray ionization in positive-ion Multiple Reaction Monitoring (MRM) mode, (2) optimized collision energy levels for selected precursor ions, and (3) monitoring two transitions for analytes and internal standards.

Validity of the methodology was assessed using drug-free blood and urine that were fortified with 100ng/mL–2000ng/mL of the analytes. The following analytical parameters were obtained: (1) average extraction recovery, derived from five different sources of blood and urine, was higher than 75%; (2) matrix effect (ion suppression) was observed, except for blood samples of 4-chloroamphetamine at the 100ng/mL and 250ng/mL concentration levels, but was adequately compensated for by using respective deuterated internal standards; (3) intra-/inter-day precision (%CV) and accuracy ranges for blood were 0.6%–7.0%/3.7%–10.2% and 85%–109%/93%–105%, while the corresponding ranges for urine were 0.8%–5.1%/3.5%–17.7% and 86%–110%/92%–106%; (4) calibration linearity ( $r^2$ ) for all analytes were >0.997; and (5) the limits of detection for 4-fluoroamphetamine, 4-fluoromethamphetamine, 4-chloroamphetamine, and 4-chloromethamphetamine in urine and blood were 2.5ng/mL, 0.5ng/mL, 1ng/mL, 5ng/mL and 0.5ng/mL, 0.5ng/mL, 2.5ng/mL, 5ng/mL, respectively.

In conclusion, this relatively simple protocol was found effective and reliable for routine identification and quantification of these NPS in blood and urine. This method was applied to the analysis of a limited number of postmortem specimens (one blood and four urine) from forensic cases during the April-July 2018 period. 4-chloroamphetamine and 4-chloromethamphetamine were found in the blood and the urine specimens from the same case, with 233ng/mL and 11,151ng/mL for blood and 807ng/mL and 185,095ng/mL for urine. 4-fluoroamphetamine was found in the other three urine specimens with the concentrations ranging from 183ng/mL to 2,526ng/mL.

#### Phenylethylamine Derivatives, Postmortem, UHPLC-MS/MS

## K78 Staying Relevant in an Ever-Changing Climate: The Development and Validation of a Confirmatory Qualitative Synthetic Cannabinoid Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Method in Human Whole-Blood

Rebecca A. Mastrovito, MS\*, NMS Labs, Willow Grove, PA 19090; Stephanie Kumor, MA, NMS Labs, Willow Grove, PA 19090; Joseph Homan, MS, NMS Labs, Willow Grove, PA 19090; Parul Shah, BS, NMS Labs, Willow Grove, PA 19090; Denise Nicole Schiller, MSFS, Bristol, PA 19007; Sherri L. Kacinko, PhD, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs/Center for Forensic Science Research and Education, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will be able to discuss the designer-drug class of synthetic cannabinoids with a focus on the latest trends and will be able to undertake the development and validation of a confirmatory analytical assay using LC/MS/MS for their detection in biological fluids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the abuse and toxicity of synthetic cannabinoids as well as their detection in biological samples.

Since 2009, synthetic cannabinoids have presented a challenge to toxicology laboratories. As new compounds become available within the recreational drug market, labs need to update their analytical methods to stay relevant. The development and validation of quantitative methods can be a long and demanding process, especially when there is a lack of deuterated internal standards for every analyte in the panel. Developing a qualitative confirmation method allows faster updates to incorporate new compounds as they emerge, due to the less-stringent criteria. Synthetic cannabinoids used in abused products are continually changing with slight structural alterations to circumvent drug control regulations created for earlier generation analogs. Since these positional isomers have identical molecular weights and very similar fragmentation patterns, they are indistinguishable by MS/MS detectors.

The proposed scope contained 27 analytes, including 10 new analytes. Concentrations range from 0.05ng/mL–1.0ng/mL.

MDMB-CHMCZCA	ADB-CHMINACA	MMB-FUBICA
MMB-CHMICA		5-fluoro-EDMB-PINACA

\* 5-fluoro-ADB and 5-fluoro AEB are reported as pairs  
+ MDMB FUBINACA and EMB FUBINACA are reported as pairs

This assay was developed to detect and qualitatively identify synthetic cannabinoid compounds in whole blood. Whole blood was fortified with internal standard, pH adjustment with 0.1 M TRIS buffer pH 10.2, and single-step liquid/liquid extractions. Separation was achieved using two different chromatographic methods run on an Acquity® UPLC BEH C18 (100mm x 2.1mm, 1.7-micron) column coupled with a VanGuard® BEH C18 1.7-micron guard column with mobile phases consisting of 0.1% formic acid in deionized water and an acetonitrile/methanol mixture. Analytes were detected using positive-ion electrospray MS/MS on a Waters® TQS MS/MS coupled with a Waters® Acquity® Ultra Performance LC System.

The methods were fully validated according to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines. During method development, it was demonstrated that running a calibration curve improved the precision around the cut-off concentration. However, the quantitative controls for several analytes did not meet the stringent requirements required for the quantitative validation, usually because of the lack of a labeled internal standard. Therefore, the method was validated qualitatively according to laboratory Standard Operating Procedure (SOP), including the evaluation of the cut-off concentration, sensitivity/specificity, carryover, matrix effect, interfering substances, and stability. Linearity was established using five calibrators. Replicates ( $n=5$ ) at each concentration were analyzed and the correlation coefficient was  $>0.99$  for all analytes. All ten synthetic cannabinoids were measured at three different concentrations to give precision  $\leq 15\%$  CV and accuracy  $\pm 15\%$  for both within- and between-run experiments. Stability experiments ( $n=6$ ) indicated that the synthetic cannabinoids listed above were stable in blood for up to two days at room temperature, and for at least 30 days if kept refrigerated or frozen. Exceptions were MMB FUBICA, which was not stable at room temperature, and 5-fluoro EDMB-PINACA was only stable for seven days refrigerated.

Four hundred fifty-six blood samples that had screened positive for synthetic cannabinoids using an LC/MS/MS screening method were tested using this updated method. Twenty cases tested positive for one or more of the newly added cannabinoids. Seven cases tested positive for 4-cyano CUMYL BUTINACA and three samples were confirmed positive for MMB-FUBICA in combination with other new designer cannabinoids (5-fluoro MDMB-PICA and 4-cyano CUMYL BUTINACA). Of the cases with demographic information available, the median age of the subjects was 33, and included 15 males and 1 female.

### Synthetic Cannabinoids, Novel Psychoactive Substances, Validation

### K79 The Development and Validation of an Analytical Method for the Identification of New Psychoactive Substances (NPS) Using the Retention Index and Gas Chromatography/Mass Spectrometry (GC/MS)

Gabriella H. Giudice, BSc\*, Brazilian Health Regulatory Agency, Brasília 71205-050, BRAZIL; Angelo H. Lira Machado, DSc, University of Brasília, Brasília, Distrito Federal 70910-900, BRAZIL; Jorge J. Zacca, Setor Sudoeste, Brasília, DF 70673-046, BRAZIL

**Learning Overview:** After attending this presentation, attendees will understand NPS and the application of some principles of GC and retention indices to identify controlled substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a validated GC/MS analytical method that could eliminate or minimize the need for NPS analytical standards to perform systematic illicit drug identification. This method is suitable for laboratorial forensic routine after a simple validation protocol.

The United Nations Office on Drugs and Crime (UNODC) defines NPS as “substances of abuse, either in a pure form or a preparation, that are not controlled by the 1961 Single Convention on Narcotic Drugs or the 1971 Convention on Psychotropic Substances, but which may pose a public health threat.”<sup>1</sup> The rate at which these substances are introduced into the market poses a challenge to both regulatory and law enforcement institutions.

In 2016, Brazil adopted a generic classification for the synthetic cannabinoid group, the most widespread NPS class worldwide, to anticipate controls upon the arrival of new substances in the country. After that, a generic classification for synthetic cathinones was also included as a controlled group.

Additionally, forensic science institutes in Brazil have faced analytical challenges when dealing with the unequivocal identification of these new seized substances. Some of these challenges are related to the unavailability of analytical chemical standards due to changes to the functional groups in the molecule during synthesis, the slow rate of commercial production in comparison with drug market changes, high costs, etc.

To work around this problem, the present work benefits from Kováts Retention Indices, which make use of a homologous n-alkane series to both reference and normalize retention times. This type of retention index has been used for high accuracy chemical compound identification with relative standard deviations smaller than 0.35% in the case of illicit drugs.<sup>2,3</sup> It allows for inter-laboratory applicability and verification, and it is robust under different gas flow conditions.<sup>4</sup>

The proposed GC/MS method has been validated with resolution, robustness, and precision measures as figures of merit. A mixture of 21 drugs have been tested to cover as much of the elution time window as possible. The mix was composed of three synthetic cannabinoids (AM-2201, MAM-2201, JWH-081), one cathinone (N-ethylpentylone), three phenylethylamines (5-MAPB, 2-FA, 25C-NBOMe), two piperazines (o-CPP, p-CPP), one opioid (U-47700), one tryptamine (5-MeO-MiPT), one aminoindane (5-IAI), one of vegetal origin (*Salvia divinorum*), methiopropamine, and seven traditional drugs (THC, heroin, amphetamine, methamphetamine, MDMA, cocaine, ephedrine). The GC/MS method has shown to present enough resolution to separate the majority of compounds. One coelution occurred between methiopropamine and methamphetamine. In such cases, mass spectra interpretation may be used in compound disambiguation. The lowest resolution (1.09) was obtained for N-ethylpentylone. The smallest Kováts index difference (4.9) occurred between amphetamine and 2-FA.

These preliminary results seem to indicate the association of Kováts indices with GC/MS as an efficient, low-cost, easy-to-adapt alternative to forensic labs in both the identification and categorization of NPS.

### **K80 Postmortem Pediatric Forensic Toxicology**

*Robert A. Middleberg, PhD, NMS Labs, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, University of California-San Francisco, Palm Springs, CA 92262-6451; Sarah E. Avedschmidt, MD\*, University of Michigan, Ann Arbor, MI 48109; Alexander Robert W. Forrest, LLM\*, School of Law, Sheffield, South Yorkshire S3 7ND, UNITED KINGDOM; David R. Fowler, MD\*, Office of the Chief Medical Examiner, Baltimore, MD 21223; Greg Vincent, MD\*, Farmington, CT 06032*

---

**Learning Overview:** After attending this presentation, attendees will understand the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and case-specific sense.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

During this 19<sup>th</sup> Annual Special Session within the Toxicology Section, pediatric cases involving toxicological findings will be discussed. As a relative dearth of interpretive information involving toxicological findings exists in the pediatric population, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation or issue-specific concern, including pharmacokinetic data and other relevant ancillary information, followed by audience participation to provide interpretive clarity around case-specific impacts of the toxicological findings. This session, attended by various sections of the Academy, allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause of death in children.

Four cases will be presented that highlight the difficulty in assessing the role of toxicants in each case or the lengths one must go to in some cases. Sarah Avedschmidt, MD, David Fowler, MD, Robert Forrest, LLM, and Greg Vincent, MD, will be reviewing cases from their experiences as forensic pathologists that highlight the issues and confounders in the pediatric population.

Dr. Avedschmidt will be discussing a case of a 4-year-old with Cri du Chat and sickle cell disease who expired in an emergency room. The postmortem toxicology demonstrated the presence of oxycodone. The steps taken to determine the role of the oxycodone in the death will be examined in the face of known pathologies, a number of other factors, and the ever-present unknowns.

Dr. Fowler will draw on his years of experience as a forensic pathologist in an inner city to discuss cases of note.

Dr. Forrest will dive deep into a 19<sup>th</sup>-century case involving strychnine, the initial diagnosis, and how a conclusion was reached given the availability of scientific data at the time. He will also discuss the likelihood of a proper diagnosis if a child were to present with similar signs and symptoms today.

Dr. Vincent will bring forward a case involving the death of an 8-year-old in a fire and how failure to perform proper toxicological testing may lead to an overlooked cause of death. The twists and turns of the case are both fascinating and caution-bearing.

### K81 Next-Generation Drug Surveillance in Public Health and Medicolegal Death Investigations

*Jeri D. Roper-Miller, PhD\**, RTI International, Research Triangle Park, NC 27709; *Kemp Chester, MA\**, White House Office of National Drug Control Policy, Washington, DC 20503; *M.J. Menendez, JD\**, Organized Crime Drug Enforcement Task Force, Washington, DC 20530; *Jeffrey R. Locke, JD\**, Springfield, VA 22150; *DeMia P. Pressley, MS\**, Drug Enforcement Administration, Springfield, VA 22152; *Conner Brooks, MSc\**, Bureau of Justice Statistics, Washington, DC 20001; *Margaret Warner, PhD\**, Center for Disease Control and Prevention, National Center Health Statistics, Hyattsville, MD 20912; *Andrew M. Baker, MD\**, Hennepin County Medical Examiner Office, Minneapolis, MN 55415; *Barry K. Logan, PhD\**, NMS Labs/Center for Forensic Science Research and Education, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will have an understanding of federal- and state-level efforts to enhance and implement drug surveillance programs to strengthen investigations involving drug-related deaths in the United States and promulgate information about the needs of the Medicolegal Death Investigations (MDI) community to facilitate their work. Attendees will also have gained evidence-based knowledge regarding infrastructure-related challenges faced by medical examiners, coroners, and their forensic laboratory services; acquired perspectives about lessons learned from local, state, and federal efforts working with and within the MDI community; and learned about resources that are in place to overcome some of these obstacles, including tangible resources, changing laws, and advances in technology, science, and availability of key data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how these national and state-wide data can improve our understanding of the state of medicolegal death investigation systems, highlighting valuable tools for public safety and public health, and sharing of these analytical data can facilitate comprehensive public health and death investigation efforts.

Investigations of drug-related deaths in the United States is at an unsurpassed critical “breaking point” that calls for enhanced, integrated sentinel drug surveillance efforts. Many surveillance efforts at a federal and state level are progressively relying on multidisciplinary teams to evaluate emerging drug trends; historical, current, and potential patterns of abuse; safety or dependence liability; public health risks and lethality; and analytical characteristics.<sup>1</sup>

In 2015, nearly 2.5 million people died in the United States.<sup>2</sup> Of these, approximately one million were referred to the nation’s Medical Examiner and Coroner offices (MECs), which accepted about half of these cases.<sup>3</sup> MEC caseloads are at an all-time high because many of these deaths require a complex, in-depth investigation.<sup>4</sup> Drug overdose deaths require significant resources to investigate, and the exponential escalation of drug-related deaths in the United States have led to national efforts to implement more effective and timely awareness of the epidemiology, drug statistics, and unprecedented challenges that burden MECs. In general, there is limited information about the state of the MDI community on a national scale concerning drug surveillance.

Several national MDI stakeholder meetings have focused on multiple federal and state agency efforts within the MDI community. It is important to highlight what these agencies are doing, how their work ties together and how they are collaborating, and how MDI practitioners are finding value in and implementing better practices using data from these efforts.

In summary, this special session will discuss the needs, progress, and current programs that will assist the forensic science community in achieving the next generational advancement of drug surveillance in MDIs.

#### Drug Surveillance, Drug Overdose, Medicolegal Death Investigations

### LW1 Doyle: The Bitemark Case That Started It All!

*Roger D. Metcalf, DDS, JD\*, Tarrant County, Fort Worth, TX 76179; Janice W. Klim-Lemann, DDS, Redlands, CA 92373*

---

**Learning Overview:** The goal of this presentation is to provide some background history about the seminal bitemark case in United States forensic odontology and to discuss its subsequent ramifications.

**Impact on the Forensic Science Community:** After attending this presentation, attendees will have a better appreciation of the *Doyle* bitemark case.<sup>1</sup> This presentation will impact the forensic science community by providing some historical background to the field of bitemark analysis.

James A. “Jimmy” Doyle was arrested in west Texas, not far from Abilene, in December of 1952 for public intoxication. The night before Doyle’s arrest someone had broken into Oscar Peacock’s grocery store in the small town of Aspermonte, and had stolen a number of items, including two bottles of whiskey and 13 silver dollars. In addition, a “large block of cheese” was found left on a countertop in the store, and it was noted there were “pronounced teeth marks” in the cheese.

During routine inventory of his personal property at the jail, Doyle had been found to have had 13 silver dollars in his pocket. So, while Doyle was incarcerated, on a “hunch,” Sheriff Frazier requested that he bite into another similar block of cheese in order to make an exemplar for comparison purposes. Doyle readily agreed and did so.

The cheeses were sent for analysis by a novel-at-the-time procedure and were examined by a Texas Department of Public Safety firearms and tool mark examiner, Mr. Taylor. The cheesy marks were also evaluated by a long-time, well-respected member of the Texas State Board of Dental Examiners, William Kemp, DDS, of Haskell, TX.

Mr. Doyle was charged with and convicted of burglary in a jury trial in Stonewall County. Mr. Doyle then applied for *certiorari* with the Texas Court of Criminal Appeals, Texas’ court-of-last-resort for criminal cases, and the Court agreed to hear his case. Doyle claimed on appeal that the request from Sheriff Frazier to make an exemplar bite in the second block of cheese violated his right against self-incrimination, because he had not received the pertinent warning required by statute in Texas at that time (predating *Miranda* by more than a decade). The Court did not find Doyle’s reasoning persuasive, and the verdict was upheld.

*Doyle* is Texas’ first known bitemark case and the first known *reported* (in the legal sense) bitemark case in the United States. The case is often cited by odontologists, but many may not know the interesting “back story.” This presentation will provide greater understanding about the history of a very important case and an appreciation of subsequent developments.

Please note that this case report was first presented in the Odontology Section Scientific Session of the 2016 AAFS Annual Scientific Meeting.

### LW2 Cosmic Forensics: Can the Sky Fall on Our Heads?

*Annarita Franza, PhD\*, Department of Experimental & Clinical, Florence, ITALY; Vincenzo Lusa, JD\*, Rome 00151, ITALY; Mario Di Martino, PhD, Italian National Institute for Astrophysics, Pino Torinese 10025, ITALY; Vanni Moggi Cecchi, PhD, Natural History Museum, University of Florence, Florence 50122, ITALY*

---

**Learning Overview:** The goal of this presentation is to familiarize attendees with the role of forensic sciences in geosciences and space research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic scientific community by providing useful information to those engaged in the study of extraterrestrial materials (i.e., meteorites, micrometeorites, and interplanetary dust particles) in a judicial contest. This presentation will focus primarily on meteorites, which have been documented to strike structures and objects or injure human beings.

Despite having been the subject of mineralogical, chemical, astronomical, and even archeological studies, meteorites have remained a riddle for the human mind. If reason has succeeded over the centuries to make most of their mysteries intelligible, the fascination of these “stones fallen from the sky” nevertheless continues to pose new questions.

The National Aeronautics and Space Administration (NASA) has released the Near Earth Object Program, which tells us that approximately 100 tons of “fairly small natural objects,” mainly rock fragments and dust particles, fall onto the Earth from interplanetary space every day. As they enter the atmosphere at more than 62,000 miles per hour, they heat up and catch fire, forming a luminous trail. They are then called meteors (or shooting stars). Although most meteors burn up completely before they reach the ground, some of them collide with the Earth’s surface. A meteor that does not burn up as it crosses the atmosphere becomes a meteorite. It partly disintegrates on hitting the ground, and its fragments can weigh anything from a few ounces to a couple of tons and spread over several miles. Laboratory, astronomical, and theoretical studies have shown that meteorites are products of collisions that occur within the asteroid belt between approximately 2.1 and 3.3 Astronomical Units (AU) from the Sun (one AU is the average distance from Earth to the Sun, approximately 93 million miles). It is within this region that strong gravitational perturbations by the planets, especially Jupiter, can put meteoroids (the name given to bodies of matter moving in space before they enter Earth’s atmosphere) into Earth-crossing orbits. However, not all meteoroids are formed in the asteroid belt. A few may be the remains of cometary nuclei that originated outside this region, and fewer than 1% of meteorites are recognized to be samples of debris from the surface of the Moon and Mars that have been ejected by impacts.

This presentation is divided into two parts. In the first part, attendees will learn how to identify a meteorite and the phenomenon of the black market in meteorites, which is as organized as any drug trade and just as illegal, will be discussed.

Subsequently, this presentation will present an analysis of 53 meteorites that, from the early 19<sup>th</sup> century to 2018, have hit artificial structures, animals, and people. Although scholars have not been able to confirm the accident nor the fall, on January 16, 1825, scientific memories reported the first “death by meteorite”: a man was killed and a woman injured during a meteorite fall in Oriang, India. Two years later, on February 16, 1827, a man was wounded severely in the arm by an ordinary chondrite meteorite that fell in Mhow, India. On November 11, 1836, chronicles reported the first animal to be killed. It was a cow hit by a shower of meteorites in Macau, Brazil. On August 8, 1863, a 5.4-Kg enstatite chondrite penetrated the roof and floor of a building in Pillistfer, Estonia. On September 15, 2007, a fireball was witnessed landing near Carancas, Peru. Villagers were sickened by the fumes released from an underground water supply tainted with arsenic after the impact. On February 15, 2013, a meteorite exploded above Chelyabinsk, Russia, injuring 1,200 people and causing \$33 million in damage.

In conclusion, particular attention will be devoted to the case of Ann Hodges, who was hit by a meteorite that crashed through the roof of her home and smashed into her hip, leaving a pineapple-shaped bruise, on November 30, 1954, in Sylacauga, AL. The event caused a worldwide media sensation and a year-long legal battle. The meteorite, which weighs approximately 3.85kg, is on permanent display at the Alabama Museum of Natural History.

### Case Report, Cosmic Forensics, Meteorite

### LW3 The Epic of the World War II (WWII) Italian Submarine *Macallè* and the Death of Carlo Acefalo: How Forensic Science Brought a Soldier's Remains Back Home

Matteo Borrini, PhD\*, Liverpool John Moores University, Liverpool, AE L3 3AF, UNITED KINGDOM

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the potential and the ethical implications of the forensic anthropological approach on historical cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an example of an investigation to recover, identify, and bring back to his home country the remains of a WWII soldier.

In June 1940, the Italian submarine *Macallè* left berth at the naval base in Massawa to hunt for British ships in the Red Sea. Soon after the boat's air conditioning was turned on, a deadly invisible gas, methyl chloride, began leaking throughout the hull. At 02.35 a.m. on June 15, the incapacitated crew led the submarine to collide with the reef of Barra Musa Kebir, a small island 65 nautical miles southeast of Port Sudan. *Macallè* remained trapped between the corals for nearly a day, allowing the crew of 45 men to make it ashore.

The captain sent three men in the submarine dinghy for help in Italian-controlled Eritrea, approximately 200 miles away. With an improvised sail made with shirts and bedsheets, the trio crossed miles of sand bars and marshy coasts; after six days, they were spotted by Italian coastal troops and were able to report the wreck of *Macallè*. Meantime, conditions on the small desert island were steadily deteriorating. The lack of food and water was further weakening the men already poisoned by the methyl chloride. The crew tried without success to distill water and the few fish and birds they were able to catch were insufficient to keep them all alive.

At approximately 3.00 p.m. on June 19, the young Chief Torpedoman, Carlo Acefalo, died of poisoning and starvation and was buried by his comrades under a few inches of sand.

Nearly a week after the sinking of the submarine, the sound of a plane's engine was heard. The joy of an expected rescue was soon tempered when the survivors realized it was a British Royal Air Force aircraft that dropped a note instructing the crew to prepare to be taken to Port Sudan on a Royal Navy vessel. However, a few minutes later, another plane was heard, an Italian one that assured the men that a friendly submarine was on its way to save the castaways. Submarine *Guglielmotti* rescued the crew of *Macallè* just hours before the arrival of British forces, who found only the grave of Carlo Acefalo and the diary of one of the soldiers.

That diary, as well as documents of the "Special Commission of Inquiry into the loss of the *Macallè*", have been used by an Italian-Argentine team to plan a survey in Barra Musa Kebir in October 2014. The underwater photography expedition found metal debris of the sunken submarine 55-60 meters deep in the sea around the island. In addition, on the island, possible clues of Acefalo's grave were found: a circle of stones and rusty fragments. The metal pieces apparently belonged to a Davis auto-respirator, an underwater escape device used by Italian submariners.

After more extensive archival research led to the location of Acefalo's relatives and families of other crew members who provided additional documents, a new scientific expedition was organized in October 2017 with the support of the Sudanese government. The forensic archeological excavation of the burial site was conducted for three days under very difficult environmental conditions. The remains appeared extremely fragmented and damaged due to the characteristics of the grave and the intense heat of the sand under which they had rested for more than 70 years. However, the forensic anthropological examination, as well as the analysis of contextual information and the comparison with historical data, allowed a positive identification of Carlo Acefalo.

The remains of the Italian soldier were turned over to the Sudanese authorities in a ceremony held at Port Sudan on October 9, then consigned to the Italian Ambassador on April 18, 2018, for the final journey home, where Carlo will be buried next to his mother, who died in 1978 awaiting his return.

---

#### Forensic Anthropology, WWII Soldiers, Human Identification

### LW4 Three in One Homicide Fire Victims: Dental Identifications the Hard Way

Warren D. Tewes, DDS\*, *Office of the Chief Medical Examiner, State of MD, Queenstown, MD 21658-1101*

---

**Learning Overview:** The goal of this presentation is to demonstrate (the principle of) diligence in forensic odontology for dental identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by inspiring creative thinking in a seemingly unproductive investigation by reevaluating existing evidence from fresh and different perspectives, while revealing new evidentiary findings by interdisciplinary collaboration.

This principle is presented via related case illustrations and the demonstration of three burned-beyond-recognition fire victims. Diligence, far beyond the usual and customary, is required for this triple homicide scenario because no antemortem dental images or written records existed. More obstacles were present in this 1998 case because modern digital technology was not available to supplement data analysis that is commonplace today. Adding to objectives of diligence is the work ethic of dedicated problem solvers to re-think and create alternative approaches to a seemingly exhausted investigation when conventional methods become fruitless. The diligence becomes contagious for law enforcement and forensic professionals as a spontaneous cohesive devotion evolves and presents as an interdisciplinary team. They guide an effort that is focused and dedicated to the victims' family. Their analysis of the existing available and newly recovered data, in a very timely fashion, leads to the formation of accurate and positive outcomes in grieving circumstances.

The proposition of this presentation is to show that, in the absence of conventional data to perform a more standard human dental identification, with creativity, resourcefulness, collaboration with law enforcement, and scene trace evidence, scientists can yield successful results. The components of this previous statement alone can be considered a composite definition of diligence, dedication, and devotion.

The presentation synopsis is an individualized account of three, burned-beyond-recognition homicide fire victims. While each victim had some teeth missing that could have expedited a positive identification for each, the family reported that they extracted their own teeth. Consequently, no antemortem dental records were ever made and thus were not available for conventional antemortem and postmortem comparisons. Further, in this extraction technique, the teeth were made mobile slowly over weeks using left and right finger pressure movement on the painful tooth. This resulted in no root fractures and minimal trauma to hard and soft tissues, which then facilitated healing.

To conclude, the spirit of diligence, dedication, and devotion, fosters team building across all law enforcement and forensic sciences. This presentation reinforces and encourages an adage of older, experienced members to younger forensic sciences community members, guiding them to "think outside the box."

---

**Dental Identification, Alternative Dental Records Search, Forensic Scientists' Collaboration**

### LW5 A Modern Case of Pitt-Hopkins Syndrome With Comparison to a Historic Case of a Feral Child Discovered in the Forest of Germany

Cristin Marie Rolf, MD\*, State of Alaska, Anchorage, AK 99507

**Learning Overview:** The goal of this presentation is to educate attendees about the recognition of a rare congenital disorder characterized by breathing abnormalities with apnea and seizures, which could lead to sudden death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the recognition of a recently described, rare genetic syndrome in a historic case with documented dysmorphic features in hand-rendered pictures, such as a painting, and symptoms in written documentation.

The case was that of a nine-month-old female child with congenital anomalies and mental disability who was referred to the medical examiner as a sudden death under unknown circumstances at her residence. She was born at 34 weeks gestational age via vaginal delivery with intrauterine growth retardation at 1,510 grams and a head circumference of 28 centimeters. Labor was induced due to worsening oligohydramnios. Prenatal ultrasound revealed fetal anomalies including a 2-vessel umbilical cord, situs inversus of the stomach (on right side), cardiac anomalies (interrupted inferior vena cava with continuation through the azygous vein, patent ductus arteriosus, patent foramen ovale and levocardia), hypoplastic corpus callosum and feet positioning abnormalities. Genetics testing revealed chromosomal 18q21.2q23 deletion. Symptoms included periodic breathing with desaturations and severe developmental delay, marked eczema, poor growth, increased sweating, and suspected cortical blindness. At the time of her death, she was known to have had diarrhea for five days. The infant was placed in a bassinette on her right side the evening prior to death and was heard early the next morning making her usual sounds. Later that day, she was found unresponsive, in a supine position with no airway-obstructing materials nearby.

Autopsy revealed an atraumatic, less than third percentile size, mildly dysmorphic female infant. Findings included microcephaly, deeply set eyes, low frontal hairline, curly hair, eczema of the forehead and scalp, prominent lips, situs inversus of the stomach, polysplenia, and appendix. A thin corpus callosum with absence of the cavum septum pellucidum was noted. Gross and microscopic examination of the small and large intestine were unremarkable for pathogenic changes. The toxicology screen was negative. The vitreous electrolytes were significant only for a mildly elevated urea nitrogen of 43mg/dL. The cause of death was attributed to complications of Pitt-Hopkins Syndrome. The mechanism of death most likely originated from abnormalities of breathing with hypoxia or a seizure.

Research in the present case disclosed a historic case of a male child of unknown parentage discovered in the forest of Germany in 1725 by a hunting party of King George I of England. This feral child was uncivilized, walking on all fours, without language skills. When moved to London, attempts to teach him to speak, read, or write were unsuccessful. He had typical features seen in Pitt-Hopkins Syndrome, such as course, curly hair, drooping eyelids, short stature, curvy “Cupid’s bow” lips, and thick lips. After the initial public curiosity, the child was moved to live the remainder of his life on a farm in Northchurch England. Because he would wander off, a leather collar with the inscription “Peter the Wild Man” was placed around his neck. He died around the age of 71 or 72 in 1785 and was buried in Northchurch with a gravestone stating “Peter the Wild Boy.”

Pitt-Hopkins Syndrome is a congenital condition manifesting as moderate to severe intellectual disability with characteristic dysmorphic features and symptoms of breathing abnormalities with apnea and hypoxia. Seizures, delayed psychomotor skills, and stereotypical extremity movements are also seen. Autistic features are also common. The genetic anomaly most commonly seen is a deletion of chromosome 18 (18q21.2q23). The gene affected is Transcription Factor 4, which codes for a protein controlling cell differentiation and apoptosis in the brain, muscles, lungs, and heart. The physical findings seen in a painting and later hand-rendered pictures of Peter and written documentation of his psychomotor disability were recognized as those found in Pitt-Hopkins Syndrome. This is an interesting and educational comparison of a modern case to that of a historical case of a man who beat the odds of surviving for an unknown time alone foraging in the woods with severe disabilities.<sup>1-5</sup>

### LW6 The Mystery of a 17<sup>th</sup>-Century Epidemic Solved Through Forensic Genealogy

*Colleen M. Fitzpatrick, PhD\*, Fountain Valley, CA 92708*

---

**Learning Overview:** After attending this presentation, attendees will understand how multidisciplinary forensic analysis has been used to determine the cause of a devastating epidemic that plagued the residents of Sigolsheim, a village in 17<sup>th</sup>-century Alsace Lorraine, France. The only evidence that an epidemic took place at all was provided by the local church registry of village births, marriages, and deaths, indicating that from 1674 to 1684, nearly every pregnancy in the village resulted in either a miscarriage or stillbirth. Before this, the church records showed that the village had a healthy birth rate and was growing, and that afterward, the population quickly returned to its former level. It was as if a “birth-switch” was abruptly turned off in 1674, only to be turned back on ten years later. The only other telltale clue was a brief increase in death rate in 1664-1665, including the deaths of the entire 11-member Naegler family with the exception of the oldest child, their 18-year-old son, Christopher.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how much information can be extracted by applying a multidisciplinary approach to very old mysteries where little documentation has survived. While it is exciting to see modern forensic tools applied to modern cases, it can be even more interesting to see these same tools applied to solving old historical cases in a context inconceivable to those who lived so many generations in the past.

Historical reasons for the epidemic are scant. There were no major wars in Europe at that time that would have reduced the birth rate by drawing husbands and sweethearts away from the area for such an extended period. Contaminated water could also be ruled out, as could the possibility of a communicable disease—otherwise the entire village would have perished. Changes in childbirth practices could be eliminated since there were few deaths recorded among women of childbearing age. So, what was the cause of this mysterious epidemic that seem to affect only unborn children, but hardly any other villagers?

The answer might be ergot, a fungus that grows on rye. Ergot has been suspected as the cause of the Bubonic Plague as well as the Salem Witch Trials. It was so common during the Middle Ages that it was thought to be a natural part of the rye plant. Ergot is the original source of LSD.

### Y2 Persistence of Tool Marks on Bones After Burial

Cydnee A. Wolfe\*, Arizona State University, Gilbert, AZ 85296

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how tool marks persist on bones after burial for varying lengths of time in different substrates and at different depths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an increased understanding of the reliability of tool mark data taken from bones found in outdoor environments.

When biological remains, such as bones, are part of a crime scene, it is known that biotic and abiotic factors are immediately at work, affecting the presentation of evidence to crime scene investigators. The impact of various biotic and abiotic factors will change over time with increasing exposure of the remains to these factors. In an attempt to quantify the impact of such factors on the reliability of data collected from remains, this study created a controlled experiment in which soil type, burial depth, and length of burial time was varied. This study obtained 36 fresh bovine bone fragments, each approximately 10cm in length, and coarsely cleaned the flesh from the bones, although there was still a significant amount of flesh present on the bones prior to burial. The bones were stored frozen to halt any biotic action prior to placement in the treatments. The bones were “tool marked” using a standard Dremel® blade to create repeatable mark types, but to varying depths and lengths. The depth of the cuts were treated as a continuous variable and ranged from superficial to ~3mm in depth. Each bone was marked three to six times with varying depths of the mark. From each marked bone, a cast was made using Mikrosil™, and the depths of the marks were measured from the casts using a digital caliper. The bone fragments were divided into four bins (nine bones apiece); two bins were filled with store-bought play sand and two were filled with clay-soil obtained from the local environment. The soil type was quantified using standard soil sieve sets. Bones were buried at three depths, top, middle, and bottom. The bins were kept in an outdoor experimental facility with chain-link fencing on all sides, including the top, and were therefore exposed to naturally occurring biotic and abiotic influences, but vertebrate scavengers were effectively excluded. Bones were retrieved at one week, two weeks, and four weeks, starting with the most shallow bones so as not to disturb bones remaining in the treatments. As each bone was recovered from each bin, they were brushed clean, a Mikrosil™ impression was made of the tool marks, and the dimensions of the tool mark casts were again measured with a digital caliper and recorded.

The resulting data indicated a change in the size of tool marks over time, with superficial tool marks decreasing in size and some deeper tool marks appearing to increase in size, with no clear effect of soil type. Time in the bins and depth of burial seemed to amplify this trend, although additional experiments are needed to tease out the different factors more clearly.

*Thank you to the School of Mathematical and Natural Sciences for providing funding for this research as well as the Arizona State University Student Government for travel support.*

### Y4 Analysis of Upconverting Nanoparticles for Latent Fingerprint Detection

*Hannah K. Weppner\**, Rochester Institute of Technology, Rochester, NY 14623; *Sierra R. Rasmussen, BS*, South Dakota School of Mines & Technology, Rapid City, SD 57701; *Jon Kellar, PhD*, South Dakota School of Mines and Technology, Rapid City, SD 57701; *William Cross, PhD*, South Dakota School of Mines and Technology, Rapid City, SD 57701

---

**Learning Overview:** The goal of this presentation is to present research conducted with the Security Printing and Anti-Counterfeiting Research Experience for Undergraduates (REU) at the South Dakota School of Mines and Technology. The research focused on testing and optimizing applications of upconverting nanoparticles to improve latent fingerprint detection on difficult substrates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an investigation into a potential latent fingerprint detection method that, if fully optimized and implemented, could improve the detection of latent fingerprints on fluorescent substrates. This presentation details current application methods, analyzes the utility of alternative application methods, and suggests the direction of future research.

Because of fingerprints' value as forensic evidence in courtrooms around the world, continued research into latent fingerprint development methods remains important. In this study, two novel application methods for NaYF<sub>4</sub>:Yb,Tm Upconverting Nanoparticles (UCNPs) are considered. UCNPs have previously been investigated for their utility as latent fingerprint-detecting powders given their anti-Stokes properties that can allow for the visualization of fingerprints on colorful, fluorescent backgrounds, which are currently incompatible with many traditional development techniques. Donor fingerprints were deposited on cleaned glass and silicon substrates using a split print method to directly compare the effects of two methods. The UCNPs were prepared in organic solvent dispersions of toluene and chloroform and a soybean oil-in-water emulsion and applied by immersing the substrate, and, in the case of the emulsion, spraying the substrate. The results were subsequently imaged using a 980nm laser and camera, a Scanning Electron Microscope (SEM), an optical profilometer, and a video spectral comparator (VSC).

The UCNPs emulsion was found to have little utility as a fingerprint development agent because of the oil residue left on substrate. This residue was difficult to remove and impaired imaging. The toluene dispersion appeared more promising, especially when prepared in a concentration of 1wt% and when washed by immersing in toluene following the application of the dispersion. Additionally, the fingerprints did not appear to dissolve in the toluene when submerged for short periods. With this application and proper imaging, visualization of fingerprint ridges was possible on some of the glass and silicon substrates tested. Further research should concentrate on the formulation and application of organic solvent dispersions to improve the adhesion to the print, reduce background staining, and improve imaging procedures. Additionally, investigating upconverting nanoparticles of varying sizes may also optimize imaging.

### Y6 Using Cell-Free DNA to Improve Short Tandem Repeat (STR) Analysis of Sweat Samples

*Nathan R. McFadden\*, Pittsburgh, PA 15203*

---

**Learning Overview:** After attending this presentation, attendees will learn how cell-free DNA may be a suitable source of DNA from sweat samples to improve upon STR profiles of low copy number DNA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving upon low copy number samples, such as touch DNA (tDNA), through the use of cell-free DNA.

In the forensic community, tDNA samples are known to be difficult samples to obtain an ample amount of template DNA and produce DNA profiles using STR analysis. Cell-free DNA (cfDNA) is DNA present outside the cell and is found in bodily fluids, such as sweat, saliva, and blood serum. The use of cfDNA has typically been for cancer and prenatal diagnoses of a mother and her child. However, previous research has thought cfDNA could be used to enhance DNA profiles obtained from tDNA samples. For forensic purposes, extractions have not been conducted with a cfDNA extraction kit.

In the first phase of this study, QIAGEN® extraction kits were used to extract DNA from blood serum samples. The two QIAGEN® kits used were the QIAamp® DNA Mini Kit and the QIAamp® Circulating Nucleic Acid Kit. The Circulating Nucleic Acid Kit uses vacuum filtration through a silica membrane with different lysis and wash buffers than the DNA Mini Kit. DNA yields and STR profiles were compared between the two kits and confirmed the Circulating Nucleic Acid kit provided larger amounts of extracted DNA and improved profiles.

In the second phase, sweat samples were collected on glass beads, with a diameter of 0.5cm, then extracted with the Circulating Nucleic Acid Kit. The samples were quantified with Quantifiler™ and genotyped with Promega® Fusion 6C to validate the use of cfDNA for forensic use. Quantitation values found in the second phase were consistent with the quantitation values found in the first phase, using blood serum. STR profiles generated from the extracted and amplified samples showed signs of major and minor contributors. Although Relative Fluorescence Units (RFU) values were small, there were prominent peaks and smaller peaks present in some of the electropherograms. The possible source the minor contributor could be attributed to the handling of items and interactions with others throughout the day.

The third phase of this research will include a larger sample size and will look to find the source of DNA by quantifying and genotyping both the cell pellets and supernatant from the extraction of each sweat sample. If cfDNA can be validated using sweat samples, cfDNA could be a key component in the genotyping of touch DNA samples. The forensic use of cell-free DNA still needs to be validated further, but if quantities and STR profiles of low template number DNA can be consistently reliable using cfDNA, it may lead to stronger evidence and further the use of DNA genotyping.

### Y7 Detection of Undeclared Substances and Heavy Metals in Alternative Medicines by Chemical Analysis

*Nicole Almeter, BS\*, Arcadia University, Glenside, PA 19038; Jonathan Orr, Arcadia University, Glenside, PA 19038; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038; Shanán S. Tobe, PhD, Arcadia University, Glenside, PA 19038; Heather L. Harris, JD, Glenside, PA 19038*

---

**Learning Overview:** After attending this presentation, attendees will understand the possible dangers of herbal medicines that can be legally purchased in the United States. Attendees will recognize useful presumptive and confirmatory tests that can be used to characterize these medicines and to identify possible heavy metals and undeclared drugs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a variety of analytical techniques that can be used to characterize unknown substances within complex matrices.

Modern herbal medicines based on traditional Chinese medicines have become an increasingly common choice for consumers to treat many ailments from backaches to allergies to migraines. Many people choose these medicines because they believe they are safer alternatives to, or contain more natural ingredients than, western pharmaceuticals. However, recent reports in scientific literature have indicated possible heavy metal poisoning or adverse effects from undeclared substances present in herbal medicines. Despite these case reports, herbal medicines, like other dietary supplements, are unregulated by the Food and Drug Administration (FDA). Herbal medicines are forensically relevant because undeclared substances may appear in toxicological analysis or these medicines may be found at a crime scene and analyzed by a forensic chemist. Thus, more research is needed to characterize possibly adulterated herbal medicines.

This research aims to identify heavy metals, including arsenic, lead, and mercury and/or organic adulterants, including undeclared drugs, in herbal medicines through various analytical techniques that can be implemented in a forensic laboratory. Ten different herbal medicines have been purchased from traditional Chinese medicine shops in different cities in the United States, including Seattle, WA, New York City, NY, and Philadelphia, PA. Presumptive tests, such as polarized light microscopy, Fourier Transform Infrared Spectroscopy (FTIR), and color tests have been performed. These tests are important because they can guide the analysis of herbal medicines that often contain unknown substances and have complex matrices.

Polarized light microscopy was found useful to identify fillers in these medicines, including sand and starch. Both transmission and Attenuated Total Reflectance (ATR) sampling were used with FTIR in order to indicate possible adulterants, including warfarin, dextromethorphan, and netilmicin, as well as provide information on major components of the medicines. Color tests were used to test for heavy metals and possible drugs. Using the Reinsch test, four samples had a positive indication for arsenic and one sample had a positive indication of mercury. Using Mandelin's reagent, one sample had a positive indication of ibuprofen. From the results of these tests, future work can include analysis by Atomic Absorption (AA) spectroscopy and Gas Chromatography/Mass Spectroscopy (GC/MS).

### Y8 The Analysis of Fentanyl Analogs by Gas Chromatography/Solid State Infrared Spectroscopy (GC/IR)

*Emily Prisaznik, MS\*, 2815 W Highland Street, Allentown, PA 18104; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104*

---

**Learning Overview:** After attending this presentation, attendees will be introduced to a new method that meets the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) guidelines for the analysis of fentanyl and its analogs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing forensic labs and scientists to utilize a new method for the analysis of fentanyl and its increasing analogs.

An investigation of the analysis of fentanyl and ten fentanyl analogs by GC/IR has been performed. GC was performed using an Agilent® 6890N gas chromatograph. IR spectroscopy was performed on a Spectra-Analysis® DiscovIR-GC® using an operation system with Thermo™ Galactic™ GRAMS 8.0. The cryofocused disk was cooled with liquid nitrogen to -40°C and the dewar was set to 20°C for all experiments. GC/solid-state IR spectroscopy has shown to be capable of identification of fentanyl and ten of its analogues (4-ANPP, acetyl fentanyl, acryl fentanyl, alfentanyl HCl, butyryl fentanyl, cyclopropyl fentanyl, crotonyl fentanyl, furanyl fentanyl, isobutyryl fentanyl, valeryl fentanyl). The method, using the conditions in this study, is capable of producing a reproducible quality solid-state IR spectrum from injection of 1µL of a 1mg/mL methanolic solution of sample onto a chromatographic column. Using the chromatographic conditions in the method developed, most of the fentanyl analogues can be separated such that IR spectra can be produced for identification of the compound. Most of the fentanyl analogues were separated with 99% confidence ( $s=3sd.$ ) except for three pairs, isobutyryl fentanyl/fentanyl, fentanyl/acryl fentanyl, and butyryl fentanyl/cyclopropyl fentanyl. Multiple injections of the fentanyl compounds resulted in reproducible retention times (standard deviation=0.023 and a CV% of 0.012 %). The data also produced spectra containing absorption peaks with an average standard deviation=0.272 and an average CV%=0.022, showing good reproducibility for the IR spectra. The solid-state IR spectra of fentanyl and the ten fentanyl analogues analyzed in this study were quite similar but were easily discriminated by comparison of the fingerprint region of the spectrum. The amide region ( $1,650\text{cm}^{-1}$ ) clearly showed different absorption peaks and pattern as well as the region for the C-H stretches of the aromatic and alkyl region ( $2,700\text{cm}^{-1}$ – $3,050\text{cm}^{-1}$ ) and the spectral region between  $1,200\text{cm}^{-1}$  and  $1,500\text{cm}^{-1}$ . The linear retention indices for the fentanyl compounds were calculated using a qualitative retention index standard mixture.

Overall, GC/solid-state IR spectroscopy is a viable and reproducible method for the analysis and identification of fentanyl and fentanyl analogues that may be found in seized drug material.

### **Y9 Are Intra-Alveolar Hemorrhage and Aspiration of Bacterial Colonies Pathognomonic in Asphyxia by Suffocation in Infancy?**

*Cara A. Mitrano\*, Midland, MI 48642; L.J. Dragovic, MD, Oakland County Medical Examiner's Office, Pontiac, MI 48341; Andrew Hanosh, MD, Oakland County Medical Examiner's Office, Pontiac, MI 48341; Bernardino Pacris, MD, Oakland County Medical Examiner's Office, Pontiac, MI 48341; Ruben Ortiz-Reyes, MD, Oakland County Medical Examiner's Office, Pontiac, MI 48341; Kanubhai P. Virani, MD, Oakland County Medical Examiner's Office, Pontiac, MI 48341*

---

**Learning Overview:** After attending this presentation, attendees will understand: (1) histological findings present in cases of infant death due to asphyxia by suffocation, (2) the mechanism of death that supports these findings, (3) key techniques in slide analysis, and (4) how to apply these lessons in the context of death investigation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illuminating a relationship between intra-alveolar hemorrhage, freshly aspirated bacterial colonies, and infant death due to asphyxia by suffocation. The distinction is critical in medicolegal death investigation that is case-specific. When an infant is discovered unresponsive, it is typically rushed to the nearest emergency room facility, resulting in a disturbed scene of death. Physical findings documented at the scene are compared with those documented at the time of autopsy. The rather randomly reported microscopic findings of sub-pleural and intra-alveolar hemorrhage and freshly aspirated bacterial colonies in the alveolar space (without signs of inflammatory response) are useful in diagnosing asphyxia by suffocation. Results of this study provide an additional diagnostic tool that improves the accuracy of investigation and determination of cause and mechanism of death.

The purpose of this study was to examine intra-alveolar hemorrhage and freshly aspirated bacterial colonies as possible pathognomonic findings in cases of infant asphyxia by suffocation. To study this relationship, a review of autopsy materials (1970–2017) archived at the Oakland County Medical Examiner's Office (OCMEO) was conducted and revealed 1,161 infant deaths. Available histological slides were examined independently by multiple pathologists for evidence of intra-alveolar hemorrhage and freshly aspirated bacterial colonies. The independent review by multiple parties was necessary to determine the statistical significance of these findings in cases of infant death due to asphyxia by suffocation. The year 1992, when mandatory thorough death scene investigation was fully implemented in Oakland County, led to discontinuation of the diagnosis of Sudden Infant Death Syndrome (SIDS). This energized efforts in prevention of infant deaths through implementation of safe sleep environments and detailed documentation of evidence at the scene of death using re-enactment. In these cases, histological findings with consensus among reviewers were compared to autopsy reports and notes from scene investigations. This provided full context of each case. Cases of infant asphyxia were then compared to infant deaths due to other causes as controls.

Preliminary findings indicate that intra-alveolar hemorrhage is present in most cases of infants suspected of dying from asphyxia by suffocation. Freshly aspirated bacterial colonies are frequently accompanying, though somewhat less common. No significant morphologic difference has been observed in cases of accidental vs. homicidal asphyxia by suffocation. These findings provide additional information to pathologists and death investigators seeking clarification in cases of infant death due to asphyxia by suffocation, especially in the absence of evidence supporting another cause of death. In conclusion, intra-alveolar hemorrhage and freshly aspirated bacterial colonies are useful in determining cause of infant deaths due to asphyxia by suffocation.

### Y10 Comparison of Periodic Acid-Schiff Staining With Lugol's Iodine for the Detection of Vaginal Fluid in Dried Material

Melissa Rogers\*, North Wales, PA 19454; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** The goal of this presentation is to illustrate the stark differences observed between vaginal fluid, saliva, and urine when stained with the Periodic Acid-Schiff (PAS) stain.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the foundation for a potential confirmatory test for vaginal fluid, and so provide context for sexual assault investigations.

Forensic science literature presents a variety of tests to confirm the presence of various bodily fluids; however, such a test for vaginal fluid is still needed. A confirmatory test for vaginal fluid will provide critical context for forensic casework, especially in sexual assault cases in which no semen is present. In the past, Lugol's iodine was used as the main method for determining the presence of vaginal fluid by staining glycogen.<sup>1</sup> However, this type of staining has been shown in the present study to produce positive results for both saliva and urine, demonstrating its lack of specificity. Although not frequently used as a test for the presence of vaginal fluid, the PAS reagent has been reported to be effective in staining epithelial cells high in glycogen.<sup>2</sup> This study aims to compare the ability of these two stains to detect the presence of vaginal fluid in dried material.

Following Institutional Review Board (IRB) approval, multiple vaginal swabs, saliva swabs, and urine samples were obtained from female participants who varied in age, menstrual cycle, and birth control methods. The first stage of this study involved extracting the glycogen from these samples, then adding a 3% solution of Lugol's iodine to each extract to sample wells in a microtiter plate. The absorbance of each sample was then measured with subsequent quantitative analysis for glycogen using a standard curve. The results of this method indicated that the concentration of glycogen in urine was very similar to that of vaginal fluid, and so could not be distinguished from each other. Concentration values in saliva were also not appreciably lower. Staining of vaginal smears on microscope slides with Lugol's iodine also did not show observable differences between the three fluids. Conversely, for the second stage, vaginal smears showed significant observable differences in glycogen staining with PAS when compared to smears made from saliva and urine. Differences were so pronounced that absorbance assays would simply be redundant. Results between women of varying age were comparable.

Not only do these results bring to light a more effective stain for vaginal fluid, but also provides the foundation for a potential confirmatory test that could be used in serology laboratories. Development of such a test for vaginal fluid will help provide context for sexual assault investigations.

### Y11 The Analysis of Fentanyl and Its Analogs and Metabolites in Postmortem Blood Using Biocompatible Solid-Phase Microextraction (BioSPME) and Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS)

Gabriella Smith, BS\*, Cedar Crest College, Schnecksville, PA 18078; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104; Chandler Marie Grant, MS, Allentown, PA 18106; Marianne E. Staretz, PhD, Cedar Crest College, Allentown, PA 18104; Thomas H. Pritchett, MS, Cedar Crest College, Allentown, PA 18104

---

**Learning Overview:** After attending this presentation, attendees will be informed on a new possible analysis method for fentanyl and its analogs using a BioSPME extraction and LC-MS/MS that decreases analysis time.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a newly validated method for an efficient extraction and overall analysis of fentanyl and its analogs in the height of the opioid epidemic.

In 2016, approximately 13 people died of a drug-related overdose each day in Pennsylvania. In all, 4,642 drug-related overdose deaths were reported that year by Pennsylvania coroners and medical examiners. In 52% of these cases, fentanyl and fentanyl-related substances were identified in decedents, with heroin being the second most frequently identified substance. This is an increase of 27% from the previous year. Due to the ease with which these illicitly manufactured fentanyl and fentanyl analogs can be synthesized, it is essential that new validated methods be investigated. In addition, it is often difficult to synthesize standard reference materials for the increasing number of illicitly manufactured fentanyl analogs. It is also expensive for laboratories to purchase all the standards needed for developing methods and analyzing samples with these compounds included in the panel. Structural similarities among many of these analogs also present unique challenges for toxicology laboratories. For example, by adjusting the position of a single additional methyl group, a total of 15 different analogs can be synthesized. The presence of fentanyl analog isomers and isobaric compounds causes great difficulty in separation using LC. Additionally, the fentanyl epidemic is also causing an increase in casework. Therefore, the development of more efficient techniques for screening postmortem samples for fentanyl and its analogs would greatly benefit toxicology laboratories.

The purpose of this study is to compare a new *in vivo* BioSPME technique to an existing technique used in the toxicology department at Health Network Laboratories (HNL) located in Allentown, PA. The toxicology department at HNL is a full-service toxicology laboratory, providing therapeutic drug monitoring, compliance drug testing, workplace drug testing, Driving Under the Influence (DUI)/Driving Under the Influence of Drugs (DUID), and postmortem toxicological services. BioSPME was developed as an extraction method that could quickly extract drugs from biological fluids without the binding of macromolecules, which was a concern for previous SPME techniques. The use of BioSPME fibers allows for the direct analysis of a free analyte fraction on traditional Liquid Chromatography/Mass Spectroscopy (LC/MS) methods. These tips also open the door to the possibility of future direct MS analysis that could greatly impact the field by providing a rapid detection method for these fentanyl compounds, a capability that could drastically reduce sample preparation and analysis times.

In this study, a method to analyze 19 different fentanyl analogs in postmortem blood is being developed using both BioSPME and HNL's extraction method. The method will utilize both Time-Of-Flight/Mass Spectrometry (TOF/MS) as a screening method and LC-MS/MS as a quantitative method.

#### Fentanyl, Toxicology, LC-MS/MS

## Young Forensic Scientists Forum— 2019

### Y12 Optimization of a Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS) Method for the Separation and Identification of Synthetic Cannabinoids on Prison Mail Samples

Alyssa Hurd, BA\*, Harrisburg, PA 17112; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA 15282

**Learning Overview:** After attending this presentation, attendees will understand the importance of developing analytical methods to better screen for drug-soaked paper disguised as mail samples being sent into prisons across the country and will understand why there remains a need for established research to ensure that drug-soaked prison mail samples do not pose a further threat to prison staff and inmates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the method development and validation results using synthetic cannabinoids JWH-018, JWH-073, AM2201, XLR-11, AB-CHMINACA, 5F-ADB, and AM-2233, the most commonly seen as published in the National Forensic Laboratory Information System (NFLIS) Special Report on Synthetic Cannabinoids and Cathinones.<sup>1</sup>

Synthetic drugs, colloquially named with street names such as K2 or Spice, have seen a surge in popularity over the past decade. This popularity has posed a number of problems within the prison system, including the difficulty of detecting drugs coming in through the mail as well as the safety risk it poses to both inmates and prison staff. While numerous published methods exist for human drug screenings after the inmates consume the synthetic drugs, there remains the need for an established method to screen for the drug-soaked mail samples as they are being sent into the prisons.

In this study, a reliable and valid LC-MS/MS method was developed for separating and identifying synthetic cannabinoids utilizing seven synthetic drug standards: JWH-018, JWH-073, AM2201, XLR-11, AB-CHMINACA, 5F-ADB, and AM-2233. All seven drug standards were soaked into white printer paper in equal ratios and used as samples for method development. Matrix effects were accounted for using commonly encountered mail contaminant, such as pen, crayon, and lipstick, due to the unpredictable nature of prison mail. Ultrasonification was utilized to extract the synthetic cannabinoid from the paper substrate, followed by the development of an LC-MS/MS method by varying solvent ratios and optimizing mass spectral parameters. The developed method was then validated by analyzing 47 actual mail samples recovered from the Allegheny County Jail to test the ability of the method in analyzing true synthetic cannabinoid-soaked paper. The findings of this study suggest that a valid and reliable method can be developed, given the variety of synthetic cannabinoid classes tested. Matrix effects were not observed with the tested contaminants, suggesting that the extraction method is sufficient in removing extraneous substances other than the analyte in question.

## Young Forensic Scientists Forum— 2019

### Y13 The Effects of Household Cleaners and Paints on the Detection of Bloodstains Over Time

Katelin Vietri, BA\*, Mesa, AZ; Maria Cruz Blas, Arizona State University, Glendale, AZ 85306; Kimberly S. Kobjek, MS, Arizona State University New College, Phoenix, AZ 85069-7100

**Learning Overview:** After attending this presentation, attendees will better understand the potential effects on bloodstains from household cleaning products and paint products used when attempting to alter or eliminate bloodstain evidence at a crime scene.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) identifying potential methods that criminals may use to hide or cover up bloodstains; and (2) illustrating potential challenges with the current methods of bloodstain detection.

Blood and bloodstain patterns are often valuable sources of evidence found at crime scenes. It may be found that the suspect or suspects in the case have attempted to clean up the blood evidence in an attempt to destroy any probative value of such stains. Because of these attempts at clean up, it is important for crime scene specialists and investigators to be aware of the potential challenges that may be faced with collecting or analyzing blood evidence at such a crime scene.

Kastle-Meyer (a phenolphthalein test) has been used for more than 100 years as a sensitive method for the detection of possible blood.<sup>1</sup> Chemiluminescent reagents may be used in conjunction with Kastle-Meyer in an effort to detect “invisible” blood, to include blood or bloodstain evidence in which an attempt has been made to alter or destroy it. Despite the sensitivity of the Kastle-Meyer test and chemiluminescent reagents, there may be unforeseen challenges facing those who process the crime scene and collect bloodstain evidence.

Previous research has demonstrated both that the physical chemiluminescence properties of bloodstains can be altered by cleaning products and that paint will affect the detection of bloodstains; however, research on the effects of both the cleaning and concealment of bloodstain evidence is scarce.<sup>2-4</sup> Additionally, there seems to be a lack of applied research regarding the effects of clean-up on bloodstains; no previous study has discussed whether a bloodstain can be covered up and rendered undetectable by traditional forensic means. A grant awarded to Arizona State University through the National Science Foundation focusing on the implementation of a course-based undergraduate research experience allowed for the development and execution of a research project that would address the lack of applied research in this area.

Blood was applied to a substrate that mimics a substrate that is commonly found at crime scenes and was left to dry. Each bloodstain was subjected to a different combination of clean-up and cover-up procedures. Following these procedures, two common forensic blood indicator tests were used. The results of both the controls and the experimental bloodstains yielded surprising results despite the sensitivity of both the Kastle-Meyer and chemiluminescent reagents, regardless of the clean-up and concealment that took place. The implication of both sets of results could manifest differences in the method for which a crime scene may be processed; investigators could derive helpful information from concealed or covered-up bloodstains, but only if they are aware of the presence of such evidence.

This material is based upon work supported by a National Science Foundation grant. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

### Y14 Analysis of Drugs Used in Crimes Using Solid Phase Extraction (SPE) and Liquid Chromatography-Tandem Mass Spectrometry (LC-MS/MS)

Kimberly E. LaGatta, BS\*, 15 Union Road, Oswego, NY 13126; Vadoud Niri, PhD, State University of New York Oswego, Oswego, NY 13126; Shokouh Haddadi, PhD, State University of New York Oswego, Oswego, NY 13126

---

**Learning Overview:** The goal of this presentation is for attendees to learn of an alternative to detecting drugs in very low concentrations that are used in the facilitation of crime.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community as this project aims to develop a more efficient and sensitive method to detect drugs that are commonly used to facilitate crime. The optimized method in this project has lower Limits Of Detection (LOD) than methods currently used in forensic laboratories.

Benzodiazepines are a class of antianxiety drugs that are also known as predator or date-rape drugs used in Drug-Facilitated Crimes (DFCs)—crimes that include robbery and the maltreatment of the elderly and children, as well as rape and other sexual assaults. Identification of these drugs or their metabolites in biological specimens such as urine, blood, saliva and hair of victims is commonly proof of exposure to the drug.

Like other psychoactive drugs used in DFCs, benzodiazepines are highly potent and have short half-lives. The combination of potency and a short half-life makes the time window for when the drug is still detectable in biological samples very small. Victims of DFCs usually experience short-term memory loss and often report the crime days after they happened, which adds to the challenge of detecting the drugs in the biological samples by the currently used analytical methods in forensic toxicology laboratories. The goal of the current project is to develop a method for the detection, identification, and quantification of benzodiazepines, including 7-aminoflunitrazepam, alpha-hydroxyalprazolam, alprazolam, bromazepam, chlordiazepoxide, clonazepam, diazepam, flunitrazepam, lorazepam, and nitrazepam, at very low concentrations in aqueous solutions, which can be adopted for the analysis of these drugs and their metabolites in biological samples such as urine and blood.

An SPE coupled to an LC-MS/MS method was successfully optimized. A Supel™- Select HLB 54183-U 200mg cartridge was selected for SPE. Washing and condition of the packing was completed using 12mL of methanol and 2mL of ultra-pure water, respectively. After sample introduction, the analytes of interest were eluted using 5mL of a 50:50 mixture of methanol and acetonitrile. The elutant was evaporated using rotary evaporation and, upon dryness, was reconstituted using 1mL of 0.01M ammonium acetate. The reconstituted sample was then subjected to LC using a C18 HPLC column (particle size: 1.9µm; length: 20cm) with gradient elution with a mixture of acetonitrile and 0.01M ammonium acetate buffer solution. The elution started with 100% 0.01M ammonium acetate and was gradually decreased to 10%, while acetonitrile was increased to 90% and held for one-half minute. Then 0.01M ammonium acetate was increased back to 100% and held for 4min. For mass spectrometry detection, a Selected Ion Monitoring (SIM) method was started at minute 3.00 of analysis until minute 8.00. Using the optimized SPE and LC-MS/MS method, this study achieved the LOD for ten analytes and their metabolites to be in the range of pg/mL to ng/mL levels, which is much lower than LODs for the common methods used in forensic labs.

### Y15 Fingerprints and Ancestry: Is It All in the Details?

Jessica R. Ford\*, Oklahoma City Police Department, Oklahoma City, OK 73114

---

**Learning Overview:** The goal of this presentation is to discuss the plausibility of using Galton features, specifically the types, locations, and number of minutiae, to determine a person's ancestry.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating a greater understanding of criminalistics, specifically as it relates to the viability of fingerprints left at a crime scene.

This concept of ancestry from fingerprint minutiae has been explored over the years by Sir Francis Galton, and more recently, Fournier and Ross.<sup>1,2</sup> Galton studied and compared the fingerprints of English pure Welsh, Hebrew, Negro, and some Basques from Cambo in the French Pyrenees to look for differences in patterns and minutiae characteristics<sup>2</sup>. His study had a sample size of more than 100 individuals. While his study did not yield significant scientific results, Fournier and Ross conducted a similar study with the purpose of exploring the influence of sex, ancestry, and pattern type on minutiae in African descendent and European descendent males and females.<sup>1</sup> Overall, 243 right index fingerprints were chosen to include 61 African American females and 61 African American males for a total 122 African Americans as well as 60 European American males and 61 European American females for a total of 121 European Americans. Based on this study, fingerprint minutiae, specifically the total number of bifurcations, show promise as a method to predict the ancestry of an individual to some degree of certainty.

Researchers at the University of Central Oklahoma have been conducting a study made up of 250 participants: 25 Hispanic descendant males, 25 Hispanic descendant females, 25 Asian descendant males, 25 Asian descendant females, 25 Native American descendant males, 25 Native American descendant females, 25 African descendant males, 25 African descendant females, 25 European descendant males, and 25 European descendant females. The sex and ancestry of each participant is ascertained based on self-identification and demographic information. In order to collect the prints, each participant had their right index finger rolled on a ten-print card using fingerprint ink. Each print shows a complete nail-to-nail roll to be recorded for later analysis of friction ridge detail. Because of the statistical likelihood that the right index finger is the print most often encountered at crime scenes, those prints were used for analysis. With the assistance of AFIX Tracker<sup>®</sup> technology, each print was analyzed and marked by the researcher for each of the five main fingerprint minutiae characteristics: bifurcations, enclosures, dots, ending ridges, and short ridges. It has been found that the amount of bifurcations in one's fingerprint yields significant results as relates to ancestry. Interestingly, it has been found that African American descendants have slightly more bifurcations than European American descendants.

Significant results in the above research yields new possibilities for law enforcement personnel. Deriving someone's ancestry from their fingerprints can serve as corroborative evidence that could aid in the conviction of criminals who could otherwise walk free. This presentation could greatly impact the forensic science community by shedding new light on innovative ways fingerprints can be used in the application of criminalistics to crime scenes.

### Y16 Accuracy of Ammunition With the Addition of Luminescent Markers

Jared E. McAtee\*, Renfrew, PA 16053

---

**Learning Overview:** The goal of this presentation is to educate attendees on the possible benefits of using luminescent markers in gunpowder for Gunshot Residue (GSR) detection, as well as explain how they affect the accuracy of ammunition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by potentially allowing GSR analysis to be conducted in a timely manner, as well as limiting false positive and false negative results from the Scanning Electron Microscope coupled with Energy Dispersive X-ray Spectroscopy (SEM/EDS), without affecting the accuracy of ammunition

When firearms are discharged, this creates a plume of particles known as GSR composed primarily of lead, barium, and antimony. This residue can be collected and analyzed from a person's hands, face, or the clothing that they were wearing when the firearm was discharged. GSR is commonly analyzed using SEM/EDS, but can also be analyzed using other technologies, such as Raman spectroscopy. The downside to SEM/EDS is the length of time it takes to analyze samples, as well as becoming less robust as manufacturers are ceasing to use lead in their ammunition. The addition of luminescent markers within the gunpowder has been shown to be a viable technique to enhance the collection of GSR, while also having the potential to eliminate collection of non-GSR samples, by using an Ultraviolet (UV) light.

The accuracy of ammunition with the addition of luminescent markers was tested on three different firearms: a .222 rifle, a 30-06 rifle, and a .357 revolver, each at their optimized range (50 yards, 100 yards, and 25 yards, respectively). Ammunition was hand re-loaded while adding luminescent markers in varying weight percentages to the gunpowder that was used in each specific firearm, including 2%, 4%, and 6%. Five samples were loaded in each of the different groups, including a control group in which no luminescent markers were added. After the first and fifth shot in each trial, the hands were observed under a UV light where some particles could be observed. A *t*-test concluded that there was no significant difference between the accuracy of the control groups for each firearm and any of the samples with the luminescent markers. A second trial was performed by removing gunpowder equal to the amount of luminescent powder that was added to ensure that the overall amount of powder remained the same within each cartridge. The same procedure was performed as in the first trial. The results showed at low amounts of luminescent markers replacing gunpowder (98%:2% and 96%:4%), there was no significant difference in the accuracy when a *t*-test was performed comparing them to the control. As more gunpowder was replaced with luminescent markers, the accuracy became significantly worse than the control. Velocities were tested for a sample in each trial at Peterson Cartridge in Warrendale, PA, to see the effects of the luminescent powders. It was found that luminescent markers did affect the velocity for the .222 rifle and 30-06 rifle, but not the .357 revolver.

Production of luminescent markers with a higher temperature resistance is needed for further trials to optimize the ratio of gunpowder to luminescent markers. If it is possible to create ammunition that contains luminescent powders and not significantly affect accuracy, this could greatly increase the potential for GSR analysis being conducted in a timely manner, as well as help limit false negative or false positive results from the SEM/EDS.

### **Y17 A Comparison of Sol-Gel Adsorption Phases and Their Extraction Efficiencies of Explosives Using Closed Headspace Sampling Coupled With Capillary Microextraction of Volatiles (CMV)**

*Amy Salyards\*, Sharpsburg, GA 30277; Michelle N. Torres, BS, Florida International University, Miami, FL 33199; Kelsey Patterson, Allentown, PA 18106; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199*

---

**Learning Overview:** After attending this presentation, attendees will better understand how changing the sol-gel chemistry of a CMV device can alter the percent recoveries of explosive compounds.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting a faster, more sensitive sampling technique to analyze explosive compounds.

When analyzing explosive residues from a crime scene, one common sampling technique for the detection and extraction of volatile explosive compounds involves headspace sampling, including the use of Solid Phase Microextraction (SPME). Although SPME sampling and extraction is sensitive, CMV, a faster and potentially more sensitive sampling technique is proposed as an improvement over the equilibrium-based SPME extraction. SPME is considered a passive air sampling technique, while CMV is an active air sampling technique; this makes CMV extraction have more mass transfer and reduces sampling time. Previous laboratory studies incorporated a trimethoxymethylsilane sol-gel adsorption phase within the CMV sampler (CMV-A) to analyze low nanogram quantities of volatile explosives. The overall goal of this current effort is to create a new sol-gel adsorption phase and evaluate the extraction efficiency of three example explosives (or compounds associated with explosives and propellants) using the new phase.

The purpose of changing the adsorption phase was to investigate new intermolecular interactions between the sol-gel and the incoming explosive sample, similar to changing phases in column chromatography to increase or decrease interaction with the solute. The new sol-gel polymer containing 3-cyanopropyltrimethoxysilane (CMV-F) was created and is reported here for the first time. A detailed comparison of the extraction efficiencies between CMV-A and CMV-F for 1,3-Dinitrobenzene (1,3-DNB), 2,4-Dinitrotoluene (2,4-DNT), and Diphenylamine (DPA) through closed headspace sampling are reported. The listed explosives were chosen as they are commonly detected in Gunshot Residue (GSR) analysis, an application previously reported on using CMV-A. Future work will include a more in-depth look into the interactions between the cyanopropyl functional group and the three target compounds selected for this study. A Keyence® digital microscope was used to image the morphology of each phase and Fourier Transform Infrared (FTIR) was used to chemically characterize the sol-gel coating on the CMV-F glass filters. The results showed that CMV-F increased the recovery of DPA by one order of magnitude for a 75ng spike over CMV-A. These results are potentially useful for detection of extremely low (sub-ng) quantities for GSR since DPA is the most common organic compound residue found on the hands of persons who had recently fired a gun. The overall conclusions of this effort suggest that CMV-F has potential as an improvement for the extraction of other explosives and compounds associated with explosives and propellants.

## Young Forensic Scientists Forum— 2019

### Y18 A New Assay for 1,3-Dimethylamylamine: An Emerging Drug of Abuse

Sandra M. Pieczonka\*, Loyola University Chicago, Crystal Lake, IL 60014

**Learning Overview:** After attending this presentation, attendees will be able to understand the dangers of 1,3 Dimethylamylamine (DMAA), learn about techniques that other scientists have used previous to this research, and discover how this research has changed the way this compound can be analyzed using easier methods and more inexpensive materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new way of analyzing banned substances more accurately, more quickly, and more cost effectively.

The subject compound, DMAA, is marketed as a “natural” stimulant in nutritional supplements and is often found in weight loss and athletic performance-enhancing products. Recent studies have linked this amphetamine-like compound to cardiovascular problems such as shortness of breath, tightening in the chest, and possible heart attack. Consumption of DMAA, also known as methylhexanamine, geranamine, and 2-amino-4-methylhexane, has been linked to multiple deaths.<sup>1</sup> This compound was banned in 2010 by competitive sports authorities, such as the International Association of Athletics and the International Olympic Committee, both of which abide by the policies set forth by the World Anti-Doping Agency.<sup>2</sup> Any quantity of DMAA found in an athlete’s urine results in automatic suspension and sanction. In the past few years, DMAA has been identified in seized drug exhibits by the Drug Enforcement Administration (DEA).<sup>3</sup>

Qualitative and quantitative methods previously reported in the literature have used High-Performance Liquid Chromatography/Ultraviolet (HPLC/UV), Proton Nuclear Magnetic Resonance (<sup>1</sup>HNMR), Mass Spectrometry (MS), and Gas Chromatography (GC).<sup>4-7</sup> This new method uses GC/MS and Flame Ionization Detection (FID) to assay DMAA in commercial products, usually in the form of the hydrochloride salt (DMAA.HCl). Sample preparation consists of extracting DMAA.HCl with aqueous HCl in the range of 0.1M–0.5M followed by conversion of DMAA.HCl to the free base with aqueous sodium hydroxide (NaOH) solution and extraction into chloroform. On-column derivatization to the DMAA-alkanoyl amide was achieved in chloroform with the addition of a lower alkanoyl anhydride and triethylamine. Compared to the free base, DMAA-acyl amide derivatives have increased volatility and decreased surface activity, which results in enhanced chromatography, detector response, and specificity. Additionally, this new method does not require heating or sonication prior to analysis and uses readily available laboratory chemicals for derivatization, such as acetic, propanoic, and butanoic anhydrides. The use of various alkanoyl anhydrides provides method versatility across a broad product line and avoids interference from components in certain commercial products. Acylation of DMAA with a homologous series of anhydrides creates amides with predictably later retention times. Lastly, the resolution of the diastereomeric analyte pairs was enhanced as the molecular weight of the derivatizing agent increased.

### Y19 The Prevalence of Male DNA Under a Female's Fingernails

*Alexis Baxter, BS\*, Cedar Crest College, Allentown, PA 18104; Janine Kishbaugh, MS, Cedar Crest College, Allentown, PA 18104*

---

**Learning Overview:** After attending this presentation, attendees will understand that male DNA under a female's fingernails holds probative value in casework when a full Y-chromosomal Short Tandem Repeat (Y-STR) profile is obtained. When a partial Y-STR profile is obtained, it is typically due to deposit during everyday activities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how, through the results obtained in this research, fingernail evidence collection and DNA analysis of this evidence will be affected and led into a direction of optimization.

The frequency of finding a male DNA profile under a female's fingernails is currently unknown by the scientific community. When a victim comes into contact with a male assailant during a violent or sexual assault, DNA analysis is performed to find the presence of foreign male DNA on the victim. Evidence is collected with a sexual assault evidence kit, which includes cutting, scraping, or swabbing of the victim's fingernails. However, finding male DNA may not necessarily reflect the context of how the transfer occurred and may not be the profile of the assailant. Considering that the sensitivity of DNA methodologies has improved, DNA analysis may be detecting previously undetected DNA that is actually being transferred through casual contact. In addition, secondary and even tertiary transfer may be detected. Previous studies have shown that the origin of foreign DNA under fingernails can be associated to cohabitants. Assessing the random nature of male-to-female transfer throughout the day is the basis for this study.

Y-STRs were used for typing of detected foreign DNA. Female participants in this study either lived with or frequently encountered male individuals in their daily lives. All samples were collected via cutting with fingernail clippers. All nails from one hand were combined and analyzed together. The fingernails were stored in a microcentrifuge tube and kept at -20°C until the samples were extracted. Extraction was performed on the fingernails using a QIAamp® DNA Investigator® kit combined with the Lyse&Spin kit. Quantitation was not performed in this study due to the amount of male DNA being extremely low. Amplification was performed with the PowerPlex® Y23 system. Genotyping was performed using an Applied BioSystems® 3130XL and fragment analysis was performed with GeneMapper® IDX v1.5. The sensitivity was set to 50 Relative Fluorescence Units (RFUs), and anything detected below that was not included in interpretation. Fifteen females participated in this study, resulting in 90 samples that were analyzed. Of the samples tested, partial profiles were produced from single and multiple contributors. In some cases, profiles were linked to male cohabitants via reference profiles provided. When the male cohabitant profile was detected, most allele calls were linked back to that individual. Since only partial profiles were obtained in this study, it is hypothesized that full male profiles obtained during casework may be more indicative of close, immediate contact between the victim and their assailant. Also, since the male cohabitant profile contributed to most allele calls, any foreign alleles present should be carefully interpreted.

---

#### Fingernail Clippings, Y-STR, DNA

## Young Forensic Scientists Forum— 2019

### Y20 The Detection of Male DNA Using Y-Chromosomal Short Tandem Repeats (Y-STRs) in Post-Coital Samples of Vasectomized Males

Sarah Lighthart, BS\*, Cedar Crest College, Allentown, PA 18104; Janine Kishbaugh, MS, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** After attending this presentation, attendees will be more knowledgeable about the potential Y-STR DNA results from extended collection intervals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by becoming assisting attendees in becoming more knowledgeable and aware of the results of collecting azoospermic sexual assault samples at extended intervals.

In the United States, one in six women will be raped. The perpetrators of these crimes are male 94% of the time.<sup>1</sup> In the case of a male perpetrator and female victim, there is the potential for deposition of semen in the vaginal cavity; however, not all cases with semen present will contain sperm. A study reported that approximately one-third of men that commit sexual crimes suffer from some form of sexual dysfunction, which can result in a decrease or complete lack of sperm.<sup>2</sup> Ejaculate with a reduced amount of sperm vastly decreases the amount of DNA present for subsequent testing. This study sought to establish how long after an assault a viable DNA profile may be obtained from samples without sperm.

Semen without sperm was simulated using vasectomized male participants. A total of five vasectomized couples participated in the study by completing a collection packet. Each couple participated in four different trials using post-coital intervals of one, three, five, and seven days. In each trial, the female swabbed the vaginal cavity twice. During each insertion, two swabs were used simultaneously for a total of four swabs for each interval. The two swabs inserted together were extracted together using a solid phase extraction kit. Low Copy Number (LCN) procedures were utilized to help detect any low-level amount of DNA in the sample. Quantitation was performed using a commercial kit that detects the total DNA concentration as well as male DNA. No quantitation results were obtained; however, the samples were amplified with a commercial Y-STR kit. The resulting DNA profiles were analyzed to determine the total number of male-specific alleles present for each time interval. After one day, the results from five couples contained an average of 20.6 of 23 alleles (89.5%), ranging from 13 to 23 alleles present. The average number of alleles found after three days was 4.4 (19.1%) with a range of 0 to 10 alleles present. An average of 3.2 (13.9%) alleles were present after five days with a range of 0 to 8 alleles. After seven days, the average number of alleles identified was 0.8 (3.4%) with a range of 0 to 2 alleles present. Thus, the time frame to detect nearly full DNA profiles from samples without the presence of sperm is approximately one day post-coitus based on the current results. Though full profiles may not be obtained, the presence of alleles can aid in suspect elimination. Future work utilizing LCN methods may increase the amount of alleles obtained from longer intervals.

### Y21 The Implementation of a Method for Rapid Direct Polymerase Chain Reaction (PCR) on Diluted Saliva

Mallory Baud, BS\*, Miami, FL 33174; Georgiana C. Gibson-Daw, PhD, Lincoln, NE 68521; Bruce R. McCord, PhD, Florida International University, Miami, FL 33199

---

**Learning Overview:** After attending this presentation, attendees will better understand a method for rapid and direct PCR on diluted direct saliva.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results that show how run time and reagent costs can be reduced using this combined rapid and direct PCR method. This project will improve current forensic DNA analysis by reducing time and steps involved in sample analysis. The removing of the extraction step in sample analysis decreases extraction-based sample loss as well as potential lab contamination due to sample transfer steps. Attendees will see results of an experimental design-based method to optimize direct and rapid PCR amplification of diluted saliva. These results provide a procedure to reduce the time of the PCR leading to the rapid production of a 7-locus DNA profile for sample screening. This method can be very useful for suspect screening, (e.g., booking stations, customs, and mass disasters).

While current DNA analysis procedures are highly automated, multiplexed, and efficient, they are relatively slow on a per-sample basis. Thus, there is still a need for rapid screening of single-suspect samples. One solution to reduce analysis time is to use rapid direct PCR, which combines cell extraction and PCR amplification in the same tube. Rapid direct PCR procedures can greatly reduce the processing time by screening suspects for presumptive results. This decrease in processing time and reagent use leads to a quick turnaround and inexpensive processing of large numbers of samples.

In order to do this, specially engineered enzymes, such as OmniTaq (a triple mutant of Taq polymerase that makes it resistant to inhibitory effects of body fluids and soils), and high-speed thermal cyclers, capable of temperature changes as fast as 15 degrees per second, will be used to process a specifically designed 7-locus multiplex. The goal is to reduce the analysis time to less than ten minutes by elimination of the extraction step. The MP7 primers consist of the following Short Tandem Repeat (STR) markers: D5S818, D13S317, D7S820, D16S539, CSF1PO, Penta D, and amelogenin loci. These loci cover from 100 to 450 base pair. Work was also performed on a miniSTR multiplex consisting of TH01, FGA, CSF1PO, D21S11, D5S818, D7S820, TPOX, D18S1, and amelogenin—STR loci that cover 51 to 281 bases. These shorter loci are suspected of needing less time to amplify. Those primers, being much smaller, would reduce the annealing time leading to a shorter reaction. Next, 2 $\mu$ L of DNA is added to 8 $\mu$ L of PCR reaction, which is amplified during 32 cycles at 98°C for 3 seconds and 62°C for 14 seconds. Once amplified, the sample is run on ABI® Prism® 310 Genetic Analyzer or a microfluidic device. The PCR reaction mixture was optimized using experimental mixture designs. The experimental design considered salt concentration, buffer addition, dNTP addition, primer addition, and PCR enhancers to develop experiments to maximize amplification of straight saliva. Those modifications created a faster PCR reaction which was obtained in 12 minutes 36 seconds. The output was optimized base on the overall peak heights of a 7-locus multiplex.

The result of this study demonstrates the application of rapid direct PCR for the analysis of STRs to obtain a presumptive DNA profile in under 13 minutes. Without any extraction, the PCR reagents and enhancers have been shown to work with the inhibitors present in saliva.

## Young Forensic Scientists Forum— 2019

### Y22 The Effect of Demographic Factors and Mortality-Related Health Conditions on Postmortem Biometric Data

*Samantha Upton, BA\*, University of Tennessee, Knoxville, TN 36996; Anielle Duncan, BA\*, University of Tennessee, Knoxville, TN 37996; Elizabeth Albee, BA, University of Tennessee, Knoxville, TN 37996; Kelly Sauerwein, PhD, Standards Coordinating Body, Gaithersburg, MD 20899; Dawnie W. Steadman, PhD, University of Tennessee, Dept of Anthropology, Knoxville, TN 37996*

**Learning Overview:** After attending this presentation, attendees will understand the influence of demographic and health-related variables on the deterioration of fingerprints, which are commonly used as a biometric indicator.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying the effect of sex, age, and various antemortem health conditions on the quality of postmortem biometric data that are commonly relied upon to obtain positive identifications for previously unknown individuals.

Biometrics are measurable unique physiological or behavioral characteristics that are used to classify both living and deceased individuals. Previous research has indicated that fingerprints are comparatively the most successful biometric indicator for positive identification, generally due to the longevity of postmortem fingerprint capture. Therefore, in this study, fingerprints were used as the primary indicator to examine biometric degradation and quality data acquisition. For the purposes of this study, *quality data* refers to a threshold met by a ratio of numerical scores provided by two types of biometric scanning technologies. Fingerprint quality was determined by the National Institute for Scientific Standards (NIST) Fingerprint Image Quality (FIQ) v.2.0 algorithm where prints are scored on a 1-5 scale, with 1-3 denoting adequate to excellent prints and 4-5 denoting poor quality prints. As the purpose of the scanning technologies is to provide a match (i.e., positive identification) based on biometric indicators, the scores predict the likelihood that the fingerprint image meets the quality threshold to achieve a positive match. Along with researcher experience, these numerical scores are considered when determining enrollment for longitudinal postmortem studies at the University of Tennessee's Anthropology Research Facility. Biometric scanning technologies were used to capture digital images of all ten digits, where applicable, of 150 donated individuals upon their initial intake into the William M. Bass Body Donation program between April 2014 and July 2018. If 50% or more of the digits were at or above adequate quality (i.e., NFIQ score between 1-3), the individual was then accepted for longitudinal biometric research. Though 150 individuals, between the ages 18 and 94, have been scanned from the beginning of this study, less than 50% met the quality threshold for longitudinal data collection. Therefore, this study examines the correlation between certain demographic variables (e.g., sex and age), mortality-inducing health conditions (e.g., cancers, diabetes, heart disease, pulmonary disease), and other significant conditions (e.g., smoking and alcoholism) with the quality of biometric data during the postmortem period. For each of the 150 individuals in this study, data were collected from the Forensic Anthropology Center's donation database on the following variables: sex, age-at-death, Cause Of Death (COD), and self-reported medical history. The goal of this study was to examine the impact of these variables to overall fingerprint quality.

The preliminary results of this study show that while biometrics do remain viable over time, age was the most significant factor affecting the retention of identifying features of the fingerprints. Among individuals aged 70 years and older ( $n=75$ ), 66% ( $n=50$ ) were rejected for longitudinal enrollment. Similarly, 64% ( $n=7$ ) of individuals 60 years and less ( $n=11$ ) scanned met or exceeded the quality threshold and, therefore, were eligible for further data collection. However, proportions of individuals between 60 and 70 years of age are relatively equally distributed between enrolled and not enrolled categories. Explanations for such results warrant further analysis. There were no substantial differences when sex of individuals and fingerprint quality were examined (enrolled/not enrolled females:  $n=33/32$ ; enrolled/not enrolled males:  $n=39/46$ ). Furthermore, this study has yet to show any apparent trends in the relationship between health-related conditions and fingerprint quality; however, analyses are ongoing. This study builds upon previous work and continues to support the utility of physiological biometric identifiers to obtain positive identifications in postmortem contexts. Postmortem biometric research has the potential to make important contributions to forensic anthropology and the law enforcement, military, and medicolegal communities.

#### Biometrics, Demographics, Mortality

## Program Committee Financial Disclosure – 2019

As a sponsor of continuing education, the American Academy of Forensic Sciences (AAFS) must ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation; and (2) with any commercial supporters of the activity. (Significant financial interest or other relationships can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) AAFS has an established policy regarding conflicts of interest that includes decisions the Program Committee members may make in selecting content for the Annual Scientific Meeting Program. By serving on the committee, regardless of the role, each member has agreed to comply with Section 1.4.7. of the *AAFS Policy and Procedure Manual*.

To serve on the 2018-19 Program Committees, it is required that relevant AAFS staff members, program committee members, and/or reviewers complete a Financial Disclosure Form before being provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve. The executed Faculty Disclosure Forms are on file in the AAFS Office.

## Presenting Author Financial Disclosure – 2019

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s); however, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS Office.

## Presenting Author Financial Disclosure – 2019

Joshua White, BS – H120

Discloses no financial relationships with commercial entities.

Teresa A. White, MA – W02

Discloses no financial relationships with commercial entities.

Ray Wickenheiser, MBA – W10

Discloses no financial relationships with commercial entities.

Emily F. Wieggers, MA – A21

Discloses no financial relationships with commercial entities.

Carl Wigren, MD – W03

Discloses no financial relationships with commercial entities.

Rachel E. Wiley, MFS – B86

Discloses no financial relationships with commercial entities.

Emily J. Will, MA – J34

Discloses no financial relationships with commercial entities.

David A. Williams, DDS – B36

Discloses no financial relationships with commercial entities.

Joyce P. Williams, DNP – B36

Discloses no financial relationships with commercial entities.

Loren M. Williams, BS – J28

Adobe® Photoshop®, BioTuring (Discussion of Unlabeled/  
Investigational Use of Product/Device).

Sheila Willis, PhD – W10

Discloses no financial relationships with commercial entities.

Taylor J. Willis – I26

Discloses no financial relationships with commercial entities.

Gregoreese Willocks – B14

Discloses no financial relationships with commercial entities.

Bailey M. Wills, BS – B111

Discloses no financial relationships with commercial entities.

Teresa V. Wilson, PhD – A97

Discloses no financial relationships with commercial entities.

Rebecca J. Wilson-Taylor, PhD – A16

Discloses no financial relationships with commercial entities.

Allysha P. Winburn, PhD – A145

Discloses no financial relationships with commercial entities.

Janis Winchester, MS – J19

VP-8 Image Analyzer (Discussion of Unlabeled/Investigational  
Use of Product/Device).

Agnes D. Winokur, MS – BS4

Discloses no financial relationships with commercial entities.

Andrew J. Winter, MS – B68

Discloses no financial relationships with commercial entities.

Eric D. Wish, PhD – W05

Discloses no financial relationships with commercial entities.

David Witzke, BA – G22

Discloses no financial relationships with commercial entities.

Michael Wixted, MA – W12

Discloses no financial relationships with commercial entities.

Denise Wohlfahrt, BS – B85, B130, H32

Discloses no financial relationships with commercial entities.

Emily Wolak, DO – H164

Discloses no financial relationships with commercial entities.

Cydnee A. Wolfe - Y2

Discloses no financial relationships with commercial entities.

Rebecca Wood, MFS – E123

Discloses no financial relationships with commercial entities.

Robert E. Wood, DDS, PhD – G5, G24, G40

Discloses no financial relationships with commercial entities.

Taylor A. Wood – B23

Discloses no financial relationships with commercial entities.

Grace S. Woods, BS – H133

Discloses no financial relationships with commercial entities.

Charlotte J. Word, PhD – F43, W10

Discloses no financial relationships with commercial entities.

Franklin D. Wright, DMD – G4

Discloses no financial relationships with commercial entities.

Patrick M. Wright – E106

Fuji IR camera; Sirchie ALS Lights (Discussion of Unlabeled/  
Investigational Use of Product/Device).

Jingjie Wu, PhD – K20

Discloses no financial relationships with commercial entities.

Sulin Wu, PhD – H183

Discloses no financial relationships with commercial entities.

Charis Wynn, MSc – K52

Discloses no financial relationships with commercial entities.

### Y

Vamsi Yadavalli, PhD – B125

Discloses no financial relationships with commercial entities.

Aylin Yalçın Sarıbey, PhD – B13

Discloses no financial relationships with commercial entities.

Chu-An Yang, MS – K14, K77

Discloses no financial relationships with commercial entities.

Duygu Yavuz – F31

Discloses no financial relationships with commercial entities.

Dana M. Yenke, BS – B50

Discloses no financial relationships with commercial entities.

Hatice Yilmaz, BSc – F3

Discloses no financial relationships with commercial entities.

Leena Yoon – B12

Discloses no financial relationships with commercial entities.

Kenichi Yoshizawa, MPharm – E104

Discloses no financial relationships with commercial entities.

John L. Young, MD – I8

Discloses no financial relationships with commercial entities.

Elizabeth Young Laanemets, MSc - W5

Discloses no financial relationships with commercial entities.

### Z

Jorge J. Zacca – K79

Discloses no financial relationships with commercial entities.

Carlos J. Zambrano, PhD – H156

Discloses no financial relationships with commercial entities.

Victoria Zeger – E22

Discloses no financial relationships with commercial entities.

Ellyn A. Zeidman, BS – B44

Discloses no financial relationships with commercial entities.

Mengliang Zhang, PhD – B150

Discloses no financial relationships with commercial entities.

Mingchang Zhang – H184

Discloses no financial relationships with commercial entities.

## Presenting Author Financial Disclosure – 2019

## Presenting Author Index – 2019

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2018 Annual Scientific Meeting. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Anthropology	J	Questioned Documents
B	Criminalistics	K	Toxicology
C	Digital & Multimedia Sciences	LW	Last Word Society
D	Engineering Sciences	BS	Breakfast Seminar
E	General	ES	Evening Session
F	Jurisprudence	L	Luncheon
G	Odontology	S	Special Session
H	Pathology/Biology	W	Workshop
I	Psychiatry & Behavioral Science	Y	Young Forensic Scientists Forum
